The primary reason for holding stock in a pharmaceutical supply system is to ensure availability of essential items almost all the time. The selection of items to stock should be based on their value to public health and on the regularity and volume of consumption. VEN (vital, essential, nonessential) and ABC analyses are useful tools for defining which items on the formulary list must be held in stock (see [Chapter 40](#)). Although ABC analyses are often based on the value of the medicines, for inventory management, ABC analyses based on order frequency and volume are also important.

Key issues in inventory management are service level and safety stocks. The *service level* is the measurement of service from a supplier or from a warehouse, with

the goal of never having stockouts. The principal determinant of service level is safety stock—the higher the level of safety stock in the warehouse, the higher the service level. However, excessive safety stocks cause excessive inventory-holding costs. The basic method for setting safety stock is multiplying the lead time by the average monthly consumption, but adjustments may be needed to cope with variations in consumption and lead-time patterns. The other key determinant is the turnaround time with the supplier or the warehouse, that is, the time taken to fill and deliver an order once it is received by the supplier or the warehouse. This turnaround time is a component of the overall lead time that is used by the user-level stockholder to determine inventory levels.

The ideal inventory model is the optimal stock movement pattern, in which inventory levels are as low as possible (without risking stockouts) and optimized, consumption patterns are consistent, and suppliers always deliver on time—but this model is rarely achieved in practice. As described in Section 23.6, the three common inventory models used in pharmaceutical supply systems are defined by how often regular orders are placed with suppliers—

- Annual purchasing (one regular order per year)
- Scheduled purchasing (periodic orders at set times during the year)
- Perpetual purchasing (orders are placed whenever stock becomes low, or when stock levels reach predetermined reorder levels)

Average inventory levels (and holding costs) are expected to decrease with more frequent orders.

The basic formulas for calculating order quantity are relatively simple; two useful formulas are minimum-maximum and consumption based. Both incorporate several essential factors—

- Average monthly consumption
- Supplier/warehouse lead time
- Safety stock
- Stock on order
- Stock in inventory
- Stock back-ordered to lower levels

The more complicated mathematical formulas, such as economic order quantity and exponential smoothing of demand, do not necessarily lead to better services than the simpler approaches and are not recommended for most pharmaceutical supply systems.

Whichever formulas are used, purchase quantities should be adjusted to take into account factors such as seasonal demand, expiry dates, expected changes in use or prices, currency fluctuation, and availability of storage space.

Key ways of minimizing total costs include—

- Lowering order processing, purchase, or delivery costs through efficient procurement
- Lowering stock-holding costs through good store-keeping practices
- Controlling stock levels and minimizing stockouts by using effective inventory control techniques
- Minimizing financial costs through use of attractive financing methods

Primary considerations in promoting efficiency are the costs of purchasing and holding stock in inventory. A regular and accurate stock count and standard methods for valuing the inventory are needed to determine the base inventory value. Other relevant costs are the operating costs associated with procurement and with holding inventory.

The objective of good inventory management is to maintain a steady supply to operating units (and patients) while minimizing the costs of holding inventory and managing procurement. Compiling information on the total costs of inventory management (pharmaceutical acquisition costs, inventory-holding costs, purchasing operations costs, and shortage costs) allows managers to evaluate strategies for reducing costs.

23.1 Introduction

Inventory management is the heart of the pharmaceutical supply system; in fact, the nonspecialist might say that inventory management *is* pharmaceutical management. That would be simplistic, as the other chapters of this book demonstrate, but without a healthy inventory management system, the pharmaceutical supply system as a whole will not be viable.

Inventory management for pharmaceutical supply sounds easy—all that must be done is to order, receive, store, issue, and then reorder a limited list of items. In reality, the task is difficult, and in many countries, poor inventory management in the public pharmaceutical supply system leads to waste of financial resources, shortages of some essential medicines or overages of others resulting in expiration, and decline in the quality of patient care.

“Sick” inventory management systems generally feature subjective, ad hoc decisions about order frequency and quantity, inaccurate stock records, and a lack of systematic performance monitoring. These problems are directly related to lack of knowledge and appreciation of what inventory management means as well as to ineffective management. In many cases no systematic procedures and rules exist to guide staff, a problem compounded by lack of understanding of the basic issues of proper inventory management on the part of managers.

Seven basic issues must be carefully considered when an inventory management system is being initially designed or upgraded—

1. Definition of the context in which the inventory management system must function
2. Determination of the types of stock records and inventory reports needed

3. Selection of items to be stocked as standard items
4. Maintenance of appropriate service levels for different classes of items
5. Adoption of a decision rule or a model for determining when to reorder
6. Adoption of a decision rule or a model for determining how much to reorder
7. Identification and control of inventory management costs using product classification systems such as ABC analysis, VEN analysis, level of use, and other cost-minimizing techniques. (See [Chapter 40](#) for further details on minimizing costs.)

To address these issues, managers may use mathematical formulas and models to set policies concerning stock levels, reordering frequency, and reorder quantity. Because inventory management is so vital in maintaining supply systems—public or private—a number of formulas have been developed over the years, some fairly simple and others using complex mathematical models that not only are difficult to construct, but also are hard to solve. In the great majority of pharmaceutical supply situations, the simple models, formulas, and methods work as well as the complex models, so the simple approach is emphasized in this chapter.

One goal of inventory management is to achieve a reasonable balance between holding costs, on the one hand, and purchasing and shortage costs, on the other. In order to maintain this balance, the relevant costs need to be identified and quantified and then examined for how they interrelate. This analysis allows managers to see the “big picture” in the system and consider the effect of potential changes. [Chapter 40](#) illustrates different approaches to controlling costs in pharmaceutical management.

23.2 The context of an inventory management system

Before defining rules for inventory management, the context in which an inventory management system operates must be defined. Two factors are relevant—*independent* versus *dependent* demand, and the use of “push” versus “pull” systems for distribution.

One factor that defines the context is whether the inventory system supports a supply system in which clients (health facilities) order finished products from a warehouse or other supply source, or whether the system supports primarily internal manufacturing; this factor determines whether the system is an independent demand system or a dependent demand system. The fundamental inventory management concepts and resulting procedures are quite different for the two systems.

Independent demand systems are applicable to the management of procurement and distribution of finished goods. The order intervals and quantities are derived from forecasts based on historical consumption by clients, tempered by knowledge of expected changes in consumption. Inventory levels are set to provide a defined level of service to clients, at an acceptable cost.

Dependent demand systems manage inventory requirements for raw materials and supplies based on what is needed for production in a manufacturing or repackaging operation. They are also known as *materials requirement planning systems*. Ordering intervals and quantities as well as inventory levels depend on projected production schedules. The just-in-time system is an example of inventory management in this context.

Because a typical pharmaceutical supply system is involved mainly in the procurement and distribution of finished pharmaceutical products, this chapter focuses on the independent demand system. However, in some pharmaceutical supply situations (such as local manufacturing or repackaging), a dependent demand system would be more appropriate. Readers who need information on dependent demand systems can find sources in References and Further Readings (Dear 1990; Waters 2003).

The other factor that defines the inventory management context is whether the distribution system is a pull system or a push system. In the *pull system*, operating units order medicines from a warehouse or supplier according to local determination of need. In the *push system*, a central authority orders medicines from suppliers and determines the quantities that will be shipped to the operating unit, based on the annual distribution plan and on information transmitted to the warehouse about need at the operating unit. The best-known example of a push system in pharmaceutical supply is the ration kit system, discussed in Chapter 26. Note that a push system has some features of a dependent demand system—a plan is set for distribution

to operating units, and procurement is done to carry out that plan.

The inventory management methods discussed in this chapter can be applied in either a pull or a push system. In certain complex systems involving multiple levels of storage located, for example, at central, provincial, district, and health facilities, both push and pull systems may be at work in different levels of the system. Both systems may possibly be used at the same time for limited periods, for example, when introducing a limited push system to supplement supplies while addressing inefficiencies in the pull system.

Before readers go further, they may find reviewing the procurement glossary at the end of Chapter 18 useful. It contains commonly used terms that have a specific meaning in the discussion of inventory management.

23.3 Stock records and standard reports

This section discusses the types of stock records and reports that form the foundation of effective inventory management.

Stock records

Stock records are the core records in the inventory management system. They are the primary source of information used in the various reordering formulas discussed later in this chapter; they are also the source of data used to compile performance reports discussed in this section. Stock records can be either manual or computerized. Commonly used manual stock records include—

Vertical file cards: File cards are stored vertically in alphabetical or numerical order in a card file or drawer.

“Kardex” system: File cards are stored in a visible-edge record-tray system, with names and stock numbers on the lower edge, overlapped to provide an index.

Bin cards: File cards are physically kept with the stock. This system makes a visual check easy, serves as a reminder to keep records, and serves as a backup to records previously described. If a product has two different batches with two different batch numbers and expiry dates, two sets of bin cards should be maintained. However, only one stock card containing information on both batches needs to be used.

Ledger system: Records are kept on ledger sheets in a bound or loose-leaf book.

Many supply systems maintain two stock records for each item to improve accuracy and accountability. Typically, a bin card is kept with the stock, combined with a ledger, Kardex, or computer system kept in the central office. The use of these record systems in a large warehouse is discussed in

Chapter 44, and the maintenance of stock records in health facilities is treated in Chapter 46. Examples of manual and computerized stock records can be found in those chapters.

In most supply systems, computerization is desirable if the local situation can afford and support automation. Use of computers is an efficient way to manage inventory with perpetual or periodic purchasing; moreover, a good software program, properly used, makes information retrieval and reporting much easier than a manual system (see Chapter 50). However, much depends on the type of software program used, how well the system is operated, and the accuracy of data entry. In most pharmaceutical supply environments, stock can still be controlled with manual records, if necessary.

The key point about stock records, whether manual or computerized, is that they must be current and accurate. Managing the reordering process well is impossible if stock movement cannot be tracked.

Several factors contribute to inaccurate stock records; some are entirely avoidable, but some are not—

- High-volume, repetitious entries lead to occasional entry errors just by the nature of the task.
- Medicine names and descriptions are similar—ten items may be different forms of the same medicine, and an entry may be made for the wrong form, or different strengths of the same item may be confused.
- Duplicate entries for receipts or issues may be caused by duplicate paperwork provided separately to different clerks.
- Spoiled or junk stock may be destroyed but not written off the records.
- Theft produces inaccurate records, except when they are deliberately altered to conceal the theft.
- Physical stock counts may be rarely or never taken, they may be inaccurate, or the records may not be reconciled after stock counts.
- Sloppy storekeeping and warehouse practices may make carrying out accurate stock counts difficult and prevent reconciliation of physical stock with recorded stock, especially when stock of the same item is stored in different locations.
- Clerical and stock management staff may be poorly paid, poorly trained, and poorly motivated.
- Supervision of warehouse staff or clerical staff is often minimal, and management may make limited or no effort to reconcile discrepancies.

Automation and newer technologies, such as bar coding, reduce some of the problems related to inaccurate data entries, but this technology is still expensive to implement and does not solve all the problems. The best way to promote greater accuracy is better training and closer supervision, with spot checks of records and stock status by supervisors.

Stock counts are important, both for reordering purposes and for determining the inventory value. Some pharmaceutical supply systems still never count stock and rely totally on inventory records, but most systems have a policy of conducting stock counts at least annually (although they may not really be carried out every year). The best approach to tracking the quantity actually in stock is *cyclic counting*.

In cyclic counting (sometimes known as continuous counting or perpetual inventory), the entire inventory is divided into counting groups, and one group is counted each week (or each month), with reconciliation of discrepancies; another group is counted the next week (or next month), and so forth. A cyclic counting program provides for every item in the inventory to be counted at least once a year and for a reconciliation to be carried out between physical and recorded stock. A regular, cyclic stock-counting procedure is generally accepted as superior to an annual stock count. Two main reasons account for the change to cyclic counting—

1. With an annual stock count, a whole warehousing and distribution operation is shut down for a day or two to a week or more. This procedure disrupts the supply system and causes frustration for warehouse and financial staff, who must rush to get the whole process completed as quickly as possible.
2. When discrepancies are found in an annual count, tracing exactly where the problem arose during the year is difficult, so the records are simply corrected to reflect actual stock, and any losses are written off.

Cyclic counting, in contrast, can take place without interrupting normal operations. With more frequent counting, tracking down the source of discrepancies may be possible. Moreover, more frequent counting may make it harder for staff to pilfer stock.

One method of cyclic counting is to assign the counting frequency and timing by ABC category (defined in Section 23.4), counting A items three or four times a year, B items twice, and C items once; any B or C items that are prone to disappear may be worth adding to the A category.

For best results, the staff members who perform the stock counts should not be the ones to reconcile discrepancies; a system of rotating different staff members through both functions helps maintain the integrity of the process.

Activity reports and performance monitoring

The most accurate stock records have little value if the information in them is not compiled in reports for use by the managers who make purchasing and stock management decisions. Two similar but separate types of reports are useful: periodic analyses and routine reports.

The inventory management system's health can be measured periodically using standard performance indicators. Box 23-1 lists performance indicators commonly used by commercial firms. The assessment guide at the end of the chapter cites indicators that have been tested in public supply systems.

Routine reports on purchasing and inventory management activities should be produced monthly to quarterly in a computerized system and at least annually in a manual system. The following lists illustrate the types of reports that are useful for improving inventory management.

Storage facilities should report on—

- Stock position—stock on hand and on order, globally and by item, reported as absolute quantities and in terms of months' worth of consumption; listing inventory by descending stock value and also by descending (or ascending) number of available months of consumption is also useful
- Beginning and ending inventory value, and the average inventory-holding costs
- Value of all supplies received and issued during the reporting period
- Changes in inventory value and any discrepancies noted during stock counts
- Value of stock adjustments carried out during reconciliation

- Consumption patterns for all stock items and an ABC analysis of consumption—with computer assistance, this analysis can be done globally and for each operating unit
- Service level from suppliers to medical stores and from medical stores to health facilities
- Medicines at risk of expiry in inventory and an estimate of how much stock is likely to expire before it can be used
- Quantity and value of obsolete stock waiting for disposal and stock destroyed or junked

Purchasing and financial departments should report on—

- Budget status—year-to-date expenditures versus targets, and amount remaining
- Purchases and expenditures, broken down by supplier and by operating unit
- Summaries of accounts payable to suppliers
- Status of outstanding orders
- Comparison of expected and actual lead times for completed orders
- Supplier performance
- Comparison of actual purchase price and projected cost
- Comparison of actual items purchased and original needs projections

Box 23-1

Performance indicators used by commercial firms

Inventory management performance indicators are used in commercial companies throughout the world to measure how effectively inventory is being managed; these indicators can and should be used in public pharmaceutical supply systems when data are available.

Net sales to inventory (also called *inventory turnover*): The total value of medicines distributed, minus write-offs, divided by the value of the inventory. The higher the ratio, the lower the average inventory level (and average holding cost). Most private companies would expect a turnover ratio of twelve or higher; in public pharmaceutical supply systems, the ratio is dictated to some extent by the purchasing model, but a ratio of at least six is realistic in most cases.

Inventory shrinkage: The sum of beginning inventory value plus purchases, minus the sum of the cost of goods sold, plus ending inventory value. Ideally, this figure would be zero, but any value less than 10 percent of inventory value is within expectations in most public pharmaceutical supply systems.

Expense ratio: Total operating expenses divided by net sales (or value of medicines distributed). In one view, the lower this ratio, the more efficiently services are being managed.

Service level: The percentage of items ordered or requested that is filled from stock by the supplier or warehouse. From the public health viewpoint, the higher the service level, the better, as long as inventory costs do not rise to insupportable levels.

Average inventory-holding cost: The average cost of holding inventory as a percentage of average inventory value. In a public pharmaceutical supply system, 30 to 40 percent is a reasonable target.

Incremental ordering cost: The average incremental cost of placing each order. In a private company in an industrialized country, this might be 100 to 200 U.S. dollars per order. It should be considerably lower in most public pharmaceutical supply systems.

- Operating costs attributable to stock management and to purchasing

Accurate reporting is possible with either a manual or a computerized information system, but the information is much more readily compiled with computer assistance. Again, source data for the reports—stock records and purchasing records—must be maintained accurately and kept up-to-date. The key is for senior managers to demand these sorts of reports, use them in making policy decisions, and take corrective action when reports are not produced.

23.4 Selection of items to be held in stock

Stock must be held for several reasons—

To ensure availability: In the typical pharmaceutical supply system, one cannot forecast demand with complete accuracy or be certain about suppliers' performance. Proper inventory management allows the absorption of fluctuations in supply and demand and reduces the risk of stockouts.

To maintain confidence in the system: If stockouts occur regularly, patients and staff lose confidence in the system, and patient use drops for both curative and preventive services.

To reduce the unit cost of medicines: Ordering medicines in bulk allows quantity discounts from suppliers and reduces shipping and port-clearing costs.

To avoid shortage costs: If emergency orders are needed to cope with stockouts, the unit cost is likely to be much higher than for a regular order. Also, when a pharmaceutical sales program is operating, stockouts result in lost revenue, because clients go elsewhere for medicines.

To minimize ordering costs: Purchasing costs increase when items are ordered frequently. These costs include salaries and benefits for purchasing and accounting staff members, office space costs, utilities, supplies, and other costs associated with tenders and regular orders.

To minimize transport costs: Medicines can be delivered less frequently, enabling transport resources to be used more economically.

To allow for fluctuations in demand: Changes in demand for specific medicines are often unpredictable, and an adequate inventory allows the system to cope with demand fluctuations.

Obviously, pharmaceutical supply systems need to hold a certain level of inventory; however, holding high stock levels has disadvantages (see [Figure 23-1](#)). Substantial capital can be tied up in inventory and thus be unavailable for other purposes. As inventories become larger, the costs for personnel, utilities, insurance, storage facilities, and other costs

of holding stock increase. High inventory levels also increase the likelihood of losses caused by spoilage, expiry, obsolescence, and theft. These adverse effects of high stock levels compel managers to practice proper inventory management by balancing stock-holding costs, ordering costs, and stock-out costs; otherwise, supply systems would simply hold large quantities of stock at all levels so that no chance of shortages would exist.

Most pharmaceutical supply systems try to regularly stock all items that are on the formulary or essential medicines list (see [Chapter 16](#)). In many cases, items that are not on the approved list but that are regularly requested by physicians are also routinely held in stock. Often no differentiation is made between vital and nonessential items, between high-cost and low-cost items, or between items that move quickly and those that are rarely used. This lack of discrimination often leads to an accumulation of slow-moving stock and excess capital tied up in inventory.

One way to decide which items should be stocked is to look at records of stock movement in and out of the storage facilities and identify the high-volume items that definitely need to be stocked, as well as items that have shown little or no movement in the past year. A good tool for reviewing stock movement is ABC analysis, which categorizes items by the volume and value of consumption during a specific period of time, usually one year. Class A items—10 to 20 percent of items, representing 75 to 80 percent of expenditures—are mostly high-volume, fast-moving medicines. Class B items are usually 10 to 20 percent of items, and 15 to 20 percent of expenditures. Class C items often represent 60 to 80 percent of the items but only about 5 to 10 percent of the total expenditures; these are the low-volume, slow-moving items. Thus, class C is a good place to look for items that might not be needed in stock at all times.

The VEN system is another method for categorizing stock, as vital (V), essential (E), or nonessential (N). This system is sometimes modified to two categories—V and N. VEN analysis is often used to prioritize procurement when not enough funds exist to purchase all items requested. The system can also help determine which items should be kept in stock and which can be ordered when needed. Clearly, V medicines would be more likely to be regular stock items than N medicines. Both ABC and VEN analyses are discussed in detail in [Chapter 40](#).

Not all medicines have to be stocked at each level of the system. One way of classifying stock versus nonstock items is according to the approved level of use. For example, a medicine such as aspirin would be a stock item at all levels of the system, but a third-generation cephalosporin or a drug used in cancer chemotherapy might be a stock item only in tertiary-care hospitals. Classifying medicines according to their eligibility for routine use at each level helps minimize stock levels and ensure that only qualified staff members prescribe dangerous or expensive

Figure 23-1 Balancing benefits and costs in inventory management

medicines. Another option is to stock slow-moving items only at the central level, then consolidate orders and distribution.

Finally, the issue of local availability must be kept in mind. If a medicine is vital to patient care (even if rarely used) and it cannot be obtained quickly when needed, that medicine will probably need to be kept as a stock item. When no local sources of supply exist and all medicines are imported, with long lead times, all medicines need to be held in stock somewhere in the system. In most countries, however, opportunities exist to purchase some medicines as needed from local sources, and considering which of those items need to be constantly held in stock is worthwhile.

Whichever approaches are used to designate stock and nonstock items, some scheme is needed for periodically reevaluating the stock status. If the system is computerized, the software can be programmed to automatically recategorize items at specified intervals based on recent patterns of stock movement.

23.5 Service level and safety stock

After the decision has been made about which items will be routinely held in stock and which will be ordered only when they are needed, the discussion turns to how much stock should be held at each level of the system. Different points of view are likely to exist: stock controllers and clinical staff

may feel that inventory levels should be high, to avoid shortages; financial managers, however, hope to minimize inventory levels to hold down costs.

One of the most common ways to measure the performance of a commercial supplier or public warehouse is to calculate the service level provided to clients. Suppliers try to balance service level and the costs of holding stock. The single most important factor in establishing that balance is the average stock held by the supplier and, in particular, the safety stock.

Service level to operating units

The *service level*, in its most simple form, is the percentage of individual items ordered from a supplier or warehouse that is issued from stock on hand. It is measured by counting the total number of items issued and dividing by the total number of items requested.

$$\text{Service level} = (\# \text{ items issued} \div \# \text{ items requested}) \times 100$$

If twenty products are listed on a request, and ten units of each product are requested, 200 items are on the order; if only 170 items are issued, the service level is 85 percent. When assessing the annual service level of a supplier, the key is the total number of items requested on all requisitions and how many of those items were supplied from stock on hand at the supplier's warehouse.

Some commercial suppliers (and public warehouses) are prone to making partial shipments. When an order is received, an initial shipment is made with part of the request; later, one or more additional shipments are made with the remainder of the order quantity. For purposes of measuring the service level, only the initial shipment after each order should count.

In some supply systems, counting all items requested and issued is too time-consuming, and a count of line items (the number of different products ordered, disregarding order quantities) is used. This scheme makes it hard to decide how to count line items when only part of the request was shipped. Suppliers would argue that any of an item shipped should count as a full shipment for service-level measurement, but many clients would disagree. Systems have evolved to measure line-item service level in categories, for example, the percentage of line items that falls into the categories “none issued,” “part issued,” and “issued in full.”

Other ways to measure service level include—

- The percentage of individual items or line items requested that are *delivered* within the promised lead time (this can be useful when delivery times vary).
- The value of all items shipped from stock as a percentage of the value of all items ordered.
- The percentage of full orders completely filled from stock. Two variations exist—in one, either the whole order is shipped or not; in the other, performance is categorized as discussed for the line-item method.
- The percentage of time that a product was found to be in stock during a period of one year. For example, if a product was found to be out of stock for 36 of 365 days in a year, the service level could be calculated as $(365 - 36) \times 100 \div 365$, equal to a service level of 90 percent.
- The percentage of *products* that are supplied (e.g., if 100 products are ordered and 70 are supplied in any quantity, the product service level is 70 percent).
- The percentage of *units* supplied (e.g., if 100 boxes of ampicillin vials were ordered and 70 were supplied, the unit service level is 70 percent).
- A strong overall measure of service combines product service and unit service (e.g., 70 percent \times 70 percent equals a 49 percent service level).

Whatever measure is used, what is meant by a reasonable service level? Many private-sector pharmaceutical wholesalers promise 95 percent service levels to customers (although they do not always fulfill this promise). Is this level sufficient? The point to remember is that every percentage point decrease in service level by a supplier or warehouse represents a corresponding increase in shortages at the client facility. If a supplier promises a 95 percent service level, 5 percent of the requested items are not expected to be shipped immediately (implying a potential 5 percent stock-

Figure 23-2 Safety stock requirements to maintain various service levels

out at the receiving facility). If the level drops to 90 percent, it follows that 10 percent of the items are not being shipped when they are needed. A public-sector pharmaceutical supply system should strive for a 100 percent service level, at least for vital items; setting lower goals might be reasonable for nonessential medicines and supplies.

Service level is directly determined by the average inventory level, and particularly by the average level of safety stock, held by the supply source. [Figure 23-2](#) illustrates the typical relationship between safety stock and service level from a supply source (either commercial or public).

Note in [Figure 23-2](#) that although the safety stock requirements increase as the service level increases, the relationship is not linear. As the service level increases above 80 percent, the amount of additional safety stock needed to produce a further increase in service level rises steeply. The amount of safety stock required to achieve a 99 percent service level may be double that required to achieve a 95 percent service level. For example, where a safety stock of 2,000 units is needed to achieve a service level of 95 percent, 4,000 units may be needed to raise the service level to 99 percent.

For both the supplier and the client, the balance between cost and service is really a matter of trade-offs. If the supplier cannot or will not maintain adequate inventory levels to sustain an acceptable service level, the client will either have to change suppliers or have to increase safety stock levels at the receiving units. For the supplier, the trade-off is between incurring higher inventory costs to maintain the promised service level and running the risk of shortage costs, as clients go elsewhere for service.

In commercial enterprises, safety stock levels are set using standard formulas that incorporate knowledge about demand patterns, inventory costs, sales income lost from stockouts, and other factors. If a stockout occurs, it is normally accepted as the cost of tight inventory control. In

Box 23-2 Estimating safety stock

The minimum safety stock needed to avoid a stockout is the quantity of stock used on average during the average lead time from the supplier. Thus, if an order is placed as soon as the stock level falls to the safety stock level, if demand is no greater than average during the lead time, and if the supplier delivers within the average lead time, a stockout will be avoided.

The most common method for estimating safety stock needs is to determine the average lead time for each item from the current supplier and the average consumption (per month or per week). If stockouts occurred, consumption must be adjusted to what would have been used, as described in [Chapter 20](#), Section 20.4.

In calculating the amount of safety stock, it is also important to consider warehouse storage capacity. It is no use to order the appropriate amount of safety stock if the warehouse does not have the space for it.

The formula for setting the basic safety stock (SS) level is lead time (LT) multiplied by the average consumption (C_A)—

$$SS = LT \times C_A$$

For example, if the average lead time is three months and the average monthly consumption is 1,000 units, the minimum safety stock would be 3,000 units.

Unfortunately, consumption patterns are not always smooth, and suppliers do not always deliver within the average lead time, so most supply systems increase the basic safety stock—at least for critical items—to cope with variations in consumption and lead time.

The simplest approach for coping with varying consumption and lead time is adding an arbitrary multiplier to the basic formula for safety stock; member countries in the Organisation of Eastern Caribbean States Pharmaceutical Procurement Service, for example, multiply the basic safety stock by 1.5 for vital items, to protect against stockouts.

Another simple way of adjusting the safety stock for variable consumption is to review a one-year period and determine the maximum quantity consumed during

the average lead-time period for the current supplier of the item and the average quantity consumed during that same lead-time period. For the example cited above, the average consumption during the three-month average lead-time period was 3,000 units; suppose that for any three-month period during the year, the highest consumption was 4,000 units. Using this method, the minimum stock level would be 3,000 units, and the additional safety stock allotment would be 1,000 units.

The information from lead-time analysis (see [Chapter 40](#)) can be used to predict the next lead time, as follows—

$$DD_E = DD_P + (OD \times OD\%)$$

where—

DD_E = expected delivery date

DD_P = promised delivery date

OD = average overdue period in days

OD% = percentage of orders overdue

[Chapter 40](#) cites an eastern Caribbean supplier that had a contract lead time of 45 days but was late on 50 percent of shipments, with an average delay of 43 days. According to the formula above, this supplier has an expected delivery date of 66.5 days, calculated as—

$$DD_E = 45 + (43 \times 50\%) = 66.5$$

When calculating safety stock needs for products from this supplier, using a lead time of 66.5 days would be safer than using 45 days.

When both consumption and lead times are highly variable, some commercial firms use a mathematical approach using the standard deviation of the average consumption and the average lead time to set safety stock levels (see Section 23.9).

Note that all these adjustments tend to increase inventory-holding costs by increasing the safety stock level; therefore, it is important to monitor consumption and lead-time patterns continuously and adjust safety stock to the lowest levels compatible with current patterns. In a computerized inventory control system, this adjustment should be done automatically by the software.

Figure 23-3 Ideal inventory control model

public pharmaceutical systems, the cost of additional safety stock must be weighed against the potential adverse health and political effects of stockouts.

When one designs or restructures an inventory management system, safety stock policy is an important consideration. The policy may differ at each level of the system, between products, or between different facilities at the same level (depending on VEN and ABC classification systems, lead times, and consumption patterns). The objective is to provide maximum service levels throughout the supply system with minimum necessary *total* safety stock.

Methods for setting safety stock levels

Many ways exist of estimating the level of safety stock required to achieve specific service levels. All consider two major factors: average consumption and average lead time. [Box 23-2](#) discusses simple methods for estimating safety stock needs. In most supply systems, the more complex mathematical models for estimating safety stock needs will probably not provide any significant advantage over simple methods (see Section 23.9).

23.6 Inventory control models and reorder frequency

The ideal inventory control model is shown in [Figure 23-3](#). In this ideal model, pharmaceuticals are issued in response to demand, but stockouts are not permitted; the stock on hand steadily declines until the point at which an order

must be placed. The stock on hand consists of two components, the working stock and the safety stock (SS). In the ideal model, the supplier performs according to plan, the shipments arrive on time, the quantity ordered (Q_0) is received, and the inventory level is back to its starting maximum point ($Q_0 + SS$). Working stock varies from zero to the quantity ordered and represents the stock used to satisfy demand between deliveries. Note that in the ideal model, the average working stock is half of the order quantity—

$$\text{Average working stock} = \frac{1}{2} Q_0$$

The average inventory (I) or average stock on hand is the safety stock plus the average working stock—

$$I = SS + \frac{1}{2} Q_0$$

To reduce the average inventory and thereby reduce the inventory-holding costs, the working stock, the safety stock, or both should be lowered. When medicines are used at a constant rate, the line in [Figure 23-3](#) representing stock on hand declines with a constant slope. Large, infrequent orders lead to high average inventory levels. The average working stock can be reduced by placing smaller orders more frequently. The average inventory can also be reduced by cutting the safety stock, but this method increases the chance of stockouts. Alternatively, stock-holding costs could be reduced by minimizing the individual cost components that make up inventory-carrying costs, as illustrated in [Figure 23-1](#). These improvements would be possible

through improved storekeeping practices and better financial management.

As illustrated in Figure 23-3, any inventory control model used to manage purchasing must address the following issues—

1. Safety stock—how much stock will be kept in reserve to prevent stockouts
2. Reorder frequency—the period of time between each order for an item (also known as the procurement period)
3. Reorder quantity—the number of units specified when an order is placed

In addition, storage capacity—the amount of space available for storage—needs to be considered when determining target stock levels and ordering and replenishment frequency. As is made clear in Figure 23-4, the policy on reorder frequency has a major influence on average stock levels and inventory-holding costs, as well as on service level.

Different inventory control models based on reorder frequency have been developed to fit various situations. Two ways to classify these models are—

1. *Periodic review model*: In periodic review models, orders can be placed only at specified intervals, and the item is ordered at every interval.
2. *Perpetual review model*: In perpetual review models, orders can be placed at any time; the user (or a minimum stock level) determines when to order and how much to order.

In pharmaceutical supply systems, the most common inventory control models are—

- Annual purchasing—a periodic review model with the interval set at once a year
- Scheduled purchasing—a periodic review model in which orders are placed at prescribed intervals (such as weekly, monthly, quarterly, biannually)
- Perpetual purchasing—a model in which stock levels are reviewed each time stock is issued (or at least weekly) and orders are placed whenever stock falls below a minimum level
- Draw-downs from framework contracts

Annual purchasing

With annual purchasing (which is actually a form of scheduled purchasing), procurement is carried out once each year for all items. Order quantities are normally calculated by a large-scale quantification process (see Chapter 20).

After quantification is done, a tender or competitive negotiation (see Chapters 18 and 21) is used to purchase

Figure 23-4 Impact of reorder interval on average inventory

the entire annual amount (or as much as can be afforded). Contracts with suppliers may provide that deliveries be spaced throughout the year if problems exist with local storage space, storage conditions, or security. In virtually all supply systems using annual purchasing, mechanisms exist to make supplementary purchases during the year. Countries use annual purchasing for the following main reasons—

- Financial regulations and realities may dictate the choice.
- A single procurement can be easier to manage than more frequent purchasing, depending on staff capacities and availability of information.
- Pharmaceutical purchase prices per unit are usually lower when large-volume purchases are made. This consideration can be important when inflation or local currency devaluation is significant and progressive. In such cases, committing the funds at discounted prices and prevailing exchange rates is preferable.
- Tradition and inertia may promote continuance of annual purchasing just because it has always been done that way.
- Greater purchase volumes result in lower prices and can be accompanied by staggered deliveries to facilitate storage and distribution management, as well as a more even cash flow arrangement.

Several disadvantages stem from using annual purchasing as the sole purchasing model for the supply system—

- Actual consumption is often different from the annual forecast or the actual demand, leading to shortages and surpluses; expensive emergency orders are required to cope with shortages, and surplus stock may spoil or expire.
- Average stock levels and inventory-holding costs are higher with this model (see Figure 23-4).
- Local suppliers that win annual tender contracts may find coping with huge, single deliveries difficult.
- More storage space is required, unless deliveries from suppliers can be spaced throughout the year.

- The necessary funds to pay for the single annual purchase may be difficult to obtain, particularly if hard currency is required.
- Workload in the procurement office and main receiving points is uneven.

In general, annual purchasing is best suited to new programs, which have no existing system for inventory management. Annual purchasing may be mandatory in countries where local sources of supply are limited and lead times from foreign suppliers average several months. Annual purchasing may also be preferred when donors support pharmaceutical purchases. Even in systems that use mainly scheduled or perpetual purchasing, some items may be best purchased annually.

Scheduled purchasing

In this periodic review model, specific ordering windows are determined, and regular orders can be placed only at the scheduled intervals—for example, once each month, each quarter, or every six months. Orders are placed at the scheduled order date for quantities large enough to cover average needs until the next order is scheduled plus stock needed during the lead time for that order (plus replenishment of safety stock, if needed).

One variation on this model is staggered review, in which the procurement office reviews one group of medicines (or medicines from one group of suppliers) at one interval, another group at the next interval, and so forth. In this manner, the workload in the procurement office and the financial requirements for pharmaceutical purchasing are spread out during the year, while still limiting the number of orders placed to each supplier (which can be an important issue in supply contracts).

The ordering frequency can also be varied according to ABC category, so that more expensive, faster-moving items are ordered more frequently and other items less frequently (this system is discussed below).

Scheduled purchasing with a review period of six months can operate in much the same way as annual purchasing, but shorter intervals require one of the options for calculating order quantities described in Section 23.9. Normally, an emergency ordering system is used when stock runs low between scheduled orders or when a supplier's shipment is delayed.

In scheduled purchasing, supply contracts can be negotiated anew at each interval, or longer contracts can be negotiated at the beginning of the year, with the provision that orders will be placed as needed at the specified ordering intervals (the estimated-quantity contract; see [Chapter 21](#)).

In most supply systems, a new order is customarily placed only after the previous one is received. However, some pro-

grams use tandem ordering, with overlapping orders and different expected times of arrival, if estimated lead times are reliable.

Scheduled purchasing has several benefits—

- An estimated-quantity rather than fixed-quantity contract can be supported.
- A scheduled system may be preferable to local suppliers because it allows them to spread their demand over the year.
- Inventory-holding costs are less than with annual purchasing (see [Figure 23-4](#)).
- Less space is needed in warehouses than with annual purchasing.
- Items with variable demand can be purchased more frequently in smaller lots, reducing overstocking and costly emergency orders.
- The procurement unit can respond more rapidly to program needs and make better use of a limited pharmaceutical budget.
- In many countries, funds and foreign exchange are easier to obtain for making smaller, more frequent purchases.
- The procurement and port-clearing workload is fairly evenly spread over the year.
- Because many products need reordering at scheduled points, procurement costs are better controlled, especially in instances where the procurement process is lengthy and cumbersome.
- It supports pooled procurement systems, where orders from all partners are joined and placed as a single order. See [Country Study 23-1](#).

One potential difficulty is that when orders are placed late in the fiscal year, the purchasing cycle will not be complete before the end of the year. This schedule may result in a conflict with regulations regarding spending time limits. Shortages caused by poor forecasting or changes in demand are less likely with this model than with annual purchasing, but they can still occur with scheduled review periods three to six months apart.

If progressive inflation and devaluation are problems, an escalator clause may be required in annual estimated-quantity contracts; if a separate contract is negotiated at each ordering interval, prices are likely to increase throughout the year. In such cases, the best strategy may be to procure as many essential items as possible, along with any items likely to increase in price, in the first part of the year.

Scheduled purchasing works most effectively when consumption patterns are relatively stable, at least for the duration of the period between orders. If needs fluctuate widely from month to month, perpetual purchasing would be preferable, assuming that it is logistically feasible.

Country Study 23-1 Scheduled purchasing in the eastern Caribbean

Scheduled purchasing is used in the Pharmaceutical Procurement Service (PPS) pooled procurement program. PPS is an agency serving the nine member countries of the Organisation of Eastern Caribbean States (OECS). The OECS/PPS operates a centralized, restricted international tendering system in which all approved suppliers are prescreened by a vendors' registration questionnaire. Prequalification is necessary to assess the quality standards, technical competence, and financial viability of competing suppliers. The supply contracts are awarded every eighteen months based on estimates of needs submitted by the nine member countries and compiled by the OECS/PPS. The pooled procurement list represents large-volume class A and B items for which demand is consistently high in the participating countries.

The countries use a scheduled purchasing system in which orders are placed every February, July, and October; some countries order from all suppliers at each

interval, and others use a staggered method. The reorder quantity is calculated using the consumption-based forecasting formula.

In this scheme, each country has a revolving drug fund at the Eastern Caribbean Central Bank; the country can order pharmaceuticals only up to the value of their allocated national budget during any order interval. Emergency purchases are made when shortages occur because of delayed shipments, or when unusual demand depletes stock before another order is due to be placed with a contract supplier. If the primary contract supplier defaults, an order is placed immediately with an alternative supplier.

The contract suppliers that are located in the region allow for more frequent orders in some cases, are frequently used as secondary contract suppliers, and are used as the primary source for emergency purchases.

Source: F. Burnett, personal communication.

Scheduled purchasing is probably the best choice as an alternative to annual procurement in countries that do not have immediate access to suppliers. The major requirements for managing scheduled purchasing are an inventory information system that can produce reliable information on consumption, stock levels, and outstanding orders, and the management and financial capacity to place all necessary orders according to the schedule.

Perpetual purchasing

In this model, a perpetual inventory record is maintained for each item. The inventory position (stock on hand and on order) is reviewed on a regular basis (usually with every transaction, but at least weekly); whenever the stock position falls below a designated reorder point, an order is initiated. As will be discussed later, the order quantity may be predetermined or variable.

Safety stocks and average inventories are much lower with this model than with either scheduled or annual purchasing, but some safety stock is still needed. The chief advantage of perpetual purchasing over scheduled and annual purchasing is the ability to rapidly respond to sudden changes in consumption, because the inventory position is reviewed continuously and orders are placed frequently.

In some systems that use perpetual purchasing, orders are batched—that is, an order is not placed with a supplier

until several different items are needed from that supplier. If batching is used, safety stocks must be adequate to cover periods when a needed item is on hold for batching.

Perpetual purchasing is used by most hospitals and health systems in industrialized countries, where lead times for virtually all items are one or two days. In the United States, perpetual purchasing normally takes place in a prime vendor distribution system, whereby a commercial distributor supplies all contract items on short notice (see [Chapter 8](#)). This system avoids the batching issue, because all or virtually all items are ordered from the same supplier. However, in many developing countries, government regulations and difficulty in employing suitable primary distributors may make this method challenging.

If applied appropriately, perpetual purchasing produces an even workload for procurement, warehousing, and port clearing. Depending on the supply system's budgeting and financial policies, perpetual purchasing with frequent small orders may be useful in spreading cash requirements throughout the year.

Despite the many benefits of a perpetual system, it is not suitable for all public-sector pharmaceutical supply systems. Several potential constraints exist. If lead times are not relatively short (one month or less), perpetual purchasing will be difficult to use without maintaining large safety stocks (thereby defeating its purpose). If the supply system cannot maintain current and accurate stock records, the perpetual

purchasing model will fail because by the time transactions are posted, vital items may be out of stock. If formal approval from the ministry of health or ministry of finance must be obtained for each purchase and for foreign exchange permits, the time needed for approval may make perpetual purchasing awkward.

The more frequent purchases in perpetual purchasing will drive up incremental purchasing costs and perhaps total purchasing costs, but any increase in incremental purchasing costs may be offset by decreased inventory-holding costs. Perpetual purchasing may be comparatively harder to fit into public health objectives and budgetary limits, because all the small purchases must be tracked for compliance with guidelines.

Potential applications for perpetual purchasing exist in many pharmaceutical supply systems even if the entire purchasing system cannot be converted to this method. For example, perpetual purchasing might be considered for fast-moving items that can be ordered at competitive prices from local sources. A perpetual system might be used by lower-level stores and facilities that order from a larger warehouse; this could be done whether or not the main warehouse uses perpetual purchasing, so long as the ordering cycles can be coordinated.

The main requirements for perpetual purchasing are—

- Stock records that are current and accurate
- A computer with suitable software to manage an inventory of more than a few items (see [Chapter 50](#))
- Good access to and communication with suppliers and user units, with lead times of one month or less
- Ready access to funds, unless suppliers are prepared to wait for payment
- An estimated-quantity contract that allows ad hoc orders, or a purchasing environment where formal contracts are not used

Drawing down from framework contracts

A framework contract establishes the essential terms and conditions of the procurement agreement, such as time frame, product specifications, prices, quantities, and conditions of supplier performance. During the framework contract term, the supplier holds the stock until it receives orders for specific purchases. Each order is itself a separate contract that follows the broad framework terms with specific terms added, such as delivery date.

Combinations of annual, scheduled, and perpetual purchasing

Although establishing one inventory control model for all pharmaceuticals may be simplest from a management perspective, it may not be the most cost-effective solution.

A thorough review of options may reveal that some medicines are best purchased annually—for example, imported medicines in a country where local currency devaluation is a major problem, or low-priced, infrequently used medicines. Other medicines might be most effectively purchased through scheduled purchasing—for example, relatively slow-moving but regularly used items. High-volume medicines and very expensive medicines may be most effectively purchased with a perpetual model, if logistically feasible.

ABC analysis can be used to examine the effect of variations in order frequency on average inventory value for class A, B, and C items. [Table 23-1](#) shows the relationships among the average order interval, the average inventory level, and the service level for class A, B, and C medicines in a large public-sector pharmaceutical supply system. This projection is based on an average lead time of nine months. Note the difference in average inventory value needed to maintain a 95 percent service level with the various permutations of order frequency for class A, B, and C items.

Although the lowest average inventory cost is obtained in the example by increasing the frequency of ordering for all classes, this strategy may increase the procurement workload and the costs of purchasing significantly, particularly if formal tenders are required. Changing the tender frequency for class A items to twice, rather than once, a year and changing the order quantity from twelve months' to six months' usage reduce the average inventory value by almost half, while still maintaining the desired service level; this change should not increase the cost of purchasing to unacceptable levels (although a total cost analysis should be performed to check the potential effect).

Dear (1990) describes a reordering system that builds on ABC analysis, called ABC/FS. In this system, the A, B, and C items are further broken down into three categories—fast turnover (F), slow movement (S), and no movement in the past year (class C items that might be reclassified as D for dead).

Using a mixed model of annual, scheduled, and perpetual purchasing, the purchasing office in this system concentrates on the fast-moving and expensive stock items, which have the most effect on inventory costs. Vital (V) and nonessential (N) classification can be combined with ABC/FS, with interesting implications for inventory management. For example, a class A, slow-moving item that is also a vital medicine (ASV) might be accorded a higher safety stock than a class A, fast-moving, nonessential item (AFN). An AFN item might be ordered only for specific patients as needed, or a class C, slow-moving, nonessential item (CSN) might be considered for nonstock status and ordered only as needed. Clearly, combinations of annual, scheduled, and perpetual purchasing can be used in many different ways if the supply system can manage such flexibility.

Table 23-1 Value of average inventory by service level and procurement pattern

Procurement pattern and ABC category—order interval	Value of inventory (USD thousands)				
	99%	98%	Service level 95%	90%	85%
Pattern A A products—12 months B products—12 months C products—12 months	10,801	9,730	8,204	7,394	7,394
Pattern B A products—6 months B products—12 months C products—12 months	8,766	7,750	6,902	5,217	4,606
Pattern C A products—6 months B products—6 months C products—12 months	8,365	7,360	5,927	4,788	4,056
Pattern D A products—6 months B products—6 months C products—6 months	8,103	7,104	5,661	4,507	3,697
Pattern E A products—4 months B products—6 months C products—12 months	7,820	6,862	5,476	4,392	3,738
Pattern F A products—4 months B products—4 months C products—4 months	7,380	6,471	5,086	3,982	3,275

23.7 Factors to consider in calculating reorder quantity

When the basic inventory control model has been established, the final question is how much should be ordered at each order interval. This section examines the factors that must be taken into account; Section 23.8 shows how the factors are integrated into a reordering formula.

Factors in the reorder formula

Depending on the reorder formula used, any or all of the following factors may be essential variables.

Average consumption. Sometimes called *demand*, the average consumption expected in the next purchasing cycle is the key variable that determines how much stock should be ordered. Future consumption is the great unknown of inventory management, so it is given special attention in this section. However, the other factors are equally important. Even if consumption is accurately predicted, stockouts will occur if the lead time is badly underestimated or if another factor is overlooked or miscalculated.

Lead time. Lead time is the time between initiation of a purchase order and receipt at the warehouse from the

selected supplier. If a distinct trend exists in that supplier's performance, the average should be weighted toward recent performance with a moving average. However, if the pattern fluctuates—for example, two months, six months, two months, six months—it is best to apply lead-time analysis (Chapter 40) or calculate the standard deviation as discussed in Section 23.9.

Safety stock. Safety stock is the stock that should always be on hand to prevent stockouts. When lead times and consumption are predictable and stable, the reorder level does not necessarily need to include safety stock; however, when consumption patterns and lead times are highly variable, additional safety stock will be needed, as discussed in Section 23.5.

Reorder level. The reorder level is the quantity of remaining stock that should trigger a reorder of the item. In the minimum-maximum ordering system, this level is called the *minimum stock level*. The standard way to set the reorder level in a basic purchasing formula is to multiply the average lead time by the average quantity consumed during the lead time. This stock level may or may not be the same as the safety stock level, as discussed above, and in fact, may include a separate quantity of stock as a safety stock.

Maximum stock level. In most reordering formulas, this level is the target stock level, which is the stock

needed to satisfy demand until the next order after the current one is received.

Stock position. Stock position is the sum of stock on hand (working and safety stock) and stock on order, minus any stock back-ordered to clients. Overstocks may occur if several months' worth of stock are on hand or on order when a new order is placed. Stockouts may result if significant quantities from an upcoming order are on back-order to lower-level facilities and this amount is not factored into the reorder quantity.

Procurement period. The procurement period covers the time until the next regular order will be placed. In a scheduled system, the period might be in multiples of one month; in a perpetual system, it could be counted in days or weeks for the purposes of forecasting. Note that the quantity ordered plus the safety stock must cover the time until the next order is received, which is the procurement period plus the lead time.

It should be noted that in all previous cases, stock levels are dependent on accurately estimating medicine demand. If estimates are not based on accurate stock-keeping records, then stock-level computations will also be inaccurate, and health institutions will run the risk of mismanaging procurements, resulting in stockouts or overstocks.

Projecting demand

Ordering rationally requires forecasting future needs, the least predictable variable in a reordering formula. Four different methods can be used for forecasting demand—

1. *Projective*: forecasts using past consumption to predict demand (in pharmaceutical supply systems, the method most likely to produce reasonably accurate forecasts)
2. *Causal*: forecasts based on external factors such as market conditions, epidemics, changes in health system size and structure
3. *Judgmental*: forecasts based on subjective estimates of purchasing staff and advice from other staff (the least demanding method, and often the least accurate, if used alone)
4. *Morbidity*: forecasts based on the incidence of disease and the use of standard treatment guidelines

Generally, a reordering formula should be based primarily on projective forecasting, derived from average monthly consumption. The other methods can be used as appropriate to adjust actual purchase quantities. Unfortunately, although past demand is the best source of data for projection, a stable pattern or trend may not exist. In a series of observations of monthly consumption for a twelve-month period (called a time series), several components may be part of the observed demand pattern—

Base rate: demand that may be fairly stable from month to month

Trend: a steady pattern of increasing or decreasing demand, for example, increased usage caused by gradually increasing patient attendances

Seasonality: relatively predictable changes, such as increase in demand for malaria drugs during the rainy season

Cyclic demand: demand that ebbs and flows, for example, with a country's economic cycle

Random noise: unexplained variations in demand; for example, in one month, 100 bottles of amoxicilline suspension were consumed, with a pattern of thirty, ten, eighty, and twenty bottles in succeeding months, with no obvious reason for the variation

Adjustment is relatively easy for a definite trend toward higher (or lower) use or seasonality (if it is predictable). Cyclic use patterns can also be dealt with if they are apparent. The real problem is random noise, and in many consumption series at the item level, random noise seems to be the dominant component.

Fairly complex mathematical models have been developed for smoothing forecasts—exponential smoothing, seasonal indexes, and other methods. Some of these models are discussed later in the chapter. Most incorporate factors such as trend and seasonality while attempting to cope with random noise. However, the more complex models have limited value in most pharmaceutical supply situations; the following methods of tracking average consumption (to forecast demand) are suitable for most pharmaceutical supply systems—

- *Simple average consumption*: the average monthly consumption over the past twelve months (or less, such as six months, if no seasonal changes exist in consumption)
- *Seasonal average consumption*: the average consumption in the last comparable season or epidemic cycle for specific medicines
- *Moving average consumption*: the average monthly consumption in the most recent months—for example, the past two or three months

The key variables in these methods are which months and how many months (or weeks or days) are included in the review period for which consumption is averaged. Note that consumption in the three methods is stated in monthly terms, but it could be daily or weekly for a perpetual system, or yearly for annual purchasing.

Whichever review period is used, if the item was out of stock for part of the period, the consumption must be adjusted to what it would have been if no stockouts had occurred. One good method for making such adjustments is described in [Chapter 20](#), Section 20.4.

When consumption patterns during the year are fairly stable or unpredictable variations (random noise) exist, simple average consumption provides adequate results, adjusting safety stock levels to cope with variations in consumption.

When big differences exist in seasonal demand, use of simple average consumption may produce stockouts in peak demand seasons (and simultaneously set stock levels too high in nonpeak seasons). Therefore, the seasonal average is used to adjust reorder and stock levels for each season. The review period is set to the number of periods in a season. For example, if the malaria season lasts four months, look at consumption patterns for sulfadoxine-pyrimethamine in the four-month malaria season last year rather than the past twelve months to predict needs for this year's season.

Moving averages are suitable for use when a definite trend exists in consumption, up or down, in recent months and reasons exist to expect the trend to continue. Both moving averages and seasonal averages fit well with scheduled purchasing, but they can be applied (with caution) to perpetual purchasing as well.

Integrating experience and other factors

No matter how precise the reordering formula is, external factors may force an adjustment of the quantity suggested by a reordering formula. In most supply systems, the reordering formula suggests quantities, but the purchasing manager makes the final decision. If the reordering formulas are appropriate, relatively few formula recommendations should be overruled by the manager (certainly fewer than 10 percent). However, if the manager knows about an external factor, such as those cited below, or believes that the formula is producing nonsense (perhaps because reordering factors have not been properly entered), experience and local judgment should be the deciding factors.

The key is for responsible officials to understand and accept the reordering formula, so that managers are not looking for reasons to override suggested quantities. One way to ensure this acceptance is to involve operations-level managers in developing and approving the reorder formula that will be used. Examples of factors that might affect reorder quality follow.

Budget status. Most supply systems operate under a specified budget ceiling. Budget management has two basic approaches. In one, the supply system develops a purchasing budget for each item, specifying the quantity budgeted for the year. Then the orders during the year are tracked against this line-item budget. In order to increase the total annual quantity for any item, the quantity for another item must be reduced (or more funds must be located). In the other budget management approach, all procurement funds are lumped together, and orders are placed for whatever items

are perceived to be needed until funds are gone. With either budgeting approach, managers need to monitor the items and quantities on each purchase order and cumulative purchases to make sure that the budget is not overspent.

Access to funds. Even if funds are theoretically budgeted, they may not be available at the time to place an order; if funds are insufficient to purchase all the items suggested by the standard reordering formula, adjustments need to be made (see [Chapters 20](#) and [40](#)).

Pack size and minimum order. The order quantity often needs to be adjusted so that even pack sizes are ordered. For example, if the formula suggests ordering 900 capsules, it might be possible to order nine bottles of 100 capsules. However, if the contract price is based on bottles of 1,000, the order would be placed for one bottle of 1,000. Similarly, if the formula suggests ten bottles of 100 capsules but the supplier's contract specifies a minimum order of twelve bottles, then twelve bottles must be ordered (such minimums should be avoided in supply contracts, if possible).

Expected changes in use. If a change is anticipated within the next purchasing cycle in the number of health facilities or in the formulary or essential medicines list, allowances need to be made in reordering schemes, particularly in annual and scheduled purchasing models.

Expected price increase. If managers know that prices will rise significantly for a medicine or group of medicines before the next ordering cycle, they may decide that ordering unusually high quantities will be cost-effective if consumption patterns indicate that the higher quantities will be used before expiry (or loss or deterioration).

Rising delivery costs. If shipping costs are a major factor in total pharmaceutical costs and they are expected to increase significantly, the approach is similar to the one used for rising prices. The medicines affected should be ordered in higher quantities, with the same precaution concerning capacity to use the entire quantity.

Quantity discounts. Some suppliers routinely offer quantity discounts—for example, 10 percent off with a certain total monetary order, or one item free if twelve are ordered. In such cases, particularly for fast-moving items that will definitely be used, the reordering system should be flexible enough to take advantage of the discounts, within funding limits. Again, the main limitation is the capacity to use the item before expiration or loss.

Excess stock of slow-moving products. If senior managers discover an excessive average inventory level, the temptation is to order a cutback in all purchasing. But this policy will only lead to shortages of fast-moving items, with no reduction for most of the problem stock. Strategies to promote the use of slower-moving items by substitution for other medicines (as appropriate), close review of reorder levels and quantities, and careful monitoring of the ordering procedures, without a purchasing freeze, are better alternatives.

Losses to theft and wastage. If losses are significant, they need to be considered in the order quantity (see [Chapter 20](#)).

Storage space. In the case of certain bulky products, order quantities may need to be reduced to accommodate storage space limitations.

Short-dated products. Certain pharmaceutical products come with a very limited shelf life. In such cases, order quantities should be limited in relation to the expected monthly consumption rate to prevent risk of medicine expiry.

23.8 Standard reordering formulas

The previous section discussed factors that need to be incorporated into the reordering formula. This section looks at two approaches to the question of how much to order—

1. Minimum and maximum stock levels
2. Consumption-based reordering formulas

Minimum and maximum stock-level formula

This formula is often used in scheduled purchasing with set order intervals. Using this approach, one defines a theoretical maximum stock for each item to provide sufficient, but not excessive, stock to last from one order to the next, as well as a minimum stock level or reorder level that determines at what point an order should be placed. Safety stock may be included in the minimum stock level, or an additional quantity may be assigned to protect against variations in demand and supplier performance.

Some supply system managers set the minimum and maximum stock levels arbitrarily for all items, but better inventory control is obtained with a flexible calculation for each item, based on standard reorder parameters—

- Average monthly consumption, adjusted for stockouts (C_A)
- Supplier lead time (LT)
- Procurement period—time until the next order will be placed (PP)
- Safety stock—additional stock to cope with variability in consumption and lead time (SS)
- Stock on hand in inventory (S_I)
- Stock now on order from a supplier but not yet received (S_O)
- Quantity of stock back-ordered to lower levels (S_B)

The basic formula for setting the minimum stock level is the average consumption multiplied by the lead time, plus any additional safety stock. Times are usually expressed in months, and stock quantities, in basic units (see the glossary at the end of [Chapter 18](#)). Options for setting safety

stock levels were discussed in Section 23.5; any safety stock needed in addition to the minimum stock level might be defined arbitrarily or by calculating the difference between average and maximum consumption. The equation for calculating the minimum stock (S_{MIN}) is—

$$\text{Minimum stock} = (LT \times C_A) + SS$$

The maximum (target) stock level (S_{MAX}) can be calculated as the minimum stock plus the procurement period multiplied by the average consumption; the equation is—

$$(S_{MAX}) = (S_{MIN}) + (PP \times C_A)$$

An example of minimum-maximum level calculations is a case in which the lead time for tetracycline capsules is two months, the average monthly consumption (adjusted for stockouts) is 1,000 capsules, and the additional safety stock allocated is 2,000 capsules. For a procurement period of six months, the following minimum and maximum quantities would be set—

$$\begin{aligned} S_{MIN} &= (2 \times 1,000) + 2,000 = 4,000 \text{ capsules} \\ S_{MAX} &= 4,000 + (6 \times 1,000) = 10,000 \text{ capsules} \end{aligned}$$

When the stock level is found to be at or below the minimum level, the order quantity (Q_O) is calculated as the maximum stock plus stock back-ordered to clients, minus the sum of stock on hand and stock on order. The formula is—

$$Q_O = (S_{MAX} + S_B) - (S_I + S_O)$$

In the example above, suppose 3,000 tetracycline capsules are in stock and another 2,000 are on order. Because the tetracycline has been in stock, there are no back orders to health facilities. The quantity to order would be calculated as—

$$Q_O = 10,000 - (3,000 + 2,000) + 0 = 5,000$$

Some variation of this system is used in many different countries. As long as the minimum and maximum quantities reflect current lead times, consumption patterns, safety stock needs, and order intervals, this system works as well as any other basic reorder formula. The key is regular updating of the minimum and maximum levels. Otherwise the original minimum and maximum levels will become obsolete, because average consumption and lead times usually change with time for many items. Then the formula will produce shortages of items that are moving faster than when the levels were set and overstocks of the items that are moving slower than before.

These problems are most likely to occur when the levels were set for each item by hand in one massive effort, with

no formal plan for reviewing and updating the quantities. If several thousand items are used, at least one full-time worker is needed to keep the minimum and maximum quantities updated using a manual review system. Any supply system that uses this reorder formula to manage a large inventory would be well advised to obtain computer software that does the minimum-maximum quantity updating automatically, according to a formula similar to those above. In addition, by using an ABC analysis of all items, managers can prioritize the setting and reviewing of minimum and maximum quantities for items by class A, B, and C.

A supply system using the minimum-maximum method needs supplementary orders to cover situations in which the stock for an item has not sunk to the minimum when regular orders are placed but does so in the middle of the interval between orders, or when the order is not placed as soon as the reorder level is reached. In those situations, the stock will not last until the next regular order has been placed and received, unless safety stocks have been set very high.

One way to deal with emergency orders in a minimum-maximum system is called *modified optional replenishment*. With that system, there is a reorder level, which is the same as the standard definition for minimum level, as well as a second minimum stock level, which might be called the *emergency warning level*. If the stock position is above the reorder level at the reorder date, no order is placed. If the stock level falls to the emergency warning level between scheduled orders, an emergency order is placed.

Although the terminology can vary, this sort of emergency warning level can be useful in any supply system. Of course, emergency purchases must be closely monitored by managers. Some temptation may exist to disregard the regular system and rely mostly on emergency orders (which can be ruinously expensive).

Consumption-based reordering formula

This formula bypasses the step of setting (or calculating) minimum-maximum levels and instead calculates the proposed reorder quantity directly. The formula recommended here is basically the same as the formula for consumption-based quantification in [Chapter 20](#) (except for back orders, which are normally not an issue in large-scale forecasting). The suggested next order quantity is calculated for each item based on the average consumption, lead time, desired safety stock level, stock position, and period to be covered by the purchase. The safety stock level in this formula serves a function equivalent to the minimum stock level in the previous formula, in that it is the level that warns of possible stockouts if an order is not placed. However, with this formula, an order quantity can be calculated at any time without waiting to reach the safety stock level.

Note that the variables are the same as those used in the maximum-minimum method; in fact, the proposed reorder

quantity should be the same with both formulas, assuming the same variable values. This formula facilitates management of scheduled purchasing, because the formula always suggests an order quantity whenever stock is not enough to cover the next procurement period, without regard to any predetermined reorder level. Another advantage with this formula is that when emergency orders are needed in a scheduled purchasing system, the same formula is used to compute emergency order quantity as would be used for a regular order.

This consumption-based reordering formula is suitable for perpetual purchasing, assuming that computer software is available that recalculates suggested order quantity on command, ideally after each transaction. [Country Study 23-1](#) shows how scheduled purchasing is managed with this formula in the Organisation of Eastern Caribbean States.

The variables in the recommended formula are—

- Average monthly consumption, adjusted for stockouts (C_A)
- Supplier lead time (LT)
- Procurement period—time until the next order will be placed (PP)
- Safety stock (SS)
- Stock in inventory (S_I)
- Quantity of stock now on order from a supplier but not yet received (S_O)
- Quantity of stock back-ordered to lower levels (S_B)

In this formula, the minimum safety stock (which can be modified as discussed in Section 23.5) should be the lead time multiplied by the average consumption during the lead time: $C_A \times LT$.

The complete formula to calculate the quantity to order (Q_O) for each item (without considering intrasystem back orders) is the adjusted average consumption, multiplied by the sum of lead time and procurement period, plus safety stock, minus the sum of stock on hand and stock on order. The symbolic formula is—

$$Q_O = C_A \times (LT + PP) + SS - (S_I + S_O)$$

If the supply system uses back orders internally, and quantities are outstanding to operating units that must be filled when an order is received, the formula would add back orders (S_B) to the projected demand requirements in the formula (as was the case for the minimum-maximum formula), yielding—

$$Q_O = C_A \times (LT + PP) + SS + S_B - (S_I + S_O)$$

For example, suppose (because of an epidemic of cholera) no tetracycline capsules are in stock, and 2,000 are back-ordered to lower-level facilities at the time scheduled

for reordering. One order is outstanding to the supplier for 3,000 capsules. The lead time for this supplier is two months, the average monthly consumption is 1,000 capsules, the safety stock is calculated as 2,000 capsules, and the procurement period is six months. The quantity to order is calculated as—

$$Q_o = 1,000 \times (2 + 6) + 2,000 + 2,000 - (0 + 3,000) = 9,000$$

23.9 Mathematical models for reordering

The goal of inventory management is a system that responds to what patients actually need, not one based on the results of modeling. The most advanced commercial supply systems are moving toward using technology to track what customers buy, then reporting the information throughout an integrated supply chain to the manufacturer. However, until those technologies become the norm for pharmaceutical supply, many authoritative sources agree that simple models to determine product orders, such as those presented in Section 23.8, are preferable to more complex models in most situations. Objections to complex models include (1) that the refinements gained in controlling stock even in the best cases are not substantial in comparison to minimum-maximum and consumption-based formulas; (2) that in most cases, the information fed into the equations is only an estimate, leading to results that are not precise despite the air of precision lent by sophisticated calculations; and (3) that in many cases, staff members do not understand the more complex models, do not trust the results, and make their own subjective determinations of order quantities and desired stock levels.

Mathematical models have been developed to address most aspects of inventory management. The most widely known of these models is the economic order quantity (EOQ), but others are worth mentioning, such as the economic order interval (EOI) and some of the mathematical approaches for smoothing forecasts of demand and lead time and for estimating safety stock requirements. EOQ and EOI are illustrated in some detail here, followed by brief discussions of some of the other models.

Economic order quantity

The EOQ concept has been around for more than fifty years and is widely applied in commercial firms that use a perpetual purchasing model. The basic idea is that an ideal order quantity exists for any item, which strikes an optimum balance between inventory-holding costs and incremental ordering costs (see [Box 23-3](#) and [Chapter 40](#)).

With its precise outputs, EOQ seems very sophisticated. EOQ might appear to be exactly what is needed in all pharmaceutical supply systems, or at least those that use per-

petual purchasing. In fact, the need to order by package means that some deviation from the true EOQ will occur for many items. Another limitation is that the EOQ formula assumes that lead times and consumption rates are predictable, orders are received instantaneously, and stockouts are not permitted. Because that is obviously not true, additional calculations are required to establish the appropriate safety stock level, which introduces uncertainty even if the basic EOQ calculation is exact.

Some have contended that EOQ is really “the square root of two times a guess, times a scientific guess, divided by a precise guess, times management’s guess.” Nevertheless, the EOQ is still a reasonable choice for estimating order quantities in a perpetual purchasing system in which access to suppliers and funds is such that orders can be placed at any time. The quantities calculated using the model should, however, be treated as guidelines and not absolutes.

When other reordering formulas are used to manage inventory, calculating the EOQ periodically for high-use, high-value items (class A) may be useful for comparing the theoretical ideal order quantity with current practice.

Economic order interval

A concept related to EOQ is EOI—the theoretical ideal interval for spacing orders placed for the EOQ. As is the case with EOQ, the EOI changes, depending on the values of the individual variables; with a much higher acquisition cost, the EOI decreases (more orders per year), and so forth. Also, like EOQ, the EOI formula produces recommendations that must be rounded.

Although EOI has its main application in systems that use EOQ to set the order quantity, EOI can be used in pharmaceutical supply systems to check the theoretical ideal ordering intervals for scheduled purchasing and then to group items that would best be ordered monthly, quarterly, semiannually, and so forth. The EOI is also illustrated in [Box 23-3](#).

Exponential smoothing

Exponential smoothing is a common technique for coping with variation in consumption or lead-time patterns. In this technique, a smoothing constant (called *alpha*) is used to adjust the observed average consumption or lead-time values.

One application of exponential smoothing calculates the projected demand (D) by factoring in the average consumption from the three-month lead time (C_L), the consumption from the past month (C_A), and the smoothing factor alpha (α), which for these purposes is usually set between 0.1 and 0.2. The equation is—

$$D = C_L + [\alpha \times (C_A - C_L)]$$

Box 23-3 Economic order quantity and order interval

EOQ

Although many variations exist, the most basic formula for the EOQ is—

$$\text{EOQ} = \sqrt{(2 \times U \times O) \div (H \times C)}$$

where—

U = annual use, in units

O = incremental ordering cost

H = average holding cost (percentage of average inventory value)

C = projected net acquisition cost

Considering an example of dextrose bags for IV injection, assume a projected annual use of 25,000 bags at an average acquisition price of USD 2 per bag. Also assume that the estimated incremental ordering cost is USD 70 per order placed, and the average inventory-holding cost is 40 percent. The calculation proceeds as follows—

Step 1: $2 \times 25,000 \times 70 = 3,500,000$ ($2 \times U \times O$)

Step 2: $2 \times 0.4 = 0.8$ ($H \times C$)

Step 3: $3,500,000 \div 0.8 = 4,375,000$
($[2 \times U \times O] \div [H \times C]$)

Step 4: Square root = 2,091.65

Thus, according to the EOQ model, dextrose bags should be ordered in quantities of 2,091.65 bags. Before going further, the reader should consider what happens when the individual variables go up or down. For example, if the item's acquisition cost is USD .20 (with all other vari-

ables the same), the EOQ would be 6,614.38 bags; if the price is USD 20, the EOQ would be 661.44 bags. If only consumption changes, annual use of 5,000 bags produces an EOQ of 935.41 bags, and annual use of 50,000 bags yields an EOQ of 2,958.04 bags. When incremental costs of purchasing go up, the EOQ goes up (to decrease the ordering frequency); as the holding cost percentage goes up, the EOQ goes down, to increase order frequency and decrease stock levels.

EOI

The formula for calculating the EOI uses the same variables as the EOQ but combines them as follows—

$$\text{EOI} = \sqrt{(2 \times O) \div (U \times H \times C)}$$

where—

U = annual use in units

C = projected net acquisition cost

O = ordering cost

H = holding cost

The EOI produces its result as fractions of a year (assuming that consumption is based on a year). For the EOQ example above, the EOI for orders of 2,091.65 bags would be 0.084 years, which converts to 1.004 months, 4.35 weeks, or 30.5 days. The calculation is—

Step 1: $(2 \times 70) \div (25,000 \times 0.4 \times 2)$

Step 2: $140 \div 20,000 = .007$

Step 3: $\sqrt{.007} = 0.08366$ years

If, for example, an item had averaged 150 units consumed per month over the last three months but 200 were used in the last month, the smoothed average using an alpha value of 0.1 would be—

$$D = 150 + [0.1 \times (200 - 150)] = 155$$

Clearly the difference between the simple average and the smoothed average would be greater with larger consumption values and with a higher alpha factor.

This equation is not complex in itself, but choosing the value for the alpha factor is tricky (most authorities recommend trial runs using various values, then observing results and trying again). The higher the alpha, the more “adaptable” the forecast is to recent trends; however, the higher the alpha factor, the lower the reliability when a large random noise factor is present in the consumption pattern.

Standard deviation of consumption and lead time

The standard deviation of consumption and of lead time can be used in mathematical models to adjust forecasts when variation (random noise) in the consumption or lead-time pattern is considerable. Standard deviation is basically an estimate of how much an individual value is likely to vary from the average of all values in a series (see Rowntree 2003 for methods for calculating standard deviation).

The following equation illustrates how the standard deviation of lead-time consumption (SD_{LTC}) is calculated, for use in setting safety stocks—

$$SD_{LTC} = \sqrt{(LT \times SD_C^2) + (C_A^2 \times SD_{LT}^2)}$$

where—

C_A = average monthly consumption

LT = average lead time

SD_C = standard deviation of consumption

SD_{LT} = standard deviation of lead time

For example, if consumption of an item averages 1,000 units per month with a standard deviation of 100, and the lead time averages three months with a standard deviation of 0.75 months, the average consumption during the lead time period is 3,000 units, and the standard deviation of that lead time consumption is calculated as—

$$\sqrt{[3 \times (100 \times 100)] + [(1,000 \times 1,000) \times (0.75 \times 0.75)]} = 769.74$$

Most values in any series of observations show a normal distribution pattern around the mean (average) value. (For example, in a population of men who average 6 feet in height, about half the men will be taller and about half will be shorter rather than exactly 6 feet.) Normal distributions characteristically demonstrate that the standard deviation times about two will encompass 95 percent of the values clustered above and below the average (see Rowntree 2003). Thus, in the example here, 95 percent of the time, the monthly consumption will fall within two times the standard deviation of monthly consumption.

This calculation could be used with any reordering formula to assign safety stock in order to theoretically achieve

a 95 percent service level. For the example given above, 2×770 equals 1,540 units needed as safety stock, in addition to average lead-time consumption. In a minimum-maximum formula, the minimum level would be 3,000 units ($C_A \times LT$), and the added safety stock would be 1,540 units. In a consumption-based formula, the total safety stock would be 4,540 units. ■

ASSESSMENT GUIDE

Performance indicators

As discussed in Chapters 36 and 48, indicators have been developed expressly for use in public-sector pharmaceutical supply systems. Some of them should be considered as tools to measure inventory management performance, although no standards exist yet for the acceptable range of performance. These indicators include—

- Average percentage of inventory variation in the stock record-keeping system, at a sample of warehouses and facilities
- Percentage of stock records that correspond with physical counts, at a sample of warehouses and facilities
- Percentage of a specified set of indicator medicines that are in stock at a sample of warehouses and facilities
- Average percentage of time out of stock for the set of indicator medicines
- Average lead time from suppliers and from warehouses to facilities

Context for inventory management

- Are all supply system operations related to finished goods, or does the system also manufacture pharmaceuticals?
- At what levels of the system are pharmaceutical orders placed, either to suppliers or to other levels of the system?

Selection of items for stock status

- How do managers and operations personnel determine which items should be held in stock and which (if any) should be ordered only as needed?

Costs associated with inventory and purchasing operations

- How is inventory valued, and what procedures are used to physically count stock and reconcile records?
- How many months' worth of stock is on hand at central storage facilities? At regional and district facilities? At hospital pharmacies, health centers, dispensaries, and other clinical facilities?
- What information is available on inventory values, operating costs of warehouses, operating costs of the purchasing department, and costs associated with shortages? If such information is available, how is it used?
- Are techniques such as ABC value analysis, VEN analysis, and total variable cost analysis used in for-

mulating inventory management strategies? If so, in what areas?

Stock records and routine reports

- What inventory needs exist at each level of the health care system? How accurate and how current are the records? Do they supply the information needed for procurement and distribution decisions?
- If a computerized information system is in use, is it a general purpose inventory management package or a special-purpose package developed for managing public-sector pharmaceutical supply systems? Does it automatically calculate minimum and maximum quantities or consumption-based order quantities?
- What standard reports are produced on inventory status, procurement operations, and consumption patterns? How is the information used?

Safety stocks and service levels

- How are safety stock levels calculated at each level of the system?
- What adjustments in safety stocks are made for variations in consumption and lead-time patterns?
- What percentage service levels are normally achieved by warehouses supplying lower levels of the system? What percentage service levels are provided by major suppliers to the system?

Purchasing model

- How frequently are pharmaceutical orders placed at each level that places orders? Is the same model used for all items?
- What percentage of orders are routine and what percentage are emergency orders?
- Do any special factors dictate the choice of inventory management strategies, such as government financial and administrative regulations, staff, existing management information systems, supplier access, or contract procedures?

Reorder formulas

- What reordering formulas are used to determine purchase quantities? Is the same formula used at all levels and all facilities?
- What source data are used in the formulas?
- How much weight is given to the manager's experience and judgment? What other factors are considered?

SUMMARY

The purpose of an effective and efficient importation and port-clearance process is to ensure that pharmaceuticals and related health supplies are cleared from a land, sea, or airport with the least possible delay after their arrival.

Port delays can have costly consequences, such as—

- Reduced shelf life or, for vaccines and other very temperature-sensitive items, possibly a complete loss of potency
- Deterioration of product
- Damage to product cartons and other packaging or damage to outer identification
- Increased chance of theft
- Storage fees (demurrage), which can result in prohibitively high costs
- Stockouts, resulting in emergency purchases made at higher unit cost and with the potential for unassured quality
- Cash flow problems caused by pharmaceutical products being tied up for indefinite periods in port

The port-clearing process consists of—

- Managing preshipment issues, such as documentation, which are often required for the clearance process
- Identifying and anticipating the arrival of shipments
- Locating the shipments and the particular consignments
- Obtaining the documents needed for clearing before the arrival of supplies at a port, and ensuring that the documents are in accordance with the country's port and customs requirements
- Making timely payments relating to the clearance process

- Ensuring that appropriate storage space is available to receive the shipment and that transport is available immediately
- Delivering goods to the warehouse or other storage facility as appropriate

Expediting port clearing is an important function, requiring either a well-organized, paper-based activity-monitoring system or a computerized information system, as well as suitably trained human resources.

Port clearing may be slowed by government customs and import regulations, and inefficiencies within agencies that import goods. Private companies are sometimes able to achieve more rapid port clearance than government agencies. Two private-sector choices are available: either the supplier can be made responsible for the port-clearing process and delivering goods to a nominated warehouse, or the task can be contracted out to a clearing and forwarding agent. Retaining the services of experienced and well-trained staff can significantly improve the port-clearing process. A cost/benefit analysis should be carried out to establish the most suitable method for managing port clearance—either in-house or outsourced to the private sector. In addition, any changes to clearance formalities must be monitored continuously to prevent unnecessary delays when new regulations come into force.

Losses and damage in transit can be substantial. In order to recover insured losses, the import unit must lodge insurance claims systematically and expeditiously, because insurance companies usually have specific periods within which claims must be made.

24.1 Managing importation

This chapter discusses systems and procedures to improve the efficiency of port clearing. The port-clearing process is vital to the efficient operation of a public pharmaceutical supply program, whether it is performed by public employees or contracted out.

In many countries, clearing pharmaceutical consignments from airports and other ports is an inefficient and time-consuming activity that leads to financial losses. Unlike products that are nonperishable or indestructible, medicines and medical supplies can be damaged by poor handling and inadequate or poor storage conditions. They are also highly attractive to thieves. Thus, there is a criti-

cal need to clear pharmaceuticals and other temperature-sensitive and high-value products, such as HIV test kits, as quickly as possible after delivery to any port. The speed of this process is particularly important in landlocked countries, where goods may travel long distances overland, subject to unexpected delays, in less than desirable storage conditions.

Financial losses caused by poor port-clearing management, such as the following, can be extensive and are often proportional to the delay in the port.

- Shelf life can be affected when products are kept in the port under incorrect storage conditions. In the case of vaccines and other temperature-sensitive products, the

product may be rendered unusable or extra costs may be incurred to test the potency of the items.

- The likelihood of theft and product deterioration or damage is increased, especially when cartons are damaged by poor handling or are handled multiple times.
- Storage fees (demurrage) can result from delays in clearing; such fees are often substantial.
- Port-clearing delays result in longer delivery lead times. Unless funds are invested to increase safety stocks, stockouts may occur at storage and dispensing facilities, leading to extra expenditures on emergency purchases and supply chain disruption.
- Capital funds are tied up by port-clearing delays, which worsen cash flow problems in programs operating a revolving drug fund.

In many countries, the efficiency and economy of port clearing are hindered by cumbersome, bureaucratic, or obsolete regulations and by the poor systems and procedures used by customs and port authorities. The resulting delays for importers are substantial, yet improving performance can be difficult. The common practice adopted by private companies and individual importers is to obtain the services of a private clearing agent on a contract basis. An experienced agent has the best chance of negotiating the regulatory labyrinth in the shortest possible time.

24.2 Using a clearing and forwarding agent

Importation and customs clearance is a specialized area of work. Unless the pharmaceutical program already has an experienced team with clearing and forwarding skills, contracting with a specialized clearing and forwarding agent is strongly recommended.

If a private-sector agent is used, tenders for these services should be obtained from several companies, particularly if a large volume of business is involved. Any tender must clearly specify the service levels required and request pharmaceutical handling experience and references from current and previous clients. Tenderers should be asked to specify all charges and rates and to clearly identify the duties they will perform (see [Box 24-1](#)). Before an agent is appointed, it is important to obtain satisfactory business references from other clients and verify documents that have been submitted with the tender offers. The agent's offices and warehouses should also be inspected to ensure that good business and materials-handling practices are observed. Pharmaceuticals require special handling, and the agent should show an understanding of the problems associated with such commodities and demonstrate the ability to deal with these problems.

The import agency must have a broad understanding of the regulations and procedures related to customs and

Box 24-1

Contracting for port clearing

The following list includes the main features of a contract for port-clearing and forwarding services. Professional advice should be sought to ensure that terms and conditions are locally appropriate, legally enforceable, and realistic.

Scope of work

- Dealing with customs formalities
- Arranging clearance from the port or airport
- Arranging transport to the agent's warehouse or the consignee's premises
- Reviewing existing warehousing and identifying any potential problems in terms of capacity, security, ease of access, and availability of handling equipment
- Providing safe and secure warehousing prior to delivery, if required
- Arranging for delivery to final destinations, if required, which may include ensuring that lists of authorized signatories for taking over goods are available to maintain security
- Specifying documentation to be provided by the

supplier and by the consignee (for example, shipping advisory, bill of lading, air waybill, packing list)

Performance standards

- Time periods allowed for each stage in the import and port-clearing process
- Procedures for regular performance monitoring

Service requirements

- Reporting
- Quoting for individual consignments
- Payment arrangements
- Penalties for poor performance
- Security
- Dealing with defective shipments in a timely manner
- Restrictions on the sublease of services to other companies

Payment terms

- Port or airport charges itemized in detail
- Agent's costs itemized in detail

port clearance, whereas the clearing agent must be familiar with key local officials and understand local rules, practices, and culture to help the recipient through the routines required. For example, differences in standard work weeks because of cultural or religious customs could make clearance and delivery procedures unfeasible on particular days of the week (for instance, arrivals should not be scheduled in Muslim countries on Fridays). The agent should obtain documentation from the import agency in advance of the arrival of goods in port to avoid storage charges, and should also assist in obtaining relevant permits, waivers, or bonds. The agent must also be up-to-date with current legislation and promptly notify the principals of any changes.

The agent must take full responsibility for ensuring that the cargo is cleared and delivered with minimal delay, in a secure and appropriate way, and at the lowest cost (or at a cost consistent with the contracted rate). Even if this system is in place, it is critically important for the recipient

to understand all the stages of the importation and port-clearing process.

24.3 Organizing an import unit

An alternative to contracting with a private-sector clearing agent is to empower an import unit in the supply system to handle port-clearance responsibilities. This unit's responsibility should be specifically defined and include standard operating procedures, and the responsible officials should be accountable to the pharmaceutical supply program for prompt, reliable port clearance. The unit should have one or more experienced clearing agents on staff. Before the decision is made to organize an in-house import unit, its cost-effectiveness should be compared with that of using a contract with a private clearing agent. [Chapter 44](#) discusses the responsibilities of an import unit attached to medical stores.

24.4 The port-clearing process

The most important steps in the port-clearing process are discussed in this section. Shippers and their forwarding agents must check conditions at the relevant port at each end of the journey. This step includes establishing any limitations on the use, size, and availability of containers and container-handling equipment; determining storage conditions in warehouses or storerooms in the port; and ascertaining the availability and functionality of refrigeration equipment to store vaccines and other temperature-sensitive products.

Notify buyer of expected arrival date of shipments

As soon as a consignment of medicines is shipped (in the case of air freight, preferably twenty-four hours ahead of dispatch), the seller has the responsibility of telling the buyer the name of the carrying vessel, aircraft, or vehicle and its expected time of arrival at the buyer's port. This step is often done by e-mail or fax. The seller then dispatches to the buyer copies of all the documents mentioned in [Figure 24-1](#) and [Box 24-2](#). When the buyer receives these documents, the local agents for the shipper or carrier can be contacted to obtain exact arrival details.

Locate shipments

The shipper's local agent provides final details specifying the quay, airport, or land destination where the shipment will arrive. Typically, a land destination will be a customs-bonded warehouse that can be publicly or privately owned (often by the importer) and is often located right at the port of entry, which minimizes handling and therefore risk. Subsequently, the agent provides details of the specific port or customs warehouse to which the consignment will be cleared. During the time that goods are parked in a bonded warehouse, duties do not have to be paid. Duty is not due until the product is taken from the bonded warehouse to sell or consume; if the products are reexported or destroyed, then duties will not have to be paid at all. Storage in a bonded warehouse also allows time for pharmaceuticals to be quality-tested before being released to the market. Such warehouses require adequate security to prevent theft or diversion of pharmaceutical shipments and also should have the capacity to store medicines at the right conditions, including appropriate temperature, to prevent damage.

Obtain documents needed for clearing

The port authorities require the original copies of the documents described in [Box 24-2](#) to permit clearance by the buyer or its authorized clearing agent. Having an established

list of duly authorized persons able to sign for goods helps ensure full security and accountability. Along with the original documents described in [Box 24-2](#), the buyer or the clearing agent prepares customs and port authority entries. The drug regulatory authority may also inspect the shipment to make sure that the pharmaceuticals are registered, have been imported by a licensed importer, and any charges have been fully paid. After these steps are completed, customs duties (if applicable) as well as port authority and other charges must be paid before the consignment of medicines is removed from the custody of the customs and port authorities. When import agencies do not make advance preparations to have the required funds ready, clearance is delayed and storage fees accumulate.

Deliver to warehouse

Except in the case of medicines requiring special storage conditions—for example, a cold room or a dark location—the consignment is kept in a general-purpose port or customs warehouse until delivery. Such warehouses should be checked to ensure that they have appropriate handling and storage facilities for medicines in addition to straightforward container handling. The loading of the consignment onto trucks must be supervised by wharf officers from the import agency or its authorized clearing agent. To avoid delays at the delivery site, drivers should be told precisely where the consignment is to be delivered and informed of any particular timing issues related to warehouse closures or lack of receiving staff.

24.5 Expediting port clearing

Port facilities in many countries are inefficient. Nevertheless, the port-clearing department or port-clearing agent can improve the situation by adopting better systems and procedures. Typical problems experienced by an import unit, and some methods for expediting work, are discussed in this section.

Use of an activity monitoring system

One of the greatest problems experienced by the manager of an import unit or port-clearing department is the supervision of staff engaged in clearing shipments of medicines at the port. Unlike the staff of other departments, such as procurement and inventory control, many of the personnel involved in clearing medicines spend much of their time outside the office. Hence, supervision, assignment of duties, and progress monitoring are difficult. Careful selection of appropriate staff for port-clearing positions and consistent communication via radios or wireless telephones are important.

Figure 24-1 Processing of import documents

Box 24-2 Documents used in port clearing

Air waybill (AWB). Document prepared by the shipper that provides details about the contents of the shipment, the route and carrier, and the shipping charges.

Bank bill (BB). A bill presented by the buyer's bank to the buyer that covers the total cost of goods received and any bank charges for processing the order (cable charges, interest on letter of credit, fees).

Bank guarantee (BG). In certain circumstances, the lack of necessary documents may make it impossible for the buyer to clear a consignment of medicines that has arrived at the port. In such instances, a bank guarantee from the buyer's bank can facilitate port clearing.

Bill of lading (BL). A document certifying that the goods are in the charge of the carrying vessel and dated on or before the last date for shipment as given in the letter of credit. The document is issued by the shipper and signed by the master of the vessel.

Certificate of origin (CO). Document stating that the product under consideration has been produced by the manufacturer in the country concerned. Such a certificate should be obtained from a national chamber of commerce or similar institute of the exporter's country.

Certificate of quality (CQ). A buyer usually insists on certification from the supplier, such as batch certificates and a WHO-type certificate of a pharmaceutical product from the exporting country's drug regulatory authority (see [Chapters 19](#) and [39](#)).

Insurance policy (IP). Pharmaceutical consignments are generally insured against damage, pilferage, and complete loss. The insurance policy indicates that a certain sum of money has been paid as a premium to cover the consignment of medicines. This document normally pro-

vides information about the nature and extent of coverage provided and the terms and conditions under which it is valid.

Invoice (IN). Document provided by the supplier indicating costs, freight, insurance, and any other payment due on the order.

Letter of credit (LC). An interbank document issued by the buyer's bank. It states that a certain sum of money is available for the seller to claim from the bank as soon as a consignment is shipped and the required documents are presented, as specified in the letter of credit. It becomes irrevocable when appropriated and numbered by the bank.

Packing list (PL). Prepared by the seller, this document describes in detail the contents of each package in a consignment of medicines, including strength, pack size, number of packs per carton, and number of cartons per package. This information helps the buyer check whether medicines actually shipped are in accord with the packing list and the purchase contract.

Pro forma invoice (PI). Provided to the buyer by the supplier. It includes information such as the price of the product, shipping and insurance charges (if applicable), total value, a detailed description of the product offered, and terms of payment. In some cases, the PI must be authorized by the country's drug regulatory authority before clearing can be completed. The PI can also form the basis of assessing the fee payable to the drug regulatory authority by the importer.

Registration documents (RD). In some countries, the customs department or the drug regulatory authority requires registration documentation before pharmaceuticals can enter the system.

Under such conditions, the import manager may also find it helpful to maintain an information system that is capable of monitoring current port-clearing activities, causes of delays, and assignment of personnel and equipment. This system should also be able to expedite clearance of urgently needed consignments. In some instances, an information system includes the issue of logbooks for all officers, whether in-house or contracted, who are responsible for customs and port clearance, to record their activities. Logbooks can be used to identify possible causes for delays and solutions for avoiding them.

Information and documentation for expected consignments

Another major problem is lack of information on expected shipments. Commonly, the import unit spends a great deal of time checking with shipping agents to ascertain whether goods have arrived. In many instances, the import unit learns of the arrival of consignments only after the goods have actually landed. In some cases, high port-storage charges have already been incurred and goods requiring special storage may have been delayed or damaged by the

Table 24-1 Flow of importation documents

Document	Who generates?	By when?	How transmitted?	Who receives?
Purchase order	NGO distributor	Within 2 weeks of contract approval	Scanned copy sent by e-mail or regular mail	Supplier
Pro forma invoice	Supplier	1 week from receipt of purchase order	E-mail or fax	NGO distributor
Import permit	Ministry of health	3 days after receipt of pro forma invoice	Collection by NGO distributor	NGO distributor
Import declaration form	National revenue authority at ministry of finance	3 days after receipt of import permit	Collection by NGO distributor	NGO distributor, through clearing/forwarding agent
Invoice	Supplier	Within 3 days of receipt of import declaration form	Scanned copy sent by e-mail	NGO distributor and then to clearing/forwarding agent
Packing slip	Supplier	Within 3 days of receipt of import declaration form	Scanned copy sent by e-mail	NGO distributor and then to clearing/forwarding agent
Ocean bill of lading	Suppliers' agent	Within 1 week of shipment	Scanned copy sent by e-mail	NGO distributor and then to clearing/forwarding agent
Air waybill	Suppliers' agent	Within 1 day of shipment	Scanned copy sent by e-mail	NGO distributor and then to clearing/forwarding agent

time notification is received. Table 24-1 shows an example of a nonprofit distributor's importation document flow.

Excessive delays in port clearing and high port-storage charges are usually caused by a breakdown of communication between the supplier and the purchasing department. As described in Chapter 39, the procurement contract should clearly specify the number of copies of invoices, shipping documents, and any other supporting documentation needed, such as product registration papers or import licenses. One copy of the shipping document must be sent to the purchasing office by fax or other expeditious means when the shipment leaves the supplier's warehouse.

Often, the documents needed for clearing are not received on time from the supplier or too few copies are sent, resulting in additional delay and expense. Overcoming this problem requires the maintenance of good communication among the supplier, the freight forwarder, the consignee, and all other parties; a good practice is to use established, detailed document requirements that are agreed on by all parties involved in the process. In addition, reports of supplier inefficiency should be incorporated into the general merit-rating system for suppliers (see Chapter 21).

Country Study 39-2 describes how Papua New Guinea has addressed delays in port clearance by awarding contracts that require suppliers or their agents in the buyer's country to be responsible for customs, port clearance, and delivery of goods to warehouses designated by the buyer. In such cases, the seller is motivated to clear consignments and make the delivery immediately, because payment is not made to suppliers until receipt of the shipment.

24.6 Lodging insurance claims

When damaged goods or short shipments are identified, completing the insurance claim quickly is important. Recovery of insured losses depends on the existence of a thorough, systematic routine for inspecting all shipments when they are accepted at the port or at the central warehouse (see Chapter 44), and submission of claims within the time stipulated by the insurance company. Consistent recovery of insured losses also depends on the assignment of qualified staff members to carry out claims processing. An effective monitoring system reduces the chance that claims will be forgotten or unduly delayed. This function should be part of the system used for monitoring the port-clearing process. ■

ASSESSMENT GUIDE

Existing arrangements

- Which air, sea, and land ports are used? What proportion of total supplies comes through each port?
- What is the average time to clear goods from each port?
- Do any particular problems exist at each site, and how do they affect the clearance process?

Port conditions and clearance procedures

- Are cold rooms, freezers, and locked warehouses available? Do they have appropriate temperature controls? Are security personnel on duty at all times? Does security include fenced areas, alarms, or other controls? Are medicines damaged by climatic conditions?
- What are the causes of recent port losses?
 - Physical damage
 - Theft
 - Poor storage conditions
 - Lost shipments caused by crowding or disorganized port management
 - Delayed port clearance
 - Lack of human resources
 - Lack of appropriate handling equipment
- Who is responsible for port clearing?
 - Central medical stores staff
 - Ministry of health or government import unit
 - Private import agents
- Do port-clearing staff members know in advance when and where a shipment is due? Is this information used to speed port clearance? Do the same problems recur regularly, and if so, are remedial procedures being implemented?
- Are port-clearing staff members trained in import documentation and port-clearing procedures?
- Does the import unit workload vary significantly throughout the year? If so, when? Does this variation cause any difficulties?
- Do port authorities assign priority to pharmaceutical and other “sensitive” shipments?

- Do customs and import control regulations affect port-clearing efficiency? Do other agencies assist or impede port clearing? If the latter, can this situation be rectified?
- Are storage fees regularly incurred, and are they justified? Can they be avoided through remedial action?
- Are adequate and secure procedures in place for receiving and checking pharmaceuticals?
- Is adequate and suitable transport for distribution available?

Private clearing agents

- Are private clearing agents available? Are they competent to handle pharmaceutical shipments?
- How do charges for contracting with a private agent compare with the cost of existing arrangements?

Communications

- Does the import unit or agency have direct access to a reliable overseas telephone line and e-mail access? Does it have a fax machine and a computer?

Monitoring and evaluation

- What is the average time needed to clear shipments from the port or airport?
- Are effective systems in place for monitoring and evaluating import procedures? If not, which elements are missing?
- What is the annual cost of port losses as a percentage of the value of pharmaceuticals received? Do significant variations exist between ports? Why?
- If delays in port clearance are chronic, what are the causes?
 - Poor procedures by the buyer
 - Bureaucratic delays at the port
 - Inadequate communications
 - Lack of human resources
 - Missing or incomplete documentation
 - Lack of funds to clear goods

SUMMARY

Unreliable transport for pharmaceutical supplies is a major problem in many health care programs. Good transport practice demands reliability, efficiency, safety, accountability, timeliness, affordability, and sustainability.

Transport is difficult to plan and manage well. Politicians and senior program managers generally assign greater priority to other, more visible, aspects of health care delivery. However, policy makers and administrators need to appreciate that effective and responsive health service depends on always having medicines available when and where they are needed, which requires the secure and proper transport of pharmaceuticals and medical supplies. If the pharmaceutical sector has to compete with other services for planned and emergency logistics, the consequences may be critical to public health.

Transport is provided for pharmaceuticals and related supplies either by the subject facility, by the supplier, or by an outsourced transport service. The type, volume, frequency, and duration of transport services required are determined by the nature of the health service. For practical purposes, main stores or central medical stores require major transport when moving pharmaceuticals from port to warehouse. If the store has branches in different parts of the country, it will need to transport the supplies to the branches. Facility-level transport requires a sophisticated transport network, involving in-house vehicles, rental services, or supplier delivery.

When planning transport system improvements, managers must—

- Thoroughly review and understand the existing transport system
- Select suitable vehicles
- Ensure adherence to standard operating procedures
- Ensure that vehicles are used for their intended purpose
- Maintain vehicles properly
- Replace vehicles before they wear out or become too expensive to operate
- Provide funds for vehicle maintenance and replacement
- Consider the formation of a vehicle pool system
- Consider alternatives, such as third-party and private-sector contracts

Major determinants of the transport system, which require special attention, are the vehicles and their operation and management. The costs of purchasing, running, and maintaining vehicles are high. If funding is inadequate, transport services will not be sustainable.

Transport services require effective management, which is particularly difficult to achieve in countries where transport is challenging and the pool of qualified managers is relatively small. When a shortage of transport exists, health service vehicles are frequently misused for the personal benefit of health service staff. Strong management is necessary to eliminate abuses and to ensure that vehicles are used appropriately. Although cost is a limiting factor, the logistics needs of the pharmaceutical sector can be adequately met if vehicle costs are shared with other services.

In many countries, the burden of managing transport and transport maintenance services can be reduced by contracting out these services to private or parastatal companies that specialize in such operations and are able to provide competitive rates. Before taking such action, the private or parastatal sector must be assessed based on its capacity and past performance, and existing operating costs must be accurately assessed so that a realistic cost comparison can be made. Transport contractors should then be carefully selected and monitored, and contract terms should be clearly drawn up and enforced. These measures also make monitoring transport costs easier.

Contracting out transport services will be inevitable where air transport, and to a large extent, sea or river distribution is involved. However, in many developing countries with scarce transport resources, efficient private-sector transportation companies are still evolving and may not be sufficiently competitive or efficient. In such situations, regional and interregional cooperation and collaboration among various government agencies, nongovernmental organizations (NGOs), donors, and the private sector can help maximize available transport resources.

Effective quality assurance procedures are needed to ensure that pharmaceuticals are correctly handled before, during, and after transit, to avoid damage.

25.1 Planning in-house transport systems

The existing transport system should be thoroughly reviewed to make efficient and rational use of existing resources. Current operating costs should be accurately assessed and compared with the projected cost of alternative systems. This section examines the issues that must be considered when planning improvements in a transport system.

Understand the existing transport system

To understand the existing transport system and its problems, one needs an assessment to provide a clear understanding of the health system's purpose and organization. This assessment requires a determination of—

- Frequency, type, and payload of transport needed according to the nature of the health service, including the amount of inventory holding, which determines the frequency of resupply.
- Location and scope (mapping) of transport needs of all warehouses and health facilities.
- Performance record of the existing pharmaceutical transport system. A detailed inventory must be made of vehicles in use at every level in the distribution system, listing age, condition, operational status, and actual versus intended use. Obtaining this information is an essential starting point for any transport assessment and should be carried out thoroughly. The data collected may be used to determine whether the existing transport fleet, in its current state, is capable of satisfying program needs.
- Estimated costs for the repair of defective vehicles.
- Location and availability of spare parts, and vehicle servicing capacity.
- Location and availability of fuel.
- Geographical, climatic, and political factors that affect transportation.
- Population distribution. Transport costs per capita are much higher in sparsely populated areas than in areas of high population density. This factor is important to take into account so that funds can be targeted in a balanced manner.
- The condition, capacity, and limitations of road, rail, air, water, and other transportation networks.
- Alternative transportation resources at every level. These resources include vehicles belonging to other government agencies, to NGOs, and to private-sector carriers. Vehicle sharing between programs is often a good option for reducing costs and improving reliability. Public transport should also be considered where suitable. Unconventional forms of transport such as bicycles or boats may be highly cost-effective, particu-

larly for smaller-volume distribution in rural areas. For low-volume, time-critical, and high-value products, an international commercial shipper is a useful and dependable alternative. Such services are available in bigger towns.

- The annual cost of the existing transportation system. A crude index of performance can be obtained by considering this cost as a percentage of the value of pharmaceuticals delivered.
- Staff management issues related to transport, including the availability of key staff and management time available to devote to transport management.

If information is not already available, it should be collected using a structured survey (see [Chapter 36](#)). Total cost analysis is a good method for compiling cost data (see [Chapter 40](#)). Most information requires regular updating if it is to remain useful. Some data, such as vehicle breakdown reports, are required at monthly to quarterly intervals. Other data, such as road improvement information, need only occasional updating.

Plan routes and schedules

Pharmaceutical delivery routes should be planned at every level to make the best use of available resources. The following guidelines should be adopted—

- Arrange delivery routes and schedules so that vehicles start each journey fully loaded. Using a large vehicle to deliver small quantities of medicines is inefficient. Unless full loads are being dropped off at a single delivery point, a delivery circuit may be cheaper to operate than a series of trips back and forth.
- Always seek out a return load to maximize vehicle use, or alternatively, try to combine deliveries with supervisory visits.
- Make maximum use of good roads. Shortcuts along poor roads may save fuel and time, but driving on good roads improves vehicle life. Isolated travel routes also pose security concerns.
- Use vehicles that are appropriate to the route. Using four-wheel-drive vehicles on surfaced roads is a waste of resources.
- Arrange routes so that the vehicle can be parked in a secure compound during overnight stops.
- Plan routes to take account of fuel availability. If fuel is scarce, carrying fuel drums or fitting vehicles with long-range fuel tanks may be necessary. This need will reduce the space available for carrying supplies.
- Consult experienced drivers before deciding on the route. Drivers often have the best knowledge of local road conditions, fuel availability, weather, and security hazards. Their advice can be extremely valuable.

Country Study 25-1 Determining the appropriate fleet mix needed to transport pharmaceuticals in Zambia

The following analysis uses three sets of data from Zambia to plan a transport fleet based on deliveries from the Medical Stores Ltd. (MSL) to district health management teams (DHMTs) and hospitals. Below is an example of a schedule, for Route A.

Route A	Delivered at (departure date plus x days)	CYCLE 1			CYCLE 2			CYCLE 3		
		Order to stores	Truck departs stores	Delivery at health facility	Order to stores	Truck departs stores	Delivery at health facility	Order to stores	Truck departs stores	Delivery at health facility
Drop Point 1	1	23-Dec-04	3-Jan-05	4-Jan-05	20-Jan-05	31-Jan-05	1-Feb-05	17-Feb-05	28-Feb-05	1-Mar-05
Drop Point 2	1	23-Dec-04	3-Jan-05	4-Jan-05	20-Jan-05	31-Jan-05	1-Feb-05	17-Feb-05	28-Feb-05	1-Mar-05
Drop Point 3	1	23-Dec-04	3-Jan-05	4-Jan-05	20-Jan-05	31-Jan-05	1-Feb-05	17-Feb-05	28-Feb-05	1-Mar-05
Drop Point 4	2	23-Dec-04	3-Jan-05	5-Jan-05	20-Jan-05	31-Jan-05	2-Feb-05	17-Feb-05	28-Feb-05	2-Mar-05
Drop Point 5	2	23-Dec-04	3-Jan-05	5-Jan-05	20-Jan-05	31-Jan-05	2-Feb-05	17-Feb-05	28-Feb-05	2-Mar-05
Drop Point 6	3	23-Dec-04	3-Jan-05	6-Jan-05	20-Jan-05	31-Jan-05	3-Feb-05	17-Feb-05	28-Feb-05	3-Mar-05
Drop Point 7	3	23-Dec-04	3-Jan-05	6-Jan-05	20-Jan-05	31-Jan-05	3-Feb-05	17-Feb-05	28-Feb-05	3-Mar-05
Drop Point 8	3	23-Dec-04	3-Jan-05	6-Jan-05	20-Jan-05	31-Jan-05	3-Feb-05	17-Feb-05	28-Feb-05	3-Mar-05
Drop Point 9	4	23-Dec-04	3-Jan-05	7-Jan-05	20-Jan-05	31-Jan-05	4-Feb-05	17-Feb-05	28-Feb-05	4-Mar-05
Drop Point 10	4	23-Dec-04	3-Jan-05	7-Jan-05	20-Jan-05	31-Jan-05	4-Feb-05	17-Feb-05	28-Feb-05	4-Mar-05
Drop Point 11	4	23-Dec-04	3-Jan-05	7-Jan-05	20-Jan-05	31-Jan-05	4-Feb-05	17-Feb-05	28-Feb-05	4-Mar-05
Drop Point 12	5	23-Dec-04	3-Jan-05	8-Jan-05	20-Jan-05	31-Jan-05	5-Feb-05	17-Feb-05	28-Feb-05	5-Mar-05

The next set of data outlines the number and weight of cartons for each drop on the route and establishes a minimum and maximum loading weight. For example, the spreadsheet below shows that information for Chiengi DHMT. Combine with the route timing information above to develop fleet mix data for each route with the times for each delivery.

Station	Jan-04		Feb-04		Mar-04		Apr-04		May-04		Jun-04		Totals		Average		Max		Min	
	No	Wt	No	Wt	No	Wt	No	Wt	No	Wt	No	Wt	No	Wt	No	Wt	No	Wt	No	Wt
Chadiza DHMT	61	878	154	1,089	98	1,014	16	608	60	840	52	612	441	5,041	74	840	154	1,089	16	608
Chama DHMT	113	959	155	1,213	183	1,262	37	956	93	1,680	31	316	612	6,386	102	1,064	183	1,680	31	316
Chavuma DHMT	103	968	6	228	119	838	10	328	105	742	23	233	366	3,337	61	556	119	968	6	228
Chavuma Mission H					3	6			4	6	86	1,023	93	1,035	16	173	86	1,023	3	6
Chibombo DHMT	104	1,601	119	1,052	132	1,720	51	1,246	189	2,181	33	1,021	628	8,821	105	1,470	189	2,181	33	1,021
Chiengi DHMT	80	386			88	407	74	814	35	448	38	304	315	2,359	53	393	88	407	35	304

The weight for each route will determine the payload required for each vehicle. The payloads (shaded) are not large, but they help to create the appropriate fleet mix. Other information to consider in the calculation includes the average time the driver spends waiting at delivery and whether the facility accepts deliveries on Sunday.

From	Location	Station	Average		Driving Time	
			Boxes	Kg	Dry	Rain
Route A

Chiengi	MSL				23	23
	Total		1,127	11,708	79	86
					106	113

- Compare the costs of alternative combinations of routes and vehicles before making a final choice. [Country Study 25-1](#) describes Zambia's approach to vehicle selection. Transport cost assessment is described in Section 25.5.
- In the case of air transport, consider periodic deliveries (for example, monthly or quarterly), and select air transport contractors through public tenders, when applicable.
- Where sea or river distribution is involved, periodic deliveries to or collections by health facilities may be arranged by using boats owned or hired by the health facilities.

Analyze transport alternatives

The following are major transport options—

- Trucks, vans, and cars are the most common means of transporting medicines and supplies, but there are many other potential forms of transport.
- Air transport is frequently used for delivering emergency, costly, or heat-labile products, such as vaccines. Commercial air-freight charges are high, although packaging costs may be lower than with land transport. Theft may also be less common where airport security is good. In some settings, such as countries with many islands or challenging terrain, air transport may be not only the most cost-effective option, but also the only option for routinely transporting medicines. Light aircraft may be used to transport medicines and health workers to remote and otherwise inaccessible outposts and in emergency relief situations.
- Boats are appropriate in some areas with island communities, coastal settlements, navigable rivers, or large lakes. Pharmaceuticals transported by boat must be packaged and stored to protect them against water damage.
- Railways are an excellent and cheap means of transport, provided the service is reliable. Rail transport is particularly suitable for bulk shipments between major depots. One disadvantage is that the supplies usually need to be transferred to another form of transport at the end of the rail journey. Trans-shipment increases the risk of theft and damage.
- Private-sector trucking companies can offer a cost-effective delivery service, especially between major population centers. This issue is discussed in Section 25.6.
- Box trailer units increase load-carrying capacity without the need to buy additional trucks. Small trailers, towed behind cars or pickup trucks, can also be used to transport medicines in rural areas.
- Buses, minibuses, and other means of local passenger transport can be used by health workers for transporting small quantities of medicines.
- Transport resources owned or accessed by other government, nongovernmental, or donor agencies can be shared.

Many programs also use so-called intermediate transport to augment the major transport mechanisms. [Table 25-1](#) compares the capacity and daily range of common intermediate transport mechanisms.

Prepare a transport plan

After the existing transport system has been analyzed and the transport alternatives assessed, the logistics team should choose among the various options and balance sometimes conflicting priorities. A detailed transport plan should then be prepared that describes how all warehouses and facilities will be served. [Figure 25-1](#) shows an example of a multisite transport plan. Such a plan must include resource ownership; transportation routes and schedules; schedules of people, transportation equipment, and related sources; information on movement of vehicles, people, and goods; distances from the source to the delivery points; overnight stops; people driving and accompanying deliveries; fuel needs; per diem and contingency funds; alternative routing in emergencies; and accompanying documents, such as waybills, travel permits, logbooks, and vehicle and driver details.

Any arrangement including items held in a duty-free bond—at an airport or shipping port, for example—introduces a new set of variables to plan for, including securing the release of the shipments and transporting them by the client or forwarding agent to their required destination.

An inventory of special environmental and legal route-use requirements must be maintained for trip planning; for example, weigh stations, seasonal blockage by rain, security-restricted routes, security checkpoints, and toll roads. If a national security office exists, it can supply information to ensure safe driving through certain security-sensitive areas, such as recommending joining a convoy if the situation dictates.

Transportation planning systems help calculate the volume that needs to be transported to a certain location and at what time. Transportation planning systems provide management with details on multiple routes, schedules, operators, and the type and volume of loads. Such a system can be maintained manually or electronically, and it can be used to analyze transport operations and costs. A global positioning system (GPS) makes possible the monitoring of physical movement and location of vehicles.

Table 25-1 Performance characteristics and relative costs of some intermediate forms of transport

Vehicle	Maximum number of people carried ^a	Supplies carried (kg/m ³)	Maximum speed (km/hr)	Maximum range (km)	Route limitations	Relative cost ^c
Porter	—	25–35 0.25 m ³	5	20	Unlimited	0–10
Standard bicycle	1	20 ^b 0.25 m ³	20	60	Reasonably flat	50–90
Load-carrying bicycle	1	25–100 ^b 0.35 m ³	10–15	30–40	Reasonably flat	60–100
Bicycle and trailer	1	150 0.5 m ³	10–15	30–40	Reasonably flat, wide track	90–150
Bicycle and sidecar	1	150 0.4 m ³	10–15	30–40	Reasonably flat, wide track	90–150
Tricycle	1	150 0.5 m ³	10–15	30–40	Reasonably flat	150–200
Pack animal	—	50–200 ^b Varies	5	20	Unlimited	Variable
Animal-drawn cart	Varies	500–3,000 Varies	5	20	Reasonably flat, wide track	100–180
Motorcycle	1	50–75 ^b 0.25 m ³	40–90	100–200	Steep hills	250–600
Motorcycle and sidecar/tricycle	1	200–300 ^b 0.5–1.0 m ³	30–60	80–150	Moderate hills, wide track	350–800
ATV (quad bike) ^d	1	50–75 ^e 0.5 m ³	30–60	60	Rough, hilly terrain	750–1,500
Single-axle tractor and trailer	Varies	1,500 Varies	15–20	50	Steep hills, wide track	1,500
Utility vehicle	Varies	500–1,000 2.0 m ³	60	60	Steep hills, wide track	3,000

Source: Adapted from Hathaway 1985.

^a Number of people carried with full load of goods.

^b The maximum load weights for these intermediate modes of transport are 50 percent of the values quoted by Hathaway (1985). Figures have been reduced to take account of the risk of damage to valuable commodities if unstable vehicles fall over when heavily loaded. In many cases, the volume carried, not the weight, is the limiting factor.

^c Typical ranges are quoted. These are relative costs—no specific currency is implied.

^d All-terrain vehicle, two-wheel drive and four-wheel drive.

^e Payload given is without trailer. Trailers can be attached to all-terrain vehicles

25.2 Vehicle acquisition and disposal

This section examines various methods of vehicle procurement, policy options for vehicle replacement, the process of selecting appropriate vehicles, and methods for disposing of broken or obsolete vehicles.

Select method of vehicle procurement

A health program can procure vehicles, boats, or aircraft in four ways: purchase, donation, lease, or rental from the private sector. Contracting out transport to a private carrier should be considered as an alternative to procurement.

Purchase. Health programs generally acquire vehicles through purchasing, which involves capital expenditure. This method builds the capital base of the institution and makes the vehicle readily available. Recurrent costs include

vehicle insurance, servicing, and maintenance. A cost-recovery system can be introduced that makes the vehicle available for contracting out or personal use for a mileage-based fee when not needed by the program.

Donation. Vehicle donations are useful in some situations; in some countries, donations are the main source of vehicles. This arrangement usually does not involve capital expenditure, although importation taxes and duties may still need to be budgeted. There may be disadvantages, however. Donors may not fund insurance, servicing, and maintenance, and the health program will have to pay these expenses. Donors may wish to supply vehicles manufactured in the donor country, whether or not spare parts and maintenance skills are locally available, which can lead to serious problems. Careful analysis of the advantages and disadvantages should be made before soliciting or accepting vehicle donations. It is important to keep in mind that

Figure 25-1 Multisite transport plan

Plan 1: Start of trip from central store (A) to first destination site (B). Continue to sites B1 and B2 and return to central store (A) after completing delivery.

Plan 2: Start of trip from central store (A) to first destination site (C). Continue to sites C1, C2, and C3 and return to central store (A) after completing delivery.

Distribution plan	Route	Schedule	Mileage	Travel time	Vehicle tag	Driver/assistant
1	A to B	Depart A on Mon 12 May at 8.00 Arrive B on Mon 12 May at 10.00 Deliver at B at 10.30 Continue to site B1	45 km	2 hrs	XD 23401	Bob Ray/Mike Todd
1	B to B1	Depart B on Mon 12 May at 13.30 Arrive B1 on Mon 12 May at 15.00 Deliver at B1 at 15.30 Overnight at B1	30 km	1.5 hrs	XD 23401	Bob Ray/Mike Todd
1	B1 to B2	Depart B1 on Tue 13 May at 8.00 Arrive B2 on Tue 13 May at 12.00 Deliver at B2 at 14.00 Overnight at B2	70 km	4 hrs	XD 23401	Bob Ray/Mike Todd
1	B2 to A	Depart B2 on Wed 14 May at 8.00 Arrive A on Wed 14 May at 12.00	65 km	4 hrs	XD 23401	Bob Ray/Mike Todd
2	A to C	Depart A on Mon 12 May at 8.00 Arrive C on Mon 12 May at 13.30 Deliver at C at 14.00 Overnight at C	85 km	5.5 hrs	XD 10002	Bill Ryan/Ted Able
2	C to C1	Depart C on Tue 13 May at 8.00 Arrive C1 on Tue 13 May at 10.30 Deliver at C1 at 11.00 Continue to C2	25 km	2.5 hrs	XD 10002	Bill Ryan/Ted Able
2	C1 to C2	Depart C1 on Tue 13 May at 11.30 Arrive C2 on Tue 13 May at 13.00 Deliver at C2 at 14.00 Continue to C3	25 km	1.5 hrs	XD 10002	Bill Ryan/Ted Able
2	C2 to C3	Depart C2 on Tue 13 May at 14.30 Arrive C3 on Tue 13 May at 16.30 Overnight at C3	40 km	2 hrs	XD 10002	Bill Ryan/Ted Able
2	C3 to A	Deliver at C3 on Wed 14 May at 8.00 Depart C3 on Wed 14 May at 8.30 Arrive A on Wed 14 May at 11.00	50 km	2.5 hrs	XD 10002	Bill Ryan/Ted Able

Notes: Time for meals and rest must be taken into consideration. The recipient facilities must be given advance notice of the delivery so that they can make receipt arrangements prior to the arrival of the delivery van.

sustainability is the key issue, whereas donor agreements are of limited duration. The health system may not have the capacity to maintain vehicles; if it does not, the donated vehicles will have a limited life.

Lease or rental. If an in-house transport system is to be maintained, the costs of leasing and purchasing should be compared. Leasing or rental companies provide vehicles on a short- or long-term basis and may also be able to supply drivers for an additional charge. An advantage of leasing or rental is that additional vehicles can be obtained readily, and broken-down vehicles can be replaced as part of the contract agreement at no cost to the system.

Contracting out. Private or parastatal trucking companies may have better transport management capacity than government agencies. Trucking companies are likely to be most competitive on the major routes. Contracting out the major routes means that the health service does not need to acquire and manage heavy vehicles, nor does it need to train drivers and maintenance staff for these vehicles. However, when outsourcing transportation services, managers need to have the skills to administer and monitor the contracts (see Chapter 39).

Establish vehicle replacement policy

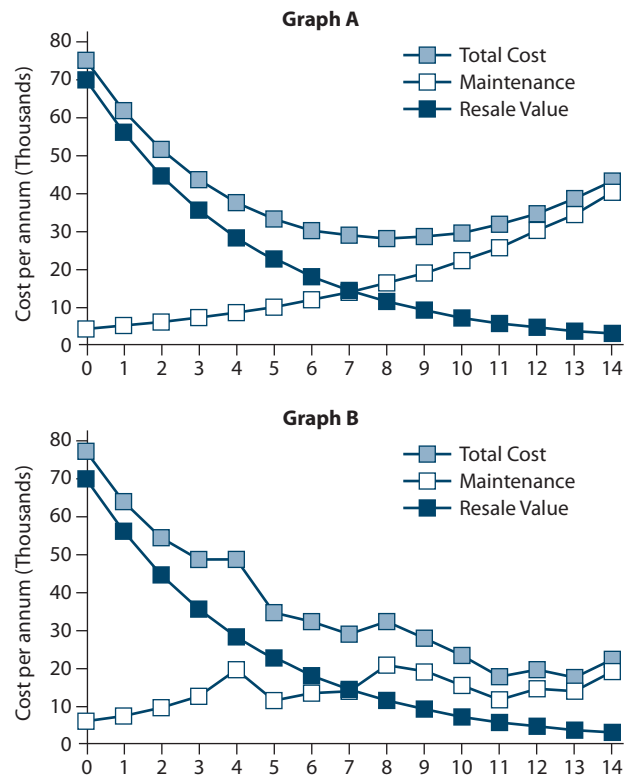

Implementing a transport plan is only the first step; in-house transport systems quickly collapse if there is no vehicle replacement policy.

Reviewing the transport plan regularly and analyzing vehicle operating costs carefully are essential. Most important of all is to negotiate adequate funding to maintain the system. As vehicles get older, the cost of servicing and repairing them increases. Eventually, they will have to be replaced. The balance between capital and recurrent expenditures therefore changes from year to year. This fluctuation can pose a problem, particularly when many new vehicles are suddenly acquired from a donor. These vehicles will deteriorate at similar rates and will need to be replaced at about the same time.

Four basic policy options are available for vehicle replacement—

1. A target life is set for each category of vehicle. All vehicles in a category are replaced when they reach this set age, regardless of mileage or condition.
2. A target mileage is set for each category of vehicle. All vehicles in a category are replaced when they reach this mileage, regardless of age or condition.
3. Vehicles are replaced, regardless of age or mileage, when they exceed a preset maintenance cost.
4. Vehicles are replaced when their operational availability (reliability) falls below a defined level. The aim should always be to operate a dependable fleet with a manageable number of breakdowns to address.

Figure 25-2 Replacement policy graphs

In practice, some combination of these four alternatives will probably be needed. For instance, a policy could be based on target life and mileage. Replacement occurs when one or the other of the two targets is exceeded. The chosen approach depends on the availability of funds and patterns of vehicle use. Commercial organizations have to operate their fleets as profit centers. Traditionally, government organizations and NGOs view their transport fleets as cost centers. Institutions that lease or rent vehicles from the private sector should follow similar replacement policies, because dependability and safety are also concerns for these vehicles.

Figure 25-2 shows two graphs indicating the decline in resale value compared to the rise in maintenance costs over time. Graph A illustrates an idealized model for determining the best time to replace a vehicle. If this model is used, vehicles are replaced as soon as annual maintenance costs exceed the capital value of the vehicle—in this example, after seven years. In practice, vehicle resale value is difficult to predict accurately over a long period, especially when operating conditions are harsh, and the resale value of older vehicles is determined more by condition than by age. Moreover, maintenance costs do not rise in a smoothly increasing curve over time; rather, the maintenance cost curve is “lumpy,” as illustrated in Graph B, with peaks occurring whenever major components have to be replaced. Maintenance costs still exceed capital value after seven years, but by a smaller

and fluctuating amount. Moreover, a significant proportion of these maintenance costs are fixed costs: preventive maintenance, tire replacement, and other costs that cannot be avoided, whatever the age of the vehicle.

The replacement policy should be reviewed regularly, based on an analysis of real data obtained from vehicle maintenance costs and operational reliability records. The operational costs of vehicle breakdowns should also be taken into account. These costs can be controlled to some extent by carefully planned preventive maintenance, but as vehicles age, the risk of unforeseen failure increases.

The condition of every vehicle in the fleet should be reviewed annually and compared with its planned life span and replacement target. If a vehicle has to be replaced prematurely, it is important to understand why.

Transport plans should be adaptable to respond to changing circumstances. For example, when funds are short, a vehicle may be kept beyond its planned replacement life, provided the vehicle is reliable and spare parts are still available.

Select appropriate vehicles

Over the years, programs often acquire a random mix of vehicles from a wide range of manufacturers, which complicates maintenance and support. Selecting vehicles wisely is essential, whether they are purchased or donated. Vehicle type, fuel, spare parts, temperature control, and need for refrigeration are critical issues.

Determining the size and mix of the transport fleet must be done based primarily on the weight of the shipments that the fleet must carry for each established route, as well as the basic characteristics of those routes, including the number of days needed to complete a route and any restrictions, such as the working hours at health facilities. [Country Study 25-1](#) shows how to analyze data to determine the appropriate mix.

Vehicle type. Limit the variety of vehicles to simplify maintenance and enable vehicles to be interchanged within the distribution system. Choose vehicles that are in common use throughout the country. Nationwide availability of spare parts and maintenance capacity are the most important considerations in choosing a vehicle. If feasible, choose the same type of vehicles as other programs use. This strategy allows spare parts and servicing skills to be shared among programs.

Choose vehicles that are simple in design, robust, easy to maintain, and suited to local road conditions. Buying or securing four-wheel-drive vehicles is an ineffective use of resources if they will be used exclusively on paved roads. Choose vehicles that have interchangeable components, particularly items such as tires, batteries, engines, and transmissions. If an emergency arises, or if a vehicle is badly damaged, vehicles with interchangeable components can be used as sources of spare parts for others in the fleet. Vehicles

that are tropicalized hold up better in difficult tropical and underdeveloped areas. Tropicalized vehicles are outfitted to withstand adverse climatic and road conditions such as excess heat, humidity, and rain. Features of a tropicalized vehicle may include heavy-duty tires and high traction to manage rough roads and mud, an extra fuel tank for long-distance driving, flood lighting for dark driving, air-conditioning, and a dust guard.

If possible, choose vehicle manufacturers that do not redesign models frequently. This strategy helps ensure the continuous availability of spare parts. In addition, assessing a vehicle's reliability is easier if it has been sold for a number of years, and maintenance personnel need less retraining.

Fuel. Diesel-powered vehicles are usually more cost-effective than gasoline-powered vehicles. They are more expensive to buy and maintain, but they are more fuel efficient and may be more reliable and longer lasting. However, at temperatures below -5° to -10°C , diesel vehicles can be difficult to operate unless fuel-line heaters or special low-temperature fuel is available. If fuel quality is a problem, select vehicles that can be adjusted to run on low-octane or adulterated fuel. If transport distances are long and fuel availability is unstable in rural areas, buying cars with an extra, built-in fuel tank is advisable.

Accessories and spare parts. Every vehicle should carry a tool kit, first-aid kit, fire extinguisher, and spare tires. Purchasing an adequate supply of spare parts, including oil filters, tires, and batteries, is essential. The quantity purchased will depend on future funding arrangements. If adequate funds for recurrent expenditures are ensured, the stock of spare parts can be renewed annually. If availability of such funds is not assured, vehicles should be purchased with several years' worth of spare parts. This precaution should be taken particularly with donated vehicles.

Temperature control. Vehicles should be painted white to reduce internal temperatures during hot weather (where applicable). They may also need to be fitted with ventilator units. In India, unrefrigerated but insulated vehicle bodies have been used to control transport temperatures. Most pharmaceuticals should not be stored for prolonged periods at temperatures above 30°C . Even in temperate climates, this temperature can be exceeded when a vehicle is parked in the sun. Some medicines, vaccines, and blood products can be damaged by exposure to temperatures even well below 30°C . These items should be transported in cold boxes or refrigerated vehicles.

In very cold climates, blood products and some pharmaceuticals and vaccines need protection against freezing during transport. Goods compartments may need to be heated; alternatively, products can be transported for limited distances using vaccine cold boxes fitted with "warm packs."

Refrigerated vehicles. Refrigerated vehicles are more difficult to maintain than conventional vehicles and should be used only in countries with a good maintenance

infrastructure. Rather, it may be best to choose vehicles that have independent body units. The refrigerated body lasts longer than the vehicle to which it is attached and may be transferred to a new chassis.

Refrigeration units that can be powered by an independent engine will continue to operate even if the vehicle itself breaks down. All units should have electrical backup power units for use during overnight stops, and suitable power outlets should be provided at the stopping points.

When refrigerated vehicles break down, the shipment can be exposed to unacceptable temperatures within a few hours. It is important to ensure that adequate contingency plans (such as extra cold boxes) exist for this hazard.

In countries with cold winters, refrigerated vehicles should be fitted with a heating circuit to prevent sensitive products from freezing.

Manage vehicle disposal

As a general rule, any vehicle that has been broken for six months should be discarded. Most countries have committees that are responsible for deciding when to dispose of obsolete vehicles and equipment, which is the most accountable and transparent method. However, this procedure can be cumbersome, and large numbers of broken vehicles can be left to accumulate. These vehicles can be used to advantage in some countries. For example, they can be sold or dismantled for spare parts. The main constraint on sales is that proceeds usually accrue to the finance ministry rather than to the health ministry. Arranging for this money to be reallocated to the health service may be difficult.

25.3 Vehicle use

This section examines the issues involved in managing vehicles efficiently, safely, and cost-effectively and suggests ways to minimize system abuse.

Use onboard computers

The use of onboard computers helps a central transport operation to manage and monitor its vehicle fleet. Such technology is probably only worthwhile for large fleets that cover long routes. A system that uses GPS and short message service (SMS) allows the fleet manager to communicate directly with the driver and track the vehicle in real time.

System capabilities include—

- Alarms
- Engine monitoring (e.g., oil pressure, water level)
- Vehicle abuse monitoring (e.g., engine over-revving, harsh braking, speed violation)
- Tracking based on time or route

Prevent vehicle misuse

In-house transport systems often fail because the system is abused. Government vehicles are frequently used for private purposes, particularly by drivers and senior managers, and especially in countries where vehicles and fuel are scarce or salaries are low.

Planning and managing vehicle use and controlling misuse are difficult, but these activities are the key to sustaining a successful transport operation. Leadership and support are required from those people who have the authority to control negligent management practices.

The transport manager should control vehicle use, allocate transport resources, and be accountable for operational failures. Standard operating procedures to which drivers and users subscribe will help ensure adherence to proper use of vehicles and other transport resources. Transport should be planned and managed to achieve the following goals—

- Allocation of transport resources to meet the needs of the organization rather than those of the individual
- Prevention of unauthorized vehicle use
- Assignment of the most appropriate vehicle and driver for each purpose
- Use of alternatives, such as public transport, where appropriate and cost-effective
- Clear definitions of allowable uses by program staff and managers, to be respected by all users
- Assignment of vehicles to the primary user department, so that the department will be accountable and protect their use

Regular users should prepare written schedules of their transport needs at least a month in advance. The transport manager can then prepare a plan that makes the best use of available resources. Time for preventive maintenance should be allocated in the plan. When possible, journeys should be combined so that vehicles travel full and do not make wide detours. A detailed weekly or monthly plan should be prepared and later compared with the actual course of events, with analysis and follow-up of discrepancies. Health department lettering and insignia should be painted legibly on the vehicle to discourage unauthorized usage.

Methods of monitoring for abuses include—

- Checking the mileage recorded on the odometer every week and comparing this reading with the driver's official log.
- Requiring that the primary user/passenger sign a ledger kept by the driver when initiating and terminating a trip.
- Instituting a waybill system to document movement of the vehicles, involving the authorizing person at the point of origin and the receiving officer at destination.

- Assigning one operator to a vehicle and requiring that any transfer to another operator be accompanied by a handover note that details mileage, condition, inventory of parts, and similar details.
- Installing tachographs. These devices are legally required in European countries, but larger vehicles everywhere should be equipped with them. They record comprehensive details of every journey and can provide a check on the accuracy of the driver's log. The tachograph record also shows whether adequate rest stops have been taken.
- Introducing incentives for health facilities to prevent abuse by implementing good monitoring methods.

Misuse of motorcycles, light vans, and other small vehicles is more difficult to control, especially when vehicles are allocated to facilities in remote areas. Staff members may be encouraged to purchase motorcycles and other small vehicles from the health service at low cost; this strategy reduces vehicle abuse, generates income for vehicle replacement, and gives staff an incentive to maintain vehicles properly. An approach adopted in Zimbabwe was to sell vehicles to health workers on extended repayment terms and then to pay a mileage allowance. The health worker was free to use the vehicle for private purposes but also had an incentive to maintain it. After five years, the vehicle became the worker's property.

When vehicle misuse is discovered, the problem must be dealt with firmly and quickly. Allowing an abuse to continue ensures that it will become part of the system.

Train drivers and motorcycle riders

Drivers play a critical role in the optimal operation of transport services. Well-trained drivers and motorcycle riders have fewer accidents and better vehicle maintenance than those who are poorly trained. Driver-training modules are available from a number of sources. A driver or rider should—

- Drive or ride carefully and without aggression toward other road users
- Inspect the vehicle carefully at least once a day and after every stop for signs of damage, wear, and accidents
- Know which passengers are allowed in accordance with legal and corporate policies
- Drive within the allowable speed limit
- Be able to carry out preventive maintenance, minor servicing, and emergency repairs
- Be thoroughly knowledgeable about the routes and well informed about road and weather conditions and the location of service and refueling facilities
- Know what to do in case of an accident (requirements

for immediate reporting, documentation, how to ensure the safety and security of the load)

- Be capable of administering basic first-aid treatment

Employing drivers with many years of experience and knowledge of the local road conditions will positively affect the performance and life of vehicles. Driver-mechanics (drivers with additional technical training) have the added skills to perform preventive maintenance and handle minor problems on the road.

It is important to ensure that drivers have a legal, active license, that their vision is tested regularly, and that vehicles are duly registered and carry current ownership, insurance, and inspection documents. Taking strong disciplinary action against those who drive after consuming alcohol or taking drugs is also important; vehicle damage often results from accidents caused by driving under the influence.

Ensure vehicle security

Vehicle security is a serious problem in many countries. Vehicles are stolen for resale or for spare parts, and pharmaceuticals may be stolen in transit. Precautions to take include—

- Keeping vehicles in locked compounds or garages.
- Employing security guards.
- Planning delivery routes so that vehicles can be securely parked during overnight stops.
- Instructing drivers never to leave vehicles unattended during transit.
- Avoiding driving at night, especially in countries where vehicles are poorly maintained or have no lights. Security problems are often worse after dark.
- Installing burglar alarms, immobilization devices, or both. Fit security dead bolts on cab doors and goods compartments. Where security is extremely difficult, it may be necessary to fit grilles around the cab interior.
- Buying vehicles with sleeping compartments for drivers if long delivery trips are required.
- Ensuring that every vehicle is fitted with a fire extinguisher. Tools and spare parts should be carried so that the driver can make simple repairs without having to leave the vehicle unattended.
- Installing a mobile communication radio for communication with the base.
- Ensuring that the vehicle and goods are checked at the start of a trip and at every point along the route for any suspicious devices that could be used by saboteurs.
- Engraving vehicle registration details onto windshields.

Ideally, all vehicles carrying valuable loads should have a second driver or a driver's assistant. On long journeys, a

second driver is necessary to reduce the risk of the driver's falling asleep. If a breakdown or an accident occurs, one person can guard the vehicle while the other gets help.

25.4 Vehicle maintenance

Planned maintenance is an essential aspect of the transport system. It includes ensuring availability of spare parts, managing repairs—whether for land vehicles or boats—and disposing of waste products.

Provide spare parts and consumable supplies

Vehicles cannot be serviced and repaired without an adequate supply of spare parts and consumables—lubricants, brake fluid, tires, batteries, and oil filters. If vehicles are not serviced, they quickly become unreliable.

Senior logistics managers are responsible for emphasizing that pharmaceutical deliveries cannot be guaranteed without adequate funding for spare parts and consumables. Politicians and budget control officers must be persuaded to understand the importance of adequate recurrent funding or to consider contract alternatives to in-house transport.

Manage vehicle maintenance

A consistently high standard of maintenance increases the fleet's reliability; this standard can be achieved only if the maintenance policy is clearly defined, enforced, costed, and monitored.

Vehicle maintenance can be divided into four levels—

1. Preventive maintenance, as defined in the manufacturer's service manual, includes lubrication, oil changes, replacement of oil filters and brake pads, tire changes, and other measures that keep the vehicle operating safely and efficiently. All these can be foreseen and planned for.
2. Overhauls involve the dismantling or replacement of major components, such as engines, clutch linings, or transmissions. The mileage at which a specific overhaul is required varies from vehicle to vehicle, but overhauls can be foreseen and planned for.
3. Minor repairs include replacement of broken headlights and minor body work. They do not require the tools or skills of a specialist. Many of these will be unforeseen but can be managed if parts are available.
4. Major repairs are needed in the case of crash damage or other unforeseen problems that require specialized tools and skills.

Preventive maintenance and minor repairs can be carried out in simply equipped workshops by relatively unskilled

mechanics, and require only a small selection of frequently used spare parts and consumables. Preventive maintenance for every vehicle should be scheduled in advance as part of the management of vehicle use. Major repairs and overhauls must be carried out in well-equipped workshops by skilled mechanics, and require access to a comprehensive stock of spare parts.

A health program often needs a combination of maintenance levels. For instance, the health program can perform preventive maintenance and minor repairs in its own workshops, and major repairs and overhauls can be contracted out to a central government workshop or a private garage.

The following examples indicate the range of options for organizing maintenance services. These options are based on the assumption that the health program is government run, but they are also relevant to NGOs.

Workshops operated and funded by the health program. The main advantage of this option is that workshops, maintenance staff, and the stock of spare parts are directly controlled by the health program. The main disadvantages are that transport maintenance services may be duplicated among government agencies, often when few trained staff members are available, and that the health program may have trouble tracking the true costs to make meaningful comparisons. Duplication wastes funds and can result in maintenance units that lack proper staff or are too small to operate cost-effectively. This result is less likely if only preventive maintenance and minor repairs are carried out.

Workshops operated and funded by another government agency. A network of vehicle maintenance workshops operated by the ministry of works can be used to maintain all government vehicles. This is a traditional administrative solution. It can be satisfactory, provided that workshops are fully equipped, staff members are well trained, and the government is committed to upgrading equipment and retraining staff as vehicle technology changes. A disadvantage is that the health program has no direct control over the quality of service, and no sanctions can be applied if the service is unsatisfactory.

Privatized government maintenance services. Workshop services owned and operated by government may be transferred or franchised to a parastatal organization or to a private company. Government agencies can then buy back the service at a rate that is periodically renegotiated. Privatization of government services has been widely advocated and has been adopted in many countries. Disadvantages include the possibilities of overcharging and corrupt and abusive pricing and billing practices.

Tendered maintenance contracts with private companies. An arrangement involving private maintenance contracts that run for one or more years has several advantages—

- The health program does not have to provide workshops or maintenance staff or hold stocks of spare parts. Capital investment is thus reduced, and the health program can concentrate on core activities.
- Cost control may be better: the service contract can set a flat rate per year for maintaining each vehicle, which includes the cost of normal spare parts. Only unforeseeable items (such as accident repairs) need to be paid for, on the basis of individual invoices.
- Quality assurance clauses can be built into the contract. These can impose financial penalties whenever the service quality fails to meet set targets. Bonus payments to the contractor may also be justified if reliability exceeds target norms.

Contracts of this kind succeed only in countries with well-developed private vehicle-maintenance sectors. Tenderers must use sophisticated costing techniques if they are to offer realistic quotes, and they must have well-equipped workshops and reliable sources of spare parts and consumables. Government must have good monitoring, reporting, and accounting procedures. Otherwise, unsatisfactory service or corrupt practices may go undetected.

Private workshops run by agents of the vehicle manufacturer. These workshops may be more expensive, but they are more reliable than other private workshops because the agents have a greater sense of responsibility to maintain the manufacturer's reputation. However, such workshops may be restricted to larger urban areas, with no accessibility to them in rural or remote areas.

Private workshops with services paid by invoice. This option has advantages but provides no cost certainty or quality assurance. It is generally used only for emergency repairs or when no other maintenance facilities are available.

Ensure safe disposal of waste products

Vehicle servicing produces toxic waste products. Oil, lubricants, tires, and batteries must be disposed of safely to avoid creating public health risks. The health program should require that the vehicle service organization adopt a safe disposal policy that complies fully with local regulations.

25.5 Measuring transport performance using key indicators

Using a set of key performance indicators can help determine a transport system's efficiency.

Vehicle capacity usage

The volume that the fleet carries seriously affects costs. When calculating product costs, vehicle capacity must be

maintained at the highest levels to minimize the unit cost of transporting the product. This indicator depends on the frequency and size of orders. For example, if the fleet's total pallet capacity is 240 for twelve vehicles, and the fleet carried 200 pallets on a day, the capacity usage for that day would be 83 percent. The capacity percentage varies each day, and a cumulative percentage helps determine if the size and mix of the vehicle fleet meets the system's needs.

Vehicle time usage

A vehicle costs money whether it is being used or not. Keeping the vehicle working as much as possible (consistent with good maintenance practice) is most efficient. This indicator identifies the proportion of hours that each individual vehicle is in use compared with the total fleet. For example, the fleet of twelve vehicles from the example above has an operating day of ten hours for each vehicle, or 120 hours for the fleet. If the actual number of operational hours recorded for all twelve vehicles is ninety, time usage is only 75 percent. In addition, if customers were encouraged to change their delivery times, the number of hours available for the fleet to operate would increase further. The more the vehicles work, the more efficient the system and the less cost per delivery. Transportation planners need to maximize the operation of the fleet while considering the realities of their environment.

This indicator can also identify individual vehicles that are being used less than needed because of recurring mechanical problems, driver and personnel problems, and so on.

Vehicle total usage

A critical measurement of the fleet's effectiveness is the combination of the above two indicators. If the whole fleet is used for four hours out of ten at 100 percent capacity for those four hours, most transport managers would be happy. However, overall usage would only be 40 percent because of the remaining six hours of operational time left in the day for the whole fleet. Combining the results of the previous two indicators, which individually appear to be good, can show a different result when combined. For example, capacity usage of 83 percent multiplied by time usage of 75 percent equals a total usage of 62 percent, which shows room for improvement.

Average drops per vehicle and cases per drop

The average number of shipment drops per vehicle can be used to calculate the cost per drop. And while the number of drops may be acceptable, if the number of cases per drop is small, then the cost per delivery may be too high. These indicators may lead to a review of delivery frequency, thresholds for order sizes that can be delivered, and charges for delivery.

Table 25-2 Comparison of commercial, government, and mixed fleets

Factor	Commercial fleets	Government fleets	Mixed fleets
Government capital expenditure on vehicles	No	Yes	Yes, but reduced
Government expenditure on maintenance, insurance, wages, supervision, and per diems	No	Yes	Yes, but reduced
Flexibility to meet demand peaks	Yes	No	Yes
Fast transport beyond normal commercial routes	No	Yes	Yes
Security of pharmaceuticals in transit	Can be expected to be good	Variable	Variable
Running costs	Lowest for large loads and long hauls	Lowest for stable requirements	Can provide an optimum mix
Flexibility to change route and schedule at short notice	No	Yes	Variable
Experience in and care of transporting special products	Limited, and may cost extra to add such elements	Yes	Variable

Vehicle operating cost

Because most work activities revolve around the number of orders to deliver and the case/tons/pallet volumes associated with each order, this indicator is important. The cost of processing an order and then delivering it helps determine the level at which inappropriately sized orders should be managed differently.

25.6 Contracting transport services

This section examines the advantages and disadvantages of contracting out transport services to private transport companies. It also presents the costing decisions that need to be made and details procedures for selecting, working with, and monitoring contractors.

Private-sector transport issues

Private transport companies in some countries can offer better and cheaper pharmaceutical delivery service than the government is able to provide. These advantages are most likely to be gained in countries with a well-developed infrastructure and a good range of well-managed private transport companies. Where choice is limited, competition may be insufficient to produce real cost savings.

Private carriers will probably be most competitive on routes between major population centers. On these routes, vehicles are likely to carry a return load, an efficiency that lowers overall costs. By contrast, private carriers may be comparatively expensive when delivering to remote areas, where there is no potential for return loads; however, this cost premium may not apply if existing delivery routes already serve these areas. The health program may be able to

enter into a joint agreement with another agency that needs transport arrangements from the periphery to the center. Agricultural cooperatives are one possibility.

Whenever possible, pharmaceutical deliveries should be organized so that the transport contractor is supplied with full loads. Low transport costs depend on maximum use of vehicle capacity. Contract transport may improve the security of pharmaceuticals, provided the contractor is made responsible for any losses in transit. The health program or facility must be proactive in requiring transport companies to ensure that pharmaceutical supplies are not damaged during transport and layovers. Many private transport services are small and individually owned and may not have the capacity to maintain quality service. In such cases, using larger and more economically viable companies is preferable.

Table 25-2 compares the advantages and disadvantages of private-sector, government, and mixed transport fleets.

The preceding remarks relate principally to road transport contractors, but rail, air, river, and sea transport services may also be used for pharmaceutical deliveries. The following issues apply equally to those forms of transport.

Cost assessment

A thorough cost analysis should be conducted before a decision is made to contract out transport services. A decision to introduce private-sector transport can have far-reaching implications. For instance, existing vehicles will have to be sold if they are no longer needed. If many vehicles are sold, government workshops may no longer have sufficient work to remain viable. Unless these issues are taken into account, the overall effectiveness and efficiency of the government transport operation may decline rather than improve. Country Study 25-2 provides a sample analysis of alternatives.

In-house transport costs

Any comparison of public- and private-sector transport alternatives requires a realistic assessment of public-sector vehicle operating costs. The annual operating costs for a vehicle are made up of the following elements—

- Fixed costs
 - Amortized cost of the vehicle over its anticipated lifetime
 - Interest costs
 - Transportation taxes
 - Insurance premiums
 - Wages and overhead for the drivers
- Variable costs, based on anticipated annual mileage
 - Fuel
 - Preventive maintenance (filters, lubrication, brake pads, tires)
 - Repairs
 - Per diem payments to drivers for meals and accommodation

- Carrying costs of public-sector transport
 - Cost of transport administration
 - Cost of parking and garaging

Total cost analysis (see [Chapter 40](#)) can be used to compile cost data. When costs have been calculated, they can be used to assess the delivery cost per ton on specific routes. This cost can then be compared with quoted rates for alternative forms of transport. If the preliminary assessment indicates that private-sector transport is more economical, formal tenders to provide services should be conducted, as described in [Chapter 39](#).

25.7 Maintaining pharmaceutical quality

Transport managers are responsible for ensuring that pharmaceuticals are not damaged during transit. It is essential that medicines be properly packed (see [Figure 25-3](#)).

The pharmaceutical manufacturer's original outer packing should withstand normal handling and transportation,

Country Study 25-2 Contract-or-buy analysis in Zimbabwe

In Zimbabwe, the cost of running the drug delivery routes from the central medical stores (CMS) to the provincial stores using CMS vehicles was compared with the cost of using private-sector carriers. The results of the analysis were used to decide which routes should be contracted out to the private sector. The operating parameters and costs for CMS vehicles were as follows:

Payload of each truck	5 tons
Annual mileage of all vehicles	468,000 km
Fixed costs	USD 0.37 per km
Variable costs	USD 0.03 per km
Fixed + variable costs	USD 0.40 per km

These figures were used to calculate the cost of running each route using CMS vehicles and private carriers. Results are shown in the accompanying table, which reveals that for loads that are multiples of 5 tons, using CMS vehicles is cheaper. Although the cost differential decreases with increasing distance, using CMS vehicles remains cheaper even for distant destinations. The full cost advantage is obtained only if the trucks are hauling loads in both directions. An empty CMS truck costs the same per kilometer as a fully loaded one, but the private carrier does not charge for the return journey. If the CMS vehicle has no load to carry back, using hired transport to Gweru, Bulawayo, and Binga becomes more economical. The cost ratio in all three cases is less than 2.0.

Destination	Distance (km)	One-way cost of using own fleet (USD 0.40 per km)	Private-sector tariff (USD per 100 kg)	Cost of transporting 5 tons	Ratio of tariff cost to own costs per 5 tons	
					If full for return	If empty for return
Chinhoyi	110	44.00	2.94	147.00	3.35	1.67
Gweru	275	110.00	3.94	197.00	1.80	0.89
Masvingo	292	116.80	5.16	258.00	2.22	1.10
Bulawayo	439	175.60	4.73	236.50	1.36	0.67
Binga	880	352.00	7.69	384.50	1.09	0.55

Stay near the vehicle

Minimize deterioration of pharmaceuticals during transit
Guard against theft

Start early in the day and drive with care, especially on hazardous roads

Avoid nighttime driving

Ensure safe and timely delivery

Prevent accidents

although standards may differ in developed countries, where palletized handling exists throughout the system. At the intermediate stores, this outer packing often must be removed to allow the assembly of small consignments; these must be repacked for transport in strong cartons or reusable crates. Empty spaces in partly filled cartons or crates should be filled with newspaper, straw, wood shavings, or other loose material to stop the contents from rattling about and prevent cartons from being crushed. If mechanical handling equipment is available, loads may then be assembled onto pallets.

Pallets, cartons, or crates should be carefully and systematically loaded into vehicles on a first-in/last-out basis. They must then be held secure by straps, nets, or other means. The vibration caused by travel over rough roads can damage tablets and other breakable products; long journeys over rough roads should be avoided whenever possible.

Delivery journeys in very hot or cold weather may damage temperature-sensitive products. Appropriate precautions must be taken, as discussed earlier in this chapter. Water damage during heavy rain can be avoided by ensuring that pharmaceuticals are unloaded directly into a building and not left standing outside. Make sure that vehicles have the necessary materials to protect loads from direct sun, dust, rain, and pilferage. Canvas covers and straps are as essential as spare tires and need to be carried at all times. ■

ASSESSMENT GUIDE

Existing transport system

- Does the program have a transport management department?
- What are the major transport problems?
- Who provides the transport budget? (Compare the transport budget with actual expenditures.)
- What types of vehicles are used? (List all types used and the source, model, quantity, age, mileage, condition, and location of each.)
- Are vehicles shared with vertical programs, such as WHO's Expanded Programme on Immunization? Do availability and reliability vary among programs? If so, why?
- Do existing transport routes make effective use of vehicles?
- How are supervisory visits currently made?
- Is there a vehicle replacement policy? If so, how is replacement funded?
- Is there a policy for writing off broken-down vehicles? Is it implemented?
- Is there a preventive maintenance policy? Is it effective?
- What percentage of vehicles is in working condition? Describe by type and location of vehicle.
- Is there a policy to control and monitor vehicle use? Is it effective?
- Is there a driver training program? Is it effective?
- Is there a policy on transport security? Does it control losses?
- Are vehicles loaded correctly?
- What is the number of vehicles, compared to the number of drivers?

Transport alternatives

- What are the transportation terms for overseas and in-country suppliers? Could these be changed to require direct delivery to lower-level stores?
- Which of the following modes of transport are available?
 - Program vehicles
 - Motor pool vehicles

- Buses
- NGO vehicles
- Intermediate forms of transport
- Railways
- Water transport
- Commercial, government (including military), NGO flights

Private-sector transport alternatives and cost comparisons

- Do vehicle rental and leasing companies exist? What are the charges?
- Are commercial carriers available? Are they capable of transporting pharmaceuticals at rates equal to or lower than costs of in-house transport?
- Is the private transport alternative dependable? Does it have experience in transporting special products like pharmaceuticals?

Maintenance alternatives

- Are health program or other government workshops offered?
- Are privatized government workshops available?
- Are contracts with the private sector a possibility?

Monitoring and evaluation

- Are there effective systems for monitoring and evaluating transport costs and performance? If not, which elements are missing?
- Is a checklist used to ensure timely registration, licensing, and renewals?
- Are standard operating procedures (SOPs) in place for transport operation?
- Are vehicles checked regularly after making a long trip?
- Do the SOPs contain guidelines on what to do in the event of an accident?
- Are vehicles checked daily for safety using a checklist?

SUMMARY

Pharmaceutical kits contain selected medicines and medical supplies, in predefined quantities, that are used for primary pharmaceutical supply, supplementary supply, or emergency supply. Emergency health kits are well standardized and widely used by the main international relief agencies, and they can prevent many common problems associated with pharmaceutical donations. Ration kits provide standard quantities of essential medicines for routine use in rural health care at dispensaries and health centers, and sometimes at hospitals. The relevance of pharmaceutical kits depends on a country's ability to manage its pharmaceutical supply system; using a kit system can help countries with weak capacity.

A pharmaceutical supply system based on kits has the following advantages—

- Selection of a limited range of essential medicines
- Simplified budgeting, procurement, storage, transport, and supply management
- Reduced risk of theft
- More reliable supply
- More rational prescribing
- Possible lower indirect costs

Ration kit systems have the following disadvantages—

- Less flexible contents than in an open-order system
- Difficulty adjusting the medicine list to suit seasonal or regional variations in morbidity
- Possibility of shortages and surpluses
- Special management skills and additional space and staff required for kit packing
- Discouragement of local development of distribu-

tion and inventory control skills

- Difficulty in monitoring expiry dates
- Lack of fit in a cost-sharing system
- Large payments when prepacked kits are procured
- Higher direct costs, such as additional handling and packing

Kits should be considered when—

- Pharmaceutical supply to rural areas needs to be drastically improved.
- Pharmaceutical supplies are required for an emergency or time-sensitive situation.
- Record keeping, drug ordering, and inventory control capacities are limited.
- Central medical store capacity is limited.
- Diversion and theft of medicines are common.
- Medicine needs are such that the number of different kits can be kept to a minimum.

A distribution system that is completely based on kits is usually viewed as a temporary solution to a logistics problem; however, changing from kits based on a push system to a requisition-based system can be difficult, and combining basic kit distribution with allowing limited ordering for some products may be necessary. Realistically, once a kit system is in place, its convenience paired with the challenges of a pull system often result in this temporary solution lasting much longer than originally planned. A flexible system for distributing medicines should be instituted as soon as the necessary managerial capacity and administrative structures can be created.

26.1 Pharmaceutical supply kits

Prepacked kits, also known as pharmaceutical ration kits, contain an assortment of medicines and medical supplies. The quantity, range, and purpose of kits vary according to situation. Some comprise essential medicines and supplies targeting various levels of health facilities. Others comprise special products to meet specific program needs. The medicines are packed centrally into sealed cartons and distributed unopened to the health facilities where they will be used. Typically, each kit is designed to supply a given number of patients (for example, 1,000).

The kit system is a typical example of an allocation, or “push,” system. Supplies are distributed on the basis of a centrally estimated need and not on the basis of a specific request. This system is the opposite of a requisition, or “pull,”

system, in which health units order supplies on the basis of demand (see [Chapter 22](#)).

Different types of kits have been widely used in emergency relief efforts. Since the early 1980s, several countries have adopted kit systems like ration or supplementary kits for the routine supply of essential medicines and supplies to rural health care facilities, usually monthly or quarterly. These two major uses of kits, for emergency situations and for regular supply, are discussed separately.

26.2 Kits for emergency situations

In acute emergencies, medicines and medical supplies are often a first priority. Needs are difficult to assess on short notice; many of the large international relief agencies there-

Box 26-1 The Interagency Emergency Health Kit

This resource explains how to use standardized packages of essential medicines, supplies, and equipment after large-scale emergencies and disasters. The concept and contents of the kit were developed by the World Health Organization in collaboration with international and nongovernmental agencies. In the 1990s, the kit was called the WHO Emergency Health Kit; however, WHO was dropped from the name, recognizing that now the main contributors are organizations with greater emergency field experience. The Interagency Emergency Health Kit is geared mainly to relief agencies, but it also serves as a reference for national authorities and hospital managers interested in stockpiling medicines and supplies.

A complete emergency kit contains two separate sets of medicines and supplies for 10,000 people for approxi-

mately three months. The first set consists of ten identical packages of basic units containing medicines and supplies for 1,000 people each, intended for use by primary health workers with minimal training. The supplementary kit for 10,000 people contains medicines, renewable supplies, and equipment needed by well-trained health care workers working in referral health facilities.

All kits now provide medicines for malaria and for the prospective treatment of rape victims. In response to resistance of the malaria parasite to chloroquine and sulfadoxine-pyrimethamine in most places in the world, the kit contents were revised in 2006 to include artemether + lumefantrine fixed-dose combination tablets and artemether injections.

Source: WHO 2006.

fore rely on ready-made kits that contain a selection of the most commonly needed items.

The most popular kit is the Interagency Emergency Health Kit, which is now generally recommended for basic health care immediately after a disaster. Formerly known as the New Emergency Health Kit 98, the interagency kit was redesigned and updated through a collaborative process and finalized in 2006 (Box 26-1). Many international and nongovernmental organizations (NGOs) have agreed to use the same kit, and that agreement has made possible the maintenance of a permanent stock for immediate dispatch when an emergency arises. Thousands of kits are used every year in a variety of emergency situations (see Country Study 26-1). The kit contents and their intended use are described in a World Health Organization (WHO) information booklet (WHO 2006).

The kit measures about 4 cubic meters and weighs about 900 kilograms. It contains essential medicines, disposable supplies, and basic equipment for primary care up to the level of a health center. It can serve a population of 10,000 for three months (or about 10,000 consultation visits). The kit contains ten units for use by paramedical workers. It also contains a supplementary unit, with additional medications and supplies for minor medical and surgical care at the health center level.

This emergency health kit is adequate for the first phase of an emergency, when exact needs have not yet been established. When it is possible to define needs more precisely, some items in the standard kit may prove to be unnecessary, and other items may be insufficient or lacking. Most organizations then switch to other systems. Some of them—Médecins Sans Frontières (MSF) and the

Red Cross, for example—use different kits for the second phase.

MSF (www.msf.org) has created about forty medical kits, consisting of different modules. They include a basic dispensary module with simple treatment guidelines and modules containing dressings, surgical instruments, immunizations, intravenous infusions, and laboratory materials. The appropriate modules can be dispatched after MSF field staff have assessed local needs. Some MSF kits are specifically designed to address a particular health crisis—for example, Ebola kits, which include medications and protective gear, are used in outbreak locations.

The Red Cross organizations (www.icrc.org) use small kits to restock health facilities in emergency areas that are particularly busy. In addition to the hardware kit already available in these facilities, they may use a dispensary kit, a dressing kit, a pediatric kit, a sutures kit, an injection kit, and any others that are required.

The use of these kits prevents many of the problems with pharmaceutical donations that are discussed in Chapter 15.

26.3 Use of kits as a distribution strategy

In the early 1980s, the supply of essential medicines to rural facilities had become so unpredictable that several countries, including Kenya, Democratic Yemen, Tanzania, Uganda, and Bhutan, started to use ration kits for rural health care (see Country Study 26-2). The aim was to make a range of cost-effective essential medicines and supplies directly available to dispensaries and health centers, bypassing the district hospital. At that time, most of these programs were

Country Study 26-1**Emergency medicines after the Asian earthquake and Indian Ocean tsunami**

On December 26, 2004, a powerful earthquake off the coast of Indonesia sparked a devastating tsunami in the Indian Ocean. The disaster resulted in hundreds of thousands of people dead and missing and more than a million people displaced in Asia and Africa—with the hardest-hit areas in Indonesia, Sri Lanka, and India.

An initial assessment of one of the hardest-hit areas of Indonesia, by WHO, the Indonesian government, the United Nations, and the U.S. military, showed that no master list existed that detailed the overall medical supplies and medicines being provided to interim health posts from various donations worldwide. One common complaint to the assessors was that aid groups brought in only enough supplies to treat clients and

did not leave behind any supplies when they departed, rendering the community health care centers unable to treat patients. Initially, the temporary field hospitals met the acute needs of the population, but after the first few weeks, those affected most needed the restoration of primary health care and preventive services. The International Dispensary Association Foundation mobilized 350 Interagency Emergency Health Kits in two weeks for shipment and distribution to affected areas. The kits provided medicines and supplies sufficient for basic health care for 3.5 million people for three months and helped fill the gap until supply services could be reestablished.

Source: WHO 2005.

Box 26-2**Using patient kits to improve management and use of tuberculosis medicines**

The Global Drug Facility (GDF) is an initiative to increase access to high-quality tuberculosis drugs for DOTS (directly observed treatment, short course) implementation. To help countries provide drugs to treat up to 10 million patients and reach TB control targets, the GDF's activities revolve around facilitating pharmaceutical management, increasing treatment adherence, and promoting rational medicine use. As part of this strategy, the GDF developed a TB patient kit, which was introduced in the Philippines in 2004. The patient kit contains enough medications, including two-drug and four-drug fixed-dose combinations (FDCs), for a full course of treatment for one patient.

The purpose of the kit is to improve the logistics of pharmaceutical supply, since fewer items will need to be ordered, distributed, and stocked in health facilities. In addition, the kit promotes rational medicine treatment because all medicines are available in the appropriate dosages and quantities when they are needed.

Two different kits conform to patient treatment guidelines for TB. The first is for newly diagnosed patients (Categories I and III) and contains all medications needed to treat one patient in the weight band (55–70 kg).

The recommended STOP TB Kit contains the following in two separate boxes—

1. Intensive phase: Six blisters of four-drug FDC tablets (FDC-4) (rifampicin/isoniazid/pyrazinamide/ethambutol 150/75/400/275 mg)
2. Continuation phase: Twelve blisters of two-drug FDC tablets (FDC-2) (rifampicin/isoniazid 150/75 mg)

Tablets are packed in blister sheets of seven rows of four tablets each.

The second kit is for patients who have relapsed or failed initial treatment (Category II), which contains all medicines needed to treat one patient in the weight band (55–70 kg).

The STOP TB Kit contains the following in three separate boxes—

1. Intensive phase: Nine blisters of four-drug FDC tablets (FDC-4) (rifampicin/isoniazid/pyrazinamide/ethambutol); fifty-six vials of streptomycin, water, syringes, and needles (S 1 g)
2. Continuation phase: fifteen blisters of three-drug FDC tablets (FDC 3) (rifampicin/isoniazid/ethambutol 150/75/275 mg)

Source: Stop TB Partnership/Global Drug Facility <<http://www.stoptb.org/assets/documents/gdf/whatis/FS%20DP%20Brochure%20FINAL.pdf>>

heavily supported by external donors; some of them still receive substantial external support.

The careful selection of medicines and the parallel development of treatment guidelines in the 1980s introduced the essential medicines concept to many national planners and rural health workers. The kit programs of the 1980s assisted in the dissemination of generic medicines and the promotion of the essential medicines concept in several countries.

A similar distribution strategy based on the kit concept is the use of patient packs for disease-specific treatment. A patient pack is essentially a medication kit for individual patients that includes the correct dose of the correct combination of medicines of assured quality. [Box 26-2](#) discusses the development of patient packs for tuberculosis (TB) treatment. In Ethiopia, a kit for prevention of mother-to-child transmission of HIV/AIDS is composed of HIV test kits and antiretroviral medicines, which addresses the service and management needs of local prenatal care clinics.

The number of programs using kits for regular medicine supply has declined. The main reasons for this decrease are a reduction in long-term donor commitments, a general shift away from centralized public-sector funding for medicines, the incompatibility between kit systems and cost sharing, an increasing desire to implement more flexible requisition systems, and improved capacity in pharmaceutical supply management. However, countries with inadequate pull systems may opt to use kits as a supplement to their regular supply,

especially where challenging geography or a weak transportation system makes distribution difficult or where there is a lack of skilled human resources to properly maintain a well-functioning pull system (see [Country Study 26-3](#)).

26.4 Advantages and disadvantages of kit systems

The benefits of a kit system depend greatly on the quality of the planning and on the initial kit design. Advantages and disadvantages need to be carefully weighed before a decision is made to adopt the kit approach (see [Figure 26-1](#) and [Section 26.6](#)).

Potential advantages of a kit system are—

- Rational selection of a limited range of essential medicines and medical supplies
- Simplified budgeting, procurement, storage, transport, and supply management, with reduced risk of diversion to hospitals and theft in transit
- Decreased handling needed at the central medical store level, which saves resources
- Scheduled supply intervals leading to more secure delivery to rural health units
- Better and more equitable availability of essential medicines and medical supplies at the primary health care level, which results in improved community confidence

Country Study 26-2

Use of the kit system as a distribution strategy in Kenya

Kenya has been distributing kits containing selected medicines and medical supplies to health facilities since the early 1980s as part of its regular pharmaceutical distribution system. The kit concept has helped promote the dissemination of generic medicines and has supported the growth of the pharmaceutical industry in Kenya.

The kits are designed to serve various levels of care, including provincial general hospitals, district hospitals, subdistrict hospitals, health centers, and dispensaries. Each box is expected to last a month for 1,000 patients at a particular facility; however, because the workload varies from facility to facility, distribution supervisors at the district level have the option to increase or decrease the supply of kits. The Medical Officer of Health can order additional medicines to supplement the kits, although because the use of kits has led to poor inventory control systems, additional medicine

orders may not be based on real consumption data, but rather on educated guesses as to the needs of the facilities. Another problem is that differing consumption patterns among the districts have resulted in overstock, which theoretically should be redistributed, but weak infrastructure and transportation problems have led to extra stock accumulating where it is not needed.

Consequently, the government of Kenya has begun to shift away from the kit concept. The change has occurred because of the disadvantages associated with kits and the restructuring of the distribution system to create an autonomous entity from which districts will requisition their supplies on a cash-and-carry basis. Hospitals will be expected to requisition medicines from a predefined list, but health centers and dispensaries will continue to receive kits during the transition, because the poor staffing levels in those facilities means they lack the capacity for more complicated inventory control.

- Support for the development of treatment guidelines and prescriber training programs, contributing to more rational prescribing
- Indirect savings

Disadvantages are—

- Less flexibility in the selection of essential medicines for specific health problems in different regions, climatic zones, or types of health units
- Resistance by senior prescribers because of the limited range of medicines in the kit
- Need for special management skills, space, and staff for central kit packing
- Requirement that all funds be available at once, assuming that contractors deliver kits in one installment
- Lack of flexibility in the quantities of medicines, leading to shortages or surpluses of certain items
- Need for multiple kit types to handle different usages at various levels of the health care system
- Difficulty in supplying or returning individual items, which may lead to wastage caused by expiry
- Difficulty in monitoring expiry dates
- Absence of information at the central level on the usage of individual medicines, which hurts the ability

to track consumption trends at the national level

- Negative effect on development of supply management systems and skills for inventory control, quantification, ordering, and distribution planning
- Added cost of kit packing
- Difficulty in combining kits with a cost-sharing program
- Difficulty in evaluating the quality of individual products, because the national drug regulatory authority may have to depend on information provided by the kit supplier
- Difficulty in transitioning to a pull system once the simpler kit system has functioned for a long time

The inflexibility of the kit system is its greatest problem. When kits are packed overseas (and they often are), a year may pass before a change in content reaches the rural facilities. In the meantime, stockouts of certain items may occur, while there may be surpluses of other items. This problem is frequently perceived as serious, yet a WHO evaluation (Haak and Hogerzeil 1991) showed that in most long-term governmental kit programs (as opposed to emergency or incidental external kit projects), stable kit content was reached in about two years. In the short term, the problem was sometimes solved by redistributing the accumulated

Country Study 26-3 Implementing a kit system in Papua New Guinea

In the 1990s, Papua New Guinea was experiencing serious shortages of essential medicines and supplies in its health centers. In 2000, the National Department of Health asked the AusAID-funded Health Services Support Program to design a health center kit to supplement the regular requisition supply system for two years, while the primary system was revamped. Two types of kits were introduced in 2001, a standard kit containing sixty-five essential medicines and medical supplies, and a supplementary kit with twenty prescription-only medicines. The standard kit was supplied to all health centers and provincial hospitals, while the supplementary kit was sent to health facilities that had a medical officer. The kit quantities were based on patient morbidity data and designed to meet the average patient-visit load in a small health center. The number of kits supplied to health centers varied depending on their average patient visits during a year. The kits were designed to meet 40 percent of the national demand, while the other 60 percent would continue to be met through the primary supply system.

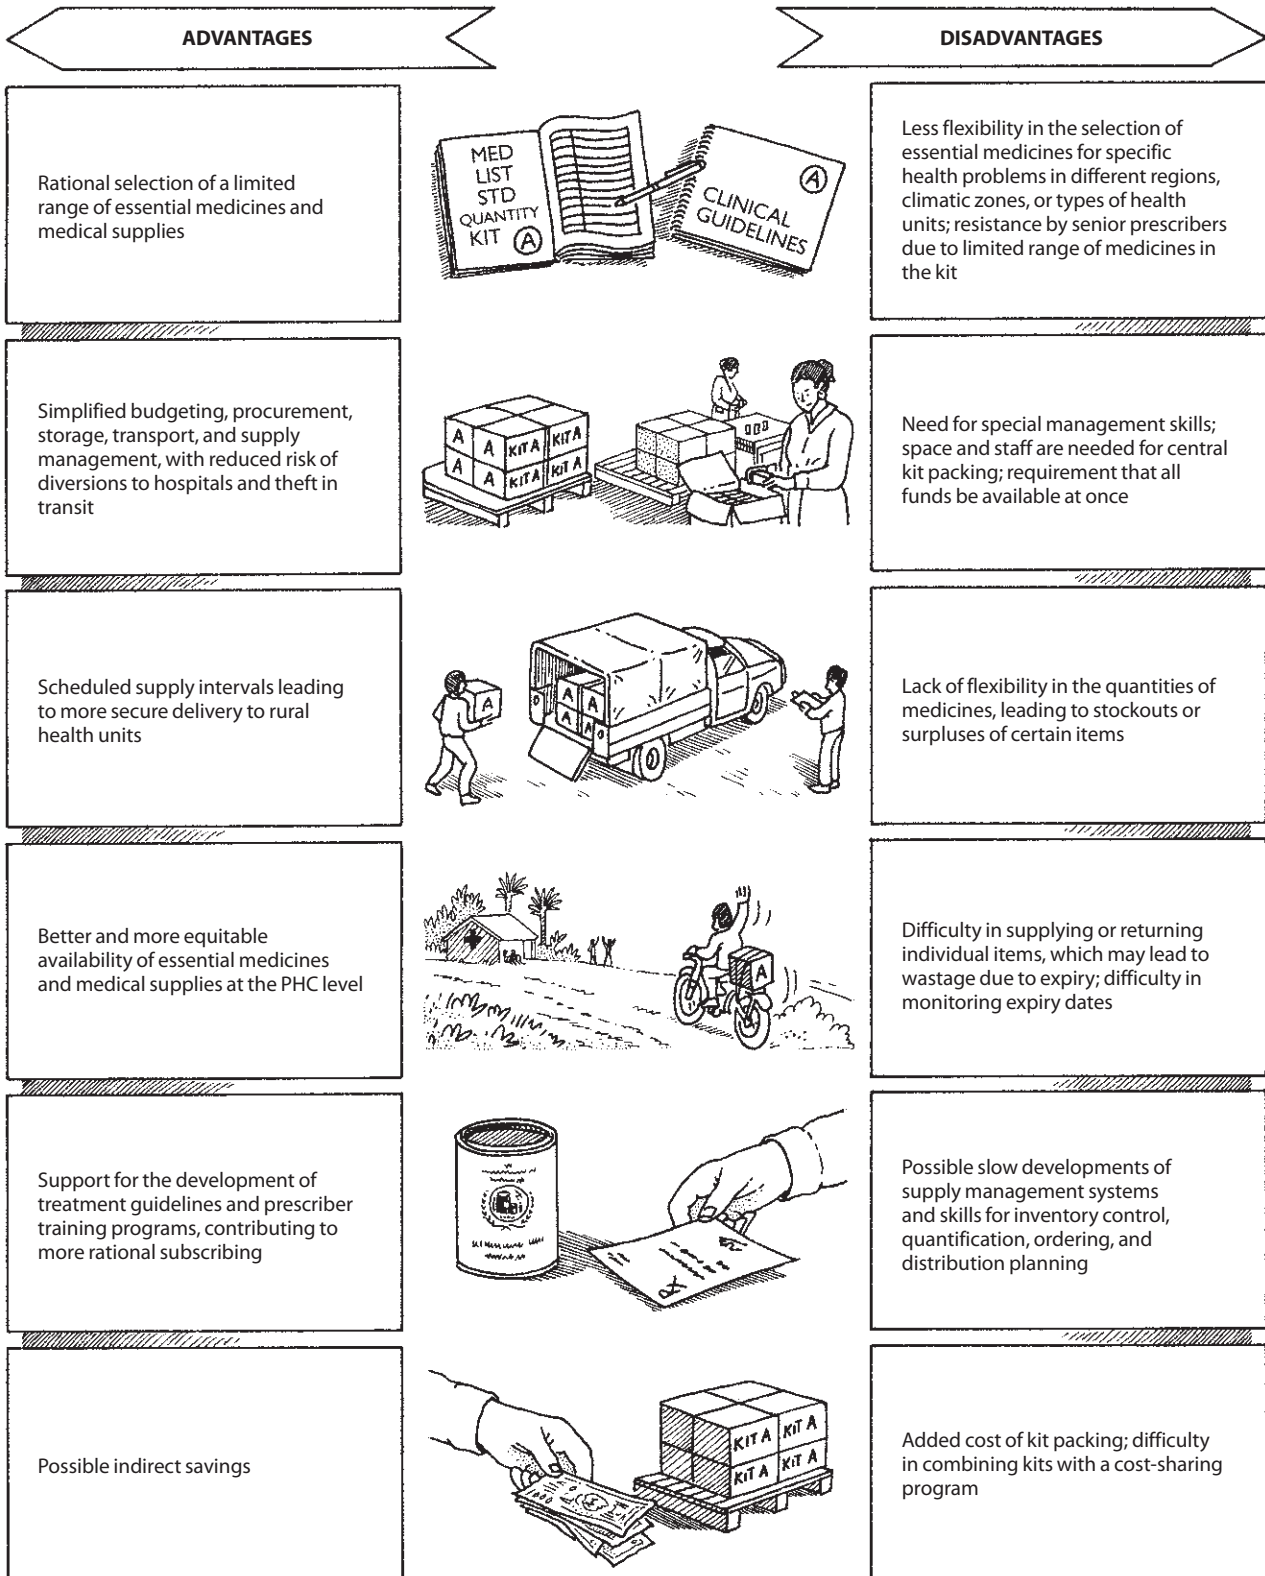

Since mid-2001, thirteen rounds of kit distribution have been made every four months, with the distribution

from the capital of Port Moresby to the twenty provincial health offices outsourced to the private sector and distribution from the provincial capitals to health centers managed by the provincial health offices.

Although the initial kit supply period was two years, it was extended year by year through the end of 2008. The strategy to revamp the requisition supply system included a training program in pharmaceutical supply management for health center staff and for students of nursing and community health work. At the end of the five-year program, which began in 2003, expectations were that nationwide, skills of health center staff members in ordering, stock keeping, and stock-control practices would be adequate to return to a completely requisition-based system.

The experience in Papua New Guinea shows that improving a requisition system can be a long-term proposition that requires extensive, sustained training in pharmaceutical management at the grassroots level. The addition of a kit system can improve the availability of essential medicines by supplementing an ineffective primary pull system.

Figure 26-1 Weighing advantages and disadvantages of kit systems

Country Study 26-4 Revolving drug fund and kit management in Guinea

The primary health care program in Guinea grew rapidly and included a cost-sharing system from the start. Initially, the information system for monitoring pharmaceutical use did not function, and rural staff members were not trained in pharmaceutical management. A decision was made to introduce a kit system while keeping the cost-sharing system in place.

Although the kit contents were regularly modified, major disadvantages arose in combining the two systems—

- Cost sharing reinforced the need for good-quality care and availability of medicines.
- New kits were opened as soon as one item in the previous kit had run out. This practice resulted in an accumulation of half-used kits. The facilities then had no cash to purchase more medicines. Medicines

could be procured only as part of a kit. Any “unsold” medicines remained in stock.

- Some medicines became heavily overstocked. However, a low-cost, efficient redistribution system, based on credits for future pharmaceutical procurement, avoided large-scale waste of expired medicines.
- Management committees and health workers resented paying for kit medicines they did not need.

Although the content of the kits was reviewed several times, and standardized treatment was considered a priority, discrepancies between need and supply remained. After a few years, the kit system was abandoned and replaced with a requisition system using a limited medicine list.

medicines; in the long run, it was addressed by adapting the kit content. The latter is easier if the kits are packed within the country. In some countries, the problem was solved by changing to kits with a smaller number of commonly used medicines and by supplying additional items through a requisition system. In addition, many countries have different kits for different levels of health facilities, with medicines and quantities that attempt to better meet the needs of the facility rather than a “one size fits all” system.

The most serious problems of mismatch between need and supply have occurred in kit projects that were badly planned or were operated in isolation from other supply structures. Some problems were directly related to poor performance by overseas suppliers.

Redistributing the accumulated surpluses is not always easy. When the same item has accumulated in most health units, redistribution does not make sense. However, most products that accumulated in the past were simple, commonly used, and very stable medicines. If the products were supplied free of charge, any surpluses could simply be taken back to the central store. In practice, surplus medicines are often returned to the nearest operating level with a requisition system, usually the district hospital. A special problem arises when the kit has been paid for, in which case returning surplus medicines may meet resistance, and some sort of credit system will have to be established. This reason is probably why kit systems and cost sharing do not go very well together. The combination was tried in Guinea, but the kit system was finally abandoned (see [Country Study 26-4](#)). In countries that have adopted decentralized pharmaceutical management, transferring

surplus stock from one place to another becomes impossible. In this case, the kit system’s disadvantages outweigh its advantages.

26.5 Cost aspects of kit systems

The direct costs of a kit system are higher than those of a regular requisition system, for the following reasons. Most international suppliers add 3 to 5 percent to the price for packing the medicines in kits. If kits are packed locally, labor costs may be slightly lower, but certain investments are needed (for example, carton boxes and a strapping device). If kits are procured ready-made, the number of potential suppliers is restricted, and there is less possibility to benefit from competitive prices for individual medicines. Some waste (estimated at an average of 4 percent) is possible because of expiry of accumulating unused medicines (although this waste may not be more than with most requisition systems).

Several factors may result in reduced indirect costs. Waste is reduced because of decreased pilferage during transport and less frequent interception of medicines at the district level. A careful selection of kit contents implies that less money is wasted on items that are not cost-effective, not needed, or inappropriate. Because of the regular supply, less safety stock is needed at the facilities. The regular availability of essential medicines reduces the number of patients who refer themselves to higher levels of care, where average treatment costs are higher. Although such advantages would also be achieved by a good requisition system, the kit system has

often been instrumental in realizing these improvements, but it is probably not needed forever to maintain them.

A pure cost comparison between a kit system and a requisition system leaves out the many qualitative aspects that are not related to costs and are much more difficult to measure. The ease of supply management and the better availability of essential medicines at the primary care level may justify some extra costs. The limited time of health care providers can be used more efficiently. The quality of care may also improve, and lives may be saved. Some overstock (and potential expiry and waste) of cheap but lifesaving medicines, such as oral rehydration salts and ergometrine injection, can be justified (whereas overstock of an expensive but noncritical drug such as praziquantel cannot).

26.6 Conditions for a successful kit program

A kit system is generally most useful when—

- Emergencies or special situations cannot be handled through the existing pharmaceutical supply system.
- Record keeping and pharmaceutical ordering capabilities are limited.
- Requisitioned medicines remain at the hospital level or at intermediate distribution points and do not pass down the system.
- Infrastructural and human capacity of the central medical store is limited.
- Theft in the distribution system is common.
- Pharmaceutical needs are similar throughout the area, and only a few different kits are needed.

Before a kit can operate properly, several conditions have to be met. First, medicines have to be selected (see [Chapter 16](#)), and quantities have to be estimated (see [Chapter 20](#)). Second, funding has to be secured; this condition requires a real political and financial commitment to satisfying the health needs of the rural population. A third condition is a well-trained and dedicated management team. Finally, a program for training prescribers is essential. If the prescribers do not follow the treatment guidelines on which the kit contents are based, a mismatch will exist between pharmaceutical supply and use, and patients' health may be at risk.

When should a kit system not be chosen? A kit system does not combine well with a cost-sharing program. A kit system is not needed when health facilities are close to the warehouse and when communications and transport facilities are good. Nor is it needed when the public sector has no pharmaceutical shortages and a well-managed and reliable requisition system already exists. In situations in which management deficiencies are present but the capacity exists to overcome them, developing a sustainable requisition system may be a better option. A kit system may become

very complicated if many different types of facilities exist or considerable regional or seasonal variations occur in the incidence of health problems. Generally, a kit-based supply system is successful when the overall supply system is poorly organized and pharmaceutical product availability is limited, conditions that are especially common in rural areas.

26.7 Implementing a kit program

Careful planning is required before a kit program is introduced (see [Figure 26-2](#)). After a program begins, changing it is difficult and may require a year or more. There are twelve steps to be taken in implementing a kit program.

Step 1. Assess the supply system: is a kit system appropriate?

The balance between advantages and disadvantages has been discussed. The situation should be carefully assessed (see [Chapters 22](#) and [36](#)) before choosing between a kit-based and a requisition-based system.

Step 2. Choose the types of health units to be supplied with kits

A kit distribution system is usually most suitable for smaller, poorly managed, poorly staffed facilities. Sometimes, a mixed distribution system may be an appropriate choice. In a district hospital, for example, kits may be used in the outpatient department, and a requisition system may be used to supply additional medicines for inpatients. There is a growing tendency to reduce the number of different kits and to supplement a limited kit system with a simple requisition system.

Step 3. Prepare a list of medicines and other items for each kit

Separate kits may be prepared for different types of health facilities; for example, one kit for dispensaries and one for health centers (see [Chapter 16](#) and [Table 26-1](#)). Bulky products, liquid products, medicines with cold-chain requirements, and medicines with short shelf lives should be avoided whenever possible. If the kit system is being introduced following a long period of shortages, an additional starter kit may be designed that contains essential equipment to upgrade the facilities at the beginning of the program.

Step 4. Determine the quantities of medicines needed in each kit

Usually, kits are designed for a certain number of outpatient consultations (1,000 to 5,000). When this figure has been decided upon, the quantity of each item in the kit can be

Figure 26-2 Flow chart for kit program planning

Table 26-1 Health center kit contents, Essential Medicines Program, Kenya

Item	Description	Unit of pack
1	Lignocaine hydrochloride injection BP 2%	Vial (30 mL)
2	Adrenaline acid tartrate injection BP 0.1% (requires cool storage)	Ampoule (1 mL)
3	Chlorpheniramine maleate injection BP 10 mg/mL	Ampoule (1 mL)
4	Chlorpheniramine maleate tablets BP 4 mg	1,000
5	Hydrocortisone sodium succinate injection BP (IV use) 100 mg base, with diluent	Vial
6	Phenobarbitone tablets BP 30 mg	1,000
7	Diazepam injection BP 10 mg/2 mL (IV & IM)	Ampoule (2 mL)
8	Albendazole tablets USP 400 mg	1,000
9	Aminophylline injection BP 250 mg/10 mL	Ampoule (10 mL)
10	Clotrimazole cream BP 1%	Tube (20 g)
11	Gentian violet crystals	Pack (5 g)
12	Hydrocortisone ointment BP 1% w/w	Tube (20 g)
13	Sodium hypochlorite solution BP 4% available chlorine	Bottle (5 L)
14	Compound magnesium trisilicate BP tablets chewable	100
15	Oral rehydration salts (WHO formula – 14 g to make 500 mL)	100 sachets
16	Tetracycline hydrochloride ophthalmic ointment USP 1%	Tube (5 g)
17	Ergometrine maleate injection BP – 500 mcg/mL (requires cool storage)	Ampoule (1 mL)
18	Chlorpromazine hydrochloride injection BP 25 mg/mL, 2 mL	Ampoule (2 mL)
19	Chlorpromazine hydrochloride tablets BP 25 mg, sugar coated	100
20	Salbutamol tablets BP 4 mg, scored	1,000
21	Griseofulvin tablets BP 500 mg	100
22	Griseofulvin tablets BP 125 mg	100
23	Metronidazole suspension 200 mg/5 mL	Bottle (60 mL)
24	Multivitamins/minerals supplement capsules	1,000
25	Multivitamins/minerals supplement syrup	Bottle (5 L)
26	Compound magnesium trisilicate + simethicone	100
27	Chloramphenicol ear drops	Bottle (10 mL)
28	Cough syrup (chlorpheniramine 1 mg, promethazine 2.5 mg, sodium citrate 4.5 mg, diphenhydramine 5 mg, ammonium chloride 90 mg, and ephedrine 5 mg)	Bottle (5 L)
29	Calamine lotion	Bottle (100 mL)
30	Povidone-iodine 10% standardized	Bottle (1 L)
31	Hydrogen peroxide 100 vol.	Bottle (1 L)
32	Lysol 12%	Bottle (5 L)
33	Chlorhexidine gluconate 4%	Bottle (5 L)
34	Methylated spirit	Bottle (5 L)

defined. Kit contents are normally intended to treat only the most commonly seen health problems, and all health facilities are assumed to see the same mix of problems per 1,000 attenders.

When a new kit program is to be started, the morbidity method is the best way to estimate requirements. This method helps determine both the types of medicines and their quantities, based on the expected number of attendances at a health facility (see [Chapter 20](#)). This first estimate can then be compared with the quantities used in other kit systems.

In the first years a kit system is operating, the consumption method can be used to adapt quantities to match actual consumption. Experienced kit suppliers can supply various kinds of kits and change kit contents with each order.

Step 5. Estimate the number of kits needed

The quantity of each type of kit is determined by the number of health units served and the estimated number of attendances at each health unit. If a kit distribution system starts after a period when pharmaceutical supplies have been

reduced or are absent, increased patient attendance should be anticipated and allowed for. Taking into account long delivery times, most orders cover a period of nine to eighteen months.

Step 6. Make a pharmaceutical procurement and kit-packing plan

There are at least four ways to manage procurement and kit packing—

- Purchase prepacked kits from overseas
- Purchase prepacked kits on open tender, from local and/or overseas suppliers
- Contract a local company to pack all kits, using medicines purchased separately through local or international tender
- Set up kit packing at national or regional medical stores

The choice depends on cost, availability of staff, and availability of space at the medical stores. Kit suppliers should be prequalified as part of standard procurement procedures to avoid potential problems such as late shipments, incomplete kits, and poor-quality products. Prepacked kits are available through the United Nations Children's Fund (UNICEF), through international low-cost suppliers such as the International Dispensary Association (IDA), or from private companies. In some countries, such as Kenya, local suppliers compete in tenders for prepacked kits. Some programs begin by purchasing prepacked kits and concentrate on distribution and monitoring of consumption patterns. After the system is operating well at the periphery, the feasibility of establishing packing operations at central or regional medical stores can be considered.

Kits are usually procured by tender (see [Chapter 21](#)). Tender specifications for each medicine in the kit should be just as detailed as for individual medicine tenders. The specifications should describe how the kit is to be packed and stipulate the quality of the outer carton, the method of strapping, kit labeling, and any other relevant features. In addition, the buying agency should request sample checklists of kit contents along with expiry dates (for example, a sample checklist for every ten or twenty kits), and a buyer's representative should randomly sample kit contents by opening one in every twenty-five to fifty packed, sealed boxes. This type of quality control will help ensure that the contents and expiry dates meet the tender requirements.

Significant problems can arise in setting up a local packing operation. A kit cannot be packed until all items needed for the kit are available. If the supply of any item is delayed, the entire packing operation is held up, which may lead to stockouts at facilities. Because of this possibility, the period before expiry of the products must be as long as possible.

KIT CONTENTS MUST KEEP UP WITH STANDARD TREATMENTS

Most programs pack or purchase kits in sturdy cardboard boxes sealed with tamper-proof tape or some other form of seal that will clearly reveal any attempt to open the box in transit. Lockable, reusable plastic containers are also available for locally packed kits. However, because kit distribution systems are used mainly where distribution conditions are difficult, the containers are unlikely to be returned to the central medical store.

One person from the supplier packing the kits should be assigned to check the contents of every kit to reduce the risk of theft during the packing process and to assure it has what it is supposed to have. A list of the contents should be made, signed, and dated, and a copy should be sealed into the kit. This list should also show the expiry date of whatever product is due to expire first, and that date should be marked on the outside of the carton as well.

Step 7. Establish delivery schedules and record-keeping procedures

The delivery schedule depends on the average number of patient visits to the facility. For example, when kits for 1,000 visits are used, a facility with 200 to 300 visits per month needs only one kit every three months.

A kit system simplifies record keeping but does not eliminate the need for it. At each level of the distribution chain, stock records should show the type, number, source, condition, and value of each kit received and issued. A periodic stock count must be done. In short, a kit should be treated in the same way as any other item as far as stock keeping is

concerned. At a rural facility, a tally card or ledger should be used to keep a record of the number of kits received, opened, and in stock. As soon as a kit is opened, the contents should be entered into the item-by-item stock records at the facility. Where a kit system supplements a requisition-based system, a single record-keeping method should be used that bases demand figures on supplies made through both systems.

Step 8. Design mechanisms to minimize waste and stockouts

Actual medicine consumption should be analyzed regularly, particularly in the early stages of a kit program. Supervisors should use a simple checklist. Rural facilities need to supply the following information—

- Number of patient attendances per month
- Recent kit delivery dates
- The three medicines that are most often out of stock
- The three medicines that accumulate most often
- Proposals for changes in kit contents

Information on actual deliveries and receipts should be collected and given to planners to help monitor the program and to modify distribution plans as required. Details of stockouts, surpluses, and any proposals for change are particularly useful for adjusting the kit content.

Other mechanisms to prevent waste and stockouts are to—

- Allow individual requisitions for a few products whose consumption is variable (for example, antimalarials or

medicines for schistosomiasis)

- Assure that inventory control accounts for supplies in both the kit and requisition systems, if a mixed system is in use
- Create a simple system for returning unused stock
- Avoid containers with more than 1,000 tablets
- Specify maximum possible periods before expiry for medicines received from suppliers
- Instruct kit packers to mark the earliest expiry date on the outside of the kit carton
- Keep supply intervals as short as possible

Step 9. Prepare a training plan for good management and rational prescribing and dispensing

Staff members should be trained to use the standard treatment schedules on which the kit contents are based. A regular training schedule is important to ensure that new employees are aware of the supply system, its standard operating procedures, standard treatment schedules, and the kit composition, especially in areas where turnover in health care personnel is high, such as sub-Saharan Africa. As pharmaceutical supply improves, training and retraining in rational prescribing and dispensing are essential to prevent misuse of the medicines. Not only is in-service training necessary, but so are revisions to curricula in nursing and medical schools and for community health workers.

Step 10. Monitor and adjust delivery intervals

Any push system needs feedback, monitoring, and supervision if it is to operate effectively. Difficulties arise when

Country Study 26-5

Transition from primary health kits to a direct requisition system in Tanzania

The Tanzanian Ministry of Health and Social Welfare (MOHSW) is instituting a policy of replacing essential medicines kits with an indent (direct requisition) system in order to tailor medicine orders to fit the needs of each particular health facility and to reduce waste. The MOH introduced a pilot project in the Morogoro region in 1999, where health facilities placed their orders with the Medical Stores Department (MSD) through the District Medical Officer. It was then rolled out to five of the country's twenty-one regions.

The scaling up of the indent system put MSD operations under some strain, contributing to a slower rollout than planned. Inventory management, warehousing, and picking and packing operations all had to be reengineered. The primary health care kits comprise four prepacked

stock items that require only simple block stacking in the warehouse. Replacing the kits with the indent system means that instead of distributing more than 3,000 prepacked kits every month, MSD has to pick, pack, and deliver items according to customized orders, which is having a significant effect on the size and nature of MSD's inventory, storage, and distribution operations.

A 2007 assessment of the Tanzanian pharmaceutical distribution sector revealed that the MSD still shipped kits to some lower-level health facilities, and the rise in the number of vertical programs introduced additional program-specific kits. Staff in health facilities in only two of the six regions that had a direct requisition system had been trained in that system.

Country Study 26-6**Transition from a kit system to a modified optional replenishment system in Cambodia**

An international organization committed itself to organizing the central medical store in Cambodia in 1992. NGOs had been supporting a large number of facilities throughout the country and had delivered continuous training in pharmaceutical management and rational prescribing. It was decided to introduce a three-phase pharmaceutical distribution system—

1. *Basic kit:* This kit contained fourteen different medicines in quantities considered minimal for functioning.
2. *Complete kit:* This kit contained forty-three different medicines in much larger quantities than the basic kit. The quantities were not, however, adapted to each particular facility, so surplus accumulations and shortages often occurred.
3. *Modified optional replenishment system:* The initial maximum consumption for three months was set to be equal to the standard consumption multiplied by the expected number of attendances at each facility. These maximum levels were to be revised once a year.

The kit systems allowed the health facilities to operate, although the delivered quantities did not completely match the prescribers' needs. When the modified optional replenishment scheme began to function properly, it did a better job of meeting prescribers' needs. A

reasonable level of procurement security existed at the central medical store.

Basic kits were supplied to health facilities, which had unqualified staff and no information on attendances and medicine consumption. Complete kits were supplied only after a qualified person had been appointed and the facility's information system had improved. Finally, the modified optional replenishment system was introduced when certain minimum standards of infrastructure, management, and staffing had been achieved. The supply system was downgraded if a health facility showed signs of irrational medicine prescribing or serious mismanagement of pharmaceuticals.

In 1996, the public sector reorganized the health system, including pharmaceutical distribution, resulting in the establishment of a centralized procurement and distribution system. In this system, orders flow up from public health centers to the operational district medical stores; are approved by the provincial health departments; are sent to the Essential Drugs Bureau, where they are consolidated and reviewed; and are then forwarded to the central medical stores. The medicines are procured by a private broker and distributed through central medical stores to the operational district medical stores, then directly to facilities. Kits are still used in rural communes.

a centrally planned delivery schedule is not regularly adjusted to conditions in the field, or when planned distribution schedules are incorrectly assumed to be followed. Receipt of the kits should always be confirmed. Stock levels at rural facilities should be reported regularly to spot any persistent stockouts or surpluses. Responsibility for monitoring and evaluation needs to be identified and assigned at the provincial or district level to provide feedback to the central authority responsible for kit design and distribution.

Step 11. Revise kit contents periodically

The items and quantities in each kit should be reviewed regularly. In stable, long-term kit programs, about two years are needed to get a reasonable balance between supply and demand for the individual items in a kit. Even then, changing disease patterns and changing prescription patterns make revising the kit contents periodically necessary. The system can also be refined by adding other kits or by changing to a mixed system.

Step 12. Reassess the need for a kit system periodically

At a certain stage, the program can change to other distribution methods, as described below.

26.8 Transition to other distribution systems

After a kit system has been functioning regularly for some time, pharmaceutical supply conditions will likely improve. More information on patient morbidity and medicine consumption will be available to planners and to rural health staff. Policy makers will get used to a limited range of essential medicines. Training of staff members should have improved their management capacities. At this point, moving to a more flexible distribution system may be possible, but only if the managerial and financial capacities exist to maintain sufficient product levels to fill the individual orders. In any case, a phased approach to transition will be essential.

In addition to the administrative issues previously men-

tioned, the transition to a requisition option demands that the facilities that have been handling the kit management and distribution (for example, central medical stores) reconfigure their physical capacity completely to accommodate a pick-and-pack operation. Planners should also consider the financial ramifications of the transition, including the possible costs related to renovations, new staff, additional training, and transportation. As seen in [Country Study 26-5](#), in Tanzania, converting a kit-based pharmaceutical distribution system is fraught with challenges. [Country Study 26-6](#) illustrates how Cambodia's supply program evolved.

Preparation for transition at the health facility level is mainly a matter of training followed by supportive supervision. A reliable and complete information system is also necessary, which is a challenge for all levels of the pharmaceutical system. At a minimum, the information system should monitor the number of patients treated, medicine consumption, and morbidity patterns. These data may also help determine whether sufficient management capacity exists to change to a requisition system based on real demand—a pull system—or to a more sophisticated push system. Notice regarding the change should be given to affected health facilities, and if the supply system is mixed, the quantities in the kit contents should be progressively reduced, so that the regular pull system can absorb the reduced quantities in the kits. Three possible stages to an open-order system are outlined below.

Fixed medicine allowance system

The first step may be to change from kits to a fixed medicine allowance system. This system also defines the selection and quantity of medicines in advance. However, the goods are not physically packed in a kit and are not necessarily dispatched at the same time. Provided that feedback is available from the health facilities, this system promotes a rapid and flexible response to changing needs.

Ordering within defined limits

The second step in the transition gives health workers some responsibility for ordering. Average medicine consumption is calculated for each facility, and these data are used to define maximum and minimum stock levels for each item. Health workers are then taught to order their medications within these limits.

Open requisitioning from a predefined list

The final stage in the transition makes health workers or pharmacy staff responsible for ordering the items and quantities they need from a predefined list, as described in [Chapter 46](#). ■

ASSESSMENT GUIDE

Use of ration kits

- Which levels of health care and what percentage of facilities receive ration kits on a regular basis?
- How does actual distribution compare with the annual distribution plan?

Description of kits

- What are the kit contents, quantities, and intended number of patient contacts per kit?
- Are regional or seasonal kits in use? If so, what do they contain?
- What is the cost of each kit?
- What is the incremental cost for kit packaging versus open item procurement?

Financing, procurement, and distribution management

- Who pays for the kits (government or external donor)?
- Are kits prepared and packed locally or internationally?
- Is kit distribution integrated with the regular pharmaceutical supply system?
- On what basis are kits distributed (time interval, number of patient visits)?
- Does a procedure exist to order additional medicines or additional quantities?

- Which medicines are commonly out of stock before the next delivery of kits?
- What items are accumulating?
- Does a mechanism exist for transfer or exchange of products between facilities?
- What procedures are in place to deal with shortages? Are these procedures working?
- What procedures are in place to redistribute over-stock? Are these procedures working?

Monitoring and evaluation

- Is a procedure established to update the contents of the kit? When was this update last done?
- Is supervision of the kit program integrated with general supervisory activities?
- What is the effect of the kit system on availability of medicines and supplies?
- What is the effect of the kit system on prescription patterns?
- Are mechanisms in place to check actual distribution of kits to rural facilities against the planned distribution schedule?
- Is reporting on consumption done regularly?
- Are stock cards/bin cards maintained for each medicine?

CHAPTER 27

Managing for rational medicine use

Summary 27.2

27.1 Definition of rational medicine use 27.2

27.2 Examples of irrational medicine use 27.3
Polypharmacy • No medicine needed • Wrong medicines • Ineffective medicines and medicines with doubtful efficacy • Unsafe medicines • Underuse of available effective medicines • Incorrect use of medicines

27.3 Adverse impact of irrational medicine use 27.5
Impact on quality of medicine therapy and medical care • Impact on antimicrobial resistance • Impact on cost • Psychosocial impact

27.4 Factors underlying irrational use of medicines at various levels of the health system 27.6
Health system • Prescriber • Dispenser • Patient and community

27.5 Strategies to improve medicine use 27.9

27.6 Developing a strategy 27.10
Step 1. Identify the problem and recognize the need for action • Step 2. Identify underlying causes and motivating factors • Step 3. List possible interventions • Step 4. Assess resources available for action • Step 5. Choose an intervention or interventions to test • Step 6. Monitor the impact and restructure the intervention

SUMMARY

This chapter defines rational medicine use and gives examples of irrational medicine use and the adverse effects that can result. It considers some of the factors underlying irrational medicine use and possible strategies to address the problem.

Rational use of medicines requires that “patients receive medications appropriate to their clinical needs, in doses that meet their individual requirements, for an adequate period of time, and at the lowest cost to them and their community” (WHO 1985).

Irrational medicine use occurs with polypharmacy (when more than one medicine is used unnecessarily), with the use of wrong or ineffective medicines, or with underuse or incorrect use of effective medicines. These actions negatively affect the quality of medicine therapy, raise health care costs, and may cause adverse reactions or negative psychosocial effects.

Prescriber lack of knowledge and experience is only one factor in irrational medicine use. Other underlying factors can affect the dispensing process, patient or community decisions and use, and the health system itself.

Strategies to address irrational medicine use can be characterized as educational, managerial, economic, or regulatory. Whichever method is selected, a successful intervention is likely to focus on key factors, target facilities with the poorest practices, and use credible sources

and communication channels. Personal contact (face-to-face meetings, for example) can sometimes be used to convey a limited number of key messages; these can be repeated and clarified using a variety of media.

When implementing an intervention strategy, the logical steps are to—

- Identify the problem
- Understand the underlying causes
- List possible interventions
- Assess available resources
- Choose an intervention
- Monitor and restructure the activity as necessary

Interventions should be based on an understanding of the cause of the problem and focus on active strategies to change behavior. Experience indicates that the most effective interventions are those that—

- Identify key influence factors
- Target individuals or groups with the worst practices
- Use credible information sources
- Use credible communication channels
- Use personal contact whenever possible
- Limit the number of messages
- Repeat key messages using a variety of methods
- Provide better medicine use alternatives to existing practices

27.1 Definition of rational medicine use

The aim of any pharmaceutical management system is to deliver the correct medicine to the patient who needs that medicine. The steps of appropriate selection, procurement, and distribution are necessary precursors to the rational use of medicines.

The Conference of Experts on the Rational Use of Drugs, convened by the World Health Organization (WHO) in Nairobi in 1985, defined rational use as follows: “The rational use of drugs requires that patients receive medications appropriate to their clinical needs, in doses that meet their own individual requirements, for an adequate period of time, and at the lowest cost to them and their community.” Depending on the context, however, many factors influence what is considered rational. It may be rational, for example, for a drug seller to sell antibiotics without a prescription to earn enough income to survive.

This book uses the term *rational medicine use* in a biomedical context that includes the following criteria—

- Appropriate indication—that is, prescribing is based on sound medical considerations
- Appropriate medicine, considering efficacy, safety, suitability for the patient, and cost
- Appropriate dosage, administration, and duration of treatment
- Appropriate patient—that is, no contraindications exist, and the likelihood of adverse reactions is minimal
- Correct dispensing, including appropriate information for patients about the prescribed medicines
- Patient adherence to treatment

To conform to these criteria, prescribers should follow a standard process of prescribing, which starts with a diagnosis to define the problem that requires treatment. Next, the therapeutic goal should be defined. The prescriber must decide which treatment is required, based on up-to-date information on medicines and therapeutics, to achieve the desired goal for an individual patient. When the decision

is made to treat the patient with medicines, the best drug for the patient is selected based on efficacy, safety, suitability, and cost. Then dose, route of administration, and duration of treatment are determined, taking into account the condition of the patient. When prescribing a medicine, the prescriber should provide proper information to the patient about both the medicine and the patient's condition. Finally, the prescriber should decide how to monitor the treatment, after considering the probable therapeutic and adverse effects of treatment.

Next, the medicine should be dispensed to the patient in a safe and hygienic manner, making sure that the patient understands the dosage and course of therapy; then the patient takes the medicine. Adherence occurs if the patient (and the community) understands and appreciates the value of using specific medicines for specific indications (see [Figure 27-1](#) on the medicine use process).

27.2 Examples of irrational medicine use

Irrational medicine use occurs in all countries and in all settings for health care—from hospitals to homes. It involves cases in which no medicine is needed but is prescribed; cases in which the wrong medicines, or ineffective or unsafe medicines, are prescribed or dispensed; cases in which effective and available medicines are not used; and those in which medicines are used incorrectly by patients.

Polypharmacy

Polypharmacy occurs when patients use more medicines than are necessary; for example, a patient with an upper respiratory infection receiving prescriptions for antibiotics, cough remedies, analgesics, and multivitamins. Use of too many medicines may be a particular problem with prescribers who also dispense medicines, especially when they have a financial incentive; for example, dispensing prescribers in Zimbabwe tended to prescribe a medicine for every symptom reported by the patient, resulting in their prescribing more antibiotics, cough syrups, mixtures, and analgesics per patient than nondispensing prescribers (Trap and Hansen 2003). Polypharmacy is usually judged by measuring the average number of medicines per prescription.

No medicine needed

Many times, medications may be used unnecessarily. Use of medicines when none is needed involves many nontherapeutic uses. For example, in many countries—both developed and developing—the majority of children suffering from minor upper respiratory infections are treated with antibiotics, which are not needed. Overuse of antibiotics is not a problem limited to developing countries. France, for example, uses over three times more antibiotics per patient in primary care than does the Netherlands (Goossens et al. 2005).

Figure 27-1 The medicine-use process

Wrong medicines

For various reasons, the wrong medicine may be prescribed and dispensed. Data from developing and transitional countries indicate that less than 40 percent of patients are treated according to standard treatment guidelines (WHO 2010). In some countries, for example, many children with acute diarrhea are indiscriminately prescribed and dispensed unnecessary and ineffective antimicrobials or antidiarrheals, instead of the recommended oral rehydration therapy (ORT). Also, because of spreading antimicrobial resistance (AMR), a medicine that was once efficacious may now be the wrong treatment choice; for example, chloroquine was once standard first-line treatment for malaria, but it is now largely ineffective in many areas of Asia, South America, and East Africa.

Ineffective medicines and medicines with doubtful efficacy

Medicines that are ineffective are sometimes given to patients because of common practice or because the patient thinks that the more medicines prescribed, the better. Excessive and unnecessary use of multivitamin preparations or tonics is an example of this prescribing pattern. A review of prescription quality at a pharmacy in India showed that in one week, 40 percent of prescriptions included multivitamin or tonic preparations (Patel et al. 2005).

Unsafe medicines

The likelihood of adverse reactions outweighs the therapeutic effects when unsafe medicines are prescribed. A common

Country Study 27-1 Overuse of therapeutic injections

Poor injection practices, especially in developing countries, include the prescription of unnecessary injections and the reuse of equipment without sterilization. Unsafe injections increase the risk of transmitting hepatitis B and C, HIV, and a number of other blood-borne pathogens. Although usage studies have shown a gradual trend toward lessened use of injections, progress still remains to be made in certain geographic areas—especially countries in the Middle East and Southeast Asia.

Egypt. In a household survey of 4,197 people in two regions of Egypt, more than 26 percent reported having received an injection in the previous three months. Overall, respondents reported receiving an average of 4.2 injections per year. Of those who had recently received an injection, 8 percent reported that the providers did not take the syringe from a sealed packet. Respondents reported receiving injections from public- and private-sector physicians, pharmacists, barbers, doctor's assistants, housekeepers, relatives, and friends (Talaat et al. 2003).

Mongolia. The Ministry of Health in Mongolia collected information on injection practices through interviews and observations of a sample of prescribers, injection providers, and members of the population. The sixty-five members of the population reported receiving an average of thirteen injections per year. All twenty health care facilities surveyed used single-use injection devices, but almost 30 percent of the providers admitted reusing infusion bottles. Observations of practices showed other

breaks in infection-control procedure. Even with the high rate of injections, 90 percent of the prescribers and 49 percent of the population were aware of the potential risk of HIV transmission through unsafe injections (Logez et al. 2004).

Pakistan. A study of 198 adult patients in Karachi collected information on injection practices using a questionnaire about respondents' last interaction with a health care provider. It revealed that nearly one-half (49 percent) of respondents had been given an injection during their last visit; 91 percent of respondents reported that the doctor always recommended an injection; and 83 percent of respondents believed injections to be more powerful than alternatives. When treatments were equally effective, 83 percent of respondents preferred alternatives (pills or advice) to injections. Respondents reported that the nature of their complaint did not affect the likelihood of injection, and 30 percent had received ten or more injections in the previous year (Raglow et al. 2008).

Interventions to decrease the number of unnecessary injections and improve injection practices have shown that—

- Better communication between patients and providers can reduce injection overuse
- Increased access to single-use injection devices improves injection safety
- Managerial approaches (that is, restricting access to selected unnecessary and dangerous injectable medicines) can improve injection practices

example is the use of anabolic steroids for growth or appetite stimulation in children or athletes.

Underuse of available effective medicines

Several studies have shown that ORT was prescribed for only a small proportion of children with acute diarrhea. Regrettably, the underuse of effective oral rehydration therapy for acute diarrhea in children still occurs in many countries.

A large, multicountry survey conducted for WHO found that many people with serious mental disorders were not receiving any treatment, despite the availability of effective medicines. In developed countries, up to one-half of serious cases were untreated, while in less developed countries the figure was up to 85 percent (Demyttenaere et al. 2004).

Incorrect use of medicines

A frequent incorrect use of medicines is giving a patient only one or two days' supply of antibiotics rather than the full course of therapy. Patients may also take only as much medicine as needed to feel better, then save the remainder for a future illness; in addition, patients often self-medicate, using antibiotics or other prescription-only medicines bought from untrained drug sellers in retail drug outlets. Another common example of irrational use is overusing injectable preparations when using oral preparations would be easier and safer. This often occurs because prescribers and patients believe that injections are more efficacious than pills (see [Country Study 27-1](#)).

27.3 Adverse impact of irrational medicine use

The inappropriate use of medicines on a wide scale can have significant adverse effects on health care costs and the quality of drug therapy and medical care, as well as being a primary contributor to the spread of antimicrobial resistance. Other negative effects are the increased likelihood of adverse drug reactions and encouraging patients' inappropriate reliance on medicines.

Impact on quality of medicine therapy and medical care

Inappropriate prescribing practices can, directly or indirectly, jeopardize the quality of patient care and negatively influence the outcome of treatment. The underuse of ORT for acute diarrhea, for instance, can hinder the goal of treatment: namely, to prevent or treat dehydration and thus prevent death in children. Widespread ORT use has resulted in significant reductions in childhood death from diarrhea in the last twenty-five years; however, improvements could

still be made, as diarrhea remains the second-leading cause of mortality among children (WHO/UNICEF 2009).

The likelihood of adverse drug reactions increases when medicines are prescribed unnecessarily (see [Chapter 35](#) on pharmacovigilance for a full discussion of the effects of adverse drug reactions and events). An overdose of gentamicin, for example, can lead to permanent hearing problems. Misuse of injectable products raises the risk of transmitting HIV/AIDS, hepatitis B and C, and other blood-borne diseases.

Impact on antimicrobial resistance

A chronic use or underdosage of antibiotics and chemotherapeutic agents can contribute to the rapid emergence of resistant strains of bacteria or the malaria parasite. Health gains stemming from the discovery of antimicrobial agents are in jeopardy because of the spread of microbes that are resistant to inexpensive first-choice, or first-line, medicines. Resistance to antimicrobials is a natural biological phenomenon that can be amplified by a variety of factors, including human practices. The use of an antimicrobial in any dose and over any time period forces microbes to either adapt or die; the microbes that adapt and survive carry genes for resistance, which can be passed on. The bacterial infections in which microbial resistance is most evident are diarrheal diseases, respiratory tract infections, meningitis, sexually transmitted infections, tuberculosis, and hospital-acquired infections. The development of drug-resistant malaria and tuberculosis is of particular concern, as is the emergence of resistance to anti-HIV drugs. [Box 27-1](#) lists the global prevalence rates of AMR for several infections.

When infections become resistant to first-line antimicrobials, treatment must be switched to second- or third-line medicines, which are almost always more expensive and sometimes more toxic. In many countries, the

Box 27-1
Antimicrobial resistance global prevalence rates: 2000–2003 data

Malaria: Chloroquine resistance in 81/92 countries

Tuberculosis: 0–17% Primary multidrug resistance

HIV/AIDS: 0–25% Primary resistance to at least one antiretroviral drug

Gonorrhea: 5–98% Penicillin resistance in *Neisseria gonorrhoeae*

Pneumonia and bacterial meningitis: 0–70% Penicillin resistance in *Streptococcus pneumoniae*

Shigellosis: 10–90% Ampicillin resistance; 5–95% co-trimoxazole resistance

Hospital infections: 0–70% Resistance of *Staphylococcus aureus* to all penicillins and cephalosporins

Source: Holloway 2005.

high cost of these replacement medicines is prohibitive, meaning that some diseases can no longer be treated in areas where resistance to first-line medicines is widespread. The economic cost of antimicrobial resistance in the European community is estimated to be 9 billion euros per year (SCORE 2004). Most alarming of all are diseases for which resistance is developing to virtually all available medicines.

Impact on cost

Overuse or incorrect use of medicines, even essential ones, causes both patients and the health care system to spend excessively on pharmaceuticals and waste financial resources. For example, in Nepal, up to half of total medicine costs in one study were related to inappropriate prescribing (Holloway et al. 2001). In many places, people buy medicines out-of-pocket—particularly antimalarials—and spending money on irrational treatment can dramatically affect household expenditure, especially in the poorest homes (Breman et al. 2006).

In many countries, expenditures on nonessential pharmaceutical products, such as multivitamins or cough mixtures, drain limited financial resources that could otherwise be allocated for more essential and vital products, such as vaccines or antibiotics. Inappropriate underuse of medicines at an early stage of a disease may also produce excess costs by increasing the probability of prolonged disease and eventual hospitalization.

As an example of the global impact of irrational medicine use on costs, the switch to artemisinin-based combination

therapies (ACTs) for malaria from ineffective antimalarials has had an enormous effect on the cost of malaria control. Estimates indicate that the additional annual costs of ACT range from 300 million U.S. dollars (USD) to USD 500 million globally, which does not include the resources required to strengthen health systems to effectively deliver ACTs, including the costs of improving pharmaceutical regulations, pharmacovigilance, diagnostics, and implementing different medicine policies for different population groups (Arrow et al. 2004).

Psychosocial impact

Overprescribing encourages patients to believe that they need medications for any and all conditions, even trivial ones. The concept that there is a pill for every ill is harmful. Patients come to rely on medicines, and this reliance increases the demand for them. Patients may demand unnecessary injections because during years of exposure to modern health services, they have become accustomed to having practitioners administer injections. Studies have also shown that patient demands and expectations can lead prescribers to prescribe unnecessary antibiotics for viral infections.

27.4 Factors underlying irrational use of medicines at various levels of the health system

Many interrelated factors influence medicine use (see [Figure 27-2](#)). The health system, prescriber, dispenser, patient, and community are all involved in the therapeutic process, and all can contribute to irrational use in a variety of ways.

Health system

Factors affecting the health system include unreliable supply, medicine shortages, expired medicines, and availability of inappropriate medicines, including substandard and counterfeit products. Such inefficiencies in the system lead to a lack of confidence in the system by the prescriber and the patient. The patient demands treatment, and the prescriber feels obliged to give what is available, even if the medicine is not the correct one to treat the condition. Financial incentives inherent in a health system can promote better use; for example, Kyrgyzstan implemented an outpatient drug benefit program that based prescription reimbursements on the use of standard treatment guidelines and generics (Kadyrova et al. 2004).

A government can show its commitment to rational medicine use by implementing key policies and regulations and by providing resources for rational-medicine-use programs and research ([Figure 27-3](#)). For example, less

than one-third of low- and middle-income countries have either national AMR strategies or national AMR task forces (WHO/TCM 2006). In addition, health systems that fail to implement policies on standard treatment guidelines, essential medicines lists, and medicine formularies are missing out on well-proven methods to increase the rational use of medicines.

Prescriber

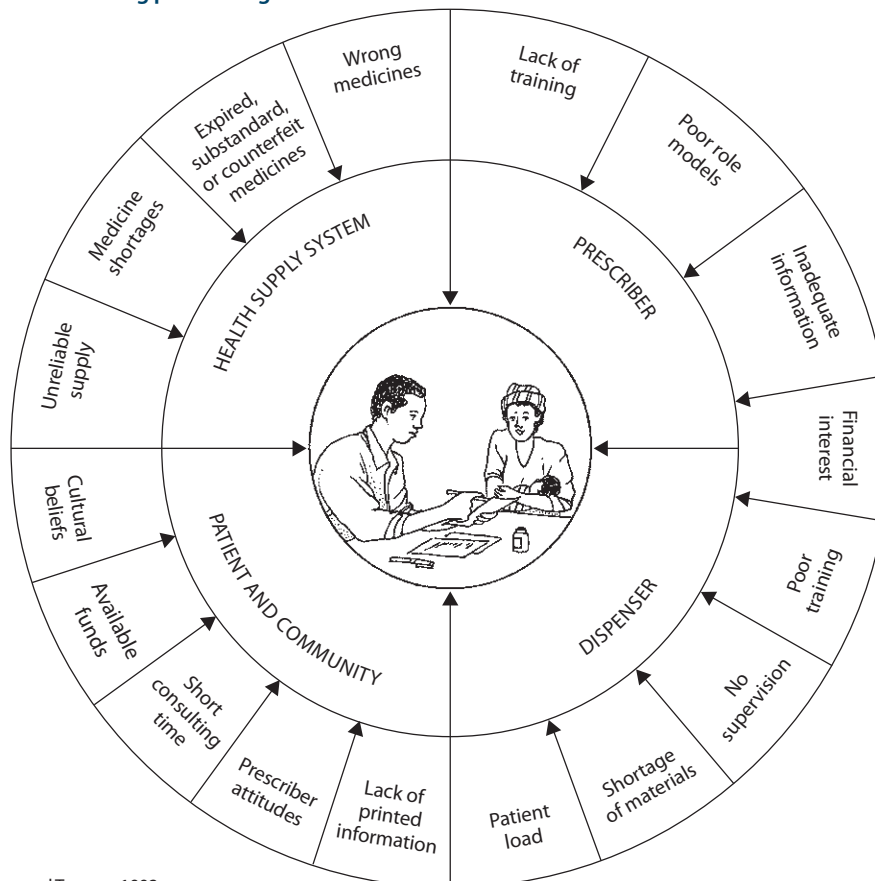

The prescriber can be affected by internal and external factors. He or she may have received inadequate training either preservice or in-service, or his or her prescribing practices may have become outdated because of a lack of continuing education and a poor supervisory system. Prescribing role models who are imitated may not prescribe rationally. Objective information on medicines may be lacking, and the information provided by supplier representatives may be unreliable. Temptation can be strong to generalize inappropriately about the effectiveness or side effects of medicines on the basis of limited personal experience. Externally, a heavy patient load and pressure to prescribe from peers, patients, and pharmaceutical company representatives all

complicate prescribing decisions. In India, doctors often prescribe ineffective tonics because many patients believe in them and will not return to a doctor who will not prescribe them, which impinges on the doctor's livelihood. Finally, profit may affect a prescriber's choice if the prescriber's income is dependent on medicine sales. [Country Study 27-2](#) describes the prescribing practices of doctors who also dispense medicines.

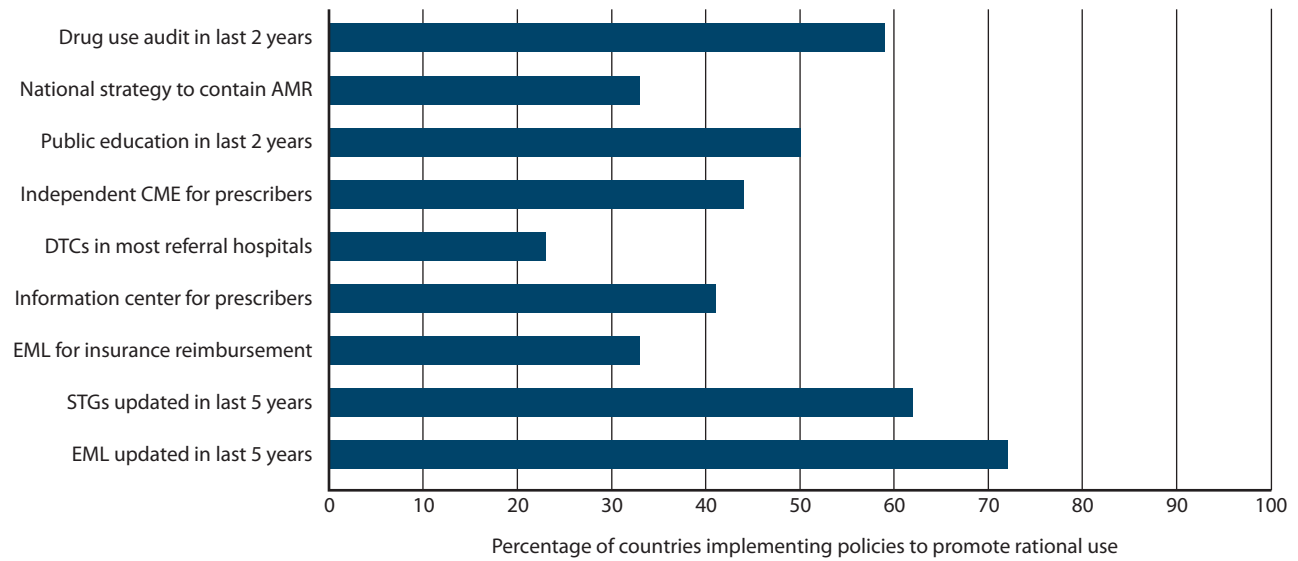

Dispenser

The dispenser plays a crucial role in the therapeutic process. Dispensing quality may be affected by the training and supervision the dispenser has received and the medicine information available to the dispenser. A shortage of dispensing materials and short dispensing time caused by a heavy patient load may also have an adverse impact on dispensing. As with prescribers, dispensers, especially private drug sellers, may have a financial incentive to dispense irrationally. In addition, in some countries, drug sellers in retail outlets are rarely trained and there is little to no structure for monitoring or supervision. Finally, the low status of dispensers affects the quality of dispensing.

Figure 27-2 Factors influencing prescribing

Figure 27-3 What countries are doing to promote the rational use of medicines

AMR = antimicrobial resistance; CME = continuing medical education; DTCs = drug and therapeutics committees; EML = essential medicines list; STGs = standard treatment guidelines

Source: Holloway 2005.

Patient and community

The individual's adherence to prescribed treatment is influenced by many factors, including cultural beliefs, the communication skills and attitudes of the prescriber and dispenser, the limited time available for consulting, the shortage of printed information, the affordability of treatment, and community beliefs about the efficacy of certain medicines or routes of administration. For example, patients may believe that injections are more powerful than capsules, or that capsules are more effective than tablets. In addition, many individuals practice self-medication, selecting and using medications on their own

for recognized illnesses. Self-medication often leads to irrational use and may include either over-the-counter or prescription medicines.

It is clear that, although the prescriber's knowledge and experience are important aspects influencing the use of medicines, they are not the only ones. As discussed above, there are many causes for irrational medicine use and many factors involved in the decision-making process.

These factors vary for each person and situation. Therefore, specific interventions to improve prescribing may work in some circumstances but not in others. Because of the complexity of factors involved, any single intervention is unlikely to work in every situation.

Country Study 27-2

The practices of dispensing prescribers in Zimbabwe

A study of twenty-nine randomly chosen private-sector dispensing doctors and twenty-eight private-sector nondispensing doctors in Harare investigated differences in prescribing practices. Data on prescribing for upper respiratory tract infections were collected from patient records and evaluated by a panel of experts based on standard treatment guidelines and the WHO/International Network for the Rational Use of Drugs (INRUD) rational drug-use indicators.

Results of the study showed major differences between the prescribing habits of dispensing and nondispensing physicians. Dispensing doctors prescribed significantly more medicines (35 percent more), antibiotics (33 percent more), and mixtures (72 percent more) per patient. The more symptoms reported by the patient, the more medicines he or she received. In addition, dispensing doctors prescribed three times more injections, and they prescribed subcurative doses of antibiotics almost 20 percent of the time.

Source: Trap and Hansen 2003.

27.5 Strategies to improve medicine use

Before attempting to change medicine use, the scale of the problem should be assessed and quantified. The underlying reasons for the problem behavior then need to be investigated. Quantitative and qualitative methods for assessing medicine use are described in [Chapter 28](#). *It is a mistake to intervene before understanding the reasons for a problem behavior.*

Several choices exist for interventions to change medicine-use practices. These approaches can be characterized as educational, managerial, economic, or regulatory (see [Box 27-2](#)). Whichever approach is used, interventions should focus on specific problem behaviors and should target prescribers, dispensers, facilities, or the public, depending on where the assessment shows the problems lie. A single intervention rarely results in sustainable changes, so a combined strategy is preferred. [Figure 27-4](#) shows a framework for improving uses.

Possible interventions for prescribers, such as training, accessing unbiased information, and using opinion leaders, are described in [Chapter 29](#). After prescribing has been addressed, the next stage of medicine use is dispensing. This crucial aspect of the provider-patient relationship is often

neglected or delegated to an untrained person. [Chapter 30](#) describes ways to ensure good dispensing. The final stage of medicine use is when the patient takes the medicine. The patient is more likely to take medicines as advised if he or she understands how to take the medicine and if there is general community awareness of rational medicine use. Developing informational materials for patients and planning public education campaigns requires an understanding of cultural norms, values, and practices. These issues as well as those surrounding patient adherence are covered in [Chapter 33](#).

Whatever problem is being addressed, health care providers and consumers need impartial drug and therapeutics information. Such information can serve as the basis for standard treatment guidelines or therapeutic standards. Information can be made available actively through drug bulletins or in a largely passive manner through drug information centers. However, in a 2003 survey, less than half of all countries—no matter what income level—had independent national drug information services for prescribers, dispensers, or consumers (WHO/TCM 2006). Medicine information is covered in [Chapter 34](#).

No matter which point in the medicine-use process becomes the focus of an intervention strategy, there are

Box 27-2

Intervention strategies to improve medicine use

Educational strategies

Training of prescribers

- Formal education (preservice)
- Continuing education (in-service)
- Supervisory visits
- Group lectures, seminars, and workshops

Printed materials

- Clinical literature and newsletters
- Treatment guidelines and medicine formularies
- Illustrated materials (flyers, leaflets)

Approaches based on face-to-face contact

- Educational outreach
- Patient education
- Influencing opinion leaders

Managerial strategies

Monitoring, supervising, and feedback

- Hospital drug and therapeutics committees
- District health teams
- Government inspectorate
- Professional organizations
- Self-assessment

Selection, procurement, and distribution

- Limited procurement lists
- Drug use review and feedback
- Hospital and regional drug committees
- Cost information

Prescribing and dispensing approaches

- Structured medicine order forms
- Standard diagnostic and treatment guidelines
- Course-of-therapy packaging

Economic strategies

- Price setting
- Capitation-based budgeting
- Reimbursement and user fees
- Insurance

Regulatory strategies

- Medicines registration
- Limited medicine lists
- Prescribing restrictions
- Dispensing restrictions

Source: Adapted from Quick, Laing, and Ross-Degnan 1991.

Figure 27-4 Framework for improving medicine use

Source: CPM/MSH 2011.

common characteristics of effective interventions. These interventions—

Identify key influence factors. Use qualitative methods to understand why a person behaves in a certain way, and identify influences that can promote and prevent change.

Target individuals or groups with the worst practices. For the greatest impact, focus on these individuals or facilities.

Use credible information sources. Involve influential, respected authorities and ensure that resource materials are well referenced and authoritative.

Use credible communication channels. Enhance the message and acceptability of its content by communicating through existing, credible channels.

Use personal contact whenever possible. Communicate key messages most effectively with face-to-face individual or small-group meetings.

Limit the number of messages. Improve understanding by confining the intervention to a few key messages.

Repeat key messages using a variety of media. People learn in different ways—some learn visually from text or graphics, some learn through spoken messages, and some learn through a combination of media. Help reinforce key messages by repeating them using a variety of approaches.

Provide better alternatives. Whenever possible, give a positive message that encourages people to do something. Negative messages tend to alienate people. With an emphasis on the positive, the negative behavior can be excluded. For example, a positive message: DO treat diarrhea with ORT. Antidiarrheals are not necessary.

27.6 Developing a strategy

Six steps to follow in developing a strategy to promote rational medicine use are described below.

Step 1. Identify the problem and recognize the need for action

Within the facility, district, or country, a consensus must exist about the most important problems in medicine use. Recognition of the primary problems may come as a result of an indicator survey or drug use review, a disaster in which patients have been adversely affected, or an economic analysis of medicine expenditures. An effective response can be planned only after all the involved parties, including prescribers, patients, and health service managers, recognize that a problem exists. If an influential prescriber or politician refuses to accept that a specific problem exists, it will be very difficult to intervene effectively. Thus, compiling the evidence that clearly details the scope of the problem, establishing a consensus that action is needed, and securing support from all interested parties are important tasks. [Country Study 27-3](#) shows how the Lao People's Democratic Republic approached the implementation of a national medicine policy to improve rational use.

Step 2. Identify underlying causes and motivating factors

As described in Section 27.4, many factors contribute to the irrational use of medicines. These factors must be investigated and understood before intervening. If this step has not been taken, the intervention is likely to fail. For example, a campaign to promote the use of generic medicines by hanging up posters in a health clinic will fail if the underlying reason for the lack of use is that the doctors do not know the generic names of the medicines. Also, a prescriber who is allowed to dispense and earn money from medication sales is going to be motivated to prescribe (and sell) more medicines and more expensive medicines, including brand-name products.

Country Study 27-3**Building a national drug policy to improve the rational use of medicines: Assessing implementation in Lao P.D.R.**

The National Drug Policy (NDP) of Laos was created in 1993 to improve the quality and use of medicines through developing drug legislation, quality control, guidelines, training, inspections, and health systems research. Since 1995, Lao P.D.R.'s National Drug Policy program has implemented the NDP through a pilot intervention program in five provinces. In each province in the assessment (pilot and control), four pharmacies at public hospitals and twenty private pharmacies were randomly selected.

The intervention comprised a number of activities in both the public and private sectors, including training private drug sellers and inspectors, developing standard treatment guidelines and indicators for rational medicine use, establishing drug and therapeutics committees, and implementing outreach to the general public on rational medicine-use concepts.

To measure the intervention outcome, researchers analyzed 110 prescriptions for children under five with simple diarrhea and 240 adult outpatient prescriptions based on twenty-nine indicators; in addition, twelve health care

managers were interviewed on knowledge and attitudes. The results of the analysis showed that—

- Health care managers in the pilot province had better knowledge of NDP concepts.
- Significantly more essential medicines were available in the private pharmacies in the pilot province.
- The proportion of prescriptions of essential medicines in hospitals was higher in the pilot province (95 percent compared with 86 percent; $p < 0.001$).
- The management of simple diarrhea in children in the pilot province was significantly more likely to follow standard treatment guidelines.
- Fewer drugs were prescribed per patient in the pilot province (2.7 compared with 3.3; $p < 0.001$).

In conclusion, the pilot province performed significantly better in several aspects of rational medicine use. This operational research provided evidence to help the Lao Ministry of Health tailor the development and implementation of a national drug policy to its own context.

Country Study 27-4**Chile's efforts to combat the overuse of antimicrobials**

In 1998, a study showing an alarming trend of increased sales and use of antibiotics in Chile was submitted to the Ministry of Health. The findings showed that in the previous ten years, sales of amoxicilline and oral fluoroquinolones had increased almost 500 percent, and sales of oral cephalosporins had increased more than 300 percent. Ministry of Health officials met with a number of stakeholders, including representatives from scientific and professional associations, the pharmaceutical regulatory agency, and consumer groups, to jointly develop a strategy to address the issue.

In September 1999, with stakeholder support, the Ministry of Health instituted measures to control the use of antibiotics by making them available only through pharmacists and only by prescription. The new policy was backed up with the distribution of

informational leaflets, posters, and widespread media coverage.

Three months later, an evaluation of sales and use pre- and postintervention showed that consumption of amoxicilline had decreased by 36 percent, consumption of ampicillin had decreased by 56 percent, and consumption of erythromycin had decreased by 30 percent between the last quarter of 1998 and the last quarter of 1999. In addition, expenditures on antimicrobials in private pharmacies dropped by USD 6.5 million.

Chile's experience has shown that political commitment, stakeholder cooperation, and public education can be combined to save money and reduce the irrational use of antibiotics.

Box 27-3 Core strategies to promote rational use of medicines

Evidence suggests that the following core policies, strategies, and interventions promote more rational use of medicines.

Establishing a mandated multidisciplinary national body to coordinate medicine-use policies. Ensuring rational medicine use requires many activities that need coordination among many stakeholders. Therefore, a national body is necessary to coordinate strategies and policy at the national level, in both the public and private sectors. This body should involve government, health professions, academia, the pharmaceutical industry, consumer groups, and the national regulatory authority.

Implementing procedures for developing, using, and revising standard treatment guidelines. Standard treatment guidelines (STGs) (or clinical guidelines or prescribing policies) are systematically developed statements to help prescribers make decisions about appropriate treatments for specific clinical conditions. STGs are made more credible through the use of evidence-based recommendations. They vary in complexity from simple algorithms to detailed protocols on diagnostic criteria, patient advice, and costs.

Implementing procedures for developing and revising an essential medicines list (or hospital formulary) based on treatments of choice. An essential medicines list makes pharmaceutical management easier at all levels: procurement, storage, and distribution are easier with fewer items, and prescribing and dispensing are easier for professionals. A national essential medicines list should be based on national STGs, and both should be revised regularly.

Establishing a drug and therapeutics committee in districts and hospitals, with defined responsibilities for monitoring and promoting rational use of medicines. This committee, also called a pharmacy and therapeutics committee, is responsible for ensuring the safe and effective use of medicines in the facility or area under its jurisdiction. The committee should operate independently, and members should represent all the major medical specialties and the administration. The primary tasks of the committee are to develop and revise institutional STGs (based on national guidelines) and to maintain an institutional essential medicines list or formulary.

Using problem-based training in pharmacotherapy based on national STGs in undergraduate curricula. The quality of basic pharmacotherapy training for undergraduate medical and paramedical students can

significantly influence future prescribing habits. Training is most successful when it is problem based, concentrates on common conditions, takes into account students' level of knowledge, and is targeted to their future prescribing requirements. In most settings, rather than focusing on basic science, problem-solving skills should be promoted and interdisciplinary problem-based learning encouraged. If the existing focus is not on problem-based training in pharmacotherapeutics, national consultative workshops may help build awareness of the value of the approach.

Continuing in-service medical education as a licensure requirement and targeted educational programs by professional societies, universities, and the government. Unlike in developed countries, opportunities for continuing medical education in less developed countries are limited because continuing education is not required for licensure. Governments should support efforts by university departments and national professional associations to offer independent, unbiased continuing medical education courses to health professionals, including medicine dispensers. The most effective in-service training is likely to be problem based, repeated on multiple occasions, focused on practical skills, and linked to STGs.

Developing a strategic approach to improve prescribing in the private sector through regulation and collaborations with professional associations. Most efforts in improving use of medicines have focused on the public sector, but the private sector often provides greater access to pharmaceuticals. Changing practices in the private sector requires an understanding of the motivations of private prescribers. A range of strategies should be considered to improve rational medicine use, including licensing regulations with appropriate enforcement, accreditation and continuing education through professional associations, and financial incentives.

Monitoring, supervision, and using group processes to promote rational medicine use. Supervision that is supportive, educational, and face-to-face will be more effective with prescribers than inspection and punishment. Effective forms of supervision include prescription audit and feedback, peer review, and group processes of self-identifying medicine-use problems and solutions in a group of prescribing professionals. Group process interventions with practitioners and patients to improve prescribing practices have been effectively used to change prescribing behavior.

Training pharmacists and drug sellers to offer useful advice to consumers, and supplying independent medicine information. In many countries with shortages of trained health professionals, pharmacies and medicine shops are a major source of information for consumers. Interventions have shown that the skills of untrained prescribers and dispensers can be upgraded. In addition, sometimes the only information about medicines that prescribers receive is from the pharmaceutical industry, which may be biased. Pharmaceutical information centers and drug bulletins are two useful ways to disseminate independent, unbiased information. They may be administered by the government, a university teaching hospital, or a nongovernmental organization, under the supervision of a health professional.

Encouraging involvement of consumer organizations, and devoting government resources to public education about medicines. Governments have a responsibility to ensure the quality of information about medicines available to consumers. Without sufficient knowledge about the risks and benefits of medicine use, people will often fail to achieve their expected clinical outcomes and may even suffer adverse effects. Regulation of consumer advertising and promotion by pharmaceutical

companies, as well as public education activities led by consumer organizations, may influence medicine use by the public.

Avoiding perverse financial incentives. Financial incentives may strongly promote rational or irrational use of medicines. Examples include the ability of prescribers to earn money from medicine sales; flat prescription fees that lead to overprescription; and dispensing fees that are calculated as a percentage of the cost of medicines, which encourages the sale of expensive medicines.

Ensuring sufficient government expenditure and enforced regulation. Appropriate regulation of the activities of all those involved in the use of medicines is critical to ensure rational medicine use. For regulations to be effective, they must be enforced, and the regulatory authority must be sufficiently funded and backed by the government's judiciary. Without sufficient competent personnel and finances, none of the core components of a national program to promote rational use of medicines can be carried out.

Sources: WHO 2002; Laing et al. 2001.

Step 3. List possible interventions

Educational, managerial, economic, and regulatory interventions can be used to address the problem of irrational use (see [Chapter 29](#) for details). Whenever possible, a combination or sequence of interventions should be used, and there should be evidence that the interventions are effective in similar settings. As seen in [Country Study 27-4](#), the government of Chile changed its regulations to restrict sales of antimicrobials to prescription only in the private sector, and supported the legal measure with a public and professional education and media campaign.

Step 4. Assess resources available for action

When deciding which intervention or combination of interventions to test, it is important to take stock of what resources are available. The most important limiting resource is usually human. Ask the following questions: Who will implement the intervention? Will that person have enough time to work on the intervention? Try to identify groups or individuals who would support the intervention. For example, manufacturers of generic medicines would support an intervention to popularize generics. Financial, transport, and material resources also need to be assessed.

Step 5. Choose an intervention or interventions to test

Factors to consider when choosing an intervention include the effectiveness with which it addresses the underlying causes of the problem; its previous success rate in similar situations, areas, or countries; its cost; and whether it can be sustained with available resources. Whichever intervention is chosen, it must be tested before widespread implementation. Again, if feasible, a strategy that combines a mix of interventions will be more effective and sustainable.

Step 6. Monitor the impact and restructure the intervention

During testing of the intervention, it is important to monitor related medicine use in order to evaluate the intervention's efficacy or unexpected and negative effect; for example, an intervention aimed at banning antidiarrheals may lead to an increased use of antibiotics. On completion of the intervention, evaluate the results to decide whether it should be expanded to involve a larger population. An intervention's effectiveness in a small area with a limited number of people does not guarantee widespread success.

[Box 27-3](#) has a list of core strategies to promote the rational use of medicines.

The remaining chapters in this section address the task of improving medicine use. All these chapters should be reviewed before planning an intervention. In addition, [Box 27-4](#) lists useful organizations and their websites, which provide further information on specific related topics. ■

Glossary

Adherence to treatment (also compliance): The degree to which patients adhere to medical advice and take medicines as directed. Adherence depends not only on the patient's acceptance of information about the health threat but also on the practitioner's ability to persuade the patient that the treatment is worthwhile and on the patient's perception of the practitioner's credibility, empathy, interest, and concern.

Antimicrobial resistance: A biological phenomenon where, as part of the natural selection process, microbes mutate and develop drug-resistant genes that can be passed on. Antimicrobial resistance can be amplified or accelerated by human behaviors, including the irrational use of medicines.

Clinical pharmacist: An individual trained in pharmacy, usually with the minimum of a bachelor's degree, who has had special-

ized training in the uses, side effects, contraindications, and dosages of medications for human use.

Clinical pharmacologist: A physician who has had specialized training in the uses, side effects, contraindications, and dosages of medications for human use.

Course-of-therapy prepackaging: Prepackaging of medicines in sealed plastic bags, each bag containing a complete course of treatment, as established by standard treatment guidelines. The package usually contains a complete label with instructions for use.

Dispense: To prepare and distribute to a patient a course of therapy on the basis of a prescription.

Dispenser: A general term for anyone who dispenses medicines. Also specifically used to mean an individual who is not a graduate pharmacist but who is trained to dispense medications, maintain stock records, and assist in procurement activities.

Generic substitution: Dispensing of a product that is generically equivalent to the prescribed product, with the same active ingredients in the same dosage form, and identical in strength, concentration, and route of administration.

Irrational prescribing: Prescribing that does not conform to good standards of treatment—for example, extravagant prescribing, overprescribing, incorrect prescribing, multiple prescribing, or underprescribing of medications.

ASSESSMENT GUIDE

- Have studies been done to identify possible problems with rational medicines use? In the country? In the province? In the facility?
- If problems have been identified, what might be some of the underlying causes in the health system? With prescribers? With dispensers? With the public?
- Does the country have a national medicine policy or policies in place to promote rational medicine use, such as national standard treatment guidelines or an essential medicines list? Are there any regulations that seek to control medicine use? For example, restricting the sales of antibiotics to prescription only?
- Does the government have any campaigns to promote rational use in the public?
- Do prescribers follow a standard process of prescribing and monitoring treatment?
- What unbiased resources are available to prescribers regarding information on pharmaceuticals?
- At each level of the health care system, who is responsible for dispensing medicines? Are prescribers allowed to dispense medicines?
- Are injections a preferable way to deliver medicines with prescribers? With the public?
- Has an assessment been done to evaluate the level of antimicrobial resistance in the country?
- Have any interventions been designed and carried out to improve rational medicine use? What were the results? Were the results shared with other stakeholders?

Labeling: Placing written or symbolic instructions on the container in which medicine is dispensed to the patient.

Medicine use: The process of diagnosis, prescribing, labeling, packaging, and dispensing and of adherence to medicine treatment by patients.

Pharmacology: The study of medicines and their actions.

Polypharmacy: The practice of using too many medicines per patient.

Prescribing: The act of determining which medication the patient should have and writing the dosage, frequency, and duration of treatment on a form.

Self-medication: The selection and use of medicines by individuals to treat self-recognized symptoms.

Standard treatment guidelines: Agreed-upon treatment practices for a diagnosed illness; may include more than details of medicine treatment.

Symbolic labeling: A system of providing written instructions for patients, using sketches or other graphic representations.

Therapeutic substitution: Interchange of one drug product with another that differs in composition but is considered to have similar pharmacologic and therapeutic activities, in accordance with written protocols previously established and approved.

SUMMARY

Medicine-use researchers, health care providers, policy makers, and managers collect data to describe patterns of medicine use, to address medicine-use problems, and to monitor medicine use over time. They use two basic methods: quantitative methods, to measure what is being done, and qualitative methods, to provide information on why it is being done. Both methods are used to better understand the causes of problems before intervening to correct them. The intervention design must include outcome indicators that are meaningful, reliable, and measurable. Appropriate study sites and a relevant comparison group must be randomly selected; outcomes need to be measured before and after the intervention in both groups. If an appropriate comparison group cannot be identified, study designs that measure change over time (interrupted time series) may be used. Medicine-use data can also help evaluate the effect of interventions.

Reliably measuring medicine use requires standardized indicators to provide consistency. In 1993, the World Health Organization (WHO) and the International Network for the Rational Use of Drugs (INRUD) produced a manual that defines core medicine-use indicators and provides a methodology for measuring these indicators for general outpatients in health care facilities. Similar indicators are needed to measure pharmaceutical use in hospital inpatients, in private pharmacies, and for pharmacy benefits for insurance schemes, as well as to measure adherence to antiretroviral therapy (ART).

Sources of data differ according to the intended use and setting. Common sources of quantitative data include pharmaceutical supply orders, stock cards, patient registers, medical and prescription records, medicine-use databases, and patient exit surveys. For qualitative studies, data routinely come from patient interviews, questionnaire surveys, patient observation, and focus group discussions. Each method has strengths and weaknesses and is appropriate for different circumstances.

Medicine-use investigations can occur in public health care facilities, in private-sector facilities, and in the community. Methods for investigating use in different settings may differ; for example, mystery shoppers or simulated patients who pose as customers with specific health problems are useful for studying practices in private-sector pharmacies, whereas public health facilities may rely on readily available, routinely collected data.

After a medicine-use study, meetings to discuss the results help health care providers, managers, and policy makers identify specific problems related to the medicine-use process and design appropriate interventions to address them. The effectiveness of different interventions depends on a number of factors, including the intervention itself, the setting, and the implementation process. Evaluating interventions is necessary to assess the overall impact of the program or to compare the relative effectiveness of different interventions.

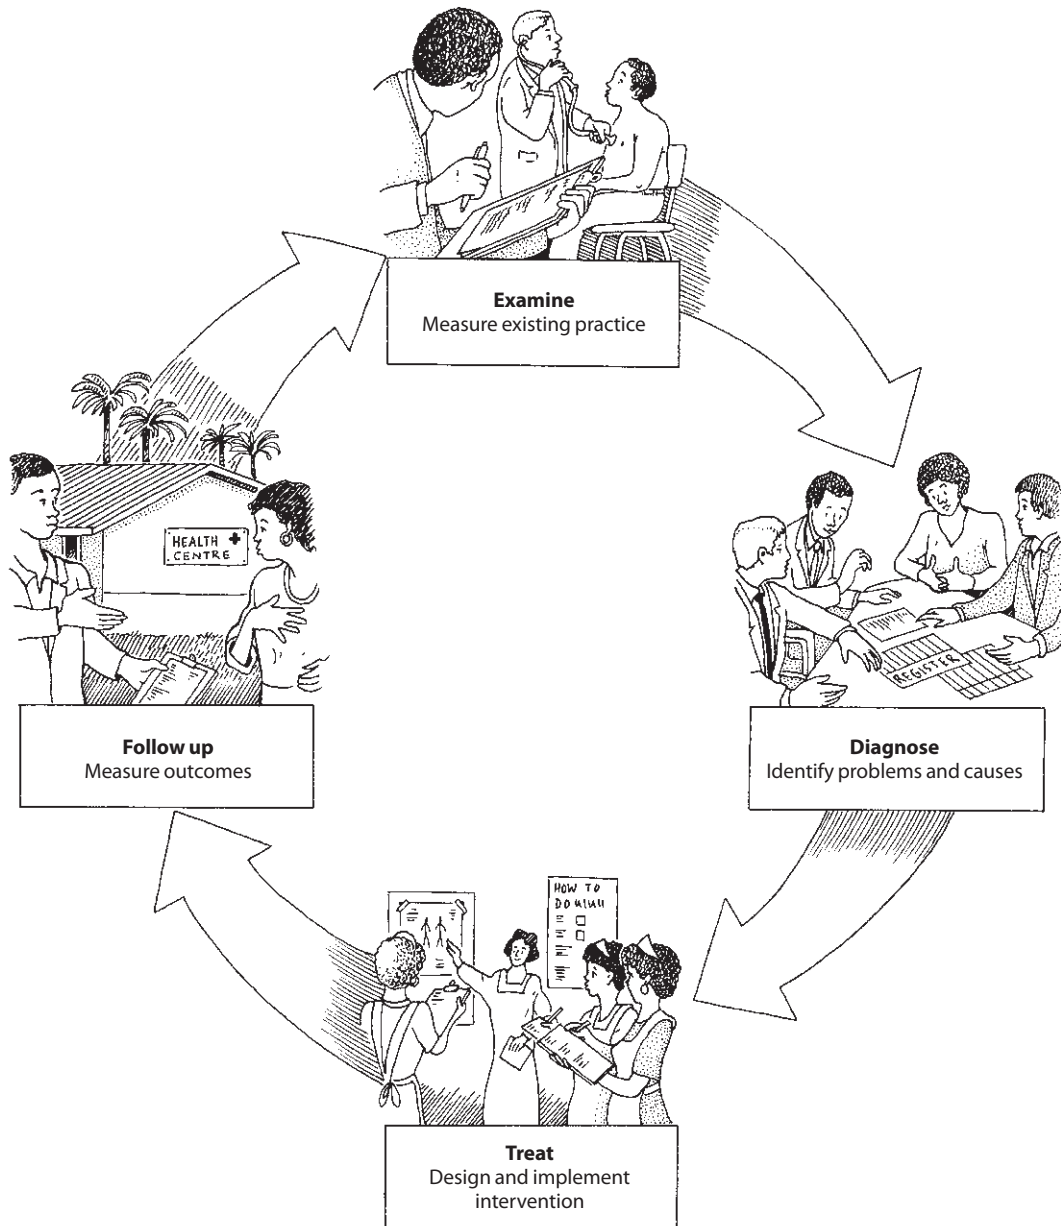

28.1 Reasons to investigate medicine use

Medicine-use researchers, managers, and policy makers collect data about medicine use for various reasons. These reasons can be grouped into three general categories—

1. To describe and compare current patterns of medicine use within a defined setting (for example, a health care facility or geographic area)—
 - Measuring consumption of particular medicines or therapeutic groups of medicines, such as acetylsalicylic acid versus paracetamol or acetaminophen
 - Comparing use by individual health facilities or prescribers
 - Deciding whether medicine use is clinically justified or cost-effective
 - Learning about the influence of prescribing on pharmaceutical costs
2. To identify and correct specific medicine-use problems—
 - Identifying the factors that cause specific problems related to medicine use
 - Designing interventions to address specific problems in prescribing, dispensing, or patient use
 - Measuring the effectiveness of behavior change interventions
3. To monitor medicine use over time—
 - Monitoring quality of care within a health facility or geographic area
 - Monitoring the efficiency and cost-effectiveness of prescribing
 - Monitoring the effect of drug regulatory interventions

A health manager who wishes to improve medicine use proceeds through a cycle of activities (Figure 28-1) that includes (a) assessing current patterns of medicine use,

Figure 28-1 Identifying and rectifying a medicine-use problem: An overview of the process

(b) identifying problems and their causes, (c) carrying out interventions to address specific problems, and (d) evaluating outcomes and monitoring subsequent practices. This process can be repeated to tackle increasingly complicated issues and to identify emerging problems.

The two main methods for gathering data on medicine use are quantitative and qualitative. Quantitative methods are better for answering the question *What is happening?* Qualitative methods are suited for answering the question *Why is it happening?*

Quantitative methods gather numerical data such as the number of antibiotics prescribed, the number of patients

on antibiotics, or the cost of antibiotic therapy. Quantitative data can be used to create rates, averages, or other summary measures to describe the nature and extent of a medicine-use practice.

Qualitative methods, often in the form of observations, descriptions, opinions, or discussions, are frequently used to describe the beliefs and motivations that underlie particular practices. Without this information, it is difficult to determine why prescribers and patients act as they do and therefore how they can change their behavior. Qualitative studies can also be used to formulate appropriate questions for a quantitative survey.

28.2 Data sources and measurement issues

Health managers often need to describe the use of specific medicines or medicine classes or therapeutic categories; or compare use among different geographic areas, administrative units, or individual prescribers before or after certain interventions. Sources of data for such purposes differ, depending on the setting. A hospital administrator who wants to measure the use of expensive antibiotics requires different data from a program manager who needs to know how children in the community are treated for acute respiratory infection (ARI). Common sources of medicine-use data and their uses are outlined in [Table 28-1](#).

Characteristics of medicine-use data

Medicine-use data differ in scope and level of aggregation. Researchers can look at previously collected data or records (retrospective) or collect specific data from one point in time forward.

Scope. Data may describe public-sector practices (in public facilities or administrative offices), private-sector practices (by private practitioners, pharmaceutical suppliers, or retail drug sellers), or community medicine use (practices in the community, independent of setting). Data on public-sector practices are the most readily available, because they flow out of routine record-keeping systems. Private-sector or community-based data are usually more expensive and time-consuming to collect.

Level of aggregation. Data on medicine use may be aggregated to measure consumption of specific medicines or medicine classes or therapeutic categories or may focus on patient-specific use. Data on patient-specific use are usually more informative, although aggregate consumption data may be sufficient to answer many cost-related questions.

Retrospective studies. These studies can be conducted using data from routine record keeping or past studies. Such existing data, although potentially incomplete, are less expensive to use. Retrospective studies can describe practices over a longer period of time.

Prospective studies. Prospective studies collect data, for example, from patient encounters. They provide information about the treatment setting, the diagnostic process, the communication between health providers and patients, or the time of consultation and dispensing.

Medicine-use encounters

A *medicine-use encounter* is the period of contact between a patient and a health care provider. Ideally, this encounter includes a number of components: history taking; the diagnostic process; selection of pharmacological and nonpharmacological treatment; prescription (and often dispensing)

of treatment; and explanations about treatment, follow-up, or prevention. Medicine-use encounters that include one or more of these components occur in most settings with health care providers, who range from highly trained medical specialists to itinerant drug sellers.

Critical information on medicine-use encounters includes (a) the specific setting, provider, patient, and date of the encounter; (b) patient age and gender; (c) signs and symptoms (patient complaint) or diagnosis (by the health care provider); and (d) medicines prescribed or dispensed, including brand or generic name, strength, and route of administration (injection, oral, topical). Data on the total dose prescribed or dispensed (number of pills and duration of treatment), the instructions given, and the cost of the medicines dispensed are all valuable for specific purposes.

Studies in several settings have found that data collection forms need to allow for at least three diagnoses per encounter and at least ten medicines prescribed or dispensed. Data on total dose, duration of treatment, and medicine cost are often difficult to collect accurately and can add substantially to the cost of data collection. Unless specific reasons exist to collect this information, such as designing an intervention, medicine-specific data can be limited to brand or generic name, strength, and route of administration.

Measurement issues

Problems in identifying, classifying, and quantifying pharmaceuticals frequently occur when measuring medicine use. The same medicine is often available under different names and in many different dosages and forms. Identifying specific medicines and their ingredients, or grouping equivalent products, can be difficult and time-consuming. Similarly, grouping cases according to health problem can be difficult in environments where record systems are imprecise and diagnoses may be uncertain. Ways to overcome these common difficulties have been developed and are discussed below.

What is in a medicine? With hundreds or even thousands of products on the market, many medicine names are similar. When deciding which medicines to place in specific groups, the following steps may be taken—

- Use a list of generic medicines, such as the national essential medicines list or national formulary.
- If a system such as the Anatomical Therapeutic and Chemical (WHO Collaborating Centre 2009) or one of the other common systems is not used, develop a system of easy-to-recognize medicine codes based on medicine names and strengths (for example, “TET250T” for tetracycline 250 mg tablets). Coding systems are discussed in [Chapters 16, 40, and 50](#).
- Use standard pharmaceutical references (MIMS, or the

Table 28-1 Sources of quantitative medicine-use data

Location of data	Sources of data (manual or computerized)	Potential uses of data
Public-sector administrative offices, medical stores	For retrospective studies: <ul style="list-style-type: none"> • Pharmaceutical supply orders • Stock cards • Shipping and delivery receipts 	<ul style="list-style-type: none"> • Aggregate patterns of medicine use and expenditures • Comparative use of medicines within therapeutic classes • Comparative use by different facilities or areas
Health-facility clinical and medical record departments	For retrospective studies: <ul style="list-style-type: none"> • Patient registers • Health worker logs • Pharmacy receipts • Medical records For prospective studies: <ul style="list-style-type: none"> • Patient observations • Patient exit surveys • Inpatient surveys 	<ul style="list-style-type: none"> • Aggregate patterns of medicine use and expenditures • Medicine use per case, overall, and by group (age, sex, health problem) • Provider-specific prescribing • Characteristics of patient-prescriber interactions
Health-facility pharmacies	For retrospective studies: <ul style="list-style-type: none"> • Pharmacy logs • Prescriptions retained in pharmacies For prospective studies: <ul style="list-style-type: none"> • Patient exit surveys • Patient observations 	<ul style="list-style-type: none"> • Aggregate patterns of medicine use and expenditures • Dispensing practices • Characteristics of patient-dispenser interactions
Pharmacies and retail medicine outlets	For retrospective studies: <ul style="list-style-type: none"> • Prescriptions retained in pharmacies For prospective studies: <ul style="list-style-type: none"> • Customer exit surveys • Customer observations • Simulated patient visits 	<ul style="list-style-type: none"> • Private-sector prescribing practices • Pharmaceutical sales without prescription • Self-medication practices • Characteristics of customer-salesperson interactions
Households	For retrospective studies: <ul style="list-style-type: none"> • Family medical records • Household surveys For prospective studies: <ul style="list-style-type: none"> • Household pharmaceutical audits • Family medical care logs 	<ul style="list-style-type: none"> • Total community medicine use • Care-seeking behavior • Self-medication practices • Family medicine use patterns • Patient adherence to treatment

Monthly Index of Medical Specialities; *Martindale: The Extra Pharmacopoeia*; USP Drug Information; *British National Formulary*) to identify ingredients in brand-name medicines. Although expensive, the most useful single reference is probably *Martindale*. Free online references, such as <http://www.drugs.com>, are also available. Organize the medicines identified into therapeutic classes or categories, as relevant for analysis.

- Count combination products as single medicines (because of the difficulty in deciding which ingredients count as separate products).

Which medicines belong together? When attempting to place medicines in specific groups, beginning with an existing system of medicine categories, such as the WHO list of essential medicines or the more elaborate ATC, is useful. If necessary, the medicines can subsequently be reorganized into more useful local categories.

How many medicines are dispensed and how much do they cost? The following procedures can be helpful when

encountering problems in estimating the amounts of medicines dispensed—

- Define the most common dispensing units (pills, milliliters, tubes, bottles) for every medicine, and be sure that enumerators record these units consistently when data from medication encounters are coded.
- Identify commonly used injections or liquids (for example, cough syrups) for which inconsistencies may occur in recording the correct basic unit (ampoule vs. mL, bottle vs. mL). Prepare a simple reference card for enumerators stating the correct units to be used for these medicines.
- For calculating medicine costs in public-sector studies, use a single, fixed set of unit costs (calculated per pill, per milligram, or per cubic centimeter; based on bulk purchase prices) for all health care facilities. This method ensures that any variations in cost are attributable to medicine selection and decisions about dosing.

How can cases be classified? When attempting to define reasons for treatment, it is important to develop explicit rules before data collection for classifying cases when only signs and symptoms are recorded and no diagnosis is made. In this way, health problems diagnosed as “malaria” can be distinguished from those recorded as “fever,” or those diagnosed as “pneumonia” can be distinguished from “cough, fever, and difficulty in breathing.” When possible, use the WHO *International Classification of Diseases, 10th Revision* (ICD-10) codes (WHO 2007). Separate categories can be developed for classifying frequently repeated clusters of problems (for example, ARI and otitis media, cough and fever).

How useful are standard treatment guidelines in measuring the quality of pharmaceutical use? One issue that frequently arises in medicine-use studies is how to apply information from standard treatment guidelines to measure the quality of prescribing. Because clinical guidelines are usually not developed as management tools, using them to measure quality of care introduces a number of practical problems. In the developing world, clinical guidelines frequently exist in the form of standard diagnosis and treatment protocols. These standard protocols are most commonly intended for use in primary health care facilities, although some countries have developed standards for secondary and tertiary care facilities as well.

Based on a given standard, some studies have tried to decide globally whether the use of medicines in a particular case is “correct” or “incorrect.” In practice, this judgment is frequently difficult to make in a valid and reliable way. Local standard treatments may not be expressed in an explicit way that allows adherence to be accurately measured. Furthermore, standard guidelines are frequently difficult to apply for real patients with multiple health problems or problems that cannot be diagnosed accurately with available facilities.

A recommended approach for using standard treatments in medicine-use studies follows—

- Have local experts agree on explicit definitions of the standard diagnostic procedures and treatments for specific health problems.
- Define one or more explicit aspects of these standards as separate indicators rather than trying to measure global adherence. Example: Was oral rehydration solution (ORS), which should always be recommended to treat diarrhea with mild dehydration, given or not? Was an antidiarrheal, which should never be recommended to treat diarrhea with mild dehydration, given or not? Was the recommended dosage form of a pharmaceutical used—for example, oral ORS rather than injectable intravenous saline solution? Was the appropriate amount of the pharmaceutical used (daily dose times and duration of therapy)?

- Concentrate on measuring adherence to the most unambiguous aspects of the standard.

Unit of analysis. The *unit of analysis* is the basic entity being analyzed in the study. Depending on the focus of a medicine-use study, the patient, the prescriber, or the health facility can be the intended unit of analysis. For community-based surveys or studies of patient-level factors such as ability to pay for medicines, the patient may be the appropriate focus. The individual prescriber may be the best unit of analysis for studies of specific prescribing practices or influences on prescribing. In many health systems, the health facility is the appropriate study unit for examining medicine use in a geographic area or the reasons for differences in treatment practice. The geographic area may also be used as the unit of analysis for large-scale medicine-use studies.

Sample size. When measuring medicine use, the required sample size depends on which practices are being measured, how precise the measurements need to be, and the unit of analysis. A trade-off usually exists between the costs of collecting data and greater uncertainty. People carrying out scientific research usually need more precise data with larger samples than do managers or policy makers who measure medicine use to make decisions. Sample size must be planned accordingly.

Focusing on specific subgroups often improves the ability to make good decisions. When possible, the sample in a medicine-use study should be stratified to compare key groups. *Stratification* involves dividing a sample into homogeneous subsamples based on one or more characteristics of the population. For example, samples may be stratified by provider age or by area of practice; strata could be urban/rural, paramedic/physician, government/mission, or public sector/private sector. Where possible, the sample size should be greater in groups that are likely to have poor practices to learn more about the groups that are likely to be the focus of future interventions.

Ethical issues. Ethical issues must be considered in any study that measures individual behavior. Managers in a health system may have the right to examine performance, but these efforts are likely to be more favorably received if they involve representatives of the practitioners whose performance will be investigated—their supervisors, for example. Studies that deal with people directly should always include appropriate efforts to obtain informed consent from participants and to describe how the data will be used. Also, the protocols for all proposed medicine-use studies should be approved by institutional review boards or another competent health authority. In addition, efforts should be made to protect the privacy of all research participants, if applicable. Finally, emphasis should be placed on adequate and timely dissemination of findings for the benefit of those under study.

28.3 Measuring medicine use: quantitative methods

Medicine use encounters occur in many environments, including hospitals, health centers, private pharmacies or drug shops, and the home. Hospital medicine use is frequently studied by medicine-use review (described in Chapter 29). Although many different methods are used to investigate medicine use, this chapter emphasizes the methods published by WHO on investigating medicine use in health facilities (WHO/DAP 1993) and in the community (Hardon, Hodgkin, and Fresle 2004).

Studying medicine use in health care facilities using WHO indicators

Health managers and policy makers often need to know about the quality of medicine use in a group of health care facilities. To simplify and standardize the study of medicine use in these situations, WHO and INRUD produced the manual *How to Investigate Drug Use in Health Facilities* (WHO/DAP 1993; Hogerzeil et al. 1993). This manual describes in detail a set of reliable indicators to measure medicine use for general outpatients and a standard methodology to collect the data for these indicators. The major points of the manual are summarized here.

The WHO manual defines twelve core and seven complementary medicine-use indicators (see Box 28-1) that measure key aspects of pharmaceutical prescribing, patient

care, and availability of pharmaceuticals and pharmaceutical information at outpatient facilities. The core indicators are highly standardized and do not require national adaptation.

Although not comprehensive, the core indicators provide a simple tool for quickly and reliably assessing a few critical aspects of medicine use. With these indicators, results should point to specific medicine-use problems that need to be examined in more detail. All the necessary data are collected from medical records or by direct observation at health care facilities.

The manual also defines a set of complementary indicators, which are less standardized and require defining variables specific to the country or location. One important complementary indicator measures adherence to treatment guidelines. This indicator requires clear, explicit criteria to be reliable and informative.

To measure medicine use, collect data from a sample of health care facilities. The number of health care facilities to include in the survey depends on the purpose of the survey. A regional or national medicine-use survey includes at least twenty facilities selected at random, with thirty medicine-use encounters sampled per facility, for a total of at least 600 encounters for the entire study. When the objective is to study medicine use by individual facilities or prescribers in a sample, at least 100 prescriptions should be obtained at each health facility or for each prescriber. When possible, the prescribing data are based on one year of retrospective encounters; prospective data can be collected if no

Box 28-1 WHO medicine-use indicators (outpatient facilities)

Core medicine-use indicators

Prescribing indicators

1. Average number of medicines per encounter
2. Percentage of medicines prescribed by generic name
3. Percentage of encounters with an antibiotic prescribed
4. Percentage of encounters with an injection prescribed
5. Percentage of medicines prescribed from essential medicines list or formulary

Patient care indicators

6. Average consultation time
7. Average dispensing time
8. Percentage of medicines actually dispensed
9. Percentage of medicines adequately labeled
10. Patients' knowledge of correct dosage

Health facility indicators

11. Availability of a copy of essential medicines list or formulary
12. Availability of key medicines

Complementary medicine-use indicators

1. Percentage of patients treated without medicines
2. Average pharmaceutical cost per encounter
3. Percentage of pharmaceutical costs spent on antibiotics
4. Percentage of pharmaceutical costs spent on injections
5. Prescription in accordance with treatment guidelines
6. Percentage of patients satisfied with the care they received
7. Percentage of health care facilities with access to impartial pharmaceutical information

retrospective data are available. Data on patient care and facility indicators are always collected prospectively.

The principal use of an indicator survey is to obtain a snapshot of current medicine-use practices to contrast with surveys from other areas or with “optimal” values for the indicators. Data from an indicator study can be presented in a variety of ways. Table 28-2 presents selected results from twenty-one studies that used this basic methodology to study medicine use. Both similarities and differences in medicine-use patterns are apparent. At the time of these studies, Ghana and Nigeria showed a relatively high number of medicines per case (4.3 and 3.8, respectively); high injection use was evident in Uganda, Sudan, Nigeria, Swaziland, Cameroon, and Ghana (ranging from 36 to 56 percent); and Ecuador had low availability of essential medicines (38 percent). The rate of antibiotic use in primary care facilities was found to vary from 27 to 39 percent in Latin America and the Caribbean, from 31 to 46 percent in Asia, and from 29 to 63 percent in Africa. By focusing attention on specific areas of concern, the indicators can help identify priority areas for action.

Although a survey based on thirty encounters per facility mainly identifies overall patterns, performance in individual health care facilities can be contrasted. These facility-specific estimates can be unreliable because of low sample sizes, but interesting patterns often emerge (Figure 28-2). These estimates can show whether values of indicators are consistent or different across facilities and identify facilities that seem to have very low or very high values for specific indicators. By using qualitative methods, the reasons for these apparent differences can be explored in more depth before designing interventions. Box 28-2 describes a set of indicators used to measure facility-level treatment adherence for HIV/AIDS with the objective of identifying appropriate interventions and monitoring improvement.

Indicators can also be used to quantify the effects of an intervention. In 2004, researchers in Kenya evaluated the effect of two specific policy interventions on prescribing generic medicines, antibiotics, and injectables in a private hospital in Nairobi. Generics prescribing increased from 4 to 24 percent, the percentage of antibiotics prescribed decreased from 83 to 41 percent, and the proportion of

Figure 28-2 Comparison of facilities in indicator studies in Uganda and Indonesia

injectables fell from 17 to 7 percent following the intervention (Ojoo, Waning, and Maina 2004). In Ghana, a study assessing the effect of managerial and educational interventions for the treatment of lower respiratory tract infection showed the average number of medicines prescribed per patient as 3.8 in the intervention sites compared to 5.0 at control sites, indicating a marginal improvement (Ofei et al. 2004). In Uganda, a randomized, controlled, community-based trial was carried out in six districts, using the full set of WHO indicators as outcome measures (Kafuko, Zirabamuzaale, and Bagenda 1997). The study demonstrated that standard treatment guidelines plus prescriber in-service training resulted in significantly lower rates of overall medicine use, injection use, and antibiotic use compared to controls. Treatment guidelines alone did not result in any significant changes.

Medicine-use indicator studies have also been undertaken on inpatients (see [Country Study 28-1](#)). However, the interpretation of the results remains controversial, and consensus on a set of useful indicators is still needed. The WHO indicators were not designed for use with inpatients in hospitals or in specialty clinics, where medicine use patterns are more complex.

Finally, an indicator study can be a simple tool to motivate health personnel and policy makers. For example, before a nationwide prescriber training program in Malawi, each of twenty-four district medical officers surveyed three health care facilities in his or her own administrative area. This strategy was more effective for educating and motivating them than randomly surveying twenty facilities for the whole country for a baseline survey. While carrying out this survey, participants not only learned basic skills for measuring key aspects of quality of care but also became familiar with ideas about standards of practice and how their own areas conformed to these standards.

The WHO indicators can be used to study medicine use for specific problems, such as diarrhea, malaria, or ARI. Such research can be undertaken after an indicator study by selecting a limited number of common conditions for secondary analysis. This secondary analysis may highlight inappropriate treatment of common conditions (for example, antibiotics for the common cold or quinine injection for simple malaria).

WHO maintains a database of medicine-use surveys in developing and transitional countries to monitor the differences between different regions, provider types, public- and private-sector facilities, trends over time, and as a tool to identify effective interventions. The data have shown, for example, that over the sixteen years between 1990 and 2006, treatments for acute respiratory tract infection and malaria did not improve much; however, the use of generic and essential medicines in the public sector increased (WHO 2009).

Using aggregate data to measure medicine use

To understand how medicines are used to treat specific illnesses, researchers often have no alternative to collecting patient-specific data. However, these data may be expensive or difficult to obtain. Aggregate data on pharmaceutical consumption are often readily available from pharmaceutical procurement records, warehouse or pharmacy stock receipts, medicine-use databases (for example, IMS Health, or others), or even pharmaceutical importers' or manufacturers' records. Sometimes aggregate data can be used to answer specific questions about medicine use. Examples of questions about medicine use that might be answered using available aggregate data include—

What is the relative use of therapeutically substitutable products? For example, what is the relative use of paracetamol (acetaminophen) generic compared with branded products, or first-line recommended antimalarials compared with second- or third-line antimalarials?

What is the per capita use of specific medicines or medicine classes or therapeutic categories? For example, what is the per capita consumption of certain medicines that may

Box 28-2**Developing and implementing indicators to measure adherence to ART**

Objectives of the INRUD Initiative on Adherence to Antiretrovirals include developing and validating a set of indicators that can be used to monitor adherence to ART and to investigate adherence rates and determinants for adherence for ART programs and individuals. During the initiative's first year, research teams in Ethiopia, Kenya, Rwanda, and Uganda tested the feasibility and reliability of a method to collect adherence data using routine pharmacy and clinic records. A validity study showed that the chosen adherence indicators correlated to increases in patients' CD4 counts and to weight gain. The five core indicators follow.

From pharmacy records for a sample of patients—

- Median percentage of days covered by ART dispensed over six months
- Percentage of patients with a thirty-day gap or more in medicines dispensed over six months
- Percentage of patients attending the clinic appointment set three months earlier on or before the scheduled appointment day
- Percentage of patients attending the clinic appointment set three months earlier within three days of the scheduled appointment day

From patient exit interviews—

- Percentage of patients who self-reported full adherence over the previous three days

On the basis of assessments using the indicators, national HIV/AIDS programs have helped clinics introduce interventions, such as appointment registers that assign blocks of time to patients and allow rapid identification of those who miss their appointments, protocols for calling or visiting patients who miss appointments, and the introduction of performance-based financing to compensate diligent staff.

Preliminary results show that these efforts have eased crowding and lessened waiting times at clinics. One clinic in Uganda reduced patients' average wait by more than an hour. These efforts have also enhanced teamwork among clinic staff, helped recruit new staff, and encouraged staff to start innovative programs for patients. One such program involved establishing groups of neighbors to share responsibility for picking up medicines so patients do not have to visit the clinics as often.

The indicators not only guide the development of appropriate interventions to address barriers to adherence, but also provide a useful way to measure facility performance both over time and in comparison with similar facilities.

be widely overused, such as benzodiazepines or narcotic analgesics such as codeine?

What proportion of the pharmaceutical budget is spent on specific medicines or medicine classes or therapeutic categories? For example, how much is spent on ciprofloxacin or cephalosporins or on medicines to treat tuberculosis?

What proportion of specific medicines is being prescribed inappropriately? For example, what prescriptions contain contraindicated medicines or contraindicated medical conditions or lack of compliance with needed laboratory tests before or during therapy?

When aggregate data are used, similar products may not share a convenient unit of comparison. If the primary focus is cost, all pharmaceutical consumption data can be converted to monetary equivalents, using either actual or average purchase prices. However, if the focus is primarily clinical, this strategy will not work. Some researchers have established systems of therapeutic equivalence for particular medicine classes, such as antipsychotic agents.

One widespread system to deal with product equivalence is the system of defined daily doses (DDD) (WHO

Collaborating Centre 2009). A DDD is the "typical" dose of a medicine used to treat the most common medical problem for which the medicine is prescribed. The official DDD is usually the adult dose for the most common condition for which the medicine is used. Adjustments must be made to study pediatric medicine use. Converting aggregate quantities to DDDs indicates roughly how many potential treatment days of the pharmaceutical are procured or consumed. By using DDDs, pharmaceutical consumption in different settings or countries can be compared; for example, [Table 28-3](#) compares patterns of use of narcotic analgesics in different countries, helping identify countries where potential overuse or underuse occurs. Because the comparison does not indicate which diseases medicines are being used to treat or in what dosages they are prescribed, these comparisons are inexact. Nonetheless, these analyses can be used to identify important medicine-use issues.

The use of appropriate denominators is important in interpreting analyses of aggregate data. Often the information sought is not how much of a medicine was used overall but how much was used per person, per visit, or

Table 28-3 Average medical consumption of narcotic medicines in Arab countries compared with three Western nations, 1996–2000 (DDDs/day/million inhabitants)

^a Consumption of exempt preparations (less than 135 mg/dosage unit).

per some other unit of analysis. The best denominator to use depends on the purpose of the analysis and the availability of data. Generally, the closer one can get to the population of concern, the better. For example, suppose the objective is to compare the use of ORS in one geographic area with its use in another area. One way would be to calculate packets of ORS used per child under five in each community. Another way would be to express use as ORS packets used per child visiting a health facility with a diagnosis of diarrhea; this method would control in part for possible differences in diarrhea incidence. For DDDs, the denominator is often per day per million inhabitants, as in [Table 28-3](#).

Reviewing case records

Useful information can be obtained from case records at hospitals or health care facilities. The audit process can start with either a disease or a medicine. Criteria are usually defined for correct and incorrect treatment of a dis-

ease or correct and incorrect use of a medicine. Then case records of patients with the specified disease or who have received the medicine are identified and reviewed, and the treatment of the disease is recorded and classified as correct or incorrect. The cost of the treatment can also be determined. When records are selected by medicine, the use of the medicine can be classified as correct or incorrect. For example, if watery diarrhea is the diagnosis selected for study, ORS may be the correct treatment in most situations. Antidiarrheals, antibiotics, and injections would be incorrect. If a medicine such as procaine penicillin is the study medicine, its use would be correct for tonsillitis, skin infections, otitis media, and pneumonia, but incorrect for parasitic infections such as worms or malaria. [Country Study 28-1](#) discusses the use of case records to investigate prescribing for hypertension in a Nigerian tertiary-care facility. Computerized case records make the data extraction process much easier.

When large numbers of records are surveyed, descriptive statistics can be generated, including the average number

Country Study 28-1

Using case records to investigate treatment for hypertension in Nigeria

Researchers reviewed 200 randomly selected case records of patients attending an antihypertensive clinic at University College Hospital in Ibadan, Nigeria. A pretested data collection form was used to collect information including the patient's age; gender; hypertension diagnosis; coexisting diseases; blood pressure reading at first clinic visit and at the time of study; and current antihypertensive drugs prescribed, including dose, frequency of dosing, antihypertensive medicine combination, documented level of patient's adherence, and documented adverse reactions. The results showed that diuretics were the most frequently prescribed class of medicines and that three-quarters of the patients were on combination therapies—but not on combinations that are recommended in standardized guidelines. Consequently, only 34 percent of patients had adequately controlled hypertension.

Because patients pay out of pocket for their medicines, the researchers hypothesized that cost considerations may have influenced prescribing patterns. In addition, the case records showed that over 17 percent of the combination prescriptions included potentially harmful pharmaceutical interactions; for example, the combination of lisinopril and amiloride or hydrochlorothiazide raises the risk of severe hyperkalemia, particularly without monitoring of serum potassium levels.

This case record study identified poor compliance with treatment guidelines and poor patient adherence as issues to address in an intervention to improve treatment practices for hypertension. Qualitative studies, such as interviews with prescribers and patients, may have been able to provide further detail on the reasons for these prescribing patterns.

Sources: Yusuff and Balogun 2005a, 2005b.

of medicines per contact, the average cost, and the percentage of patients receiving injections, antibiotics, or antidiarrheals. These indicators can be analyzed by specific diseases. A computer is required for studies in which a large number of records is surveyed and analyzed. Commercial software is available to analyze data on medicine use from large databases, but such programs are usually expensive. Spreadsheet software, such as Excel, is often used to generate such statistics. These descriptive statistics can form the basis for interventions focused on specific disease management or medicine use problems.

Investigating medicine use in the private sector

In many countries, pharmaceuticals are mostly prescribed and used in the private sector. Lack of access to data about private-sector medicine use prevents managers and policy makers from addressing problems in this area. The main method of collecting data on private-sector practices is through surveys conducted among private medical practitioners and retail medicine sales outlets. An example would be asking private doctors and other health care practitioners who prescribe medicines to provide information about their own practices. Private practitioners are often willing to share information about their behavior if they feel the reasons for collecting the data do not threaten them or their business. Private marketing companies in many countries have long collected these kinds of data from private doctors for use by pharmaceutical manufacturers and distributors; however, reported behavior is often rather different from actual behavior.

Surveys to investigate medicine use can also target retail outlets such as pharmacies, licensed drug shops, over-the-counter medicine sellers, and market vendors. Studies in many countries have found that persons selling medicines are often willing to explain what they know, to discuss their business, to have their interactions with customers observed, and even to keep records of the medicines they sell. To receive this kind of cooperation, persons collecting data must carefully explain the reasons for a study, show medicine sellers how they or their customers might benefit, and assure them of confidentiality. The *Community Drug Management for Childhood Illness: Assessment Manual* (Nachbar et al. 2003) includes techniques for assessing medicine use in retail outlets.

Many different methods can be used to collect quantitative data in retail pharmacy establishments. Some methods and the types of information they are best suited to collect include—

- Interviews with pharmacists or counter attendants to provide data about sales activity, knowledge and sources of information about medicines or clinical issues, and advising and sales practices
- Surveys of pharmaceuticals stocked or sold to measure product availability, retail cost, and sales volume
- Surveys of prescriptions received to describe the patterns of private-sector prescribing
- Observation of interactions with customers to examine customer demand, reasons for product selection, frequency of purchase without prescription, and communication about pharmaceuticals

- Exit interviews with customers to investigate knowledge about illness and medicines, care-seeking behavior, expectations, satisfaction with services, and reasons for product selection

Because reported practice is often much better than actual practice, a method for studying retail medicine use that deserves special attention is the simulated patient survey, or mystery shopper. This survey consists of visits to a sample of retail outlets by investigators posing as customers with specific types of health problems, for example, mothers of children with diarrhea (see Figure 28-3). These investigators are trained to seek advice about treatment and to respond in a standard way to questions asked by the counter attendant. They usually buy whatever medicines are recommended to complete the transaction. After leaving the shop, they record details of questions asked about signs and symptoms; advice given about medicines sold; and other advice given about case management, prevention, or referral.

Investigating medicine use in the community

Surveys of health care facilities, private practitioners, or drug retail outlets furnish information about medication decisions for cases seen by providers, but these studies do not tell much about medicine use from the community perspective. For example, studies of providers tell nothing about situations where people choose not to treat an illness or about failure to use medicines because of lack of knowledge, economic or geographic constraints, or other factors. Similarly, these studies tell little about the dynamics of care-seeking,

the use of multiple health providers, or the total pharmaceutical consumption in a community. Also, one cannot learn how patients actually consume the medicines they receive.

To learn about community medicine use, techniques must be used that differ from those already discussed. In the past, medical anthropologists or sociologists have carried out community medicine-use studies by using extensive ethnographic or participant observation methods. The WHO publication *How to Investigate the Use of Medicines by Consumers* (Hardon, Hodgkin, and Fresle 2004) describes a methodology that combines household interviews, surveys of pharmaceutical distribution channels such as health centers or pharmacies, and qualitative investigations using focus groups or in-depth interviews.

The core of any quantitative study of community medicine use is the cross-sectional household survey. The survey should include a minimum of 100 to 400 households, depending on the desired precision of the results and available resources. The sample of households is drawn so that all important groups in the community are represented. Different types of information can be collected from the households, depending on the purposes and duration of the survey. These include—

- Knowledge about medicines and illness, including sources of community information about medicines
- Reported care-seeking and medicine-use behavior in general or during specific episodes of illness
- Illness diaries, in which respondents record all episodes of perceived illness, the actions taken to deal with these problems, any medicines received for the illness, and how they took these medicines

Figure 28-3 What is reported in interviews may be very different from what is done in practice

- Pharmaceutical inventories to identify the type and source of all medicines present in the household
- Health care and pharmaceutical expenditures
- Adherence, including purchase of prescribed medicines and actual patterns of pharmaceutical consumption

A useful guide to conducting medicine-use assessments in the community is available through Management Sciences for Health (Nachbar et al. 2003). An example of how the assessment was used in Senegal is also available (Briggs, Nachbar, and Aupont 2003). Chapters 31 and 33 also discuss the importance of understanding community attitudes about medicine use.

28.4 Investigating the reasons for medicine-use problems: qualitative methods

The many factors that contribute to the irrational use of medicines are discussed in detail in Chapter 27. The best way to find out how factors such as knowledge, economic incentives, or attitudes and beliefs affect medicine use and to identify the most important constraints to changing specific behaviors is to use qualitative methods. These methods have been developed to investigate the causes of behavior and are helpful in identifying constraints to changes in behavior and opportunities for correcting the problem.

Quantitative methods are used to describe medicine-use patterns or to pinpoint specific problems that need attention, but they are usually not good for understanding why these patterns or problems exist. Qualitative techniques are better suited to examine the feelings, beliefs, attitudes, or motivations that underlie an observed problem. For example, focus group discussions with patients attending rural health facilities in Nepal revealed that patients felt they needed more medicines than they were prescribed or dispensed but said that they would be willing to accept advice from prescribers advocating fewer medications (Holloway et al. 2002).

Qualitative methods are based on talking to people at length and in depth or observing their behavior. When used in a formal way, these methods often involve highly trained interviewers or observers directed by an experienced researcher. Increasingly, managers and policy makers are using qualitative methods to rapidly assess the causes of a problem. Managers themselves do not necessarily need to know how to carry out qualitative research, but they do need to know what these methods are and when they may be useful.

Five useful techniques for collecting qualitative data on medicine use are focus group discussions, in-depth interviews, structured observation, questionnaires, and simulated patient surveys. These methods are outlined briefly

in Figure 28-4, and their strengths and weaknesses are compared in Table 28-4. *How to Use Applied Qualitative Methods to Design Drug Use Interventions* (MSH/INRUD 1996) is a useful manual that provides more detail on qualitative methods.

28.5 Defining problems and designing interventions with medicine-use data

The best understanding of the origins of problems can often be obtained by using quantitative and qualitative methods together.

Defining problems and selecting interventions

The first step in improving medicine use is to measure existing practices and identify specific problems (see Figure 28-1). This step is usually done quantitatively, by carrying out an indicator study, for example. After narrowing attention to specific problems, one must identify why they occur—the motivations and constraints—and then suggest possible actions to address the problems. The objectives of this process are to—

- Identify the problem and describe it in greater detail
- Choose an intervention to address the identified problem and evaluate its feasibility
- Target the proposed intervention to specific patients, providers, and behaviors
- Define intervention messages that can motivate changes in behavior
- Choose the most suitable format and activities to implement the intervention

Interventions implemented without gathering this information are more likely to fail. Explicit questions should be formulated to guide this process. The goal is to identify a practical strategy to change behavior. Only questions that can help in the design of an effective intervention should be asked. For example, imagine that a survey finds that 64 percent of patients treated in one district received injections, but that the percentage varies from 11 to 93 percent in the twenty facilities studied. Questions to be answered during the investigation process might include the following—

- Are injections given more frequently to adults or to children, and are they given more often for specific health problems? (greater detail)
- Do facilities with low and high injection use differ in number of staff, percentage of staff who are paramedics, patient volume, distance from the district center, or frequency of pharmaceutical stockouts? (greater detail, targeting)

Figure 28-4 Five useful qualitative methods

**Focus group discussion**

- 1.5- to 2-hour discussion
- guided by trained moderator
- group of 6 to 10 similar respondents (age, gender, social status)
- focus on defined list of topics
- informal setting
- reveals beliefs, opinions, motives

**In-depth interview**

- semistructured extended interview with respondent
- interviewer uses predefined open-ended questions
- usually covers 10 to 30 topics
- reveals attitudes, beliefs, knowledge

**Structured observation**

- systematic observation of verbal and nonverbal behavior
- usually patient-provider interactions
- trained observers use structured recording form
- assesses actual behavior

**Questionnaire**

- fixed set of standardized questions
- large sample of respondents
- respondents systematically selected to represent a larger population
- quantifies frequency of attitudes, beliefs, knowledge

**Simulated patient survey**

- someone (the "simulated patient") poses as a patient or a relative of a patient
- simulated patient seeks care for specific health problem
- questions, advice, actions of health care provider recorded after encounter
- assesses actual behavior in a standardized way

Table 28-4 Comparison of qualitative methods

Method	Key points	Strengths	Weaknesses
Focus group discussion	<ul style="list-style-type: none"> • Small; equal participation • Homogeneous; shared point of view • Informal; free interaction and open sharing of ideas • Recorded; analysis at later time possible 	<ul style="list-style-type: none"> • Good at eliciting the beliefs and opinions of a group • Richness and depth • Easy and inexpensive to organize 	<ul style="list-style-type: none"> • Need for skilled moderator • Beliefs and opinions expressed may not represent true feelings • Potential bias in analysis
In-depth interview	<ul style="list-style-type: none"> • Open-ended and in-depth questions • Targets key informants or opinion leaders • Five to ten interviews; enough to explore important issues • If target group is diverse, five to ten held with each subgroup 	<ul style="list-style-type: none"> • Unexpected insights or new ideas • Creation of trust between interviewer and respondent • Less intrusive than questionnaire • Useful with nonliterate respondents 	<ul style="list-style-type: none"> • Time-consuming compared to questionnaires • Data analysis can be difficult • Bias toward social acceptability • Need for well-trained interviewers
Structured observation	<ul style="list-style-type: none"> • Data can be coded indicators or scales, list of events or behaviors, or diaries • To count frequency of behaviors, at least thirty cases per group • To understand typical features, a few cases in five or six settings may be enough 	<ul style="list-style-type: none"> • Best way to study provider-patient interactions, including patient demand, quality of communication, or interaction time • Opportunity to learn about provider behavior in its natural setting 	<ul style="list-style-type: none"> • Threatening to those observed • Observers must spend enough time to “blend in” • Behavior may not be natural • Need for skilled, patient observers • Not useful for rare behaviors
Questionnaire	<ul style="list-style-type: none"> • Fixed or open-ended responses • Sample size depends on sampling method, desired accuracy, and available resources • At least fifty to seventy-five respondents from each subgroup 	<ul style="list-style-type: none"> • Best method to study range of knowledge, beliefs, opinions, population characteristics • Familiar to managers and respondents • Required skills often locally available 	<ul style="list-style-type: none"> • Attitudes difficult to quantify • Respondents may answer questions even if they do not apply • Results sensitive to specific questions and wording • Large surveys can be expensive
Simulated patient survey	<ul style="list-style-type: none"> • Details of the condition are standardized • Simulated patient purchases what is recommended • Each facility should be visited by at least five simulated patients • At least twenty facilities should be visited 	<ul style="list-style-type: none"> • Useful to compare knowledge and practices • Identification of different practices for rich/poor, male/female, rural/urban 	<ul style="list-style-type: none"> • Ethical issues • Need for simulators who can speak local language and are credible purchasers in the setting

- Do patients expect to receive injections, and do they tend to go to prescribers who give injections more frequently? (targeting, feasibility)
- Are health providers and patients aware that injections can transmit hepatitis and HIV/AIDS and that they can cause anaphylactic shock? (intervention messages)
- Are health providers and patients aware that injections may increase the overall cost of treatment? (intervention messages)
- How do prescribers react when they are shown data from the indicator study on their use of injections in relation to their peers? (intervention format and activities)

Asking focused questions keeps the process oriented toward intervention design. The optimal number of questions depends on how much is already known about the problem and the target group. [Country Study 28-2](#) lists the

questions that guided the diagnostic process in an educational intervention to improve diarrhea treatment by physicians in a city in southern Brazil.

After asking a set of specific questions, a manager or policy maker must choose quantitative and qualitative methods to answer them. As described earlier, each method has strengths and weaknesses. Often, the best approach is trying to answer the same question using different methods. For example, suppose one objective is to determine whether patients' demand for injections helps explain why they are given so frequently. One way to do this is to observe a sample of clinical encounters to see how many times patients indicate verbally or nonverbally that they prefer injections. Patients can also be interviewed to see if they are satisfied with their treatment or if they plan to go elsewhere to look for different treatment. Finally, in-depth interviews or focus group discussions with prescribers can explore their feelings about patient demand and their perceptions about whether it affects their practice.

Country Study 28-2 Improving diarrhea treatment in Pelotas, Brazil

A review of health center records in Pelotas, Brazil, found problems in treating diarrhea in children. Before launching an educational intervention for physicians to improve practices, the study team used patient exit interviews, in-depth interviews of physicians and patients, and observations of treatment episodes to answer questions in five areas.

Describing the problem in greater detail

- Are practices the same in facilities managed by the municipality, the university, and the state government?
- Is lack of correct knowledge about diarrhea or its treatment a common problem among physicians and patients?
- Does a lack of knowledge exist about the causes and correct diagnosis of diarrhea? About the need for ORS? About the dangers of specific antidiarrheals? About the efficacy of antibiotics or antiparasitics?
- How do physicians think other physicians manage diarrhea?

Deciding whether an intervention is feasible

- How much do patients' expectations influence physicians' treatment choices?
- How satisfied are patients with different kinds of treatment for diarrhea?
- How important is patients' satisfaction to physicians?
- Do physicians feel that patients are capable of learning about diarrhea and its treatments?
- Would physicians or other staff have time to counsel patients about diarrhea or other health problems?

Targeting the intervention

- How often do mothers ask directly for specific types of treatment?

- Do mothers influence physicians' decision making in nonverbal ways?
- How do physicians respond when asked for certain treatments?
- Do physicians feel a group identity with colleagues at the health center?
- To which respected peers do physicians turn with questions about treatment?
- How often do physicians approach colleagues with medical questions?

Defining specific intervention messages

- How important to physicians is the self-image of being a knowledgeable scientist or powerful healer?
- When physicians have changed their practices in the past, what has caused them to do so, and how do they feel about these changes?
- What do physicians think about prototype materials developed to promote correct diarrhea treatment practices?

Deciding on the format and style of the intervention

- How do physicians get information about new health problems or medicines?
- Do they ever attend continuing education sessions, and are these useful?
- Do they read any journals (which ones)?
- Do they learn about medicines from pharmaceutical package inserts, advertisements, or pharmaceutical company representatives, and is this information valued?
- How do physicians respond when presented with summaries of the practices of their health center in relation to similar facilities?
- How do physicians feel about different models for continuing education: group seminars, visits by medical experts, visits by pharmacists?

Designing interventions

Quantitative and qualitative methods address different or complementary questions whose answers can then be used to design interventions. [Country Study 28-3](#) shows how the managers of the Control of Diarrheal Diseases Program in the Kenya Ministry of Health used qualitative methods to design an intervention—questionnaires, a simulated patient survey, and focus groups—that explored the nature of problems in diarrhea treatment in private retail pharmacies. The results of these methods helped inform the design of

an intervention to train pharmacy attendants in appropriately treating diarrhea. Using the combined results of these methods, program managers targeted printed materials and training messages that proved effective in changing pharmaceutical sales and patient counseling behavior.

The intervention design process can begin with a synthesis meeting of everyone involved in the investigation process. If not everyone at the meeting is familiar with the studies, the first activity should be to present separate reports on each one. Each report should briefly cover the specific study questions addressed, the methods used, the

results, and the conclusions. Written summaries of findings and tables or graphs should be distributed. Discussion of specific findings can take place after all the reports have been presented. Sometimes findings from two methods are complementary, but other times the results contradict each other. If the findings suggest important issues for discussion, these issues should be listed as they are raised and covered later in the integrated discussion.

After systematically answering all the questions, the meeting participants should have a solid idea about an intervention that might be effective. The specific behaviors to focus

on will be more apparent, as will the specific target groups of prescribers or patients that are most likely to benefit from the intervention.

The synthesis meeting should then focus on designing an intervention. The process of synthesizing data to draw conclusions about intervention design can be difficult. Before attempting this synthesis, the group should be familiar with what is known from experience with the different intervention models and their relative effectiveness (see Chapter 29). Familiarization with these interventions will help facilitate effective implementation of new interventions.

Country Study 28-3

Assessing product availability and service quality in retail drug outlets in Uganda

As part of a program to introduce accredited drug shops in Uganda's Kibaale district, the East African Drug Sellers Initiative assessed the availability of medicines and services in retail drug shops in Kibaale and a control district, Mpigi, in 2008. The assessors used a combination of interviews with customers exiting the shops, mystery shoppers who pretended to need treatment for a child with fever, shop visits to determine medicine availability and prices for a list of tracer medicines, and household surveys to determine community health-seeking practices.

Thirty tracer medicines were available in 50 percent of the outlets in Mpigi and in 46 percent of the drug shops in Kibaale. Availability of individual medicines varied widely in each district; some medicines, such as paracetamol, were available in more than 90 percent of the drug shops, whereas other medicines, such as artemether/lumefantrine, were available in less than 10 percent of the facilities. Chloroquine tablets and sulfadoxine/pyrimethamine (SP) tablets were the most widely available antimalarial medicines, despite the change in antimalarial treatment policy to artemether/lumefantrine.

Data collectors interviewed customers as they left the shops to determine how much information they were given about the medicines dispensed. The upper table shows that most drug sellers asked about symptoms, but few gave any information on what danger signs to look for or when to seek care from a health professional.

In the mystery shopper component of the assessment, each data collector pretended to be the parent of a six-year-old child with symptoms of simple malaria. The lower table indicates the variety of treatments sold to the mystery shoppers.

	Kibaale n = 16 (%)	Mpigi n = 20 (%)
Dispensing practices		
Did the drug seller ask about the symptoms?	9 (56)	15 (75)
Did the drug seller ask about any other medicines the child may have taken?	5 (31)	8 (40)
Did the drug seller give instructions on how to take the medicines?	12 (31)	14 (70)
Did the drug seller give information on how to look for danger signs?	2 (13)	2 (10)
Did the drug seller recommend referral to a doctor or clinic?	1 (6)	0
Did the drug seller recommend referral to a doctor or clinic if danger signs arose?	1 (6)	3 (15)
Did the drug seller recommend returning if symptoms did not get better?	3 (19)	2 (10)
Medicines dispensed for malaria		
Amodiaquine	1	1
Amodiaquine and SP	0	1
Chloroquine	0	9
Chloroquine and SP	6	1
Paracetamol	0	2
Quinine	6	3
Quinine and SP	1	1
Referral	1	0
SP	1	2

The assessment will be repeated after an intervention combining dispenser training, supportive supervision, and government accreditation to measure changes in medicine availability and dispensing quality.

28.6 Evaluating interventions

Evaluation is the process of collecting and analyzing information about the effectiveness and impact of an intervention. A more technical definition describes evaluation as attributing value to an intervention by gathering reliable and valid information about it in a systematic way and by making comparisons so more informed decisions can be made or causal relationships or general principles can be understood. Every policy maker or program manager wants to have an effective intervention—appropriate evaluations are necessary to determine the effect of specific interventions.

Selecting appropriate measures

Interventions should be evaluated by looking for both intended and unintended changes in specific outcomes. For all the outcomes of interest, indicators that are meaningful, reliable, and measurable must be selected. When choosing the most useful outcomes to measure, consider the following—

- Select the key behaviors targeted by the intervention and the most likely substitute behaviors.
- Select outcomes that can be clearly and explicitly defined.
- Select outcomes that can be reliably measured, preferably using routinely collected data.
- Focus on important outcomes rather than measuring all possible changes.
- Measure more than one dimension of success, especially if some changes are secondary—for example, changes in prescribing that follow changes in knowledge about specific medicines.

Steps to take when evaluating interventions

Techniques for evaluating interventions are covered in detail in other books, but every evaluation should include the four basic steps described below.

Step 1. Select the correct study unit. Because the behavior of patients and prescribers is affected by other people, the most appropriate study unit is often the health facility. If individual prescribers are chosen as the study unit, for example, the effect of their colleagues on their prescribing behavior may make attributing any observed changes to an intervention difficult. For interventions that involve changes in administrative procedures, a region or district may be used as the unit of study.

Step 2. If possible, randomly assign study units to intervention and comparison groups. An appropriate comparison group is the most important feature of a sound evaluation (see [Figure 28-5](#)). Random assignment of study

units to intervention or comparison groups is not always possible. If it is not, choose a comparison group that is as similar as possible. In situations in which everyone will receive a particular intervention, early recipients may be compared with those who have not yet received the intervention.

Step 3. Measure outcomes before and after the intervention in both the intervention and the comparison groups. With at least two measurement points, both equality at baseline and changes in practice can be examined. Data must be collected in the same way in the comparison and intervention groups, because the process of being observed often causes changes in behavior.

Step 4. Measure effects over time. Short-term effects often disappear unless they are reinforced. To know whether an intervention really works, look at short- (one month), medium- (six months), and long-term (one year or more) effects.

Often, an appropriate comparison group cannot be identified. For example, a nationwide mass media campaign to reduce prescribing of antibiotics for common colds cannot suitably be controlled. When a control group cannot be found, interrupted time series analysis can be used to compare patterns of medicine-use before and after the intervention (see [Figure 28-6](#)).

In time series analysis, each time point should represent an equal interval (for example, one week or one month). Ideally, at least three time points should precede the intervention and the same number of time points should follow the intervention to reliably determine underlying trends. Finally, investigators must examine any major changes that could have affected the outcome (for example, changes in personnel can affect prescribing patterns, making it difficult to attribute any effects to the intervention).

Relative effectiveness of different interventions

The effectiveness of different interventions depends on many factors, including the type of intervention, the setting, and the implementation process. Generally, interventions are most effective when they target specific problem behaviors. A training program discouraging polypharmacy as a general problem is less likely to have an effect than training that targets specific commonly overused medicines or specific health problems in which polypharmacy is common. Interventions can target several problems at once. For example, an intervention to improve pneumonia treatment might combine training for health care workers in how to use a standard ARI treatment protocol with community-based education about case recognition and care-seeking. Interventions can also have unintended outcomes, such as interventions addressing the overuse of injections that unintentionally cause a decrease in immunizations.

Figure 28-5 Importance of a comparison group

This figure shows an apparent improvement in outcome score from about 40 measured at Time 1 to more than 60 at Time 2. With information only from the group that received an intervention between these two times, it is tempting to conclude that the intervention caused the improvement in outcome scores.

However, this conclusion can be misleading. The graph on the left shows that the intervention group has actually been experiencing a steady improvement in scores before, during, and after the intervention due to some external factor. On the right, the outcome seems to be seasonal, and it happened to be measured at a low point in the cycle at Time 1 and a high point at Time 2.

Only by using a comparison group can one guard against many possible incorrect conclusions about the effects of any intervention. Any reasons for change in outcomes outside of the intervention itself should affect both groups equally. Changes in the two groups can be compared to estimate the intervention's impacts.

Research has shown that combining different types of interventions is more effective than using single interventions. However, multifaceted interventions tend to be more complex and may require more resources. Research has also shown that didactic lectures and passive distribution of educational material tend to have minimal effect, whereas supportive supervision and policy changes have been reported as generally effective. Chapters 27 and 29 describe examples of interventions to improve rational medicine use.

Researchers have used the techniques described in this chapter for many years. In a number of countries, managers of essential medicines programs have also used these methods to guide their decision making (see [Country Study 28.4](#)). The INRUD website has a searchable bibliography of more than 5,000 studies detailing the effect of various interventions to improve medicine use (<http://www.inrud.org>). Similarly, the website for the International Conferences on Improving Use of Medicines makes all conference presentations and abstracts accessible (<http://www.icium.org>). ■

Figure 28-6 Using interrupted time series

Time series are a powerful method for investigating medicine use. Data that are routinely collected in many health systems about the use of different types of medicines can easily be displayed as time series. It is also possible to look at patient-specific information on medicine treatment in sample medical records. In most cases, these series are made more stable by dividing by a meaningful denominator, such as rate per 100 attendances or proportion of total antibiotic expenditures.

The figure on the left shows a sudden reduction in the level of antibiotic use following an intervention. The figure on the right shows a reduction in the trend rather than a drop in the level.

Frequently there is a drift back to the previous baselines after an intervention, as shown in the figure on the left. In some cases, there may be a level change, which can be sustained or increased over time, as shown in the figure on the right. Time series techniques allow one to assess the individual and cumulative effects of interventions over time.

Country Study 28-4

Investigative surveys undertaken as part of national essential medicines program management

In Indonesia, multiple studies have been undertaken using aggregate consumption data, indicator studies, and intervention studies. These have been used to guide national programs and World Bank-supported regional activities.

In Kenya, an indicator study was undertaken in five regions as part of the overall planning management and evaluation of the essential medicines program.

In Malawi, a national medicine use indicator survey was undertaken in every district, covering seventy-two facilities, before national training on standard treatments.

In Nepal, simulated patient studies have been used to

investigate practices of drug sellers to assist in designing training programs to improve their practices.

In Uganda, researchers studied the effect of training prior to redesign of training programs.

In Zambia, a study was performed in the capital in which different training methods were evaluated by detailed record review, using drug use review techniques.

In Zimbabwe, an indicator-based baseline survey was performed before the first national policy and planning workshop. This survey is repeated every two years, and it was expanded to include urban facilities and the private sector.

ASSESSMENT GUIDE

When assessing a country's or program's capacity to investigate medicine use, two main issues should be considered—

- Results of previous studies
- Technical capacity to undertake medicine-use investigations

Previous studies

- Have any studies been performed on facility medicine use using the WHO/DAP manual *How to Investigate Drug Use in Health Facilities*? If yes, what were the results?
- Have any special studies been undertaken to investigate specific medicine-use problems (such as injection use)? If yes, what were the results?
- Have any routine surveys such as census or household surveys included questions on pharmaceutical expenditures or use?

- Are pharmaceutical consumption data easily available for the public or private sector?
- What are the prevalent attitudes that will have a positive or negative effect on the use of health services and medicines?

Technical capacity

- Are any experienced researchers involved in studying medicine use or health-seeking behaviors?
- Can local experts assist in quantitative or qualitative surveys?
- Is a unit within the ministry of health dedicated to health systems research?
- Do the medical or pharmacy training schools undertake field research or offer student training in the field?
- What types of records are available in the public and private sectors that would facilitate research on medicine use?

SUMMARY

The ultimate goals of studying and intervening in medicine use practices include—

- Improving quality of health care through effective and safe use of pharmaceuticals
- Improving cost-effectiveness of health care through economic and efficient use of pharmaceuticals

Before attempting an intervention to change medicine use practices, underlying reasons for problem behaviors must be understood. Interdisciplinary collaboration involving health and social science experts is of utmost importance in this task.

Strategies to improve rational prescribing can be characterized as targeted or system-oriented approaches. Targeted approaches include educational and managerial interventions, while system approaches include economic and regulatory interventions.

Educational strategies seek to inform or persuade and include—

- Training of prescribers (formal and continuing education, supervisory visits, group lectures, seminars, workshops)
- Printed materials (clinical literature and newsletters, treatment guidelines, medicine formularies, flyers, leaflets)
- Approaches based on face-to-face contact (educational outreach, patient education, influencing opinion leaders)

Managerial strategies seek to guide practice and include—

- Supervision, monitoring, and feedback
- Approaches to selection, procurement, and distribution (limited procurement lists, drug use review and

feedback, hospital and regional drug and therapeutics committees, cost information)

- Prescribing and dispensing approaches (structured medication order forms, standard diagnostic and treatment guidelines, course-of-therapy packaging)

Economic strategies seek to promote positive financial incentives while removing perverse incentives for prescribers. These economic strategies include changes in how health care providers are reimbursed; disallowing medicine sales by prescribers removes the financial incentive for overprescribing.

Regulatory strategies seek to use laws and regulations to influence prescribing through restrictions and requirements. They include—

- Pharmaceutical registration
- Limited medicine lists
- Prescribing restrictions
- Dispensing restrictions

An intervention should be focused on a specific problem behavior and targeted at the facilities or people that have the greatest need for improvement. Interventions should be carefully selected with regard to efficacy, feasibility for implementation in the existing system, and cost. Before wide-scale implementation of an intervention, evaluating its effectiveness and cost in the existing health setting is imperative.

Programs to ensure rational use of medicines should be an integral part of health and medical care services. The responsibility for promoting rational use of medicines belongs to decision makers, administrators, and clinicians as well as health care professionals, consumers, educators, and pharmaceutical companies.

29.1 Improving prescribing: a conceptual framework

Inappropriate prescribing is a manifestation of irrational medicine use that occurs when medicines are not prescribed in accordance with guidelines based on scientific evidence to ensure safe, effective, and economic use. The underlying reasons for such practices on the part of prescribers and consumers need to be understood and addressed in any intervention.

Qualitative methods of research are useful in understanding why inappropriate prescribing behaviors occur (see Chapter 28). This approach makes it possible to design interventions relevant to a particular situation that form part of a

systematic cycle directed at improving the quality of patient care. Most strategies for improving prescribing practices are mutually supportive.

The first step in developing a strategy to address irrational prescribing practices must be to consider who the prescribers are. In most developed countries, prescribers are doctors or other paramedical personnel who are highly trained. In many places, however, prescribers may include nurses, paramedics, and drug sellers. The latter, in particular, may have received little or no training in the use of medicines. A comprehensive policy should try to influence prescribing behavior at all levels of the system, focusing on the priority problems and targeting the prescribers involved. [Box 29-1](#) has a list of core strategies to promote the rational use of medicines.

Box 29-1**Core strategies to promote rational use of medicines**

Establishing a mandated multidisciplinary national body to coordinate medicine-use policies. Ensuring rational medicine use requires many activities that need coordination among many stakeholders. Therefore, a national body is necessary to coordinate strategies and policy at the national level, in both the public and private sectors. This body should involve government, health professions, academia, pharmaceutical industry, consumer groups, and the national regulatory authority.

Implementing procedures for developing, using, and revising standard treatment guidelines (STGs). Standard treatment guidelines (or clinical guidelines or prescribing policies) are systematically developed statements to help prescribers make decisions about appropriate treatments for specific clinical conditions. STGs are made more credible through the use of evidence-based recommendations. They vary in complexity from simple algorithms to detailed protocols on diagnostic criteria, patient advice, and costs.

Implementing procedures for developing and revising an essential medicines list (or hospital formulary) based on treatments of choice. An essential medicines list makes pharmaceutical management easier at all levels: procurement, storage, and distribution are easier with fewer items, and prescribing and dispensing are easier for professionals. A national essential medicines list should be based on national STGs, and both should be revised regularly.

Establishing a drug and therapeutics committee in districts and hospitals, with defined responsibilities for monitoring and promoting rational use of medicines. This committee, also called a pharmacy and therapeutics committee, is responsible for ensuring the safe and effective use of medicines in the facility or area under its jurisdiction. The committee should operate independently, and members should represent all the major medical specialties and the administration. The primary tasks of the committee are to develop and revise institutional STGs (based on national guidelines) and to maintain an institutional essential medicines list or formulary.

Using problem-based training in pharmacotherapy based on national STGs in undergraduate curricula. The quality of basic pharmacotherapy training for undergraduate medical and paramedical students can significantly influence future prescribing habits. Training is most successful when it is problem based, concentrates on common conditions, takes into account

students' level of knowledge, and is targeted to their future prescribing requirements. In most settings, rather than focusing on basic science, problem-solving skills should be promoted and interdisciplinary problem-based learning encouraged. If the existing focus is not on problem-based training in pharmacotherapeutics, national consultative workshops may help build awareness of the value of the approach.

Continuing in-service medical education as a licensure requirement and targeted educational programs by professional societies, universities, and the government. Unlike in developed countries, opportunities for continuing medical education in less developed countries are limited because continuing education is not required for licensure. Governments should support efforts by university departments and national professional associations to offer independent, unbiased continuing medical education courses to health professionals, including medicine dispensers. The most effective in-service training is likely to be problem based, repeated on multiple occasions, focused on practical skills, and linked to STGs.

Developing a strategic approach to improve prescribing in the private sector through regulation and collaborations with professional associations. Most efforts in improving use of medicines have focused on the public sector, but the private sector often provides greater access to pharmaceuticals. Changing practices in the private sector requires an understanding of the motivations of private prescribers. A range of strategies should be considered to improve rational medicine use, including licensing regulations with appropriate enforcement, accreditation and continuing education through professional associations, and financial incentives.

Monitoring, supervision, and using group processes to promote rational medicine use. Supervision that is supportive, educational, and face-to-face will be more effective with prescribers than inspection and punishment. Effective forms of supervision include prescription audit and feedback, peer review, and group processes of self-identifying medicine-use problems and solutions in a group of prescribing professionals. Group process interventions with practitioners and patients to improve prescribing practices have been effectively used to change prescribing behavior.

Training pharmacists and drug sellers to offer useful advice to consumers, and supplying independent medicine information. In many countries with shortages of

Box 29-1**Core strategies to promote rational use of medicines (continued)**

trained health professionals, pharmacies and medicine shops are a major source of information for consumers. Interventions have shown that the skills of untrained prescribers and dispensers can be upgraded. In addition, the only information about medicines that prescribers receive is from the pharmaceutical industry, which may be biased. Pharmaceutical information centers and drug bulletins are two useful ways to disseminate independent, unbiased information. They may be administered by the government, a university teaching hospital, or a nongovernmental organization, under the supervision of a health professional.

Encouraging involvement of consumer organizations, and devoting government resources to public education about medicines. Governments have a responsibility to ensure the quality of information about medicines available to consumers. Without sufficient knowledge about the risks and benefits of medicine use, people will often fail to achieve their expected clinical outcomes and may even suffer adverse effects. Regulation of consumer advertising and promotion by pharmaceutical companies, as well as public education activities led by

consumer organizations, may influence medicine use by the public.

Avoiding perverse financial incentives. Financial incentives may strongly promote rational or irrational use of medicines. Examples include the ability of prescribers to earn money from medicine sales; flat prescription fees that lead to overprescription; and dispensing fees that are calculated as a percentage of the cost of medicines, which encourages the sale of expensive medicines.

Ensuring sufficient government expenditure and enforced regulation. Appropriate regulation of the activities of all those involved in the use of medicines is critical to ensure rational medicine use. For regulations to be effective, they must be enforced, and the regulatory authority must be sufficiently funded and backed by the government's judiciary. Without sufficient competent personnel and finances, none of the core components of a national program to promote rational use of medicines can be carried out.

Sources: WHO/EDM 2002; Laing et al. 2001.

The next step in improving prescribing practices is to identify the nature and scope of the problem. As described in [Chapter 28](#), this step may be accomplished by using a number of methods, such as carrying out an indicator-based prescription survey or a drug use review (DUR); looking at aggregate medicine consumption data using such tools as ABC and VEN (vital, essential, nonessential) analysis or therapeutic classification; measuring defined daily dose (DDD) consumption; collecting adverse drug reaction (ADR) data; measuring infection rates; analyzing pharmaceutical management data; or observing a particular practice or event.

If the investigation confirms that the prescribing practices are a significant problem in the health system or facility, the underlying causes should be clearly defined in step three. This process is also described in [Chapter 28](#).

The fourth step is to plan a package of interventions focused on specific problems and targeting specific actors: prescriber, patient, and community. Inputs from the target audience are important when formulating and implementing the package of interventions, because different sets of interventions may be applied to address inappropriate prescribing practices and prevent them from recurring. Each set of interventions must be monitored and evaluated to assess its impact. Evaluation of impact needs to be directed at the

specific prescribing pattern or prescribing behavior that the intervention is designed to improve. Clearly ineffective interventions can be dropped, and those that are partially effective can be revised to improve their efficacy. Effective interventions can then be incorporated and, if required, replicated on a wider scale in the health care system; therefore, producing timely monitoring data on the impact of the interventions is key. The complete cycle of medicine-use interventions is described in [Chapter 28](#), and the required actions for each step are depicted in [Figure 28-1](#).

29.2 Characterizing interventions

Interventions to improve prescribing in clinical practice can be characterized as either targeted directly toward the prescriber, such as education and managerial or administrative tactics, or system-directed, which emphasize policies, regulation, and economic strategies.

Targeted interventions

In *educational* interventions, prescribers are persuaded, by information or knowledge provided to them. These strategies may be implemented in the form of face-to-face

Figure 29-1 Facility-specific percentage of patients receiving antibiotics in Tanzania

Source: WHO/DAP 1993.

education or training, seminars, and provision of written materials. A single-shot educational intervention without follow-up and monitoring is usually least effective, and the effect—if any—is not sustainable.

In *managerial* interventions, prescribers are guided in the decision-making process, through limiting lists for routine procurements, drug use review and feedback, supervision and monitoring, provision of treatment guidelines, and monitoring of prescribers' use of the guidelines.

System-oriented interventions

In *economic* interventions, prescribers are motivated by the promotion of positive financial incentives and the removal of perverse incentives. These economic strategies include changes in how health care providers are reimbursed, such as the institution of private or public patient-centered insurance plans, capitation-based reimbursement, and quality-based performance contracts. In addition, disallowing medicine sales by prescribers removes the financial incentive for overprescribing.

In *regulatory* interventions, prescribers are forced to restrict the decision-making process in prescribing. These strategies include policies encouraging use of generic pharmaceutical products, limitations on prescribing and dispensing, and withdrawal of questionable medicines from the market. These strong strategies are often unpopular with prescribers or consumers and may also bring about unintended effects, such as a change to other inappropriate prescribing practices.

A wide range of interventions is available to address irrational prescribing. These can be categorized as preventive or curative. Preventive approaches ensure that the prescriber starts off prescribing in an appropriate manner. Curative interventions attempt to reverse a pattern of irra-

tional prescribing. As is often true in medicine, prevention is often much easier than curing when it comes to prescribing problems.

Many interventions have a limited effect over time, and although temporary improvement may occur, prescribers may revert to their previous behavior if the intervention is not followed up. When interventions of different types are combined, the effect is likely to be synergistically increased; therefore, interventions should always be considered in sets.

Irrational prescribing is a universal problem. Considerable experience indicates which interventions are effective in high-income countries and in particular public health care systems, but those interventions cannot always be transferred to other settings. Therefore, it is important that a range of interventions be considered. Those that succeed in one country may not succeed elsewhere. Health care organizations, local communication channels, level of education, and other factors all influence the effectiveness of specific strategies in different environments.

29.3 Focus and target of interventions

For an intervention to be effective, it needs to be focused to achieve a specific goal and targeted at those prescribers who have a particular prescribing problem. For example, in a training intervention, a general lecture on pharmacology is unlikely to be effective in changing prescribing. A clearly focused presentation on the correct treatment of simple diarrhea—encouraging oral rehydration solution and discouraging antidiarrheals, antibiotics, and injections—or on the treatment of acute respiratory infections, and clearly specifying when an antibiotic is necessary is far more likely to achieve the desired results.

Quantitative surveys frequently find considerable variation among facilities. For example, a survey in Tanzania found that antibiotic use varied between 20 and 70 percent (Figure 29-1). Most facilities fell within the range of 20 to 40 percent. Only three facilities showed over 50 percent antibiotic use, and seven had over 40 percent use. These high-users would be the facilities to be targeted for any intervention. Both the potential impact and the cost-effectiveness of the intervention would be greater in these facilities.

29.4 Educational interventions

Educational interventions are the most common and are often disappointing in their sustainability and limited effect. Although the basic training of prescribers is essential for promoting rational use of medicines, educational components often need to be combined with managerial and regulatory interventions. Prescribers make many

decisions concerning medicine use, and their training occurs in formal and informal ways throughout their careers. See [Chapter 52](#) for discussion of various types of training programs.

Training of prescribers

Formal education (preservice). The training of doctors and paramedical staff differs in content and approach. Doctors control the use of scarce pharmaceutical resources not only through their own prescribing practices but also through their influence as instructors, supervisors, and trendsetters for the often larger force of paramedics. Thus, sound training of doctors in good prescribing practices can have a significant effect on the rational use of medicines.

The curricula of most health personnel training institutions contain segments that deal with medicine treatment. Because prescribing is often not taught in these curricula, students often learn prescribing from what they see during clinical “model” practices. For doctors and paramedical personnel, training on pharmaceuticals and how to use them should cover—

Basic pharmacology: Principal mechanisms of pharmaceutical action, metabolism, absorption, distribution, and elimination. In learning basic pharmacology, students gain knowledge about interactions between medicines and living systems at the theoretical level.

Clinical pharmacology: Study of the various classes of medicines with regard to clinical efficacy, risks, clinical pharmacokinetics, drug-drug interactions, drug-disease interactions, drug-genetics interactions, the concept of clinical trials, and pharmacoeconomics. In clinical pharmacology training, students learn how to use medicines properly and rationally at a more practical level.

Therapeutics: The use of pharmaceuticals to treat disease.

Therapeutics is the practical application of basic and clinical pharmacology. It has traditionally received less attention than pharmacology in prescribers’ formal education.

A number of educational programs have been developed to improve the teaching of pharmacotherapy. The World Health Organization (WHO) developed a manual (WHO/DAP 1994) for undergraduate medical students on the principles of rational prescribing, intended for use in developed and developing countries. The *Teacher’s Guide to Good Prescribing* (Hogerzeil 2001) is its companion volume for university teachers. The *Guide to Good Prescribing* presents students with a normative model for pharmacotherapeutic reasoning. First, the students are taught to generate a standard pharmacotherapeutic approach to common disorders, resulting in a set of first-choice medicines, called “P[ersonal]-drugs.” In the course of developing their P-drugs, the students are taught to consult existing national

and international treatment guidelines, national formularies, pharmacology textbooks, and any other source of medicine information. Then they are shown how to apply this set of P-drugs to specific patient problems using a six-step problem-solving routine: (1) define the patient problem; (2) specify the therapeutic objective; (3) verify the suitability of your P-drug; (4) write a prescription; (5) inform and instruct the patient; and (6) monitor and/or stop the treatment.

The rationale behind this approach is that at some time in the course of their studies or early in their careers, medical students develop a set of medications that they will use regularly from then on. However, this choice is often made on irrational grounds, such as the prescribing behavior of their clinical teachers or peers, without really considering the alternatives or knowing how to choose among them. The manual not only helps students select P-drugs in a rational way but also teaches them to consult, understand, and use existing treatment guidelines in an intelligent way. For example, it teaches the students how to verify, for each individual patient, whether their P-drug is the most appropriate choice in this individual case and, if necessary, how to adapt the medicine, dosage form, dosage schedule, or duration of treatment. The training has been field-tested and evaluated in a number of medical schools, with a proven effect on the students ([Country Study 29-1](#)).

In addition to the safety and efficacy of a medicine, other important considerations for students include the use of generic names and attention to cost; supply logistics; and the effects of transportation, storage, and medicine quality on the availability and stability of medicines.

Experience shows that students usually learn about prescribing from their clinical tutors. The value of medical faculty trained in clinical pharmacology should not be underestimated. However, the task of incorporating and implementing the teaching of rational medicine use into the curricula is not solely the responsibility of clinical pharmacologists. It should become the concern and responsibility of staff from various disciplines involved in training, particularly clinicians.

In addition to giving increased attention to clinical pharmacology, medical faculties should increase their students’ awareness of the importance of pursuing medicine information throughout their clinical training and practice. As part of their training in clinical pharmacology and therapeutics in Yogyakarta, Indonesia, medical students learn to critically assess medicine information and advertisements as well as reports of clinical trials published in a local medical journal. This training has proved helpful in improving their knowledge, skills, and critical attitudes.

In the public sector, paramedical personnel are commonly the first point of contact for patients in most rural areas and in some health facilities in urban areas. Improper use of medicines by these health workers can be dangerous and wasteful, whereas prompt and appropriate use of

Country Study 29-1 Impact of a short interactive training course in pharmacotherapy

The impact of a short interactive training course in pharmacotherapy, using the *Guide to Good Prescribing*, was measured in a controlled study with 217 undergraduate medical students in Groningen, Netherlands; Kathmandu, Nepal; Lagos, Nigeria; Newcastle, Australia; New Delhi, India; San Francisco, United States; and Yogyakarta, Indonesia. The course was composed of four half-day small group seminars combined with meetings after hours and group work. Students were taught how to develop their own P-lists of drugs for common conditions and how to choose drugs from their P-lists. In addition, they were taught how to write prescriptions and how to educate their patients.

The impact of the training course was measured by three tests, each containing both open and structured questions on the medicine treatment of pain, using patient examples. Tests were taken before the training, immediately after, and six months later.

After the course, students from the study group performed significantly better in all patient problems presented than the control students, who had received “normal” teaching. This finding applied to all old and new patient problems in the tests and to all six steps of the problem-solving routine. The students not only remembered how to solve a previously discussed patient problem (retention effect) but also could apply that knowledge to other patient problems (transfer effect). At all seven universities, both retention and transfer effects were maintained for at least six months after the training session. Students in the course were able to choose appropriate medicines to use, write correct prescriptions, and better counsel patients.

Source: WHO/DAP 1994.

medicines can save lives and prevent patients from becoming more debilitated. Paramedics and nurses in a number of developing countries are not legally allowed to prescribe. In reality, however, they see and prescribe for the majority of patients arriving at health centers. Where this practice is technically illegal, developing formal continuing education for paramedics can be difficult.

Many countries find that limiting the medicines paramedics can prescribe to a specific list and providing a pocket medicine reference manual and standard treatment guideline based on that list can be a useful tool (see [Chapter 17](#)). Medical workers are encouraged to use the manual rather than depend on recall for selecting medicines and medicine dosages for all but the most frequently treated conditions. [Figure 29-2](#) illustrates the content and format of a standard treatment guideline used in Ghana. These workers do, however, need to be taught to diagnose so that they can use the appropriate treatment guidelines. Formal training in pharmacology and therapeutics provides a sound basis for paramedics to prescribe standard medicines and to understand the uses of new products that are added to their medicine lists.

In the private sector, prescribers, especially in resource-limited countries, may not be trained health practitioners at all, but instead employees or owners of informal medicine outlets where prescribing and dispensing may occur at the same time. Although countries may regulate the prescribing and dispensing practices or the level of education required in such outlets, clerks still do not often have knowledge or

training in the rational use of medicines (Rutta et al. 2009). This group is challenging to address through traditional interventions, although they are increasingly being recognized as playing probably the major role in medicine usage in resource-poor settings.

Continuing education (in-service). After their formal training is completed, prescribers develop their own prescribing practices, which are then influenced by whatever medicine information and commercial pressure they receive, the diagnostic facilities available to them, the expectations of the community, and medicine availability. Continuing education provides an opportunity for prescribers to keep informed on changes in the use of medicines.

In some areas, local associations of physicians or auxiliary medical workers have identified their need for continued training in therapeutics and have participated in seminars and other medical meetings designed to keep them up-to-date with current medicine information. Government health programs sometimes sponsor presentations for health personnel. In many countries, however, continuing education is not available for most prescribers, including those in teaching hospitals. Even when it does occur, it is often dominated by promotional messages from pharmaceutical companies that sponsor the events and are necessarily biased in favor of their products. Most prescribers are not trained to evaluate such information critically and tend to accept whatever they are told. They must also deal with the enticement of gifts and incentives proffered by pharmaceutical company representatives.

Like their physician counterparts, paramedical staff members tend to become more routine in their prescribing habits after they have been practicing for several years, which may lead to illogical prescribing. Regular teaching and monitoring by senior paramedical staff members or medical officers, with attention to the medical workers' prescribing habits, are essential.

Rational prescribing among paramedical staff can be promoted by—

- Requiring them to keep a brief listing of patients seen and diagnoses made
- Devising and making available a limited list of specific medicines with which paramedics must be familiar
- Ensuring regular monitoring and supervision, with frequent on-site refresher training

Supervisory visits. Personal supervision and case reviews are often difficult or impossible to perform. Therefore, in many programs, if paramedical staff keep a list of patients seen, with diagnoses and treatments prescribed, their prescribing habits can be quickly reviewed, and suggestions for improved medicine therapy can be made. In-service refresher courses and discussion of cases by paramedical personnel can be organized locally, using the health center as a base and the visiting doctor as educator. In this way, supervision can be educational and supportive, not punitive.

Group lectures, seminars, and workshops. Lectures, seminars, or workshops given to a relatively large number of people are the most widely practiced activities for continuing education. They may be effective in improving prescribers' knowledge but are likely to be ineffective in changing prescribing behavior. When such seminars are focused on

specific prescribing behavior, however, improvements can occur.

Printed materials

Printed materials carrying new information that is immediately relevant to the prescriber may help bring about a change in prescriber behavior. In general, however, printed materials may increase prescriber knowledge but rarely affect actual performance when used alone.

Printed materials are most useful when they are used in combination with other intervention strategies, especially those that involve active interaction between the party providing and the party receiving the information.

Clinical literature and newsletters. Many prescribers claim that they obtain information about therapeutics from medical journals. Unfortunately, many journals report research results that may not be directly applicable to daily practice. In addition, journals may overwhelm the prescriber with more information than can be digested, making it difficult to decide about the best prescribing choices.

Medical newsletters, such as the *Medical Letter* (www.medicalletter.com) or the *Drug and Therapeutics Bulletin* (www.dtb.org.uk), focus on a limited number of topics and provide summarized information in a form that is more immediately useful to the prescriber. Such information often compares and contrasts clinical choices and costs and provides recommendations about “optimal” treatments.

Treatment guidelines and medicine formularies. In many countries where an essential medicines list has been developed, treatment norms or guidelines have also been published (see [Chapter 17](#)). Such manuals are relatively inexpensive to produce and have several advantages over material from the pharmaceutical industry and sources from outside the country. They are not biased by commercial interest; include only those preparations available in the country; recommend doses that are appropriate for the local population; and provide special warnings that are relevant to local genetic, environmental, and epidemiological factors.

Consulting physicians and medical school faculty may oppose the preparation and distribution of reference manuals, fearing that they will lead to “cookbook” medicine. This fear seems to be largely unfounded, and physicians in the most prestigious medical schools in developed and developing countries are writing, using, and promoting such handbooks.

Illustrated materials (flyers, posters, and leaflets). Commercial pharmaceutical companies frequently use short, colorful, attractively printed materials to convey promotional messages. These materials usually contain only one or two ideas that are repeated in different ways, using text, drawings, tables, and charts. This type of mate-

rial is often used in conjunction with face-to-face educational outreach or focused meetings.

Approaches based on face-to-face contact

The most effective means of changing behavior has consistently been face-to-face contact. The pharmaceutical industry uses this method through its representatives because it works!

Educational outreach. One method found to be effective in improving prescribing practices after completion of training is targeted outreach education to individuals or small groups of prescribers. The efficacy of this approach has been demonstrated by the marketing done by pharmaceutical companies, whose salespeople promote their products on a one-to-one basis to carefully targeted prescribers.

In this method, principles of communications theory and behavioral science are combined with conventional educational techniques to provide information to physicians or other prescribers about medicines that are often used inappropriately and to promote their replacement with more therapeutic alternatives. Trained educators or opinion leaders can provide this contact, and it can be incorporated into the existing supervision system of health care services.

Principles of educational outreach include—

- Focusing on specific problems and targeting the audience of prescribers
- Addressing the underlying causes of the prescribing problems: misleading beliefs, poor knowledge, false perceptions
- Allowing an interactive discussion and involving the targeted audience
- Using concise and authoritative materials based on credible scientific information
- Giving sufficient attention to solving practical problems encountered by prescribers in real settings

The face-to-face approach can be successful, especially when combined with other interventions. A review of thirteen studies on the prescribing practices of health professionals found that a personal visit by a trained person to a health care provider in his or her own setting resulted in positive prescribing practice changes in every case (Thomson et al. 2000). In all instances, the face-to-face interventions consisted of several components, including written materials and feedback sessions. Face-to-face approaches have worked with non-health care professionals also. In Kenya, a vendor-to-vendor outreach program had success in improving malaria knowledge, changing prescribing practices in private medicine shops and kiosks (Tavrow et al. 2003). This outreach program also included giving dispensers job aids to help them remember the appropriate medicines and dosages to recommend.

Patient education. Patient or consumer education plays an important role in promoting rational use of medicines. Inappropriate prescribing patterns may derive from the demands or misconceptions of patients, although such demands are often exaggerated by prescribers to justify their prescribing habits.

One way to educate patients about the rational use of medicines is through individual communication during the contact between prescriber and patient. This communication often cannot take place, however, because of time constraints and a heavy patient load. In health facilities in developing countries, the average patient contact time is often only one to three minutes—too short for effective communication. Another reason may be the prescriber’s unwillingness to communicate with patients, or a lack of skill or interest in doing so. Prescribers are often not adequately trained in patient communication or are not sensitive to its importance.

Consumer education is carried out in many countries through mass campaigns by radio, television, or pamphlets and other printed materials (see [Chapter 33](#)).

Influencing opinion leaders

The attempt to train students in good prescribing practices can be frustrated by the environment in which they learn. For example, if a physician refers to medicines by their brand names during clinical training, the students will copy this practice and any other poor prescribing habits the physician may exhibit. Young doctors who have to prescribe according to the wishes of their senior colleagues can also pick up poor prescribing habits. One way of dealing with this situation is to identify the opinion leaders who influence the prescribing patterns of students and doctors in the establishment. Improving the prescribing practices of those leaders will indirectly influence the practices of the younger doctors and students.

29.5 Managerial interventions

Managerial interventions frequently require considerable effort to initiate and maintain. However, they can produce a sustained effect with small risk of adverse or unexpected consequences.

Monitoring, supervision, and feedback

Monitoring and supervision that are educational, conducted in person, and supportive—not punitive—will be more effective and better accepted by prescribers. Effective methods of supervision include prescription audit and feedback. Prescribers may be told how their prescribing compares with accepted guidelines or with that of their peers.

Box 29-2 Responsibilities of a drug and therapeutics committee related to rational prescribing

- Developing, adapting, or adopting clinical guidelines for the health institution or district
- Selecting cost-effective and safe medicines (for example, hospital or district medicine formulary)
- Implementing and evaluating strategies to improve medicine use (for example, medicine-use evaluation, liaison with antibiotic and infection-control committees)
- Providing ongoing staff education and training
- Controlling access to staff by the pharmaceutical industry and its promotional activities

Source: WHO/EDM 2002.

Involving peers in audits and feedback is particularly effective. Group processes include health professionals identifying a rational use issue and developing, implementing, and evaluating a strategy to correct the problem. This approach is used in the monitoring-training-planning methodology described in [Chapter 52](#). Additional data can be used in behavior monitoring, such as facility-specific postoperative infection rates, morbidity rates, or, where available, local antimicrobial resistance rates.

Differences exist in carrying out monitoring and supervision activities in the public and private pharmaceutical sectors. Drug and therapeutics committees (DTCs) in health facilities and district health teams can serve as a feedback mechanism for rational medicine use in places like hospitals. In fact, governments may encourage hospitals to have DTCs by making it an accreditation requirement (see [Box 29-2](#) for a list of DTC responsibilities).

Monitoring and supervision of prescription habits in the private sector, such as in retail medicine outlets, is difficult. Developing a method for monitoring, prescribing, and dispensing in such outlets remains a priority. The primary method is the use of simulated clients posing as patients with illnesses of public health importance (Madden et al. 1997).

Frequently, a formal inspection mechanism is legally mandated, but prescribing habits are rarely included in that inspection, and even then, resource limitations and a lack of good record keeping in private-sector operations make enforcing such inspection mandates difficult. Innovative public-private partnerships that use franchising and accreditation to improve services in private medicines outlets require rational medicine-use monitoring as part of the business model (see [Chapter 32](#)).

Selection, procurement, and distribution

Medicine use can be influenced by aspects of pharmaceutical management such as selection, procurement, and distribution. When the people responsible for these activities are consulted and informed, they are likely to cooperate in supporting rational prescribing.

Limited procurement list. The most common managerial intervention is selecting a limited list of medicines that will be routinely purchased. Other medicines may be made available, but require special approval (see [Chapters 16](#) and [18](#)). Managing a hospital formulary is therefore one of the key tasks of a DTC (see [Chapters 16](#) and [17](#)).

Drug use review and feedback. Drug use review is a tool to identify problems in the medication use process: medication prescribing, dispensing, administration, and monitoring. As problems are identified, strategies are developed and implemented to improve the use of medicines. If actions are successful, the result will be improved patient care and more efficient use of resources.

The approach to developing a program varies, but nine steps are important to follow—

Step 1: Establish responsibility for the DUR process. The DTC (or its equivalent) usually takes responsibility for the DUR program.

Step 2: Establish the scope for each study. A DUR focuses on the areas that show the most potential for improvement. A DUR may study one medication (such as ranitidine), a therapeutic class (H₂ antagonists), or a particular age group or diagnosis (patients older than sixty-five years of age with duodenal ulcers). DUR might focus on one step in the medication-use process, such as prescribing, or include other aspects, such as pharmaceutical product labeling or medicine administration. Pharmacists, nurses, and physicians are a major source of suggestions for focusing DUR studies. Formal mechanisms for identifying problem areas include ADR reporting, medication error reporting, or ABC and VEN analysis (see [Chapter 40](#)). DUR usually focuses on medicines or therapies that are high use, high cost, high risk, or problem prone. [Table 29-1](#) is a decision matrix

for selecting DUR studies to undertake. The higher the score, the more likely that this problem should be studied.

Step 3: Establish criteria or indicators, including benchmarks or thresholds. Criteria usually include the following components—

Uses: appropriate indications, treatment of underlying conditions, appropriate treatment of symptoms in treating underlying diseases

Selection: efficacy (comparative), safety, cost (total), duplicative therapy

Dosing: indication-specific dosing (age, diagnosis), indication-specific duration, dosing intervals

Interactions: disease, food, medicine, laboratory

Preparation and dispensing: labeling, dispensing time, stockouts, correct medicine, correct dose, correct dosage form

Administration: patient identification, handwashing, administration technique, documentation (correct patient, medicine, time, dose, and route)

Monitoring: clinical, laboratory

Outcome: therapeutic, safety

Thresholds or benchmarks are established for each indicator to define the expectations or goals for complying with the criteria.

Step 4: Collect and organize data. Data collection forms can be developed based on the criteria and configured into simple yes-or-no or fill-in-the-blank questions (see [Figure 29-3](#)). Depending on the complexity of interpretation required, the data collectors may or may not need a medical background. Pharmacists, nurses, or medical records personnel usually carry out data collection for hospital-based DUR studies. In hospitals where computers are used, the data collection may simply require printing a report from the computer databases.

The most common data sources are patient charts. Other sources are dispensing records, medication administration records, and laboratory reports. Focusing on specific indications related to the problem is important; avoid collecting too much data. A cumulative report should

Table 29-1 Selection matrix for drug use review*

Medication/health problem	High use	High cost	High risk	Problem prone	Total score
Paracetamol	1	0	0	0	1
Acute respiratory infections	2	0	1	1	4
Ceftriaxone	1	2	0	0.5	3.5
Warfarin	0.5	0	1	2	3.5
H ₂ antagonists	1	1	0	1	3
Surgical antimicrobial prophylaxis	1	1.5	0.5	1	4

* Each medicine or health problem is rated 0–2 on the basis of the use, risk, cost, and probability of problems. The highest total scores may be targeted for the DUR.

Figure 29-3 Sample form used in drug use review

Date:		Drug: ANTIBIOTIC USE IN SURGICAL PROPHYLAXIS		Data collector's initials:					
		Patient Chart No.							
		Diagnosis							
		Age/Sex/Weight							
		Date Treated							
CRITERIA AND INDICATORS		Threshold	Observed	Yes	No	Yes	No	Yes	No
Justification for medicine being prescribed:				Yes	No	Yes	No	Yes	No
1. Class of surgery: clean contaminated, dirty contaminated, ruptured, or gangrenous		100%							
2. Antibiotic on approved list for surgical prophylaxis		100%							
Process Indicators:				Yes	No	Yes	No	Yes	No
3. Dose given only one time, and not more than 45 min. before incision		100%							
4. Antibiotic administered if surgery is prolonged, 4 or more hours later		100%							
5. Postoperative doses specified for no more than 24 hours		100%							
6. Antibiotic change recommended due to: (a) adverse reaction (b) decreased renal function (c) interaction (d) cost-effectiveness increased (e) documented infection		100%							
7. Nosocomial infection is documented prior to non-surgical prophylaxis use of antibiotic		100%							
Outcome Indicators: None*									

Source: Moore et al. 1997.

* In this case, the DUR focused on adherence to standard treatment guidelines. Outcome indicators that could be measured include postoperative infection rates or adverse drug reactions.

include data from at least thirty patients or at least 5 percent of the expected volume (whichever is greater).

Step 5: Analyze data. The data need to be tabulated and reported in a standard format for comparison with benchmarks.

Step 6: Develop conclusions. The DTC reviews the results of the data analysis and develops conclusions regarding reasons for differences between results and benchmarks.

Step 7: Make recommendations. The DTC recommends actions required to improve knowledge or change behavior. The committee may recommend a more focused study or a focus group to understand the issues more clearly.

Step 8: Take action. Implementation of recommendations must be part of every DUR.

Step 9: Follow up. Did the intervention achieve its objectives? Whenever an intervention is undertaken, a follow-up evaluation should assess the impact of actions taken and determine whether further action is required. Such action may include refining the criteria and thresholds or

reanalyzing the causes of deficiencies and developing a new action plan.

Country Study 29-2 is an example of a DUR in a community hospital in the United States. Country Study 29-3 includes an example of a DUR in Kenya. The Kenya example is a variation of the methodology in Country Study 29-2, and a more appropriate application for that environment.

A self-monitoring program on medication use at health centers, based on the drug use indicators of WHO/International Network for Rational Use of Drugs, has been designed and implemented in a district day-to-day health management system in Gunungkidul district, Indonesia (Figure 29-4). With this program, prescribing indicators at the health centers are collected monthly. Prescribing data, based on these indicators, from different health centers are compared by the district health office and then fed back to the prescribers. The evaluation shows that such monitoring and feedback significantly improved prescribing patterns,

Figure 29-4 Changes in antibiotic and injection use with a self-monitoring program in Indonesia

Source: Gunungkidul District Health Office, Yogyakarta, Indonesia.

reducing polypharmacy and the use of antibiotics and injectable preparations. The average number of medications per prescription decreased from 4.2 to 3.1, and antibiotic and injection use also declined dramatically. The drug use indicators (WHO/DAP 1993) can themselves be used at the local level for self-audit and feedback.

Hospital and regional drug and therapeutics committees

Drug and therapeutics committees play an important role in improving prescribing practices at the national and regional levels, as well as at the district and institutional levels. Their role has expanded in some settings from selecting medicines for formularies to—

- Reviewing medication requisitions and revising them to fit budget allocations
- Determining which medicines should be made available to each type of health facility (if this determination is not made at the national level)
- Developing standard treatment norms for the common illnesses treated in the area or institution
- Establishing prescribing limitations aimed at controlling irrational medicine use (for example, limiting certain antibiotics to use only under the recommendation of a consultant)
- Limiting the amount dispensed at one time to curb abuse of particular medicines and reduce waste
- Reviewing antibiotic resistance patterns and revising guidelines for antibiotic use
- Stimulating medicine education activities among hospital staff
- Supervising and monitoring rational prescribing and safe medication-dispensing practices
- Developing and supervising an adverse drug event reporting system

Figure 29-5 Comparative daily cost of injectable and oral antibiotics in the eastern Caribbean

Source: Organisation of Eastern Caribbean States, Eastern Caribbean Drug Service 1993.

Cost information

Medication cost is an underappreciated aspect of prescribing. Expensive, newer medicines are frequently used when comparable well-established and cheaper ones are available for the same condition. Several different mechanisms have been used to encourage physicians and paramedical staff to consider cost in their medicine selections. These include

Country Study 29-2 Drug use review at a U.S. hospital

At a small community hospital on the West Coast of the United States, the Pharmacy and Therapeutics (P&T) Committee is responsible for a DUR program that evaluates four to six medicines or medicine therapies per year. One December, the committee received a report from the quality assurance coordinator noting that the rate of postoperative infections for abdominal surgeries was significantly higher than the national average. The pharmacy director informed the committee of his observation that cefoxitin was often used for these patients, a costly and inappropriate choice. The committee decided to undertake a DUR for antibiotic prophylaxis in abdominal surgery wound infection.

The health problem met all indications for a DUR: high use, high cost, high risk, and problem prone. The chief of surgery was a member of the P&T committee. He concurred with the committee that the criteria should be developed from recently published recommendations in the *Medical Letter*, which included medicine selection, dosing, and timing of administration. The accompanying table is a summary of the DUR study. It illustrates the benchmark targets for each indicator; the actual percentage of compliance based on quarterly data collection; and the conclusions, recommendations, actions, and follow-up.

Abdominal surgery wound infection antibiotic prophylaxis

Collection period: January–December the following year

Date of report: January, 13 months after the initial letter

Total number of cases: 162

Number of cases reviewed: 120 (74%)

Criterion	Benchmark (%)	Indicator: % Compliance per quarter			
		1st	2nd	3rd	4th
1. Antibiotic selection (per <i>Medical Letter</i>)	100	70	85	94	100
2. Correct dose (per <i>Medical Letter</i>)	95	65	90	94	97
3. Preoperative dose 0–2 hours before surgery	95	30	52	89	94
4. Postoperative dose only for dirty surgery	98	78	89	82	91
5. No postoperative infection	96	90	93	96	100
6. No adverse reactions to medicines	97	97	100	87	97

Conclusions

Criterion 1. Surgeons are selecting antibiotics that are not considered the medicine of choice for the indicated procedure.

Criterion 2. Surgeons are prescribing unnecessarily high doses of antibiotics.

Criterion 3. Preoperative doses are delayed: current procedure is for pharmacy to send medicine to operating room rather than preoperative area. Turnaround time for dispensing from pharmacy often delays medicine administration.

Criterion 4. Surgeons order postoperative antibiotics for patients who do not meet criteria for dirty surgery.

Criterion 5. High rate of postoperative infections may improve with compliance with criteria.

Recommendations

1. Send letter to all surgeons with the following information—
 - Current postoperative infection rate versus national average

- Criteria and recommendations from the *Medical Letter*

- Results of the DUR data collection
- Estimated cost impact of inappropriate medicine selection and unnecessary medicine use

2. Remove cefoxitin from formulary because of its disadvantages of short half-life and relative cost of therapy as compared with cefotetan.
3. Change procedures to administer preoperative doses in the preoperative area rather than the operating room. Instruct in-service nursing and pharmacy staff on new procedures.
4. Add approved antibiotics to floor stock in preoperative area for emergencies.

Actions

1. The chief of surgery informed the surgery committee about the DUR and the criteria in February of the implementation year.
2. A letter was sent to all surgeons in April.
3. Cefoxitin was removed from the formulary.

4. New procedures for administration were adopted in June, and in-service training of staff members began in July.
5. Antibiotics were added to preoperative floor stock in July.

Follow-up

Criterion 1. Met benchmark in fourth quarter. The education of surgeons contributed to an improvement in antibiotic selection.

Criterion 2. Met benchmark in fourth quarter. The education of surgeons contributed to an improvement in antibiotic dosing.

Criterion 3. Changes in procedures, floor stock, and in-service training of staff improved the timing of preoperative antibiotics but still not meeting benchmark. Benchmark is unrealistically high because of multitude of contributing factors for emergency procedures. Lower the benchmark to 93 percent.

Criterion 4. Education decreased unnecessary postoperative antibiotic prescribing for a short time, then surgeons began to return to old practices. P&T committee sent individual letters to specific surgeons, and the practice improved in the last quarter of the year, but it was still not meeting benchmark. Report cases of noncompliance to surgery committee for peer review and recommendations.

Criterion 5. Postoperative infection rate gradually improved throughout the year, meeting and exceeding the benchmark.

Criterion 6. Allergic reactions increased in the third quarter because of the change in floor stock procedures and preoperative nurse failure to screen for patient allergies. Previously, the pharmacy screened for allergies prior to dispensing. Nurses received in-service training for allergy screening, and the allergic reaction decreased in the last quarter, meeting benchmark.

using cost bar graphs, preparing facility pharmaceutical budgets, and printing prices in pharmaceutical manuals and on requisition forms.

Cost bar graphs. In many countries, diagrams or charts showing side-by-side comparisons of prices for alternative medicines have been circulated (for examples, see Figure 29-5). The intention is not to mandate that practitioners always choose the least expensive medicine but rather to encourage them to take cost into consideration.

Facility pharmaceutical budgets. In health programs that receive budgetary funds for pharmaceutical procurement, specific pharmaceutical budgets may be allocated to individual districts, hospital areas, or health centers. When annual estimates of pharmaceutical needs are made, or when regular requisitions for medicines are prepared, the expected acquisition cost of the medicines is compared with available funds. If reductions in medicine requests are necessary—and they usually are—the medical practitioners at the hospital or health center can participate in making the choices. This strategy puts the decision making closest to the point of medicine use. In some settings, this level of involvement by practitioners has helped create a cost consciousness that makes even their daily prescribing more cost-effective.

Printing prices in pharmaceutical manuals and on requisition forms. Even when practitioners are not required to make their medicine use conform to a specific budget, cost consciousness can be promoted by including recent pharmaceutical prices in therapeutics manuals, medicine lists, and other forms used in prescribing or requisitioning medicines. Alone, this measure may accomplish little, but in combination with some of the other measures described,

it may be quite helpful. Again, physicians and paramedical staff need not be required to pick the least expensive medicine in all cases, but the price list may encourage them to make inexpensive choices.

Prescribing and dispensing approaches

Managers can guide the prescribing and dispensing process by intervening at crucial points of the process.

Structured pharmaceutical order forms. For medicines that are frequently prescribed in hospitals, such as antibiotics, standard forms can be devised to optimize correct medicine use. The prescriber is provided with a medication order sheet containing a preprinted list of preferred medicines and dosage regimens for key medicines. Such forms have increased the cost-effectiveness of prescribing for hospital inpatients in the United States. For example, the form for antibiotics would specify correct standard dosages and an antibiotic review after seventy-two hours.

Standard diagnostic and treatment guidelines. Specific guidelines can be abstracted from formulary and therapeutics manuals (see [Chapter 17](#)). Guidelines for common conditions, such as postoperative pain, hypertension, diabetes, and various forms of cancer, can be agreed upon by the staff. Patients are treated in a standard manner according to the protocols. This approach has many benefits. Garnering agreement to follow the institutional guidelines may be time-consuming, but the active involvement of prescribers in this process can lead to significant changes in clinical practice. These guidelines can also be used as the basis of DUR and procurement lists.

Country Study 29-3 Antibiotic use review in Kenya

Antibiotics represent one of the most widely prescribed forms of medicine therapy. In some cases, the antibiotics prescribed may be inappropriate or too expensive. To ensure that antibiotics are prescribed appropriately and rationally, pharmacists have to review antibiotic usage periodically. The aim of antibiotic use review (AUR) is to determine the pattern (rates, appropriateness, and costs) of antibiotic usage in a particular setting. The results of an AUR program are often communicated to those concerned individually, through a memorandum, or through a general bulletin showing the norm and peer comparisons. The starting point of an AUR program is the formation of criteria by the drug and therapeutics committee (DTC). Prescriptions are checked for appropriateness of dosage, therapeutic indication, duration of treatment, and so on, according to the criteria. Deviant cases are recorded. AUR studies can be set up such that various clinicians, wards, and facilities can be compared.

The steps for performing an AUR are—

1. Select the subjects of the program.
2. Draft criteria and standards that define acceptable quality of care for subjects selected in step 1.
3. Obtain endorsement of the criteria and standards from the DTC.
4. Evaluate the quality of services in question using the criteria and standards.
5. Identify deficiencies in quality (if any).
6. Analyze the causes of deficiencies.
7. Formulate a plan for eliminating deficiencies.
8. Implement the plan.
9. Reevaluate the quality of services, as in step 4.
10. If usage is not acceptable, reanalyze the causes of deficiencies and devise a new plan for their elimination.

The worksheet for an AUR for amoxicilline is shown in the accompanying table, which considers ten patients from one prescriber in Kenya.

Review Criteria from DTC	Patients									
	1	2	3	4	5	6	7	8	9	10
Indications ^a	Tonsillitis	Otitis media	Urethritis	Bowel sterilization	Severe gram-negative meningitis	Boils/abscess	Severe cystitis	Surgical prophylaxis	Pneumonia	Severe wound infection
Appropriate indication?	Yes	Yes	Yes	No	No	Yes	Yes	Yes	Yes	Yes
Amoxicilline dosage ^b	250 mg tds	250 mg tds	250 mg tds	1,500 mg bd	500 mg tds	250 mg tds	500 mg tds	250 mg tds	250 mg tds	500 mg tds
Duration (usually 5 days)	5 days	7 days	7 days	1 day	10 days	7 days	5 days	5 days	5 days	7 days
Cost per capsule (KES)	30	30	30	30	30	30	30	30	30	30
Total cost ^c	470	650	650	380	1,800	650	920	470	470	1,280

^a Acceptable indications are upper or lower respiratory tract infections; genitourinary tract infections; septicemia; surgical prophylaxis; skin and soft tissue infection; osteomyelitis; and peritonitis.

^b Acceptable dosage is usually 250 mg tds. Dosage may be doubled in severe cases.

^c Total cost for usual dosage for 5 days = 470 Kenya shillings (KES). This amount includes dispensing fee of KES 20.

Calculations

1. Calculate the frequency of inappropriate prescribing—

$$2/10 \times 100 = 20\%$$

2. Total costs caused by inappropriate prescribing—

$$380 + 1,800 = \text{KES } 2,180 \text{ (a loss)}$$

Note: Only pharmaceutical costs are considered; medicines prescribed inappropriately are viewed as a waste.

Summary and comments

1. For patient #4: bowel sterilization would require a long-acting sulfonamide or neomycin tablets.
2. For patient #5: for severe gram-negative meningitis, patient would need a cephalosporin.

Source: Ministry of Health, Government of Kenya 1994.

Course-of-therapy packaging. Course-of-therapy (COT) packaging, often in the form of blister packs, has been widely used for oral contraceptives and, more recently, for tuberculosis therapy. Although such packaging adds to the cost of medicines, gains are experienced in convenience for both the dispenser and the patient. Comparative prices should be obtained before switching completely to COT; in many markets, the average difference between bulk and COT packaging is 10 percent or more. Prepacks (described in [Chapter 30](#)) are a form of COT packaging.

[Country Study 29-4](#) shows how different sets of targeted interventions, including educational and managerial approaches, were used to improve rational medicine use among prescribers in four different countries.

29.6 Economic interventions

Financial incentives—both positive and negative—may strongly affect rational or irrational medicine use; for example, setting prices and changing the way fees are collected can result in different prescribing behaviors.

Price setting and fees

The price charged for pharmaceuticals can be used to encourage more rational use of them. For example, in cost-recovery programs, vital medicines (see [Chapter 40](#)) can be sold at prices below their real costs, and nonessential medicines can be sold at prices above their real costs. This cross-subsidization can encourage the use of vital effective medicines while discouraging the sale of nonessential, less effective medicines. Charging for a course of therapy rather than for each individual treatment (injection, tablet) encourages the patient to complete the prescribed therapy. Generic medicines are usually cheaper than their brand-name counterparts, making their use rational from a cost standpoint. Pricing incentives such as preferential markup on generics and reference pricing can be used to encourage generic substitution. (See [Chapter 9](#) for more information on pricing policies.)

Flat prescription fees that cover all medicines within one prescription result in overprescribing; therefore, user charges should be made per medicine, not per prescription. [Country Study 29-5](#) shows how prescription fee systems affected prescribing behavior in Nepal. Also, dispensing fees that are calculated as a percentage of the cost of the medicines promote the sale of more expensive medicines. A flat dispensing fee, not tied to the cost of the medication, is preferable.

Insurance

The concept of insurance is assuming a greater role in resource-limited countries. Insurance systems can be pro-

vided through the government (social health insurance), through private sources (for example, employers), and through community prepaid schemes. Not all insurance systems include pharmaceuticals in their list of benefits, but when they do, certain controls on payment, prescribing, and use can affect the rational use of medicines.

Capitation-based reimbursement

When a payment to health care providers is made by a third party, pharmaceutical costs are better controlled with a fixed per capita payment as compared to a per visit or per medicine reimbursement. But caution is needed to ensure that needed medicines are not underprescribed.

Medicine sales by prescribers

If the health worker receives the profit on medicine sales, as occurs in Japan and in some Bamako Initiative projects, there is an inducement to overprescribe and to prescribe more expensive medications. Although prescribers may deny this effect, the findings are consistent across cultures and countries: prescribers who benefit from medicine sales prescribe more than those who do not.

29.7 Regulatory approaches

Regulatory approaches aim to enforce decisions that are intended to improve prescribing. These methods are frequently used but sometimes have unintended or unexpected outcomes, which may result in extra costs or adverse patient consequences. Such effects have been noted in the United States ([Country Study 29-6](#)) with the use of a limit on the number of monthly prescriptions patients could receive. That study, however, does not rule out the use of carefully structured caps.

Although most countries have some sort of drug regulatory authority and legal requirements for registering medicines, a lack of resources can deplete their effectiveness. WHO estimates that fewer than one in six member states have well-developed pharmaceutical regulation and two in six have no or little pharmaceutical regulatory capacity (WHO 2004).

Pharmaceutical registration

Most countries have pharmaceutical regulations that limit pharmaceutical sales to registered pharmaceutical products. In countries where pharmaceutical registration is enforced, it limits the types and numbers of medicines available for prescribing. An effective registration process helps keep dangerous and ineffective medicines off the market. The requirements for registering new drug substances are

Country Study 29-4

Assessing the effect of targeted approaches in improving prescribing

Indonesia. Inappropriate prescribing at primary health centers (PHCs) has been a major public health concern in Indonesia. A study found that more than 90 percent of patients with acute respiratory infection (ARI) visiting health centers received antibiotics. Also, more than 85 percent of adult patients with muscle ache (myalgia) reportedly received unnecessary injections. An intervention featured interactive, systematic, problem-based training of physicians and paramedical personnel in 122 PHCs, which were compared with a control group of forty PHCs.

The intervention consisted of three sets of training modules: medication error, evidence-based medicine, and rational use of medicines, followed by self-monitoring, supervision, and feedback by a training team. The training evaluation on prescribing patterns was conducted six, twelve, and eighteen months following the intervention.

The use of antibiotics for ARI in the intervention group decreased significantly, from 92.3 percent before the intervention to 71 percent, 50 percent, and 30 percent, six, twelve, and eighteen months after the study ($p < 0.05$). No significant improvement was found in the control group. A significant decrease in antibiotic prescribing was also found in the treatment of diarrhea in the intervention group, from 90.3 percent before the study to 53 percent, 40 percent, and 26 percent, six, twelve, and eighteen months after the study ($p < 0.05$). No significant improvement was detected in the control group. Interactive, systematic problem-based training on rational use of medicines, followed by self-monitoring, supervision, and feedback, significantly improved prescribing patterns and resulted in significant cost savings.

Kenya. The Mission for Essential Drugs and Supplies (MEDS) conducts institutional training interventions in mission hospitals. These interventions consist of three phases: a baseline survey using the International

Network for the Rational Use of Drugs indicators, training, and a follow-up evaluation one year later. Some hospitals then complement the training with their own in-house continuous medical education (CME) programs. A retrospective before/after study of three mission hospitals in Kenya with a comparison group assessed the effect of combining training with a CME program. A prescription review in each hospital looked at four prescribing indicators, including the percentage of cases prescribed antibiotics and injections. All three hospitals went through the MEDS training program, with one hospital instituting a regular, in-house CME program organized by the drug and therapeutics committee.

The postintervention results showed that in one hospital, three of four indicators showed improvement, and one of four indicators deteriorated. In the second hospital, one of four indicators showed improvement, one of four did not change, and two of four deteriorated. In the third hospital, which had the CME program, all four indicators showed dramatic improvement, especially concerning antibiotic and injection use. Study researchers concluded that training by external facilitators had mixed success in improving prescribing habits, but a complementary CME program made for a much more successful educational intervention.

Lao P.D.R. In the Lao People's Democratic Republic (P.D.R.), standard treatment guidelines were introduced to all prescribers at provincial hospitals, but they were insufficient in improving treatment practices in malaria, diarrhea, and pneumonia. To evaluate the effects of an educational intervention, a randomized controlled trial was conducted in eight provincial hospitals, matched into four pairs. The hospital drug and therapeutics committees carried out the six-month intervention, which consisted of monthly audit sessions and feedback on treatment indicator scores.

stringent in some countries. In others, however, the facilities for assessing new products are not readily available, and monitoring and enforcement are unreliable.

Limited medicine lists

Limited medicine lists can be a managerial intervention, as described earlier, or a regulatory intervention, in which case certain medicines are completely banned. Limited medicine lists (formularies) have been used since the early

1970s to control costs and promote rational use in public- and private-sector pharmaceutical programs. In Tanzania, for example, *duka la dawa baridi* (private medicine shops) are legally restricted from selling most prescription medicines, although lax enforcement and a lack of alternatives mean that most do sell restricted products. In some cases, governments have gone further, banning certain medicines or pharmaceutical classes from both public and private markets. Limited medicine lists are the main mechanism to prevent the use of dangerous, ineffective, and

From the baseline assessment to six months postintervention, the total mean indicator score for all three diseases increased significantly more in the intervention group than in the control group. The individual scores for malaria and diarrhea also increased significantly more in the intervention group, but for pneumonia, the improvement was the same in both groups. Specific improvements in record keeping and rational prescribing were seen for all three diseases. Audit-feedback systems to improve quality of care can be feasible and effective in hospital settings in low-income countries.

Mexico. Most continuing medical education activities for primary care physicians in Mexico have not improved the quality of care provided, and physicians' practices are not always in accordance with updated clinical evidence. The Mexican Institute of Social Security conducted a nonrandomized prospective controlled study to evaluate the impact of a multifaceted educational intervention to

improve case management in 175 primary care physicians divided into a study and control group. The study intervention consisted of three components over seven months: developing clinical guidelines; training clinical tutors; and a three-stage intervention including interactive workshops, individual tutorials, and roundtable peer-review sessions.

In the intervention group, improvement in medication prescribing was considerable: for acute respiratory infection, 32.7 percent of physicians improved their prescribing for antibiotics; for hypertension, 29.0 percent improved their antihypertension prescribing; and for type 2 diabetes, 25.2 percent improved their prescribing for hypoglycemic medicines or insulin. For all three, the changes were statistically significant ($p < 0.01$). No significant changes occurred in the control group.

Country Study 29-5

Using an economic strategy to improve prescribing practices in Nepal

A study including looking at practices pre- and postintervention compared with a control group was conducted in thirty-three health facilities in three districts in eastern Nepal. At the baseline, all three districts charged the same flat fee per prescription, covering all medicines, in any amount. Later, two districts instituted new fee systems, while the third kept the same fee structure. One district started charging a single fee per medicine item (using a one-band item fee), no matter what the medicine was, and covered a full course of the medicine. The second district charged a higher fee per expensive item (for example, antibiotics and injections) and a lower fee per inexpensive item (for example, vitamins) (using a two-band item fee) and covered a full course of the medicine. All the fees for two drug products equaled about 25

percent of the average daily household income. Prescribing was monitored in all health facilities before and after the changes.

The table that follows shows that both types of item fee were associated with significantly better prescribing quality than the prescription fee. The percentage of patients receiving antibiotics decreased, and the proportion of prescriptions conforming to standard treatment guidelines increased in both districts using item fees, compared with the control district. The one-band fee was associated with a reduction in prescribing of cheap vitamins and tonics, and the two-band fee with a reduction in prescribing of expensive injections.

Effects of user fees on prescribing quality in Nepal

Fee system	Control flat fee/ prescription n = 12	One-band fee/medicine item n = 10	Two-band fee/medicine item n = 11
Average number of items/prescription	2.9 → 2.9 (0%)	2.9 → 2.0 (-31%)	2.8 → 2.2 (-21%)
Percentage of prescriptions with antibiotics	66.7 → 67.5 (+0.8%)	63.5 → 54.8 (-8.7%)	60.7 → 54.3 (-6.4%)
Percentage of prescriptions with injections	23.4 → 20.0 (-3.4%)	19.8 → 16.1 (-3.7%)	21.8 → 14.9 (-6.9%)
Percentage of prescriptions with vitamins or tonics	27.0 → 22.1 (-4.9%)	26.5 → 8.4 (-18.1%)	23.5 → 15.8 (-7.8%)
Percentage of prescriptions conforming to STGs	23.5 → 26.3 (+2.8%)	31.5 → 45.0 (+13.5%)	31.2 → 47.7 (+16.5%)
Average cost/prescription (NPR)	24.3 → 33.0 (+35.8%)	27.7 → 28.0 (+1.1%)	25.6 → 24.0 (-6.3%)

NPR = Nepalese rupee.

Country Study 29-6 Unintended effects of medicine restrictions

In the United States, poor patients' health care costs are covered by the Medicaid program. This program is administered by the states in different ways.

In 1992, New Hampshire decided to limit Medicaid outpatients to three medicines per month; another state, New Jersey, chose not to place limits. Researchers studied the medicine-use patterns and hospital and nursing home admissions for patients who had been taking more than three medicines per month.

As expected, the number of medicines per patient decreased by 35 percent, but the dosages of the medicines prescribed increased. The unexpected outcome was a 120 percent increase in nursing home admissions and a 20 percent increase in hospital admissions.

After eleven months, the three-medicine limit was withdrawn and replaced with a USD 1 co-payment scheme. Admission rates and medication levels returned to the levels that existed before the medicine limit. In general, the patients who were admitted to nursing homes were not discharged.

In retrospect, the behavior of the physicians who admitted their patients to nursing homes was quite rational.

No medicine limits applied for inpatients, and patients could continue to receive their medications by entering nursing homes. Thus, Medicaid saved a little on medicine costs, but the cost of extra admissions outweighed these savings.

The monthly proportion of patients in nursing homes is shown in the accompanying graph.

Source: Adapted from Soumerai et al. 1991.

unnecessarily expensive medicines. However, the danger exists that when safe but relatively ineffective medicines (such as kaolin for diarrhea) are withdrawn from the list, they may be replaced by effective medicines (metronidazole, for example) used inappropriately. This occurred in one country when antidiarrheals were banned. Metronidazole use increased from 10 percent to 65 percent in cases of watery diarrhea.

Prescribing restrictions

In theory, after a pharmaceutical is registered, it can be prescribed by all medically qualified prescribers. Health authorities often restrict paramedical staff to a limited number of medicines on the national essential medicines list. Those limitations are imposed to reduce wasteful prescribing and inappropriate use of expensive medicines. At the health facility level, the use of expensive or powerful medicines may be limited to the more experienced prescribers. In some hospitals, the use of third-generation cephalosporins is restricted to specialist prescribers. Prescriptions by junior staff members have to be countersigned by the specialist. In some settings, the junior prescriber can prescribe such medicines only for twenty-four- to forty-eight-hour

use; any extension requires the authorization of the specialist. Prescribing limitations may take the form of pharmaceutical registration, limited medicine lists (essential medicines lists), medicine formularies, or prescribing and dispensing privileges by level of use (facility level and competence level of prescriber). Another possible restriction is to limit the number of medicines prescribed to two or three per patient. However, this restriction is easily evaded by issuing two separate prescriptions.

Dispensing limitations

Limiting the amount of medicines to be dispensed has been applied in some countries to control wasteful or potentially dangerous dispensing. Examples of this approach follow.

- One Asian country established a system of three- and five-day limits for all outpatient prescriptions, except those for chronic diseases. Most antibiotics are given for five days, and all other medicines for acute illnesses are limited to three-day courses.
- In South America, one large rural health program established a system of prepackaging medicines in unit-of-use plastic bags containing the minimum

amount of drug product needed for one course of therapy.

- The government-supplied university hospital in one Southeast Asian country put dispensing limits on items that may be abused, tend to be prescribed indiscriminately, or are potentially dangerous. Maximum dispensing quantities have been established for codeine, diazepam, vitamin C tablets, and vitamin B complex, among others.

Such limitations can have adverse effects on the treatment of some diseases. For example, antibiotic treatment for typhoid typically requires more than five days. Patients with chronic diseases such as epilepsy or diabetes are forced to visit health centers frequently and may end up missing treatments. Therefore, when setting restrictions on duration of therapy or dispensing quantities, exceptions must be built in to cover chronic diseases and exceptional cases.

29.8 Developing an intervention strategy

When a problem has been identified and quantified and its causes have been determined, a set of interventions needs to be selected. A wide range of possible interventions has been indicated in Sections 29.4, 29.5, and 29.6.

Selecting an intervention

The first step in selecting a set of interventions is to clearly define the problem to be solved. The behaviors specific to the particular health problem, as well as factors causing variability in performance, need to be identified. Assessing the beliefs and motivations of the prescribers that may contribute to the observed behavior is also important. These assessments will require further studies involving qualitative investigational methods. When the problem has been defined, a package of interventions can be considered.

Cost-effectiveness has to be considered in the selection process. The implementation of the selected interventions needs to be carefully designed. The use of a control group enhances the detection of differences. Key outcomes must be defined beforehand. An evaluation of the impact versus the cost of the intervention is also necessary. The outcome of the intervention must be fed back to the participants to reinforce the changes that have occurred.

The selection of an appropriate set of interventions should consider its—

Likely effectiveness: What intervention is most likely to be effective in addressing the specific medicine use problems and their underlying causes? Do any previous stud-

ies or documented experiences exist about this specific intervention?

Feasibility: Is the intervention feasible to implement, taking into account the existing health care system and the available personnel?

Cost: What is the cost of the intervention? Can it be borne by the available resources?

Potential effect: If the intervention is effective, what effect will it have, and what will be its magnitude? Can beneficial effects outweigh the cost and possible adverse effects?

Unintended effects: What are the possible adverse effects of the intervention?

The framework for formative and intervention studies is described in Figure 29-6. The selected interventions need to be monitored carefully during implementation.

Combining interventions

Interventions can be combined. This approach was taken in Mexico, where the treatment of diarrhea was unsatisfactory. The first intervention was an educational workshop, which improved prescribing from 24.5 to 51.2 percent compliance with a treatment norm. This intervention was

Figure 29-6 Framework for formative and intervention studies

Source: Quick et al. 1991.

Figure 29-7 Combined intervention strategy: Prescribing for acute diarrhea in Mexico City

Source: Gutierrez et al. 1994.

followed by a managerial intervention—peer review—that further improved prescribing to 71.6 percent compliance with the same norm. Only minor changes occurred in the control group (see Figure 29-7). After eighteen months, the improvement had been maintained.

Combining different types of interventions is usually more effective. A mixture of large-group education and small-group education, combined with audit and feedback, is more likely to produce sustained changes than is a repetition of the same intervention. Innovative approaches include an online, blended learning program that focuses on clinicians' beliefs about their prescribing habits, feedback on their prescribing backed with their own patients' data on antimicrobial resistance, and an introduction to how to work with patients to reduce unnecessary antibiotic prescribing (Simpson et al. 2009).

In general, regulatory interventions should be carefully structured, and active surveillance is essential to detect unexpected or unintended effects. Many countries do not have the capacity to monitor or enforce regulations, limiting the effectiveness of regulatory approaches.

Social marketing of interventions

Implementing interventions without taking into account the level of understanding and acceptance of the prescribers or consumers carries the risk of failure or unintended effects; therefore, involving key stakeholders in the intervention design and implementation is critical. For instance, a policy of prescribing generic medicines is in place in public health facilities in many countries. When prescribers are not well informed about the advantages of generics, they may not comply with generic prescribing, and they may transfer their negative perceptions to their patients, which, in turn, further jeopardizes the implementation of the policy (see Chapter 16). Withdrawing popular medicines from

the market without giving proper information to the public can create confusion and anxiety for consumers, especially for routine users of the medicines. Whenever regulatory or managerial action is taken, informational and educational approaches need to be incorporated for prescribers as well as consumers.

Evaluating the effect of an intervention

Evaluation of whether an intervention has caused the desired effect—that is, improvement in prescribing behavior in a cost-effective manner—is often neglected. An intervention strategy is often implemented without prior field-testing to prove that it works in the existing system and is effective in influencing prescribing practices. Many countries have implemented countrywide training programs without proper design and evaluation. In these cases, the waste of resources such as funds, time, and energy will only further increase the burden on health care services. Some health managers falsely assume that if any intervention program takes place, the desired goals have been accomplished. Yet the production and dissemination of treatment guidelines to health care facilities, for example, does not necessarily lead to prescribers' using the guidelines or improving their prescribing practices.

Evaluation of effects should be regarded as an important component of any intervention strategy, and ongoing production of timely data to steer the intervention design is invaluable. The following points should be considered in designing an evaluation approach—

- An evaluation plan should be devised when planning an intervention. Before implementing a program on a wide scale, field-testing is imperative to find out whether the evaluation can be implemented feasibly in the existing health care setting and whether it is effective in influencing prescribing practices.
- Evaluation of the impact of an intervention program should focus primarily on the indicators targeted by the intervention messages. Secondary indicators can also be selected, as appropriate. Depending on the objectives and scope of the intervention, evaluation may include relevant aspects, such as knowledge of the targets, changes in perception about a specific practice of interest, the process of care, and cost of prescribing.
- Apart from relevance, the selection of indicators for impact evaluation should take into account reliability and feasibility of collecting data from the existing system.
- The evaluation of any intervention should use appropriate design and methodology, with adequate sample size, sampling, and use of control groups or interrupted time series.

ASSESSMENT GUIDE

Indicators of prescribing quality

- Average number of medicines per encounter
- Percentage of medicines prescribed by generic name
- Percentage of encounters in which an antibiotic is prescribed
- Percentage of encounters in which an injection is prescribed
- Percentage of medicines prescribed from the essential medicines list or formulary
- Average consultation time
- Prescription in accordance with treatment guidelines
- Percentage of patients treated without medicines
- Percentage of patients satisfied with the care they received

Indicators of prescription costs

- Average cost per encounter
- Percentage of pharmaceutical costs spent on antibiotics
- Percentage of pharmaceutical costs spent on injections

Targeted approaches

Educational interventions

- Is there an official continuing education system on rational use of medicines for prescribers and dispensers?
- How many training sessions on medicine use were given for prescribers in the last year?
- What percentage of prescribers surveyed attended at least one training session in the last year?
- Of all the training sessions organized in the past three years, what percentage was related to medicine use?

- Is the concept of essential medicines part of the curricula in the basic training of health personnel?

Managerial interventions

- Is there a national therapeutic guide with standardized treatments?
- Do hospital drug and therapeutics committees exist? And if so, do they undertake drug use studies? What results are available?
- What kinds of managerial interventions have been tried? Were their effects evaluated?

Systems-oriented approaches

Economic interventions

- How are prices for pharmaceuticals set in the country? How do the prices compare to other countries' pharmaceutical prices?
- What are the prescription and dispensing fee systems in place? Are they flat fees or based on a percentage of the cost of the prescription?
- Are prescribers also allowed to sell medicines?
- Are there insurance or cost-sharing schemes? If so, who do they cover and what benefits do they provide?

Regulatory interventions

- At what levels of the system are limited medicine lists used?
- What other regulatory interventions have been used?
- What evaluations have been undertaken of the effect of regulatory changes?

Note: [Chapter 28](#) contains additional indicators and measures for assessing prescribing and the effect of interventions to promote rational prescribing.

- Measuring the long-term sustainability of the effect of any intervention is always desirable. Changes in prescribing behavior and practice observed immediately after an intervention often return to their baseline levels after a longer period of time. Experience shows that changes in prescribing usually return to pre-intervention levels after six months unless the intervention messages are continued. The use of time series analysis may be particularly useful in showing effects over time.

Measurements of medicine use, including measurements of the effect of intervention strategies, are discussed in more detail in [Chapter 28](#). ■

CS 30-1 Improving dispensing and counseling practices for antiretroviral therapy in Kenya 30.4

CS 30-2 The quality of medication counseling in three pharmaceutical service sectors 30.9

SUMMARY

Good dispensing practices ensure that an effective form of the correct medicine is delivered to the right patient, in the correct dosage and quantity, with clear instructions, and in a package that maintains the potency of the medicine. Dispensing includes all the activities that occur between the time the prescription is presented and the time the medicine or other prescribed items are issued to the patient.

A safe, clean, and organized working environment provides a basis for good practice. Dispensing must be performed accurately and should be done in an orderly manner, with disciplined use of effective procedures. Care should be taken to read labels accurately. The dispenser must count and measure carefully and guard against contamination of medicines by using clean equipment and never allowing skin contact with the medicines.

Staff members who dispense must be trained in the knowledge, skills, and practices necessary to dispense the range of medicines prescribed at the facility. Their performance should be regularly monitored.

Prepackaging medicines can improve efficiency in dispensing. Dispensing can also be improved by routine procedures for safety checking before issuing medicines to patients.

Cost factors inevitably lead to the use of packaging that is less than ideal. The packaging used must be the best compromise between cost and the risk of waste, with regard to maintaining standards of cleanliness.

Labeling is also affected by cost. Labels should contain information about the medicine and its correct use. The style and language of labeling should be appropriate to the needs of the patient.

Ensuring patients' understanding of how to take their medicines is a primary responsibility of dispensers. Dispensers should check understanding by asking each patient to repeat instructions.

Good records, though sometimes neglected, are an essential part of dispensing; they facilitate good management and monitoring of services provided.

30.1 Introduction

Dispensing refers to the process of preparing and giving medicine to a named person on the basis of a prescription. It involves the correct interpretation of the wishes of the prescriber and the accurate preparation and labeling of medicine for use by the patient. This process may take place in a public or private clinic, health center, hospital, or in a shop or community pharmacy setting. It is carried out by many different kinds of people with a variety of training and backgrounds. No matter where dispensing is done or who does it, any error or failure in the dispensing process can seriously affect the care of the patient.

Dispensing is one of the vital elements of the rational use of medicines. Programs to improve rational use have often been concentrated on ensuring rational prescribing habits, overlooking dispensing and the patient's use of medicines.

Dispensing is commonly assumed to be a simple, routine process that cannot go wrong. Yet all the resources involved in patient care prior to dispensing may be wasted if dispensing does not result in the named patient receiving an effective form of the correct drug, in appropriate packaging, and with the correct dose and advice.

This chapter considers the factors that influence the process of dispensing and therefore are important in ensuring "correctly dispensed" medicine.

30.2 Dispensing environment

Dispensing environments must be clean, because most medicinal products are for internal use, making it important that they be hygienic and uncontaminated. The environment must also be organized so that dispensing can be performed accurately and efficiently. The dispensing environment includes—

- Staff
- Physical surroundings
- Shelving and storage areas
- Surfaces used during work
- Equipment and packaging materials

Staff members involved in dispensing must maintain good personal hygiene and should wear a uniform or other clean clothing.

The physical surroundings must be kept as free of dust and dirt as possible. Although the dispensary must be accessible to patients, care should be taken to locate it in a protected place and not beside, or open to, a road or other area where dust, dirt, and pollution are commonly present. Ideally, the dispensary should be designed so that access to the dispensing area itself is restricted to authorized personnel only.

Figure 30-1 Illustration of a stock container label

Maintaining a clean environment requires a regular routine of cleaning shelves, daily cleaning of floors and working surfaces, and daily removal of waste (garbage). A regular schedule should be in place for checking, cleaning, and defrosting the refrigerator. Spills should be wiped up immediately, especially if the liquid spilled is sticky, sweet, or attractive to insects and flies. Food and drink must be kept out of the dispensing area, and the refrigerator used strictly for medicines. Regular monitoring of the refrigerator temperature should be an established procedure, together with detailed actions to be taken to promptly repair the refrigerator if temperatures fall outside of acceptable limits (usually +2–8°C).

Dispensing equipment is used for measuring liquids, weighing solids, or counting tablets or capsules. Uncoated tablets normally leave a layer of powder on any surface they touch, which can easily be transferred to other tablets or capsules counted on the same surface. This process is called *cross-contamination* and can be dangerous if the contaminating substance (for example, aspirin or penicillin) is one to which a patient is sensitive. Cleaning any equipment used for handling different products, both between uses and at the end of the day, is essential.

The dispensing environment must be organized to create a safe and efficient working area. Space should be sufficient to allow for movement by staff members during the dispensing process. However, the distance that a dispenser must cover during the dispensing process should be minimized to maintain efficiency.

Stock containers and prepacked medicines must be stored in an organized way on shelves, preferably according to dosage forms (for example, tablets and capsules, syrups and mixtures) and in alphabetical order. All stock containers in use must be clearly and accurately labeled to ensure the safe selection of the correct preparation and to minimize the risk of error (see [Figure 30-1](#)).

In addition, a system of stock rotation should determine which items are to be used first, on either a first-in/first-out (FIFO) or first-expiry/first-out (FEFO) basis. Regular checking of expiry dates and removal of expired stock facilitates stock rotation, as does placing stock to be used first

at the front of the shelf. Recommended storage conditions in terms of temperature, light, and moisture should be followed as closely as possible to maintain product quality. Stock bottles must be kept closed except when in use.

A limited range of preparations will be used with the greatest frequency, and these “fast movers” may be placed in the most accessible areas for the convenience of dispensers.

30.3 Dispensing person

A superficial look at dispensing suggests that it is a process of supplying goods to a patient on the basis of a written order, and that it can be done successfully by anyone who can read the prescription, count, and pour. As a result, dispensing is often delegated to any staff member who has nothing else to do, who then performs this function without any training or supervision. This situation is irrational and dangerous.

One major difference between supplying medicines or medical supplies and supplying other goods is that, with medicines or medical supplies, the recipient/patient usually does not know the correct use and is unable to judge the quality of the product he or she receives. Therefore, responsibility for the correctness and quality of medicines or products supplied lies entirely with the person dispensing them, and the patient must rely on the dispenser’s ability. Consequently, in most countries, laws mandate that the distribution of medicines and important medical supplies to the general public be carried out by professional pharmacists. In many countries, however, where a shortage of qualified pharmacists or trained dispensers makes it difficult to achieve this level of service, medicines and related products are supplied by individuals who have no training in medicines and no knowledge about their safe use.

In addition to reading, writing, counting, and pouring, the dispenser or dispensing team needs specific additional knowledge, skills, and attitudes to complete the dispensing process. These include—

- Knowledge about the medicines being dispensed (common use, correct dose, precautions about the method of use, common side effects, common interactions with other medicines or food, storage needs)
- Good calculation and arithmetic skills
- Skills in assessing the quality of preparations
- Attributes of cleanliness, accuracy, and honesty
- Attitudes and skills required to communicate effectively with patients

The level of training needed for any particular dispensing task is determined by the range of medicines dispensed and the extent to which calculation and preparation are required.

Dispensing personnel must receive an appropriate level of training, which will enable them to correctly dispense the

range of medicines prescribed in their facilities. This is true in both the private and the public sectors. At a basic health facility, where a limited range of medicines is used and the number of patients is small, dispenser training may be basic, highly structured, and built on the trainee's previous health care training. Dispensing assistants with this level of training may be employed at higher levels (for example, a district hospital) but should work under the guidance and supervision of trained pharmacy staff, such as a pharmacy technician or technologist. Dispensers in community pharmacy

shops should also be trained in the basics of good dispensing practices and the handling of medicines. Dispenser training in medication counseling and adherence is especially important to the success of programs providing antiretroviral therapy for HIV/AIDS patients, which are rapidly increasing in resource-limited settings (see [Country Study 30-1](#)).

In areas where graduate pharmacists are scarce, they are more effectively employed as trainers and supervisors rather than as technicians performing the routine tasks of dispensing.

Country Study 30-1

Improving dispensing and counseling practices for antiretroviral therapy in Kenya

Starting in 2003, the government of Kenya initiated antiretroviral therapy (ART) for HIV/AIDS patients at four health facilities serving the Coast Province, including the Port Reitz District Hospital in Mombasa. Management Sciences for Health's Rational Pharmaceutical Management (RPM) Plus Program performed a facility assessment and identified several factors related to dispensing that needed to be addressed before the ART program was initiated—

- Prescriptions were written on unofficial pieces of paper, difficult to read, and often incomplete.
- Tablet counters were available, but staff used their hands to count.
- Labeling of medicines was inadequate.
- The facility was extremely hot and no fans were available.
- Only one dispensing window was available—access to the second window was restricted.
- Patients crowded at the windows, which was distracting to the dispensing staff and made confidential counseling impossible.
- Average length of a medication counseling session was twenty-two seconds.
- No reference books or guidelines of any type were available.
- The dispensary was used to store nonpharmacy items (for example, staff members had to maneuver around a wheelbarrow).

Before the ART program began, the newly appointed head pharmacist attended an RPM Plus Promoting Rational Drug Use course. Upon returning to the hospital, the pharmacist shared the results of the RPM Plus assessment with the dispensary staff, and the team worked to identify the underlying causes of problems and develop strategies to address each issue. The staff team—

- Prepared a code of good dispensing practice and hung it on the dispensary wall
- Collaborated with the medical staff to design an official prescription form that specified patient information
- Committed to using tablet counters—supportive supervision by the pharmacist in charge encouraged the behavior change
- Designed a preprinted stamp to clearly label medication envelopes
- Installed fans in the pharmacy
- Improved dispensing conditions and confidentiality by arranging for the installation of private counseling booths and freeing access to the second dispensing window
- Worked to apply their training in good dispensing practice and medication counseling for ART to improve the quality of dispensing and patient care for all medicines dispensed
- Made use of a set of key resource materials and national guidelines that were made available to them
- Cleared nonpharmacy items from the dispensary

In a review conducted one year later, staff members commented that reorganizing patient flow was key in facilitating the improvements in dispensing and that one of their greatest achievements was improving medication counseling for all patients. The new private booths at pharmacy windows provided a welcoming and secure atmosphere. The staff members saw the confidential nature of the booths as a valuable addition: “Before when I was dispensing pessaries to a patient there would be four heads listening.” In addition, several of the dispensing staff members reported that they were applying their training on ART medication counseling to those patients taking medicines for the treatment of diabetes or hypertension.

Figure 30-2 The dispensing cycle

30.4 Dispensing process

The consistent, repeated use of good dispensing procedures is vital in ensuring that errors are detected and corrected at all stages of the dispensing process. The term *dispensing process* covers all activities involved, from receiving the prescription to issuing the prescribed medicine to the patient.

The development and use of written standard operating procedures (SOPs) for the dispensing process will improve consistency and quality of work and can be used for training and reference. The framework for such SOPs may be based on the six major areas of activity (see Figure 30-2)—

1. Receive and validate the prescription
2. Understand and interpret the prescription
3. Prepare and label items for issue
4. Make a final check
5. Record the action taken
6. Issue medicine to the patient with clear instructions and advice

Step 1. Receive and validate the prescription

Upon receiving a prescription, the staff member responsible should confirm the name of the patient. This action is particularly important when the clinic is dealing with a large crowd of people and when there is any risk that staff

or patients may mix up prescriptions. Cross-checking the name and identity of the patient must also be done when issuing the medicines. (The use of matching numbers or symbols—one attached to the prescription and one given to the patient—can also contribute to making sure the right patient gets the right medicines and is especially helpful in situations where many people share the same surname.)

Step 2. Understand and interpret the prescription

Interpreting a prescription must be done by a staff member who can—

- Read the prescription
- Correctly interpret any abbreviations used by the prescriber
- Confirm that the doses prescribed are in the normal range for the patient (noting sex and age)
- Correctly perform any calculations of dose and issue quantity
- Identify any common drug-drug interactions

It is assumed that the prescription will be in written form. Verbal orders for medications should be given only in exceptional and emergency situations. In such cases, the order should be repeated back to the prescriber to ensure accuracy, and written confirmation should be supplied within

an agreed-upon period. Computerized prescribing and dispensing systems are becoming more widespread, especially in large hospitals (see [Chapter 45](#)). If the person dispensing the medicine has any doubt about what is required by the prescriber, he or she must check with the prescriber. Illegible writing by prescribers has serious implications when many product names are confusingly similar. Checking a prescription may save a life (see [Box 30-1](#)).

All calculations should be double checked by the dispenser or counter-checked by another staff member. An arithmetical error could be fatal.

Step 3. Prepare and label items for issue

Preparation of items for issue is the central part of the dispensing process, and it must include procedures for self-checking or counter-checking to ensure accuracy. This part of the process begins after the prescription is clearly understood and the quantity has been calculated. It is good practice to write the label at this point as a form of self-check (see [Figure 30-3](#)).

Select stock container or prepack. A good dispenser selects the item by reading the label and cross-matching the product name and strength against the prescription. The dispenser should check the stock to make sure that it has not expired and choose the oldest stock (first-in/first-out) or first expiry, depending on the stock rotation method used. Most well-trained staff members deliberately read the container label at least twice during the dispensing process (see [Figure 30-4](#)). Selecting according to the color or location of

Box 30-1 Dispensing errors cost lives

A patient had been given a prescription for an antacid—something beginning with “D” and ending in “l.” The prescription was poorly written, but the dosage of two tablets taken four times a day was clear. The dispenser at the shop was not sure about the drug name but knew of a product on the market with a trade name that began with “D” and ended with “l,” and so dispensed it. That was how glibenclamide tablets (brand name Daonil) were dispensed at a level eight times the recommended daily dose, and the patient died of hypoglycemia. The prescriber who wrote out the prescription had the antacid Diovol in mind, but the handwriting was unclear. Although it is easy to see how this tragedy occurred, the fact remains that it should not have happened.

the container, without consciously reading the label, is poor dispensing practice and may have fatal consequences.

Another dangerous practice that should be discouraged is having many stock containers open at the same time. In this situation, product selection is frequently made only according to appearance, which could lead to errors. In addition, medicines continuously exposed to the air eventually deteriorate in quality. It is important to open and close containers one at a time.

Figure 30-3 Writing medicine labels

Figure 30-4 Selection from a shelf: Read the label every time

Figure 30-5 Position label upward when pouring liquids

Measure or count quantity from stock containers. Liquids must be measured in a clean vessel and should be poured from the stock bottle with the label kept upward. Using this technique avoids damage to the label from any spilled or dripping liquid (see Figure 30-5).

Tablets and capsules can be counted with or without the assistance of a counting device (see Figure 30-6). The most important rule to follow is that the dispenser's hands must not be in direct contact with the medicine. Using the hands is bad practice for both hygienic and product quality reasons. Counting should be done using one of the following—

- Clean piece of paper and clean knife or spatula
- Clean tablet-counting device
- Lid of the stock container in use
- Any other clean, dust-free surface

Immediately after measuring or counting, the stock container lid should be replaced and the stock container label should be rechecked for drug name and strength.

Pack and label medicine. Tablets or capsules should be packed into a clean, dry container, such as a bottle, plastic envelope, cardboard box, or paper envelope. Any of these containers are satisfactory in a dry climate. During the rainy season or in a humid climate, however, cardboard or paper will not protect tablets and capsules from moisture in the air, which can quickly ruin medicines and make them unfit for use. Capsules and sugar-coated tablets are the most vulnerable to moisture. Section 30.6 and Table 30-1 cover packing and labeling in more detail.

Figure 30-6 Counting methods

Step 4. Make a final check

At this point, the dispensed preparation should be checked against the prescription and against the stock containers used. Although this step can be done as a self-check, it is valuable to have the final check done by another staff member. The final check should include reading and interpreting the prescription before looking at the dispensed medicines; checking the appropriateness of doses prescribed and checking for drug interactions; checking the identity of the medicine dispensed; checking the labels; and finally countersigning the prescription.

Step 5. Record action taken

Records of issues to patients are essential in an efficiently run dispensary. Such records can be used to verify the stocks used in dispensing, and they will be required if a need arises to trace any problems with medicines issued to patients.

Three different methods can be used to keep a record of medicines dispensed. When the prescription is retained, the dispenser should initial and annotate the prescription with strength and quantities dispensed and either file it or enter the details into a record book as soon as time is available. When the prescription is returned to the patient, details of the medicines dispensed must be entered into a record book before the items are issued to the patient. The date, the patient's name and age, the medicine name and strength, the amount issued, and the dispenser's name should be entered into the register. When dispensers use computers to record the dispensing details, the computer program should retain

Table 30-1 Packaging materials for medicine dispensing

Category of packaging*	Package characteristics	Examples
Tablets/capsules		
Desirable	Clean, dry, plastic or glass container with tight-fitting cap or seal	Blister packages, plastic sachets, tightly sealing plastic or glass containers with screw or snap cap
Acceptable	Clean, dry container that provides protection from dirt and moisture	Zipper-lock plastic bags, glycine paper, tin with tight-fitting lid
Undesirable	Unclean absorbent paper, cotton, cardboard containers with no provision for closure	Unsealed plastic bags, paper bags, newspaper or other printed paper
Liquids (oral and topical)		
Desirable	Clean, dry, light-resistant glass container with tight-fitting cap	Amber or opaque bottle with screw cap
Acceptable	Clean, dry plastic or glass container with tight-fitting cap	Glass or plastic bottle with tight-fitting cap
Undesirable	Unclean paper, cardboard, metal, or plastic (not formed) container with no provision for closure	Previously used liquid-containing cartons, plastic-lined paper bags, plastic bags
Liquids (otic and ophthalmic)		
Desirable	Clean (preferably sterile), light-resistant glass or plastic container with a dropper incorporated into a tight-fitting cap or a top fitted with a dropper with a protective sleeve	Amber dropper bottle, opaque plastic dropper bottle
Acceptable	Clean, dry plastic or glass container with tight-fitting cap and a clean plastic/glass dropper (separate)	Glass or plastic bottle with tight-fitting cap, glass or plastic dropper with protective container (cardboard, zipper-lock, plastic, or paper)
Undesirable	Anything other than above	Anything else
Creams/ointments		
Desirable	Clean glass or porcelain wide-mouth jar with tight-fitting lid or collapsible plastic or metal tube	Wide-mouth jar with tight-fitting lid, cream or ointment tube with cap
Acceptable	Clean glass or porcelain jar with lid	Glass or porcelain jar
Undesirable	Anything other than above	Anything else

* *Desirable*: Packaging should meet listed requirements for a period greater than 30 days.

Acceptable: Packaging should meet listed requirements for up to 30 days.

Undesirable: Packaging provides no protection from dirt, moisture, or other contaminants, thus permitting rapid deterioration or contamination.

the information, which can then be recalled to generate summary reports.

Step 6. Issue medicine to the patient with clear instructions and advice

The medicine must be given to the named patient, or the patient's representative, with clear instructions and any appropriate advice about the medicine. The appropriate level of informational detail about possible side effects varies from patient to patient. Verbal advice is important, because illiteracy and poor labeling may both be problems. [Country Study 30-2](#) shows data collected on how well dispensers instructed patients on medication use in six different countries.

Apart from information on the dose, frequency, length of treatment, and route of administration, priority should be given to providing information that will maximize the effect of the treatment. Advice should therefore concentrate on—

- When to take the medicine (particularly in relation to food and other medicines)
- How to take the medicine (chewed, swallowed whole, taken with plenty of water, etc.)
- How to store the medicine

Warnings about possible side effects should be given cautiously. Common but harmless side effects (nausea, mild diarrhea, urine changing color) should be mentioned to prevent a frightened patient from stopping the treatment. More serious side effects should be mentioned only with the agreement of the prescriber, who needs to take those risks into account when prescribing the medicine.

Every effort must be made to confirm that the patient understands the instructions and advice. This can be difficult to do if someone other than the patient is collecting items for the patient or for several patients, particularly when the same medicines are prescribed in different dosages. Whenever possible, the staff member dispensing

Country Study 30-2 The quality of medication counseling in three pharmaceutical service sectors

As part of an overall assessment of pharmaceutical management in six resource-limited countries, Management Sciences for Health's Strategies for Enhancing Access to Medicines (SEAM) Program used standard indicators to measure the quality of pharmaceutical services, including dispensing. The data on patients' knowledge of how to take their medicine came from interviews with patients exiting public and nongovernmental organization (NGO) facilities and from simulated patients at privately owned retail outlets. The exit survey did not aim to determine whether the patient's information about how to take the medicine was correct, but to determine if the patient was able to relate any information about the medicine's intended use, based on what they had been told by the dispenser. Simulated patients entered

retail medicine outlets asking for help for their sick child. Results of the surveys are reflected in the tables below.

In general, attendants at all facilities and in all countries were lax about giving customers information on possible problems and side effects, but this finding was especially pronounced in private, for-profit outlets. The percentage of people receiving instructions on the purpose of their medication and how to take it varied, but was greatest in Cambodia and El Salvador. Of note are Cambodia's figures, where, in all three types of facilities, almost all those surveyed knew basic information on why and how to take their medications.

Sources: SEAM Program 2003a, 2003b, 2003c, 2003d, 2003e, 2003f.

Patients' knowledge of prescribed medicines at public facilities based on exit interviews

Indicator	Ghana n = 813	Tanzania n = 209	Cambodia n = varied	El Salvador n = 712	Brazil n = 178	India n = 1,391

% Encounters where attendant provided information on care and how to treat fever	14	24	69	19	16	10

Figure 30-7 Ensuring understanding

the medications should have the recipient repeat back the instructions (see [Figure 30-7](#)).

Every patient must be treated with respect. The need for confidentiality and privacy when explaining the use of some types of medicine must be recognized, and efforts should be made to structure medicine collection so that advice to patients can be as individual as possible. The person receiving the instructions may be feeling ill, and the success of treatment depends on the accuracy and effectiveness of the dispenser's communication with the patient.

30.5 Promoting efficient management in dispensing

Good dispensing practices are most threatened when dispensing staff face a crowd of patients demanding immediate attention. The need for speed must be balanced with the need for accuracy and care in the dispensing process. At this point, the patient's care, or even life, is in the hands of the dispenser. In dispensing, *accuracy is more important than speed*.

Prior agreement with the prescribers to prescribe only items that are available at the pharmacy or listed on the hospital or clinic formulary prevents unnecessary delay and confusion for the patient and improves efficiency in the dispensing process.

Organizing patient flow, such as establishing systems to receive payment and prescriptions and issue medicines, can reduce the potential for dispensing errors by removing the dispenser from the intense scrutiny of ten or more patients

Figure 30-8 Check routines, prevent mistakes

anxiously waiting at the dispensary window. Strategies such as giving information on the current waiting time and issuing numbers linked to the order in which prescriptions will be dispensed can encourage patients to use the waiting time to access other hospital or clinic services, helps to prevent long queues and crowding at the dispensary window, and can improve patient satisfaction.

One good way to reduce dispensing time and improve safety is to prepackage and label commonly used medicines. This process also distributes some of the dispensing workload to less busy periods of the day. See Section 30.7 for a more detailed discussion of prepackaging.

Another way to prevent staff from making errors when under pressure is to organize the work so that more than one individual is involved in the dispensing process for each prescription. This method introduces a system of using counter-checks, which is a wise precaution in most situations (see [Figure 30-8](#)). One example of such a system assigns one person to receiving and checking prescriptions, another to preparing the medicines, and a third person to handing them to the patient with advice; the team members then rotate responsibility for these activities at regular intervals.

Techniques to ensure quality in dispensing include—

- Requiring that all staff work in accordance with written SOPs
- Maintaining records on what medicines and products have been issued
- Scheduling worker shifts to make best use of staff: providing more staff at peak hours, maintaining enough coverage to keep the dispensary open during breaks,

and coordinating shift starting/ending times with patient flow

- Involving the pharmacy staff in hospital/facility committees to identify and resolve problems involving patient flow, communication, and other areas

Regular inspection or auditing using a checklist, together with supportive supervision, may improve dispensing in a health facility (see [Box 30-2](#)).

A number of studies have investigated determinants, other than the management of the dispensing process, that influence dispenser behavior. [Box 30-3](#) lists factors that have been cited as influential and may need to be addressed to improve the quality of the dispensing process.

30.6 Packaging and labeling of dispensed medicines

When products for dispensing have been collected from the shelf, they must be packaged so that they can be stored by the patient, and labeled to ensure patient understanding.

Containers for dispensed medicine

The purpose of a medicine container or packaging is to preserve the quality of the medicine up to the time of use, as

well as to provide a surface for attaching or writing a label with identifying details and instructions for use. The container should not affect the quality of the medicine in any way or allow other contaminants to do so.

Ideally, such a container would match standard criteria per textbooks and international standards. These describe the nature and color of the container and its closure (cap or top), as well as the requirements for good labeling. Because many health systems cannot meet this ideal for financial or logistical reasons, it is important to seek the best possible solution, keeping in mind basic principles. [Table 30-1](#) compares various options.

Liquids require clean bottles and effective caps or closures. Under no circumstances should two liquid medicines be mixed together for dispensing. They may interact chemically and become ineffective or dangerous. In many situations, suitable containers for dispensing liquids are difficult to obtain, and a policy of prescribing solid-dose preparations whenever possible is recommended. If patients bring their own bottles for liquid medicine, it is important to rinse and thoroughly drain the bottles before use.

The use of medicine reminder devices or medicine compliance aids as dispensing containers is becoming more popular as a tool for helping patients with complex medication regimens—especially elderly patients—take their medicines correctly at home. These devices typically hold seven days' supply of a patient's medicines in twenty-eight

Box 30-2 Sample inspection checklist

Environment

- Does the area appear clean and tidy?
- Is the refrigerator clean and tidy?
- What nonmedical items were found in the refrigerator?
- Is the temperature of the refrigerator checked regularly and maintained within an acceptable range?
- Are any spillages left unattended?
- Are stock containers in their proper place (or in use)?
- Are stock containers open but not in immediate use?
- Do any stock containers have incorrect or inadequate labeling?
- Are prepackaged medicines clearly labeled?
- Are sufficient counting aids or surfaces available?

General procedures

- Are all dispensed medicines checked by a second staff member before issue?
- What proportion of prescriptions are cross-checked for the patient's name at the point of receipt?
- Are dispensing containers cleaned before use?
- Are the required materials in the most efficient places?

Individual practices

- Are medicines counted into or out of dispensers' hands?
- Are there obvious self-checking routines for accuracy in calculation, selection, and labeling?
- Is equipment for measuring and counting cleaned between use for different medicines?
- What quality of advice is given to patients, and in what manner?
- Are patients able to repeat and remember vital instructions?

Box 30-3**Factors that influence dispenser behavior**

Pharmacies can often be a patient's first source of advice, and therefore, dispensers can greatly influence rational medicine use in the community. Many factors influence dispenser behavior—

- Training and knowledge
- Professional compensation (salary, prestige)
- Economic incentives (markup and volume of sales)
- Supply (cannot dispense what is not in stock)
- Available product information
- Availability of dispensing equipment (counting trays, vials, bottles, syringes, labels, and so on)
- Public- versus private-sector promotional and marketing techniques

- Social status of a dispenser and his or her role in the health care system
- Dispenser-prescriber relationship
- Lack of communication skills

A review of the literature on determinants that affect antibiotic dispensing showed that dispensers most frequently cited the desire to meet customer demand, followed by economic incentives, such as dispensing according to what the customer could afford to pay. Other factors named included a lack of regulation and enforcement, marketing influences, and a lack of knowledge (Radyowijati and Haak 2003).

total compartments, four for each day. The use of reminder devices, however, has both advantages and risks (Nunney and Raynor 2001). The obvious advantage is that the patient is able to manage his or her medication schedule better, with fewer missed doses and less confusion. Risks include patients' difficulty with opening the compartments, little space available for appropriate labeling, the possibility of product deterioration in imperfect storage conditions, and the difficulty of cleaning the compartments. Moreover, the device cannot accommodate certain dose forms, such as liquids or drops. In addition, when tablets and capsules are separated from their original containers, patients may lose track of what medications they are taking and why. A card that provides the details of physical appearance of the contents of the device can help patients with identification.

Labeling of dispensed medicine

When there is a shortage of suitable containers, the labeling of medicines is frequently inadequate or even nonexistent. As a result, dispensed medicines are often used incorrectly and therefore do not provide the patient with the intended treatment. Studies have shown that, even in countries with the most sophisticated labeling practices, only about 50 percent of medicines are taken as intended by the prescriber.

Despite these discouraging statistics, however, labeling is important, and every effort should be made to provide information about the nature and contents of the preparation, the dosage regimen to be followed, and the identity of the intended patient (see [Figure 30-9](#)). This information is important to include even if the patient is illiterate; another family member may be able to read the instructions. In addition, if a patient is admitted to the hospital for acute care

and is unconscious or unable to communicate fully, labels can provide vital information on the medication and dose for the treating clinician.

In some countries, small auxiliary labels are available with preprinted instructions, such as "Shake well before using," or cautions, such as "May cause drowsiness." Where such labels are available, they should be routinely used, as appropriate.

Prepackaged medicines should always be labeled with the name, strength, and quantity of the preparation and, where established courses of therapy exist, the dosage regimen. Such a label should leave a space for the patient's name to be added. It is important to avoid abbreviations, and unfamiliar expressions should not be used. If possible, the inclusion of the product batch number and expiry date is recommended.

Self-adhesive labels are unlikely to be available in many settings, but labels can be inserted into containers or stapled onto bags for tablets and capsules. Instruction labels may be preprinted, or the process can be simplified by having rubber stamps made for the common regimens (for example, "one to be taken three times a day"). If labels are handwritten, block capital letters should be used. Labels should be composed in the local language. If paper envelopes are used as containers, the instructions can be stamped onto them directly.

Where levels of illiteracy are high or where research has proved that written labels are not effective, consideration should be given to the additional use of pictorial or graphic labels, as illustrated in [Figure 30-10](#). Graphic symbols should always be combined with written instructions. Before any large investment is made in printing such labels, however, they should be pretested to make sure that they communicate effectively. Pictorial language can be very culture specific.

The use of computers and printers to produce labels for dispensed medicine is now common in many countries. The

Figure 30-9 Dispensed medicine label

<p>JOHN TETTEH AMOXICILLINE CAP 500 MG TAKE 1 CAPSULE THREE TIMES A DAY</p> <p style="text-align: right;"><i>Daniel Piri 3/3/07</i></p>

required software is designed for use on desktop personal computers, and this system may be considered where computers are available and affordable. Using computers can be very attractive and efficient, but the need for a continual supply of computer paper or labels and ink cartridges, as well as for a consistent electricity supply, must be considered.

30.7 Course-of-therapy prepackaging of medicines

The prepackaging done at the local level differs from that done by the manufacturer, which includes preparing fixed-dose combinations of medicines and unit-dose blister packs. This chapter focuses on prepackaging as a pharmacy-specific operation. However, blister cards and other unit-of-use packages created at the manufacturing level are useful to the dispenser because of the time saved and errors prevented by eliminating the need to count out tablets removed from a bulk package (Lipowski et al. 2002).

Local prepackaging of medicines for dispensing is valuable if the following conditions apply—

- Large numbers of patients come for medicines at the same time.
- A few medicines are prescribed frequently, and in the same quantities.
- The type of packaging used will provide protection from the environment until the patient uses the medicine.
- The package can be labeled with the drug name and strength.
- Prescribers are involved in the selection of packaging quantities and agree to prescribe the chosen quantities.

Benefits of course-of-therapy prepackaging

Course-of-therapy prepackaging has many advantages—

- Safer, easier, and faster distribution of medicines, with less room for error, which frees the dispenser from routine counting chores and allows more time for communication with patients

FACILITY <i>Utamo H.C.</i>			

- Improved credibility among users, because of the attractiveness and cleanliness of the package, which can be comparable to that of commercially purchased medicines
- More accurate and efficient prescribing by all health workers because of the standard treatments chosen for prepackaging
- Simplified dispensing for multidrug therapies (for example, copackaging isoniazid, rifampicin, ethambutol, and pyrazinamide for tuberculosis treatment), resulting in improved patient adherence with recommended regimens
- Possibility for routine prepackaging to be done by untrained staff following clear procedures and subject to appropriate quality checks and controls
- Easier and more accurate recording of inventory, with better control over supplies and more accurate consumption data

Importance of controls in prepackaging process

Prepackaging of medicines is technically a “manufacturing” process, which must be done under strict controls reflecting good manufacturing practices. In particular—

- Only one kind and strength of medicine is prepacked at a time in one work area or on one surface.

- The supervisor checks beforehand that the “prepacker” has the correct labels and that the number of labels and containers is the same and corresponds to the number of tablets or capsules to be prepacked. For example, to prepack in amounts of twenty from a bulk container of 1,000 tablets, the packer requires fifty containers and fifty labels.
- The supervisor checks the product at the end of the process.
- A written record is kept of the details (name, strength, batch number, expiry date) of the preparation to be packed, the number of packs produced, the date packed, the name and signature of the packer, the name and signature of the supervisor, and the internal batch number for the prepackaged product.

Precautions and quality checks

Prepackaging is repackaging, and the legal responsibility for the quality and labeling of the newly packed medicine is transferred from the original manufacturer to the repacker. Repackaging of medicines may compromise the original manufacturer’s expiry date, and generally an expiry date of six months, or the original expiry date if less, is given to repackaged medicines. Therefore, the quality of the product must be checked (at least a 10 percent sample) before and after prepacking. Package seals must also be checked on a regular basis to ensure that they close tightly and will protect the prepackaged medicine adequately.

The amount to be prepackaged depends on rate of use and the climatic conditions. In humid climates or during the rainy season, it may be best to prepack only an amount sufficient for a few days’ needs, especially if the new packaging cannot be tightly closed. Repackaging is a waste of time and resources if the product becomes unfit for use. [Chapter 7](#) provides more information on procedures for repackaging.

30.8 Aids in counting tablets and capsules

Aids for counting tablets and capsules include triangular or rectangular tablet counters, pan weighing scales, and electronic tablet counters.

Tablet counter

A tablet counter is a flat rectangle or triangle made of wood, metal, or plastic with raised edges along two sides. Metal or plastic is preferred because the surface can be easily cleaned or washed between uses for different products. The tablets are counted by first counting the number of rows of tablets in the counter and then pouring them into the container or package using a raised edge as a guide (see [Figure 30-11](#)).

Figure 30-11 Tablet counter in use

7 ROWS = 28 TABLETS

Key

Rows	4	5	6	7	8	9	10	11	12	13
Tablets	10	15	21	28	36	45	55	66	78	91

This simple device is good for counting small quantities of round compressed tablets, regardless of their size. The smaller the tablet, the more tablets can be counted at one time. With care, the counter can be used for sugar-coated round tablets. It is also useful as a surface on which to count any tablet or capsule, making the transfer to a container a simple process. The key for the number of rows and number of tablets is shown in [Figure 30-11](#).

Pan weighing scales

Scales can be particularly useful when counting tablets or capsules during prepackaging. The balance must be free to move, and the pans must be clean. The required number of tablets or capsules is counted and placed on one of the scale pans. Equal quantities of the same tablet or capsule can then be counted by adding to the other scale pan until a balanced position is reached.

Electronic tablet counter

When prepackaging is done on a large scale, as in a teaching hospital for use in both the ward and outpatient department, the use of an electronic counter may be justified.

30.9 Pharmacy personnel

The availability of qualified pharmacy personnel varies widely throughout the world, and the status given to different levels of trained pharmacy staff is equally varied. These

facts reflect the indeterminate role of trained pharmacy personnel in health care services.

Pharmaceuticals play such a prominent role in the provision and cost of health care that it is surprising how often the management of this resource is left to untrained and non-specialized staff. It is important to appreciate the value of an appropriately trained pharmacy workforce.

There are three recognized cadres of pharmacy staff: pharmacists, pharmacy technicians (also called technologists), and auxiliary or assistant staff. The first two normally receive their training in the formal educational sector.

Chapters 51 and 52 discuss in detail aspects of human resources and training related to pharmaceutical management.

Pharmacists

In most countries, a pharmacist is a professional who is registered with the appropriate national board or society after having obtained a university degree in pharmacy, frequently followed by a year of supervised work or apprenticeship.

Pharmacists are employed to practice in four main areas: regulation and control of medicines, hospital pharmacy, the manufacturing industry, and community (retail) pharmacy. The first two areas of practice are usually part of the public sector, and the latter two are usually part of the private sector, although manufacturers may be owned and operated by the public sector. Along with their practices, many pharmacists are also involved in teaching, training, and research.

The role of pharmacists in the supply of medicines has been altered significantly over the last twenty years. This change can be summarized as a move away from the care of pharmaceuticals (being product centered), and toward pharmaceutical care (being patient centered). A decrease in the need to compound medicines and an increase in the complexity and potency of available finished manufactured products have resulted in a change from concern about the preparation of medicinal products to involvement in the use of medicines by patients.

The training of pharmacists in industrialized countries reflects this change by providing more clinical and patient-oriented teaching, which prepares pharmacists to be participating members of the clinical team in hospitals and primary health care settings. Pharmacists are increasingly involved in deciding on and designing treatments, and are recognized by health professionals and the public as experts in medicine management and use. Their expertise and potential contribution to public and private health care have yet to be appreciated by many countries, which try to provide an effective supply of medicines and treatment without a trained pharmacist workforce of sufficient numbers.

Pharmacy technicians

Pharmacy technician training is usually a government-recognized vocational course provided on a full- or part-time basis through technical colleges or health training institutes. The length of training may vary according to the national education system. In most developing countries, courses are two to three years, whereas a course can be one year or less in industrialized countries. All courses emphasize practical skills and experience in dispensing medicines, and work experience is commonly a significant portion of the course. Basic teaching is given in pharmacology, pharmaceuticals, microbiology, and related subjects. Course content always needs to be updated to meet evolving job requirements.

Pharmacy technicians are important members of the pharmaceutical care team, and they constitute the largest group of trained pharmacy personnel in many countries. Their training qualifies them to work effectively in dispensing and pharmaceutical supply activities. They have sufficient training to be involved in decision making and supervision of other staff members, and individuals with experience can be given significant responsibility. In countries where professional pharmacists are scarce, by default pharmacy technicians are often put in charge of managing pharmacies without pharmacist supervision.

Insufficient planning has been directed to developing attractive and rewarding career structures for pharmacy technicians so that those with experience and ambition can fulfill their potential.

Auxiliary or assistant pharmacy staff

Auxiliary staff complete a relatively short on-the-job training program to assist pharmacists and technicians in the routine work of dispensing and medicine supply. Such training should be oriented to the tasks of the work environment. Assistant staff should follow written protocols and need to be supervised in their work, especially if the products of that work are given directly to patients. These staff should not be expected to interpret prescriptions on their own. Their supervisors should recognize that, with experience, these assistants can develop higher skills in particular areas.

Untrained medicine sellers

Many people rely on private medicine shops and other retail outlets as their primary source of medicines and health care, and although regulations may prohibit access to certain medicines at these outlets, often a lack of enforcement means that restricted, prescription-only medications are sold without a prescription. Countries may not have any legal requirements for the training or education of these sellers; however, sellers are increasingly recognized as

influential sources of information on illness and treatment in many areas. A number of interventions focused specifically on private-sector retail outlets have shown that training and incentive programs can improve dispensing habits among such sellers (see [Chapter 32](#)). ■

ASSESSMENT GUIDE

Dispensing indicators

- *Average dispensing communication time.* This indicator measures the time the dispenser actually spends explaining how the medicines should be taken.
- *Percentage of prescribed items actually dispensed.* This indicator is primarily a stock indicator.
- *Percentage of prescribed medications that are adequately labeled as per standard operating procedure.* At a minimum, package labeling should indicate patient names, drug name, and when the medicine should be taken (dose and frequency).
- *Patients' knowledge of correct dosage.*

Dispensing regulation

- Does a licensing system regulate the sale and dispensing of pharmaceuticals (wholesalers, pharmacists, retailers)?
- Are pharmacists legally allowed to substitute generic products for brand-name products?

- Is there an official checklist for carrying out inspections in different types of pharmaceutical establishments?

Dispensing training

- At each level in the health care system, who is responsible for the dispensing of medicines? What training do these individuals have in the principles and practices of medicine dispensing? Are standard operating procedures for dispensing and medication counseling available?
- How much supervision do these individuals receive? What type of pharmaceutical training is available in the country? Are there standardized education curricula for pharmacy personnel? Are experience requirements for dispensers clearly defined, and are these reasonable, given the numbers and geographical distribution of individuals meeting, or eligible for meeting, these requirements?

Note: See also the checklist in [Box 30-2](#).

SUMMARY

Community participation in health care is important because of the recognized value of locally tailored approaches, as well as the need for increased community financing to supplement government expenditures. For example, the Alma Ata Declaration of 1978 focused on primary health care as the best way to achieve healthy communities, and the deployment of community health workers was viewed as a key component in that strategy. More recently, the concept of community case management has evolved to respond to international recommendations to deliver community-level treatment for common, serious childhood infections. Many activities of questionable value, however, carry the label of “community participation,” which can reflect negatively on the whole field. This chapter summarizes the essential elements of a successful community participation program, with a focus on pharmaceutical management.

Community participation may involve—

- Contributing—community members contribute money, labor, or materials.
- Consulting—members are asked for their views and are informed of project plans.
- Managing—members actively participate in making decisions and in controlling resources.

When all three levels of participation are present, communities are full partners in providing services.

Full partnership in decision making means that health development is defined in terms of people’s real needs and priorities; community economic, human, and orga-

nizational resources are mobilized; and mechanisms are created to increase people’s access to information, knowledge, and skills and to help them make their goals and priorities known.

Community participation can improve pharmaceutical management through—

- Advocating for access to health care
- Promoting preventive health care
- Improving the availability of medicines and supplies
- Managing outreach services
- Managing facility-based health services
- Promoting appropriate medicine use

Formal health care professionals play a key role in facilitating community participation. They act as motivators; as supporters to the community in establishing strong organizations for community-based activities; as resource persons by establishing links between the community, government agencies, and other organizations; and as trainers and supervisors, building capacity within the community.

Community participation rarely emerges on its own. It succeeds best within an enabling environment, which includes—

- Political commitment to the concept of participation
- Interest in decentralization of health services
- Existence of a health structure
- Commitment to developing people’s managerial capabilities

31.1 Introduction

The failure of traditional top-down development approaches to eradicate poverty and improve the living conditions of the poor has led to increased interest in popular participation in development. For the first decade or so after the Alma Ata World Conference on Primary Health Care, many governments in developing countries took initiatives to expand community participation in the promotion and delivery of basic health services, including medicines. This expansion represented a response to the increasing trend toward decentralization and recognition of the value of locally tailored approaches, as well as an acknowledgment of the need for increasing levels of community financing. In the 1990s, however, countries were finding it difficult to sustain community-based health programs, especially with the increased focus on centrally run vertical programs such as those

focused on HIV/AIDS. But renewed interest in community-based approaches has resulted from countries seeking the most effective ways to accomplish the Millennium Development Goals.

Community participation can have an impact on health care, from policy to patient. At a higher level, community organizations and civil society groups have influenced policies—especially those related to the HIV/AIDS pandemic. At a more local level, a community-based focus creates a new form of governance for public health systems and alters the relationship between providers and users of health care services. Health professionals are being called upon to adopt new approaches and to work in partnership with communities: in sharing knowledge and skills, jointly deciding on plans for health care, and seeking to develop and strengthen the community’s capacity to care for itself.

This chapter presents some of the key features of community participation in the promotion and delivery of basic health services, including pharmaceutical management. The chapter draws on the experiences of many community-based health programs, among them the Bamako Initiative, which promoted community management and financing of basic health services, including medicines, and the rise of community case management, which is a strategy to deliver community-level treatment for common, serious childhood infections. The chapter also describes how community volunteers and private-sector outlets can improve access to quality medicines and services. Although some of the interventions described are not specific to medicines, they relate to improving the availability and use of medicines to improve health outcomes.

Although many methods of community participation are possible, no clear-cut or universally applicable methods exist. Participation varies from one country to another and even from one community to another within the same country, depending on socioeconomic and political contexts. Because communities are not homogeneous, this chapter provides broad guidelines for increasing community participation. The terms *community*, *users*, *consumers*, and *beneficiaries* are used interchangeably.

31.2 The power of advocacy groups and community-based organizations

Increased advocacy from various groups, such as multi-lateral organizations, bilateral donors, nongovernmental organizations at all levels, and civil society organizations, has brought about pressure to change policies and push pharmaceutical issues onto national and international health care agendas. Issues that are receiving more attention include the need for new health technologies and medicines for tuberculosis (TB), malaria, and HIV/AIDS, including pediatric formulations of antiretrovirals (ARVs) and laboratory technologies, such as more sensitive TB diagnostics, that are suitable for developing countries. In particular, the HIV/AIDS pandemic put into motion an advocacy movement that has significantly influenced issues on a worldwide scale.

The profound impact of the AIDS pandemic resulted in a unique alliance of activists and people living with the infection acting as advocates within their communities. In 1983, an advocacy group in Brazil created a nongovernmental organization to fight AIDS, a year after the first case had been diagnosed there, and additional groups followed. In addition to increasing prevention efforts and treatment in poor and remote communities, Brazilian activists are credited with assuring adequate funding for ARVs and contributing to the country's successful pricing negotiations with pharmaceutical manufacturers (Homedes and Ugalde 2006). In 1987 in New York City, the AIDS Coalition

to Unleash Power (ACT UP) was formed as a community activist group dedicated to influencing AIDS-related policy. They were the most visible example of how involvement at the community level and from people living with HIV/AIDS could greatly affect public policy and issues such as ARV access and affordability that ranged far beyond their New York roots. Since 1998, the Treatment Action Campaign (TAC) and its allies in South Africa have led a lengthy and very visible public campaign to improve access to ART through the public health sector.

Today, organizations around the world work to mobilize community support and action not only to improve the lives of local families touched by HIV/AIDS, but to keep AIDS issues—especially access to ARVs—high on the public agenda. For example, the International HIV/AIDS Alliance (www.aidsalliance.org), which was founded in 1993, works with community organizations in more than forty developing countries to strengthen the local response to HIV-related disease, and includes supporting community engagement for antiretroviral therapy (ART). The HIV/AIDS Alliance produces many resources and tools to improve the effectiveness of the community effort. A resource is also available for how to involve communities in the national AIDS response (International Council of AIDS Service Organizations [ICASO], AfriCASO, and International HIV/AIDS Alliance 2007).

31.3 What does community participation mean?

Although wide consensus exists on the central role of community participation in primary health care, the concept has varying definitions and different interpretations. In its *World Health Report*, the World Health Organization (WHO) defined communities as “groups of people living near each other, or with various social connections, and often with a shared sense of purpose or need” (WHO 2004). In practice, however, “community” may be conceptualized differently depending on the context. In general, the definition includes clients or users of health services as well as the providers of health services and medicines in the locality. An analysis of community participation suggested that the definition of community differs according to the actual level of participation (Murthy and Klugman 2004).

Community participation is best defined as a cumulative process through which beneficiaries develop the managerial and organizational capacity to increase control over the decisions that affect their lives. Therefore, community participation means that members have a strong voice in all issues that affect the well-being of the community at large. A high level of community participation implies the involvement of difficult-to-reach population groups, as well as the nongovernmental organizations that represent their

interests. The process of community participation can help these marginalized groups become better organized and more involved in decisions pertaining to their health.

When national government policies call for the decentralization of health-sector services, increased community participation is one way to help build capacity and ensure quality of services because management responsibility shifts to the local level. In this situation, however, civil society groups must advocate for the community to policy makers to ensure that the process of decentralized responsibility works effectively.

A community's full partnership in the decision-making process implies—

- Definition of health development in terms of local needs and priorities
- Mobilization of the community's economic, human, and organizational resources
- Creation of mechanisms that help people increase their access to information, knowledge, and skills; voice their opinions; and make their goals and priorities known

Three distinct approaches to community participation reflect different degrees of participation (Fox 1993)—

1. *Contributing*: Community members provide money, labor, or materials for health projects.
2. *Consulting*: Community members are asked for their views and are informed of project plans in order to secure their commitment and contributions to construction, operation, and maintenance.
3. *Managing*: Community members actively participate in decision making and in controlling community resources and are engaged in project identification, planning, organization, implementation, monitoring, and evaluation.

Many health professionals have seen community participation as mainly “contributing” to health projects; that is, the community assists the professionals with contributions of labor, materials, or money but only rarely with ideas. In both the contributing and the consulting modes, communities are regarded mainly as beneficiaries of assistance. When communities are involved with managing as well, the three concepts become synergistic; community members, in partnership with outside development workers, are able to use their heads and their voices—as well as their hands—in the development and operation of facilities and services they can genuinely call their own.

Community participation is best measured by its contribution to overall health outcomes, not only in terms of quantifiable project outputs but also in terms of the process of participation itself, including—

- Community involvement in needs assessment, planning, management of resources, implementation of project activities, monitoring, and evaluation
- People's capacity to manage and organize themselves
- People's access to new skills, knowledge, and information
- Community organization and solidarity
- Relationships between users and providers of health services
- Political will, leadership, commitment, and resources
- Transparency in project management and accountability of health services toward the public being served

31.4 Why promote community participation?

It is at the community level that women, men, and children get drinking water; that wastes are controlled to prevent disease; that nutritional deficiencies are identified and actions taken. It is in communities and in households that people choose health care providers, that families make decisions about the use of their resources, that patients obtain and decide how to use medicines. Therefore, projects aimed at improving access to and use of basic health services, including essential medicines, cannot achieve their objectives and ensure sustainability unless a genuine partnership exists with communities.

The concept of community participation in health is based on the following principles—

- Participation in one's own health care is a basic right to which all people are entitled.
- When health services are linked to local perceptions of needs and are managed with the support of local people, those services are more likely to achieve their objectives and be sustainable.
- By actively participating in project planning and decision making, people gain confidence in their ability to change their situation and better their health status.
- By solving their own problems, people become more self-reliant.
- Where public health institutions are weak, community participation in management and financing can improve efficiency, increase public accountability, restore users' confidence, mobilize additional resources to complement government resources, and improve the quality of services.
- By encouraging people to become involved, projects can benefit from local skills and resources.
- When people know from the start that a project is theirs, they show a greater sense of responsibility for the management and maintenance of services and facilities than when projects are controlled by “outsiders.”

- The positive experience of planning, implementing, and managing a successful project leads to involvement in other development activities, resulting in a multiplier effect.
- Health, nutrition, and family planning outcomes can be significantly improved and sustained only when the strengthening of health services, including medicine supply, goes hand in hand with community awareness about public health issues and personal health care.

Community participation is crucial in promoting healthy lifestyles and better health management at the household and community levels.

31.5 Community participation and initiatives to improve pharmaceutical management

Community participation has a role in pharmaceutical management, including advocacy for health care as described in Section 31.2. Communities can also—

- Promote preventive health care
- Improve availability of medicines and supplies
- Manage outreach services
- Manage facility-based health services
- Promote appropriate medicines use

Promotion of preventive health care

Governments and households could save money if efforts were made to promote preventive health care as well as rational medicine use. Grassroots community networks can play a crucial role in promoting preventive care and encouraging therapy without medicines at home for minor illnesses.

The process by which health promotion is carried out, including the time and effort that go into developing a community's sense of ownership, is critical to a program's success. In Malawi, for example, as part of an effort to control malaria, village health committees began selling insecticide-treated nets (ITNs) for beds. The demand for ITNs was very high, and committees used the revenue to finance community improvements, such as drinking-water wells. In addition, malaria cases decreased by as much as half in some villages (Lewnes 2005).

Improvement of availability of medicines and supplies

In response to the problem of declining public resources for financing pharmaceutical and other recurrent costs, some communities have adopted cost-recovery and self-financing schemes in local health centers, dispensaries, and outreach services. The aim is to improve and extend services by gener-

ating sufficient income to cover some local operating costs, such as the supply of essential medicines, salaries of some support staff, incentives for health workers, and investment in community health activities.

Community cost sharing can be based on user fees, prepayment for services, local taxes, and various income-generating activities. Communities can also help pay health care costs by contributing labor or making direct financial contributions for the improvement and maintenance of health care infrastructure. Revolving drug funds are discussed in [Chapter 13](#), while [Chapter 12](#) covers community-based health financing.

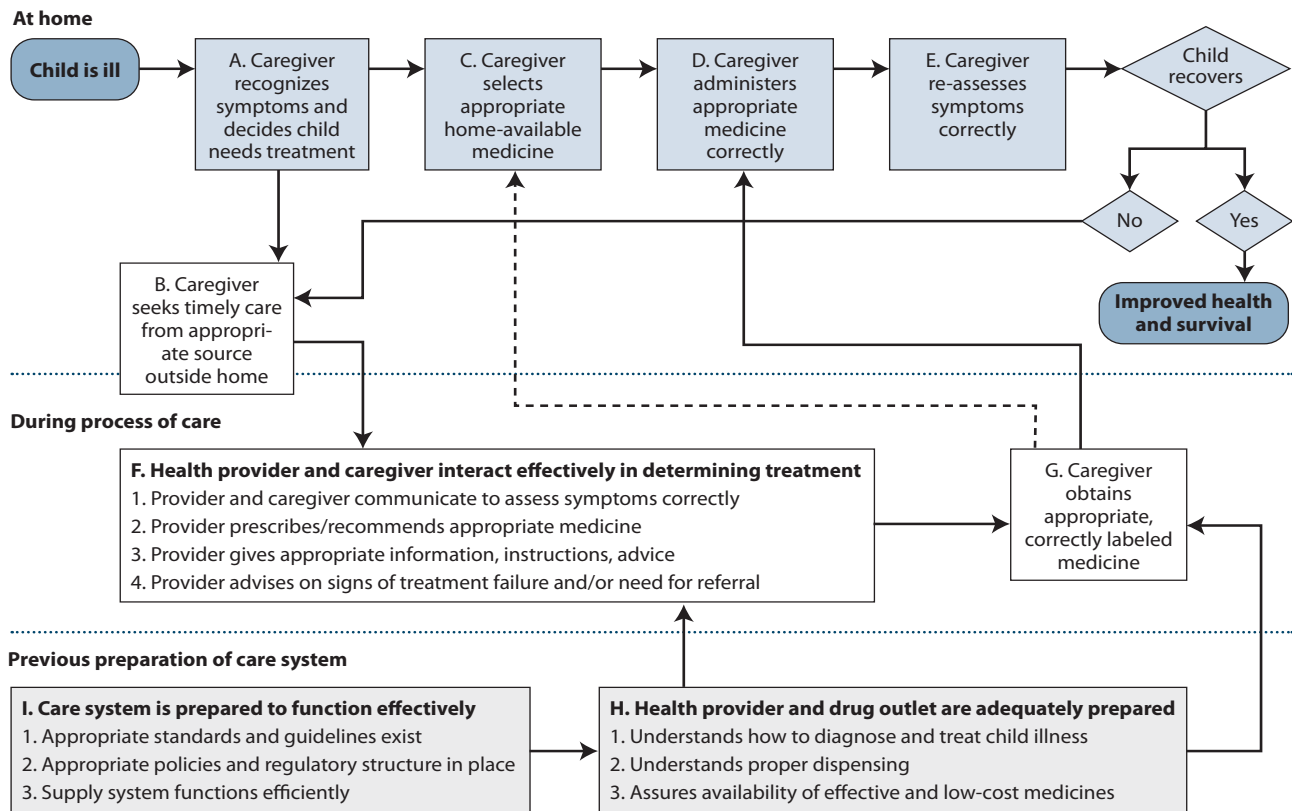

Management of outreach services

Over the past thirty years, large numbers of community health workers (CHWs) have been trained in many countries as part of national strategies for primary health care, especially for children. CHWs can be general community health resources, or part of a specialized group, such as community medicine dispensers, traditional birth attendants, or HIV/AIDS communicators. All types of CHWs typically are trained in one or more health care functions, but have no formal professional certification (Haines et al. 2007).

CHWs have been shown to be an effective means of accelerating and extending the delivery of primary health care when they receive adequate training, are regularly supervised, are provided with adequate logistical support, and are linked to established district health systems for technical backup. CHWs can also be valuable in monitoring health in the community and as a referral point between health centers and the community. However, although CHWs are often seen as an extension of the health system, supervision is a challenge to implement and is often not carried out. Supervision should be an important focus of any CHW program in order to ensure the availability and rational use of medicines. Lessons learned about CHW programs (Haines et al. 2007) include—

- *Training and individual support:* Training alone is insufficient; supervision and support increase performance and sustainability.
- *Tasks and roles:* CHWs will probably perform better with clearly defined roles and a limited number of specific tasks to carry out.
- *Incentives:* Targeted incentives, monetary or otherwise, will probably reduce attrition and improve performance.
- *Community and policy support:* Consistent support can help sustain CHW programs; active involvement of communities ensures support is available and promotes the use of community workers by community members.

Figure 31-1 Framework for appropriate Community Drug Management for Childhood Illness

Source: Ross-Degnan et al. 2008.

To be successful, CHWs, who are sometimes volunteers, need to be fully trusted and supported in the community; for example, in Uganda, volunteers selected by community members to distribute ivermectin treatment for river blindness were far more successful than those selected by the local government, who may have been viewed with some suspicion. The annual dropout rate for the community-selected group was less than 2 percent, compared with 95 percent for the others (Katarbarwa and Richards 2001).

A similar trust issue involves remuneration. Although monetary compensation to CHWs results in higher retention rates, it can also cause community members to view the volunteers as government employees rather than as true community advocates. Providing quality services in the community may earn the community health workers recognition and status, and they are often rewarded with payment in kind by community members. Research shows how incentives and disincentives affect the motivation and ultimately the retention of CHWs in the community (Bhattacharyya et al. 2001).

WHO's and UNICEF's Community Integrated Management of Childhood Illness (C-IMCI) initiative initially focused on prevention of childhood illness in the commu-

nity, with CHW responsibilities typically limited to education on sanitation, nutrition, family planning, child health, and immunizations. C-IMCI is evolving, however, and its focus has expanded to include community-based curative services or community case management of common conditions, such as malaria, diarrheal disease, and childhood pneumonia, in line with WHO and UNICEF recommendations in 2004 (WHO/UNICEF 2004). As a result, community case management through adequately trained and supervised community health workers is being increasingly promoted not only as a means of improving quality of care and rational use of medicines but also as a mechanism for increasing availability of medicines (Figure 31-1). Country Study 31-1 illustrates the success of community case management in Afghanistan, the Democratic Republic of Congo, and Nepal.

CHWs receive greater community support when they are empowered to provide curative services and medicines; however, an insufficient pharmaceutical supply can diminish the success of health volunteers. For community case management to succeed, medicines and supplies need to be available, managed appropriately, and used rationally (according to standardized treatment guidelines). Therefore, it is fundamental to pay attention to the supply management

components of any community case management program. (See [Country Study 31-2](#), which describes training community health workers in Senegal about appropriate use of medicines.)

Having informal health service providers in the community is being recognized as a means of enhancing primary health care by providing curative services. For example, in many resource-limited countries, community members often seek advice and medicines first from private drug sellers or medicine vendors; for various reasons they do not choose to seek care in the public sector—especially in rural areas, where public facilities may not be easy to reach. [Chapter 32](#) covers initiatives to improve drug seller services in the community.

Management of facility-based health services

With the economic crisis of the 1980s, particularly in Africa, infrastructure deteriorated, pharmaceuticals were often unavailable, and civil servants went unpaid for long periods. In response, many governments began to involve communities in the management of public facility-based health services. Now, health care facilities from all sectors—public, nongovernmental, and faith based—benefit from community involvement.

Because essential medicines are necessary for integrated, high-quality, cost-effective basic health services, and because people perceive pharmaceuticals as a quality indicator, medicines have often served as a starting point for community co-financing and co-management of facility-based health services.

Locally elected health committees can participate in the day-to-day tasks of managing health facilities. Such committees can—

- Assist health staff in developing an appropriate payment mechanism or mechanisms (prepayment scheme, flat rate, or fee for service) and in pricing services, including medicines
- Establish procedures for procuring and managing medicines and other supplies
- Determine criteria and develop an administrative system for those who cannot afford to pay or who should be exempt from paying for other reasons
- Establish a system of internal control of receipts and expenditures that ensures financial viability, accountability, and transparency in managing the system
- Participate in the day-to-day financial management and bookkeeping and prepare the health center's budget

Country Study 31-1

Community case management successes

Afghanistan. After decades of war, Afghanistan's child survival rates were close to the world's worst. Geographic isolation, cultural strictures, and poor security blocked many women and children from accessing care at public health facilities, so the Afghan government trained 20,000 community health workers—half of them women and most nonliterate. Their jobs include providing Integrated Management of Childhood Illness and advice to mothers on child care and family planning. About half of all sick children are now seen by CHWs, and increased access has contributed to the 25 percent decline in child mortality seen over five years (Aitken et al. 2009).

Democratic Republic of Congo (DRC). Since 2005, the community case management (CCM) program in DRC has trained hundreds of CHWs to manage uncomplicated childhood conditions. A key component of the CCM strategy was managing medicines, and training included how to track inventory and calculate medicine needs. Initial program results showed that 90 percent of twenty randomly sampled CHWs dispensed the correct quantity of medicine; all said the medicine name and formulation and how to administer it; 90 percent asked

the caregiver to repeat the instructions to assure understanding; and stockouts were rare (Bukasa et al. 2008). Investing in pharmaceutical management from program initiation has encouraged positive results, including minimized stockouts and appropriate dispensing practices.

Nepal. The Ministry of Health in Nepal trains female community health volunteers (FCHVs) to provide some health services in their community. When FCHVs were given responsibility for managing childhood pneumonia using co-trimoxazole, some observers questioned the cadre's ability to correctly diagnose and treat pneumonia, especially those who were semiliterate. These concerns were addressed by using pictorial training materials to facilitate understanding. The intervention also includes regular refresher training for the FCHVs and community orientation to the concept. In the program's first decade, districts with FCHVs doubled the number of children who receive treatment—saving an estimated 6,000 lives a year. The intervention now covers about 80 percent of children, with plans for universal coverage in the next two years (Dawson et al. 2008; Global Health Council 2009).

Country Study 31-2

Community health workers appropriately treat pneumonia in Senegal

The government of Senegal increased population access to health services by developing a network of health huts run by trained birth attendants (matrons) and community health workers. The Ministry of Health had used CHWs to treat malaria, diarrhea, and other minor ailments but had opposed their dispensing antibiotics because of fear of inappropriate use, which could contribute to drug resistance. Nevertheless, antibiotics were widely available in the market and were also inappropriately used in some health huts. In part on the basis of this information, the Ministry of Health agreed to operational research to test the feasibility of using CHWs to manage acute respiratory infection (ARI).

The research design was a nonrandomized controlled study with four intervention districts. Literate CHWs were trained for three days using a World Health Organization ARI algorithm in case management, followed by periodic one-day refreshers and ongoing supervision. Work tools included stopwatches, weighing scales, information materials, calculators, patient registers, and pharmaceutical stock cards. Co-trimoxazole was available in the health system through the national system's cost recovery, and its availability at the health hut was facilitated through store management training and supervision. Related educational activities and com-

munity mobilization were initially carried out by CHWs, who were joined by health promotion volunteers.

The training included 113 literate CHWs in ninety health huts. Postintervention tests showed marked improvement in CHW knowledge of ARI, unrelated to level of formal schooling. Under direct observation, nearly 90 percent of CHWs correctly evaluated, classified, and treated ARI cases, and more than 90 percent knew general danger signs. A record review showed that 95 percent of pneumonia cases were correctly classified, 97 percent were correctly treated, and 69 percent of severe cases were appropriately referred (an additional 22 percent received co-trimoxazole). Nearly twice as many pneumonia cases were treated in intervention areas than in control districts. The percentage of mothers knowing at least two danger signs increased from 33 percent in August 2003 to 65 percent in April 2004. Two CHWs inappropriately dispensed 552 tablets to older patients (of 36,800 tablets total), for a misuse rate of 1.5 percent. No stockouts of co-trimoxazole occurred during the study period. The study concluded that literate CHWs who are adequately trained and supported can correctly classify ARI, appropriately treat pneumonia with co-trimoxazole, and refer severe cases.

Sources: BASICS II 2004; Briggs et al. 2003.

- Carry out stock inventories of pharmaceuticals and other supplies and equipment
- Recruit and manage the support personnel hired with community funds (community pharmacy salespersons, guards, drivers, and so forth)

In some countries, health committees have a clear mandate to carry out evaluations of the performance of health staff and, if necessary, file complaints and propose disciplinary measures to district health offices.

[Country Study 31-3](#) describes experiences with community participation within the Bamako Initiative framework in three different countries.

Promotion of appropriate medicine use

The inefficient and even unsafe treatment of illnesses through inappropriate medicine use is a problem in many settings (see [Chapter 27](#)). These problems are caused by irrational medicine prescribing practices on the part of providers (which may include non-health care professionals, such as informal drug vendors or caregivers). Other

causes include popular misconceptions and nonadherence to treatment on the part of patients. Advocacy by organized consumer groups and efforts to improve public access to information are effective ways to address these problems (see [Chapter 34](#)).

Consumer education helps improve adherence to recommended medicine therapies. As part of this process, consumers are able to provide feedback to prescribers on the effectiveness of medicines, undesirable side effects, and so on. Such a process is reinforced when personal links have been established between consumers and providers at the community level and when community members are organized and vocal in demanding quality health services, such as in some social-marketing programs discussed in [Chapter 33](#).

An involved and informed community can also promote appropriate medicine use by helping to reduce disease stigma, such as for HIV/AIDS and tuberculosis, thereby encouraging early case detection and treatment adherence. For example, clinics can alert the community support group to trace a patient who has missed an appointment. Community members can also play a successful role in the treatment delivery process; for example, volunteers from the

Country Study 31-3 The Bamako Initiative in Benin, Guinea, and Mali

Since the late 1980s, the Bamako Initiative has been implemented to some degree in half the countries of sub-Saharan Africa. More than ten years later, experiences in Benin, Guinea, and Mali showed that communities were able to strengthen delivery of health services and ensure supply of essential medicines by forging a partnership between the state and organized community groups.

Before reforms were put in place, the vast majority of poor families in the three countries did not have access to affordable, quality health services or medicines, and the public health sector was in shambles. Immunization coverage was under 15 percent, and less than 10 percent of families made at least one visit per year to public health facilities. Although services were supposed to be free, patients often had to pay, and pharmaceuticals were often unavailable in the health unit. The only reliable source of medicines and care was usually in the informal private sector—mainly drug peddlers—where rural families typically spent 5 U.S. dollars per capita out of pocket per year.

In all three countries, the priority of the Bamako Initiative-related activities was to establish accountability and empower communities to take ownership of their health centers and services. A contractual arrangement between the state and communities promised delivery of basic professional health services by decentralizing decision making and management and instituting community cost sharing and co-management of health services. Communities were also involved in managing pharmaceuticals and revenue: The community pharmacies had double locks, requiring both the health center's chief nurse and a community representative to open; bank accounts required double signatures. Members of committees participated twice a year in the monitoring of health services—analyzing problems and helping to design new actions—and budgeting the use of these revenues, within clear national standard guidelines.

During the more than ten years of the Bamako Initiative in these three countries, access to community-based

health services was restored for more than 20 million people, use of services increased among children and women in the poorest segment of the population, and a sharper decline of mortality in rural areas compared to urban areas occurred in Guinea and Mali. Immunization levels increased in all three countries, with Benin averaging close to 80 percent, which is one of the highest levels of immunization among the poor in Africa (see figure below). Much of the success can be linked to ensuring the supply of affordable essential pharmaceuticals and commodities in health centers under the scrutiny of the committees and the involvement of communities in the planning and management of services, particularly immunization and maternal child health interventions.

The implementation of these initiatives were not without challenges. Top-down organization of health committees in the community tends to uphold elitism, and the rest of the population can feel marginalized. However, over time, the representation on committees improved, following guidelines from the policy makers. A remaining problem is the weak “voice” of the poorest citizens who have the least time to participate in meetings or other voluntary community support activities.

Steady improvements in immunization coverage in Benin, Guinea, and Mali

Source: Knippenberg et al. 2003.

community have been used as supporters for patients undergoing tuberculosis treatment in Cambodia and Peru (Thim et al. 2004; Shin et al. 2004), and worldwide, community-based groups have been established to support people living with HIV/AIDS.

When unregulated private markets offer pharmaceuticals of dubious quality, without prescription, and at exorbitant

prices, consumers must be sensitized to the health risks and costs involved. Community health workers, health committees, and networks at the grassroots level can, with increased access to information and technical support from health staff, serve as advocates to consumers for the promotion of reliable sources of local pharmaceutical procurement and the rational and correct use of medicines.

31.6 Health professionals' contribution to the process

Formal-sector health professionals play a key role in facilitating the process of community participation in health, and particularly in the supply and use of medicines. They serve as—

- Motivators who draw out people's untapped skills, experiences, and leadership potential
- Supporters who help the community establish strong and appropriate organizations for the planning, implementation, and management of community-based health activities
- Resource persons who establish links between the community, government agencies working in health and health-related areas, and other relevant organizations and services
- Trainers of community leaders, members of health committees, and community health workers who build on the knowledge and experiences that exist in the community
- Supervisors of community health workers who ensure delivery of quality health services

To fulfill these roles effectively and to create productive partnerships at the community level, health professionals must be able to—

- Communicate with the community and establish relationships with people, including community health workers and others who provide medicines
- Listen well and learn from the community
- Share skills and experiences with the community
- Respect people's ideas, skills, and wisdom
- Promote equity in male-female representation and in representation of the various social, economic, and age groups in local decision-making bodies
- Be aware of and respect the social practices, traditions, and culture of the community
- Foster collaboration with other projects, organizations, and services
- Promote a holistic or integrated approach to health development

31.7 Facilitating community participation in health programming

The participatory process for health programming includes community needs assessment, local decision making and participatory planning, community organization and leadership, and participatory monitoring. In the following sections, practical suggestions are given for each of these phases.

Community needs assessment

Conducting a needs assessment is the first step in initiating a community-based participatory health project. The purpose is to involve the project beneficiaries in determining their health problems, the causes of those problems, and their primary needs as the basis for planning community activities and for establishing baseline data against which progress can be measured in the future. Areas to be covered, the choice of method, and data analysis issues all need to be considered when planning such an assessment.

Key areas to be covered. Community participation in the needs assessment phase is fundamental. When undertaken as a joint exercise, a needs assessment can encourage dialogue between health professionals and community members, so that accurate and complete information is available to both parties when deciding on appropriate actions.

Basic community health needs: Assessing basic health needs begins with identifying and ranking problems, causes, cost of health care, health-seeking behavior, access to health services and medicines—including affordability of medicines and health care and use of medicines by the consumers and providers in the community. Specific needs in relation to problems identified, what the community would like to do to improve its health situation, and community resources that could be mobilized can then be considered.

Community decision-making process and power structures: How does the community work? What are the rules of the group? Who makes them? Who enforces them? How does power depend on sex, age, tribe, kinship, knowledge, money, education? Who makes decisions, and who controls resources at the household and community levels? What are the power relations between women and men, between basic service delivery systems and the community, between community and local authorities, between various socioeconomic and political groups? How do people feel about the decisions that affect their lives and the way these decisions are made?

Education and socialization: How do schooling and traditional education influence people's knowledge, attitudes, and behavior in dealing with health issues, in particular their choice of health care provider and their use of medicines?

Beliefs and values: How do beliefs, ideology, or religion affect people's understanding of health and development?

Basic population data: These data include population, number of households in the community, number of inhabitants living within five kilometers of the nearest health facility, and age and sex distribution.

Facilities and infrastructure: What community facilities (schools, churches, temples, markets), clinics, health posts, pharmacies, shops, drug shops, water supplies,

street lighting, communications, and transport (such as roads or paths) exist?

Past and ongoing health and health-related projects: Are any past, ongoing, or planned projects or programs relevant? Achievements, approaches, constraints, resources, organization, and management of activities; services involved; and potential for coordinating efforts all need to be considered.

Methods. A community needs assessment is not necessarily a formal investigation. Common sense, creativity, and ingenuity can be used to determine the most appropriate methods, modify existing methods, or suggest new methods.

It is important to start by establishing contacts in the community and by identifying key informants who could be useful in providing information and in organizing and facilitating community meetings and group discussions. This information can be gathered in the following ways—

Door-to-door visits (household surveys): Conducting structured or informal interviews at a sample of households.

Group discussions: Holding casual, focused, or deliberately structured discussions at various levels of the community or neighborhood.

Individual discussions: Interviewing private providers and shopkeepers, for example.

Participatory mapping and modeling: Involving community members in making maps (social, demographic, health, water resources), using the ground, floor, or paper. (Box 31-1 provides some tips for participatory mapping. These tips can also be used in other interactions with the community.)

Role-playing: Helping community members describe their situation and needs by taking different roles.

Seasonal diagramming: Determining through discussion with community members, seasonal variation in illnesses, health care costs, access to health services, food availability or shortage, economic difficulties and impact effect on health, and coping mechanisms.

Secondary sources: Reviewing data from files, maps, project reports, population census reports, health center records, or articles.

Transect walks: Systematically walking with informants through an area and observing, asking, listening, discussing; identifying different zones, local technologies, introduced technologies, health-seeking behavior, average distance to nearest health facility, community-felt needs, perceived solutions, opportunities; and mapping and diagramming.

Many tools exist for situational analysis or needs assessment in the community. One example related to availability and use of medicines at the community level is

Box 31-1 Tips for helping in participatory mapping

- Help people get started by letting them do it themselves.
- Be patient. It's their map.
- Look, listen, and learn.
- Facilitate. Don't dominate.
- When community members are mapping, modeling, or diagramming, don't interfere.
- Sit back and watch. Or go away!
- Keep a permanent (paper) record, including mappers' names, to give them credit for their contributions.
- If necessary, suggest that sometimes a succession of maps works better.

Management Sciences for Health's Community Drug Management Assessment tool, which uses household surveys and individual interviewing techniques to study availability of medicines and their use by clients, drug sellers, or providers. This assessment manual is accompanied by an intervention guide to orient decision makers at a variety of levels on the best interventions to improve the availability and use of medicines in the community. Box 31-2 tells how the *Community Drug Management for Childhood Illness: Assessment Manual* can assess the practices of household caregivers or patients and their medicine providers.

Data analysis. When analyzing the data, bear in mind these key points—

Ranking of health problems and health-seeking behavior:

Identify and rank the most important health problems and health-seeking behaviors for each of the major health problems identified and for vulnerable groups, such as children and pregnant women; the health care provider (traditional healer, health center, hospital, community health workers, drug sellers, self); and availability of medicines and average cost of treatment.

Wealth ranking: Identify clusters of households according to wealth, including those considered poorest and unable to pay for health care. Identify mechanisms to help the poor.

Analysis of differences: Seek opinions of all groups within the community and analyze differences in opinion by gender, age, social group, economic group, and occupation.

Trend analysis: Compare people's accounts of the past and the present; their reports of how things have changed (how health status has improved or worsened; changes in the size of families, the status of women, level of education, income, food, and nutrition); and the causes of these changes and trends.

Box 31-2**Assessing management of medicines for childhood illnesses and adult malaria in the community**

The availability, appropriate management, and rational use of medicines are critical to the successful implementation of health programs. Child survival and malaria control programs have shown that identifying and treating patients early and appropriately in the community help prevent illnesses from worsening and reduce mortality. However, activities targeting only the public sector have limited impact because they may not reach households or private-sector providers, where most childhood illnesses and malaria cases are treated.

The Community Drug Management for Childhood Illness (C-DMCI) tool (Nachbar et al. 2003) has been developed to study the practices of household caregivers or patients and their medicine providers for childhood illnesses and adult malaria. This tool helps district health managers, program planners, and regional and national policy makers identify problems in pharmaceutical management in the community at the household and provider levels through a household survey and individual interviews with different providers of medicines in the community. The tool's survey questionnaires are designed to be administered by local community members such as schoolteachers, staff of nongovernmental organizations (NGOs), or others who are not health professionals. Data from the survey responses can then be analyzed by district health teams, national program staff, or NGO staff.

The C-DMCI uses an indicator-based approach to identify strengths and weaknesses of community pharmaceutical management, as well as to provide a systematic method of monitoring the effect of interventions targeting health providers, caregivers, and patients. The data collection instrument for assessing the products and services of drug sellers and health providers focuses on pharmaceutical availability, provider knowledge, and appropriate dispensing in both the private and public sectors. The instrument for assessing the practices of household caregivers and patients provides data on their behaviors and practices when choosing, purchasing, and administering medicines. An accompanying guide

(Ross-Degnan et al. 2008) can help decision makers prioritize problems and design appropriately targeted interventions to improve pharmaceutical management for childhood illnesses and adult malaria in the community.

In Senegal, the Ministry of Health, in collaboration with the Rational Pharmaceutical Management (RPM) Plus Program and the BASICS project, conducted an assessment using the newly developed C-DMCI assessment tool. The survey took place in 2002 in two districts.

Some key findings included—

- Oral rehydration solution (ORS), which is recommended as the first-line treatment for diarrhea, was not available in private pharmacies and was insufficiently available in the public sector.
- Only 56 percent of children with fever took the first-line antimalarial medicine, and fewer than 20 percent of children with pneumonia or diarrhea took the appropriate first-line treatment (co-trimoxazole and ORS, respectively).
- In general, the medicines were not correctly administered in the home, even when instructions were given to caregivers at the time of purchase; only about 60 percent of patients took chloroquine for three days.
- Only about 30 percent of caregivers took children with symptoms of pneumonia for care on the same day symptoms started.

Based on evidence showing wide misuse of antibiotics, the Ministry of Health introduced a policy permitting CHWs, with special training and close supervision, to treat cases of childhood pneumonia with co-trimoxazole. Evaluation showed that nearly 90 percent of workers correctly evaluated, classified, and treated acute respiratory illnesses, and there were no co-trimoxazole stockouts. In addition, nearly twice as many pneumonia cases were treated in intervention areas than in control districts. As a result, the Ministry of Health extended the community-based pneumonia treatment project nationwide.

Local decision making and participatory planning

Using the information collected in the needs assessment, community members, health professionals, and decision makers collaboratively decide what actions need to be taken, how, when, and with what means. The planning process should take place in a climate that fosters two-way communication and mutual learning, so that all stakeholders feel equally involved. The steps in participatory planning are shown in [Box 31-3](#).

Community organization and leadership

Certain actions require collective efforts beyond the capacity of individuals, households, and even health committees and community health workers. The creation or strengthening of community organizational capacity is important for empowerment objectives. Creating organizational capacity can be laborious and time-consuming, but it is vital for ensuring the sustainability of community-based projects. The following tips for health professionals and community leaders can facilitate the process of community organization or group formation—

- Identify charismatic community leaders and strengthen their leadership skills.
- Ensure that the people involved are those who are genuinely concerned with community health.
- Clearly define the specific tasks to be performed by each community representative and health-service representative.
- Build on existing formal and informal functional grassroots structures that have credibility in the

community, to the extent possible. These may include women's groups, youth groups, or religious groups.

- Ensure an equitable representation of women and various socioeconomic groups on village committees.

Participatory monitoring

Information is an essential tool for local decision making, and participatory monitoring offers ways to share information. Increasing beneficiaries' capacity to collect information and use it for action is important: information confers power. By having increased access to information, communities increase their ability to make decisions and gain greater control over their own development.

Participatory monitoring can serve as an educational process, a management tool, and a surveillance system. As an educational process, it increases participants' awareness and understanding of the various factors that affect their health and development in general. As a management tool, it helps measure progress, identify problems, and inform decisions aimed at improving efficiency in the delivery of essential health services, including medicines. Finally, as a surveillance system, participatory monitoring provides community members, health services, and other related services with vital quantitative and qualitative data on the status of community health and nutrition and on consumer behavior. For pharmaceutical management and use, this information might include data on household expenditures for medicines, sources and availability of medicines in the community, and consumer medicine use practices. If the purpose of monitoring is to assess the effectiveness of a particular intervention, then the indicator measured would relate to the intervention's objectives.

Box 31-3

Steps in participatory planning

1. Encourage community members to reflect on problems identified through the needs assessment.
2. Facilitate dialogue on possible solutions, including pros and cons for each solution.
3. Decide on priority areas that need community action.
4. Set clear and measurable objectives.
5. Establish qualitative and quantitative indicators.
6. Determine resources needed to achieve objectives.
7. Determine the ability and willingness of the community to contribute time, money, and labor; what forms of contribution are needed; and what cost-sharing mechanisms will be put in place.
8. Determine the division of responsibility between the community and health professionals (who will do what).
9. Determine mechanisms for monitoring progress, supervision, and technical backup.
10. Identify training needs for community members and health professionals.
11. Determine mechanisms for ensuring transparency in project management and accountability of health services and community-elected bodies to the public they serve.
12. Determine the frequency of community meetings and the most effective channels for reporting to the community on project activities, including the amount of revenue generated and expenditures.

Some of the methods listed for community needs assessment can also be used for monitoring; for example, the door-to-door survey is essential. The main difference between the two processes is that whereas community needs assessment is usually conducted at the beginning of a project, participatory monitoring is continuous.

When developing a community-based monitoring system, the following key components of participatory monitoring should be addressed—

- Organize community members around specific tasks: data collection and analysis, presentation of information for community and health-service feedback, communication of results, facilitation of the interaction about data issues, and coordination of the participatory planning exercise.
 - Provide staff of health and health-related services continuous technical and methodological backup for the process. Use feedback sessions as platforms for maintaining a regular dialogue between service users and providers.
 - Simplify the methodology for gathering and analyzing information, so that those with little formal education can actively participate.
 - Develop a consensus as to what is the most essential information for action at the community and facility levels and what information is needed for monitoring.
 - Focus on information as a powerful tool for local decision making and action and not simply on the generation of data.
- Link community-based planning and monitoring to facility-level planning and monitoring. Information at the community level and the dialogue between health staff and users often generate quantitative and qualitative information that can be vital to improving the performance of health facilities.

31.8 Creating an enabling environment

Community participation rarely emerges on its own without some external influence. It succeeds best within an enabling environment and with the support of appropriate mechanisms at all levels. Conditions that favor the development of community participation include the following (Oakley 1989)—

- Political commitment to community participation in health development and to the general notion of people's participation
- Interest in the decentralization of health services and the corresponding strengthening of district health systems that will serve as the basic health unit for community participation
- Existence of a minimum health structure that can serve as the basis for community participation in health care
- Development of people's managerial capabilities to take responsibility for a process of participatory health development

Country Study 31-4

Creating an enabling environment in the community to encourage tuberculosis treatment compliance

The Cambodian Health Committee, a nongovernmental organization, developed a community-based approach to TB case detection and treatment compliance in Svay Rieng, one of the poorest provinces in Cambodia. Barriers to TB treatment had included a lack of access to health facilities in rural areas and the economic burdens of time spent at and in travel to health centers. The program consisted of two components—one health center based and one home based. Both components relied on a set of interventions that included pretreatment patient education, patient supporters to supervise treatment, a treatment contract, food incentives, surprise home visits, and a microfinance project that established a network of village banks. The banks' low-cost loans to families involved in treatment and the food supplements provided to patients as an incentive to take their medication were special ways of reducing poverty in the

community and raising the public visibility of the TB treatment program.

The program resulted in some of the highest TB case-detection rates in the world; case-notification rates in the home-based program were over four times higher than the national rate of 144 per 100,000 people, and cure rates in new patients were over 90 percent for both health center- and home-based components. Both loan repayment and TB cure rates were close to 100 percent for the 590 families that participated in the village bank loans. The interest charged on the loans was used to train ninety-six village health agents to conduct community education and help with patient detection and follow-up. The use of food gifts as an incentive for treatment compliance was adopted nationwide as part of the Cambodian National TB Program.

Source: Thim et al. 2004.

An enabling approach requires training sessions for community representatives and leaders so that they can acquire basic managerial and organizational skills (group formation, leadership), basic financial management skills (budgeting and accounting), communication skills, and methodologies and skills for local information management (data collection, analysis, presentation of information, and feedback).

Health staff and other development agents can promote participation by providing technical support to—

- Develop local, community-based structures through which people can participate and hold health services accountable
- Maintain a continuous dialogue between service providers and community groups—consultation with communities should take place at all stages of the process, and health committees should work with other community leaders to find feasible mechanisms for regular interaction
- Improve local-level coordination among sectors so that the underlying basis of poor health can be understood
- Gain support from nongovernmental organizations, which can provide additional resources for health as well as play an important role in promoting community participation
- Supervise activities and provide feedback to the district level
- Create enablers and incentives to encourage community involvement in health care

An *enabler* is defined as a stimulus provided to a patient, caregiver, or health care provider to facilitate adherence to treatment; for example, a voucher to cover transportation expenses to attend clinics or to visit patients. An *incentive* is an added stimulus to encourage participation in treatment, such as monthly food baskets for patients if they adhere to treatment norms and make clinic visits, or food or other rewards to community treatment supervisors who properly supervise patients. *Country Study 31-4* shows how a province in Cambodia created an enabling environment for a community-based tuberculosis program.

Finally, community initiatives and participation in health must be seen as part of the broader network of community participation in development and in all social services. ■

ASSESSMENT GUIDE

Enabling factors

- Is there political commitment to community participation in health development?
- Is there interest in the decentralization of health services and the corresponding strengthening of district health systems?
- Does a health structure exist?
- Is there a commitment to developing people's managerial capabilities to enable them to take responsibility?

Community participation indicators

- Do communities contribute money, labor, or materials to health projects or support community health workers?
- Are community members asked for their views and informed of project plans?
- Do community members actively participate in decisions and in the control of resources?
- What mechanisms exist to increase people's access to information, knowledge, and skills and to help them make their goals and priorities known?
- What organizational structures exist at the community level to facilitate participation?
- What community members provide health services or medicines or preventive health messages?

Community participation and pharmaceutical management

- Are community health workers used to help extend health care services to peripheral levels?
- Are they seen as part of the health care system? Are they volunteers?
- Who monitors them?
- What are the main sources of medicines and care in the community?

- What are the availability and use practices of key medicines in the community?
- Do mechanisms exist for consumers to provide feedback to prescribers on the effectiveness of medicines, undesirable side effects, and so on?
- Does community cost sharing exist to help cover the costs of health services and pharmaceutical supply?
- Are communities involved in the management of facility-based health services?

Involvement of health professionals

To what extent do health professionals—

- Establish relationships within the community?
- Share skills and experiences with and learn from the community?
- Ensure service quality through monitoring and supervising community health services?
- Respect people's ideas, skills, and wisdom?
- Promote equity in male-female representation and in the representation of various social, economic, and age groups in local decision-making bodies?
- Respect the social practices, traditions, and culture of the community?
- Foster collaboration with other projects, organizations, and services on behalf of the community?

Community participation in program planning

- Do communities participate in needs assessments?
- Do communities participate in the dissemination of the results?
- Do community members and health professionals plan together what actions need to be taken, how, when, and with what means?
- Are community members involved in monitoring project activities and results?

SUMMARY

Retail drug shops tend to constitute the largest group of recognized outlets for medicines in developing countries, and they are often seen as playing an important role in the community's health. Typically, however, drug sellers are untrained, regulations of shops are unenforced, and the quality of pharmaceuticals that shops sell is not assured.

Systematically improving the services and products offered by drug shops can significantly contribute to national and regional goals for improving public health. If drug shops have legal access to quality pharmaceuticals and well-trained dispensers, and regulatory standards are enforced, shops can help improve access to and appropriate use of medicines and other health care–related products to treat common conditions, particularly among underserved populations.

To develop a program that improves retail drug shops and their operations, an integrated approach is needed that is supported by national and local authorities as well as shop personnel. Certain components are also needed to establish shop standards, ensure pharmaceutical and service quality, improve the availability of essential medications, and establish mechanisms for monitoring adherence to program standards.

An integrated approach to improving retail drug shops using the accreditation model would typically include—

- Development of regulatory standards defining requirements for shop premises, personnel, and dispensing practices

- Training in dispensing and the medicines used for commonly presented medical conditions; continuing education for shop personnel to improve customer service and appropriate medicine use
- A list of essential medicines that can be dispensed legally by an appropriately trained drug seller, along with strict adherence to the standards, established with input from stakeholders, for the quality and types of medicines that are permitted to be stocked
- Incentives such as business training for owners
- Access to loans for improvement of shop premises and expanded inventory
- Establishment of record-keeping systems to allow shop owners to monitor sales, inventory, costs, and profits
- Improved monitoring and supervision mechanisms, including self-monitoring, and regular shop inspections by authorities for regulatory enforcement
- Consumer education to promote the appropriate use of medicines and public demand for quality medicines and competent services from recognized shops

Any approach to strengthen the quality of services offered at retail drug shops must focus on providing safe, affordable, appropriate, and effective pharmaceuticals to populations in need.

A website (<http://www.drugsellerinitiatives.org>) shares experiences and tools from drug seller initiatives to provide a resource for those in any country with an interest in improving access to quality pharmaceutical services and products provided by drug sellers.

32.1 Popularity of retail drug sellers in developing countries

Most people in developing countries get their medicines from retail drug sellers, which are often the most convenient source—for example, in Ghana, the chemical seller shop; in Uganda, the Class C drug shop; in Tanzania, *duka la dawa baridi* (DLDB). Although pharmacies in developing countries may have strong professional identities and well-trained staff to sell prescription medications, both pharmacies and trained pharmacy personnel are limited in number. Retail drug shops, in contrast, tend to be more numerous. They typically constitute the country's largest group of recognized (although historically unaccredited and often unregulated) outlets for nonprescription medicines. These drug outlets dot the countryside, and for those

who do not live in a city, they may be the only nearby place to buy medicines and get health advice on common illnesses such as malaria, acute respiratory infections, and diarrhea.

As small businesses, retail drug shops spring up to meet illness-related needs in their communities, providing over-the-counter medicines and other popular items. For example, caretakers often treat children at home, and retail drug sellers may be their only contact regarding their children's health (Gyapong and Garshong 2007). A review of literature looking at the role of drug sellers in Africa reported that the use of retail drug outlets during child illnesses ranged from 15 to 83 percent, with a median around 50 percent, and that caretakers used retail outlets even when cheaper alternatives existed, such as village health workers (Goodman et al. 2007).

32.2 Problems with retail drug shops

A problem with having retail drug sellers deliver health care is that they are often untrained, and therefore, customers are not counseled on or sold the proper medicines or dosages to treat common ailments. In addition, these shops frequently sell prescription medications that should be legally distributed only by licensed health centers or pharmacies. Not only is this practice unlawful, but it also likely results in incorrectly or inappropriately stored and dispensed medicines. As a result, consumers may receive medicines that are ineffective or dangerous for their condition. A 2001 assessment of Tanzania (CPM 2003b) found that few dispensers at DLDB dispensed malaria treatment according to guidelines, and other studies have found similar results (for example, Abuya et al. 2007).

Although governments recognize these dangers to public health, actions to shut down or punitively regulate retail drug shops have been almost universally unsuccessful. Most drug shops are seen as playing an indispensable role in their community's health system, especially in areas without licensed pharmacies. An increase in the number of drug sellers who legally dispense common medicines in an appropriate way would have the potential to help many people in many countries.

Overall, estimating precisely how many people could benefit from improving the quality of products and services through enhanced retail drug seller interventions is difficult; however, retail drug outlets are clearly far more accessible to populations in need than pharmacies or public health facilities. Country assessments (CPM 2003a, 2003b) estimated that Tanzania had more DLDB than all other health facilities—public and private—combined (4,627, compared with 4,288); Ghana had almost 1,000 pharmacies, located almost exclusively in urban areas, with almost 8,000 registered chemical sellers and possibly 2,000 more that were unregistered. A 2008 analysis of the pharmaceutical sector in Uganda estimated that the country had nearly 4,000 Class C drug shops (EADSI 2008). This scenario is common in many developing countries, and it illustrates the potentially broad effect of improving the quality of products and services in retail drug outlets and the huge impact closure of these shops would have on access to medicines.

Systematically improving the services and products offered by drug shops can contribute significantly to national and regional goals for improving public health. If drug shops can legally sell selected prescription medicines and have access to quality pharmaceuticals and better trained dispensers, and if regulatory standards are in place and enforced, then shops can improve access to and appropriate use of medicines and other health care-related products, particularly among underserved populations.

32.3 Strengthening the role of retail drug shops

Health managers, drug regulators, or policy makers who would like to expand access to quality pharmaceuticals should consider what role retail drug shops can play in the population. Licensed pharmacies need not be the only acceptable alternatives for improving access to and rational use of medicines. Although retail drug shops are often unregulated, consumers with longstanding habits of buying from these shops will continue to turn to them, even when such consumers have other choices to access medicines.

Taking a course of action and encouraging participation

Any approach to strengthen the quality of services offered at retail drug shops must focus on providing safe, affordable, appropriate, and effective pharmaceuticals to populations in need. The program must establish standards and requirements related to physical premises and operations before existing shops can be upgraded or new shops opened. Community-level input will help determine how to develop a drug shop initiative that best fits the specific context.

An integrated program to establish retail drug shops as a source for quality medicines must work with current drug shop owners to improve or upgrade existing retail drug shops. Consider the number of drug retail shops in the area and the quality of the services they offer, and explore incentives that may motivate existing owners to participate in a program. Many owners favorably perceive opportunities for developing new business and improving the quality of services. In addition, observing the successful conversion of an existing shop provides a powerful incentive for owners to join in. In a drug seller accreditation program in Tanzania, every DLDB owner in the pilot region of Ruvuma participated in the conversion process.

Relying on single-focus interventions for improving drug shops

Efforts to improve retail drug shops and increase access to quality medicines often rely on single-focus interventions. For example, some programs may try to improve access by educating people who dispense medicines. Others could focus on improving owners' management practices, strengthening regulations or regulatory agencies, or using social marketing for particular products. Some examples of the successes and limits of each type of intervention follow.

Educating dispensers. Educational interventions have trained dispensers to improve their knowledge and skills so they can provide appropriate treatment. Yet many factors

other than knowledge guide dispensers in the private sector (for instance, the desire to make a profit from selling drugs). To improve their effectiveness, some educational interventions have used persuasive face-to-face discussions that focus on particular problem behaviors in interactions between dispensers and consumers, such as unclear messages about when to stop taking a medicine. Some interventions have successfully included peer group discussions to

educate participants on standards set by regulatory bodies or professional societies. [Country Study 32-1](#) describes some drug seller education approaches and results in Africa.

Establishing regulations. Regulatory interventions may attempt to ban shops from selling prescription medicines without legally approved prescription authority. These efforts can prove counterproductive, especially in communities where unauthorized or unregulated shops pro-

Country Study 32-1

Retail drug seller education approaches and results in sub-Saharan Africa

Kenya

Approach: Conducting workshop training for groups of drug retailers combined with community information activities in rural Kenya. The initial drug seller training lasted four days, with annual one-day refresher workshops over the following years. Successful sellers were awarded certificates of satisfactory training in public ceremonies, and posters were displayed outside their shops showing that they had been accredited by the Ministry of Health. Public information activities to create awareness of the program focused on identifying trained retailers and giving information on the importance of early effective treatment for malaria in children, changes in malaria treatment policy, and situations for referrals. Trainers attended public gatherings (women's groups, school groups, and so on), handed out posters, and showed the program logo; local dance and drama groups conveyed program messages.

Results: The proportion of over-the-counter antimalarial medicines sold in an adequate dose rose from 8 percent to 64 percent in the intervention areas. In addition, the proportion of shop-treated childhood fevers receiving an adequate dose of a recommended antimalarial within twenty-four hours rose from 1 percent to 28 percent.

Approach: Training and equipping pharmaceutical wholesalers, both mobile drug vendors and wholesale counter attendants, to serve as volunteer outreach educators of new malaria guidelines to their drug retailer clients during normal business interactions ("vendor-to-vendor"). Components of the program included a shopkeeper job aid for a retailer to consult when selling antimalarial medicines; a client awareness poster to hang near the entrance of the outlet to generate consumer demand for the five approved brands of sulfadoxine-pyrimethamine (SP) and to communicate that SP was now available over the counter; orientation of wholesale owners; training and equipping of mobile vendors and wholesale counter attendants; and monitoring. Each

wholesaler trainee received a receipt book to record the names of the recipients of posters and to obtain their agreement to comply with the new guidelines. At the end of the training, all wholesalers received caps and shirts with the malaria dosage chart on the front.

Results: During the first six months, approximately 450–500 private drug outlets were reached. The intervention affected stocking patterns, malaria knowledge, and prescribing practices of shops and kiosks significantly, but not consistently for other types of outlets. About 32 percent of shops receiving job aids prescribed the approved first-line treatment, SP, compared to 3 percent of the control shops.

Nigeria and Uganda

Approach: The Basic Support for Institutionalizing Child Survival project designed an intervention in Nigeria that combined a short, highly focused training for patent medicine vendors with the promotion of age-specific, color-coded, prepackaged antimalarials for children under five. These activities were supported by a comprehensive social marketing and behavior change strategy, which included mass media promoting the new prepackaged antimalarials and display of shop identifiers from the training by patent medicine vendors. More than 800 medicine vendors were trained in a two-month period at the relatively low cost of about 8 U.S. dollars each. Training materials focused on immediate treatment of children under five with fever, using an appropriate dose (preferably prepackaged) of an antimalarial.

Results: Examples of postintervention assessment results showed that the number of patent medicine vendors giving the correct antimalarial and dose increased from 9 percent to 53 percent after the intervention. Also, knowledge of patent medicine vendors about the need to use insecticide-treated nets tripled (21 percent to 65 percent) between pre- and postintervention surveys.

Sources: Marsh et al. 2004; Tavrow, Shabahang, and Makama 2003; Greer et al. 2004.

vide the only available access to medicines. National or regional authorities can unilaterally introduce regulations, but enforcement may be sporadic, in part because limited resources often keep regulatory efforts from being consistent or sustainable.

Program managers need a balanced approach to developing regulations that will maintain consistent, reliable, and verifiable quality services. Program managers can create incentives that encourage shop owners to abide by regulations while making sure the owners understand what will happen if they do not comply.

Social marketing. Social marketing of condoms, contraceptives, and bed nets often uses techniques such as advertising campaigns to introduce new products through retail drug shops. For example, interventions have been used to help prevent the transmission of HIV by promoting the use of condoms and to help prevent malaria infection by encouraging the use of bed nets.

Although frequently implemented, single-focus interventions typically are less effective than programs that weave together multiple interventions as part of an integrated, holistic approach (Shah, Brieger, and Peters 2011).

32.4 Improving drug shops through an integrated approach

To develop a program that improves retail drug shops, an integrated approach that is supported by national and local authorities as well as shop personnel is needed. The program can include the proven single-focus practices that are consistent with the goals and resources available. Certain components are also needed to establish shop standards, ensure pharmaceutical and service quality, improve the availability of essential medications, and establish mechanisms for monitoring adherence to program standards.

Identifying the components of an effective integrated approach

An integrated approach to improving retail drug shops would typically include—

- Development of regulatory standards defining requirements for shop premises and dispensing practice
- Training in dispensing and the medicines used for commonly presented medical conditions; continuing education for shop personnel to improve customer service and appropriate drug use
- A list of essential medicines that can be legally dispensed by an appropriately trained drug seller, along with strict adherence to the standards, established with input from stakeholders, for the quality and types of medicines that are permitted to be stocked

- Incentives such as business training for owners to improve business practices, inventory control, marketing, and profitability
- Access to loans for improving shop premises and expanding inventory
- Availability of and training on the use of forms to help ensure accurate record keeping to allow shop owners to monitor sales, inventory, costs, and profits
- Improved monitoring and supervision mechanisms, including self-monitoring, and regular shop inspections by authorities for regulatory enforcement
- Consumer education to promote the appropriate use of medicines and public demand for quality medicines and competent services from recognized shops

National versus program standards

Many countries use a national drug regulatory authority or the ministry of health to establish national standards for essential medicine lists, treatment guidelines, and appropriate medicine use. If standards for pharmaceutical premises exist in a country, they should define the minimum required to operate a drug shop under the law. A national effort to strengthen drug shops and sellers to ensure expanded provision of quality products and services to the community would require review and revision of existing laws and regulations. For example, an accredited drug seller initiative might require new standards for training and shop premises that would have to be met and that would be enforced. Failure of a drug shop to comply would result in loss of accreditation or shop closure.

Individual shop owners or franchisees of shops can go beyond the minimum level required by law and regulations to set their operations and services apart from the competition. Individual or franchise standards, however, need to be consistent with existing national standards.

Stakeholder engagement

An integrated approach should include engagement not only with drug shop owners, dispensers, consumers, and health care providers, but also with other stakeholders concerned with public health issues, such as local government officials. Stakeholders need to work together to find ways to make drug shops and sellers effective and reliable partners in national health care delivery efforts. A successful program should seek to change the behaviors and expectations of individuals and groups that use, own, work in, or regulate drug shops.

Best practices

An integrated approach needs to encourage owners and dispensers to apply the following best practices.

Country Study 32-2 The drug shop accreditation process in Tanzania

The following example describes an integrated accreditation approach, adopted by a food and drug authority and ministry of health, that has improved retail drug shops and enhanced the availability and quality of the medicines that these shops sell.

The Tanzania Food and Drugs Authority (TFDA) had a plan to license nonpharmacy drug shops to improve public access to basic over-the-counter drugs in areas with few registered pharmacies. However, the drugs authority lacked the human and financial resources to make the plan succeed. Many drug shops, known as *duka la dawa baridi*, sold prescription drugs illegally; their dispensing staff often lacked basic dispensing training; and many operated without valid licenses from authorities.

Assessment of DLDBs

The Ministry of Health and Social Welfare assessed the DLDB in 2001 with assistance from the Strategies for Enhancing Access to Medicines (SEAM) Program (CPM 2003b) and found that the DLDB prices tended to be higher than those in all other outlets. Drugs in stock were frequently unregistered or purchased from unlicensed suppliers, so quality could not be assured. Many DLDB owners purchased illegal stock, including pharmaceuticals diverted from the public sectors of Tanzania and neighboring countries. Nonetheless, DLDB flourished. They were convenient, registered pharmacies were absent, and public health centers had stockout rates of 20 to 30 percent.

New approach

The TFDA and Ministry of Health and Social Welfare decided to explore new approaches to improve access to

affordable, quality pharmaceuticals and services in rural or periurban areas. A pilot program, developed in collaboration with the SEAM Program, aimed at establishing a regulated system of accredited drug-dispensing outlets (ADDOs) to provide a limited list of essential prescription medicines in addition to nonprescription medications and other health supplies. The list of prescription medicines they could sell was based on the medicines authorized for public primary health care facilities.

The program formulated an integrated approach for the ADDOs to—

- Improve shop premises to provide better customer service and to ensure adequate storage and security for the expanded list of medicines approved for sale
- Help ensure access to financial resources, if needed, to improve shop premises and increase inventory
- Train dispensers in good dispensing practices, treatment guidelines, communication skills, and quality control
- Provide training in business skills, regulations, and business ethics for shop owners and dispensers
- Strengthen the ward, district, and regional systems under which all the drug shops operate, which include systems for processing accreditation applications, scheduling regular inspections, and reporting to TFDA

Use of formative research

Before any ADDOs opened, the program conducted research among consumers, shop owners, shop staff, community leaders, health care providers, and political authorities.

For owners—

- Provide quality medicines at affordable prices that are appropriate to local market needs.
- Meet all premises standards required, including maintenance of adequate storage facilities.
- Hire licensed, trained, and skilled dispensers (or work in the shop yourself as a licensed, trained, and skilled dispenser).
- Facilitate access to refresher training to upgrade dispensers' skills.
- Maintain accurate records of pharmaceuticals, financial transactions, patient information, and other useful data.

- Meet all regulatory, accrediting, and licensing standards and fulfill reporting obligations.
- Meet ethical standards and responsibilities.
- Work to ensure that essential, quality medicines are available at all times.

For dispensers—

- Listen to the customer's request, and serve or advise him or her appropriately, following established protocols.
- Provide appropriate information or advice about the medicines dispensed or, if needed, referral to a clinic for needed care.

The results indicated almost unanimous concern about the quality and origin of drugs sold by the DLDBs. All stakeholders wanted trained dispensers who could provide quality medications at reasonable prices. However, the owners preferred limited regulation by the government.

SEAM sponsored formal and informal discussions and consultations to foster broad support for the ADDO program strategy as well as ownership and partnership in the change process. Based on research and discussions, the final ADDO components balanced program objectives with measures to encourage DLDB owners' participation.

ADDO program components for standards and incentives

Component	Process or requirements
Accreditation application process	A Council Food and Drugs Committee is responsible for a four-part application process for shops: an application form, initial inspection of the existing facility, reinspection after any structural changes required for accreditation, and ongoing inspection after accreditation.
Incentives for owners	Owner incentives focus on improved shop profitability and approval to sell a range of prescription medications. Incentives for owners who commit to standards include access to microfinancing for stock purchases, a marketing campaign encouraging consumers to buy ADDO-provided products and services, and more reliable sources of affordable, quality wholesale pharmaceuticals.
Building/infrastructure	The standards provide instructions for premises, layout, identification, dispensing and services areas, storage, and security.
Staff qualifications	The minimum entry-level training for ADDO dispenser candidates is currently that of a nurse assistant, with plans to expand the qualifications to any secondary school graduate.
Medicine quality	The list of products approved for sale by ADDOs includes the full range of over-the-counter medicines and a limited list of prescription medicines, including common antibiotics and oral contraceptives. ADDOs may sell only those products registered with and approved by the TFDA.
Training and continuing education	All dispensers must be accredited by the TFDA, display their accreditation certificate at their place of employment, and wear their photo identification when working. Accreditation involves completing a TFDA-approved, module-based dispensers' course. Training topics include information on medicines that are authorized to be dispensed by ADDOs; symptoms of commonly encountered medical conditions and protocols for handling patients presenting with symptoms, including referral, when needed; treatment dosages, side effects, and patient information; laws governing dispensers' work; basic business management, record keeping, and ethics; and communication skills. Continuing education is a part of maintaining dispenser accreditation. Training for ADDO shop owners focuses on ethics, regulations, and improvement of business management skills.
Record keeping	ADDOs must account for all prescription drugs sold and their selling prices, financial and sales records, and expired medications. These records may be used for supervision purposes and must be available for review by inspectors.
Regulation, inspection, and sanctions	Local government officials receive a basic inspection training course from the TFDA and are certified as local TFDA inspectors. TFDA conducts a minimum of two inspections of each shop per year, and local inspectors inspect quarterly.
ADDO-restricted wholesalers	Approved wholesalers can receive a license to sell nonprescription and ADDO-approved prescription drugs under the supervision of a full-time pharmaceutical technician.

- Provide appropriate information or advice for self-care if a medicine is not required or recommended.
- Appropriately promote associated products or services connected to the customer's needs (for example, recommend insecticide-treated nets to families at risk of malaria).
- Refer customers to a qualified health provider for services beyond the scope of the shop.
- Communicate effectively with customers who demand inappropriate services or medicines by being firm and providing explanations as to why the service or product should not be used.
- Maintain a customer-oriented attitude that meets ethical standards and responsibilities.

32.5 Borrowing from accreditation and franchising

How can shop owners be encouraged to adopt best practices and cooperate with an improvement program? Accreditation and franchising can offer shop owners some positive incentives. Within the community context, consider elements from these approaches and incorporate the elements that best fit into the program.

Accreditation

Accreditation of drug shops includes certifying or licensing dispensers, identifying shops as members of a group that

meets accreditation standards, and monitoring their ongoing adherence to standards. Accredited shops may become more acceptable to consumers than nonaccredited shops, but acceptance should be encouraged with a marketing campaign to inform consumers which shops are accredited and why this is important to them.

For example, the Tanzania Food and Drugs Authority (TFDA) and the Ministry of Health and Social Welfare developed a pilot program to establish a regulated system of licensed retail drug outlets, known as accredited drug-dispensing outlets (ADDOs), which has now been scaled up nationwide. The government accredits ADDOs to provide an expanded selection of drugs, including some prescription medicines, and other supplies. The program has provided ADDOs with links to organizations and agencies that provide financial support and reliable access to sources of quality wholesale goods. [Country Study 32-2](#) describes this example in more detail.

Franchising

Franchising encourages existing or potential shop owners to invest in shops to meet franchise standards as well as government licensing criteria. Shop owners gain the right to operate under the franchise name as long as they meet and

maintain the franchise standards. [Box 32-1](#) describes how a franchise program works.

In Ghana, a for-profit group established the CAREshop® franchise, which sets its own standards in addition to meeting government licensure and operational requirements. The franchisor provided franchisee training and supervision and negotiated with suppliers for quality medicines at competitive prices. [Table 32-1](#) summarizes the CAREshop franchise standards; note that the CAREshop franchise is no longer active, although individual shops remain in operation.

In Kenya, a nongovernmental organization called the HealthStore Foundation® developed a drug shop and clinic franchise. It consists of a network of Child and Family Wellness Shops (CFWshops™) and clinics, which are owned and managed by Kenyan community health workers and nurses. The franchisor provides franchisees with training, supervision, and access to microcredit. The franchisor also procures quality, essential pharmaceuticals for resale to franchisees at affordable prices. [Country Study 32-3](#) describes the program in more detail.

How accreditation differs from franchising

Accreditation and franchising are not mutually exclusive. Governments can establish accreditation programs to reach

Box 32-1

How a franchise program works

Requirements

Franchising programs for drug shops operate within government pharmaceutical standards and regulations, under the authority of the ministry of health and other agencies charged with licensing and overseeing legal requirements for health care facilities and products. In addition, all franchising programs require—

- Commitment to performance standards that have been agreed upon and established so customers find quality pharmaceuticals and services in every shop
- Compliance with established standards, with monitoring through a system that reviews adherence and gradually increases self-regulation, which the franchisor verifies through periodic checks
- Fees for entering into the franchise and for remaining a member

Benefits to shop owners

In return for participation and fees, the franchisor provides benefits to owners and staff, including—

- Training, both initial and ongoing, for drug shop workers, supervisors, and owners

- Access to competitively priced quality drugs and health care supplies on a consistent basis
- Incentives such as business plans and franchisor backing that facilitates access to microfinancing and loans at market rates
- Designation as a franchise member
- Marketing of program standards and identity (brand marketing) that distinguish the quality of franchisee-provided medicines and services from those offered by competitors
- Opportunities for making a profit that is maintained or enhanced through ongoing participation and compliance

Benefits to consumers

Well-organized franchises of drug shops can benefit the public, particularly in underserved communities. Customers receive—

- Improved pharmaceutical services and steady supplies of medicine
- Quality, essential medicines at competitive prices

Table 32-1 Ghana CAREshop franchise standards and benefits

Operational area	Requirements	Benefits
Standards implemented by the shop owners in the franchise		
Building/infrastructure	<ul style="list-style-type: none"> • Paint exterior using the approved colors • Provide interior shelving and ventilation • Adhere to the cleanliness standards 	<ul style="list-style-type: none"> • Franchise identification • Better customer service • Improved quality of services
Medicines in stock	<ul style="list-style-type: none"> • Procure only those drugs provided by the franchisor in compliance with the Pharmacy Council's approved list and have them delivered to the door 	<ul style="list-style-type: none"> • Reduced cost of inventory • Assured availability of products
Minimum staff qualifications	<ul style="list-style-type: none"> • Meet all Pharmacy Council license requirements 	<ul style="list-style-type: none"> • Better customer service • Improved rational drug use • Better pharmaceutical practices
Training and continuing education	<ul style="list-style-type: none"> • Complete a franchise training course in business, disease recognition, and record keeping • Participate in continuing education to maintain participation in the franchise 	<ul style="list-style-type: none"> • Improved customer service • Improved rational drug use • Enhanced sustainability • New disease-related data for the ministry of health • Better business practices and improved services
Record keeping	<ul style="list-style-type: none"> • Keep standardized inventory, sales, and customer request records to track shop performance and create community health profiles 	<ul style="list-style-type: none"> • Decreased stockouts of needed medicines • Improved profitability • Improved planning and decision making by the ministry of health
Standards implemented by the franchisor		
Medicine availability and quality	<ul style="list-style-type: none"> • Conduct quantification and tendering with suppliers on behalf of all shops • Buy only government-approved products from reliable sources 	<ul style="list-style-type: none"> • Quality products at a competitive price • Consistent availability of drugs • Enhanced profitability
Supervision and inspection	<ul style="list-style-type: none"> • Supervise and inspect the shops to maintain the quality of services and ensure compliance to franchise standards 	<ul style="list-style-type: none"> • Provision of quality care and products • Identification of problem areas • Improvement of performance

targeted areas underserved by pharmacies, while the private or nongovernmental organization sector can establish a franchising network for new or improved retail drug shops. In this way, both approaches can help fulfill the public health goals of access to and rational use of affordable, quality medicines.

Accreditation has many of the same requirements and benefits that franchising has, but with some important differences. Unlike franchisee shops, accredited shops generally remain small, independent businesses. They do not pay fees to a franchisor, nor do they receive the benefits of being part of a larger franchise system. The franchisor generally provides training and training updates to shops belonging to a franchise, whereas training for nonfranchise shop owners and dispensers to meet accreditation standards would have to come from outside organizations such as schools of pharmacy and regional training centers that offer routine, planned courses. Some franchise shops may seek additional training from outside agencies to address specific needs. Training agency courses typically are certified by an appropriate authority, and students pay course fees either directly or indirectly through their employer.

32.6 Taking steps to improve retail drug shops

A successful, integrated program requires that stakeholders' needs, interests, and expectations be taken into account. Typical stakeholders for drug shop accreditation or franchising programs include consumers, shop owners, shop dispensers, community leaders, health care leaders, and political and civic leaders. The availability of funding, partnerships, training, communications, and other resources must be determined. This section outlines the major steps involved in developing an improvement program including identifying stakeholder needs, expectations, and potential roles and formulating appropriate program components for the context.

Use formative research

As a first step, conduct research to gather local data for program planning and implementation. Formative research, which engages stakeholders through focus group discussions or other qualitative methods, can help gather information from stakeholders while involving them in the change process from the start. Failing to learn about stakeholder

Country Study 32-3

Improving pharmaceutical access and quality using franchising in Kenya

The majority of Kenyans living in rural areas get their basic essential medicines from shopkeepers in nearby markets. The Bamako Initiative established village pharmacies run by community health workers (CHWs) in certain districts. The high attrition rate in CHWs has been attributed to the difficulties they have in maintaining their activities without external support, including lack of sustained supervision or continuing education and the high cost of medicines they must purchase at wholesale pharmacies.

The Sustainable Healthcare Enterprise Foundation (now the HealthStore Foundation) established the Child and Family Wellness Shops (CFWshops™) in Kenya to engage CHWs and nurses working in their rural communities to provide access to essential health care commodities and services in a sustainable manner. The network targets the five to ten diseases causing 70 to 90 percent of morbidity and mortality among children and their families, while also providing basic health services and other products. It combines micro-enterprise and franchise principles to enable qualified CHWs and nurses to own and operate drug shops and medical clinics in underserved areas.

The franchise system provides standardized training in business and franchise management, medicine and client services management, and public health interventions in the community, including child survival interventions for malaria and acute respiratory infection. The franchisees receive a microloan that covers the costs of four-week training, initial pharmaceutical stock, and equipment and shop infrastructure. Once trained, the

franchisees run drug shops or clinics in easily accessible market centers and receive ongoing supervision and mentoring support from field-based supervisors employed by the CFWshops organization. The franchisees are required to purchase their pharmaceutical supplies through the HealthStore Foundation to ensure quality and to adhere to franchise rules for service delivery. The franchisees are licensed by the Kenyan Ministry of Health and also receive continuing education from the HealthStore Foundation to adhere to national treatment guidelines.

The first eleven shops opened in April 2000, and by 2010, 76 shops had opened and served almost 500,000 patients that year. In 2003, the HealthStore Foundation added its first medical clinic to the network of CFWshops. The clinics are franchised like the drug shops but are owned and operated by nurses who can supply a wider range of medicines and health services than provided by the drug shops.

The franchised outlets provide their communities with a reliable source of quality-assured essential medicines, delivered by a trained health worker who adheres to certain standards of service prescribed by the franchise agreement. The franchisee runs a for-profit enterprise on a full-time basis, which provides him or her with an income that ensures sustainability of the initiative. Ongoing supervision support and continuing education also contribute to the sustainability of the venture.

See <http://www.healthstore.org> for more information.

interests not only can discourage stakeholder interest in joining or collaborating with the program, but also can handicap understanding of what is going to be required to make the program work and ultimately undermine adherence to any new or existing standards.

The keys to formative research are keeping an open mind and using good listening and recording skills to gather data. Formative research is a two-way street: learning from stakeholders while involving them in the improvement process. Stakeholders may be engaged several times during the research and planning process. A sample formative research process includes—

- Interviewing a few key individuals to learn their points of view

- Presenting preliminary ideas to small focus groups of stakeholders to hear what they think of your initial program proposal
- Developing broad stakeholder commitment to improvements by sharing the program design and implementation process through dissemination workshops

Focus group discussions are particularly effective for gathering information from stakeholders while at the same time raising awareness about health and related issues, such as licensing drug shops. A focus group typically brings together a group of five to twelve people who have something in common, for example, groups of consumers, pharmaceutical professionals, or new mothers. Information from

focus group discussions can provide the basis for designing improved systems to meet as many different expectations as possible and developing communications and marketing plans to educate stakeholders and promote consumers' use of improved shops.

Establish key components with stakeholders

The second step of the design phase involves exploring with stakeholders the key components of the program, such as drug shop standards, incentives for shop owners, and ways to monitor and supervise drug shops' quality.

Every shop improvement program needs to establish standards in the following areas—

- Building/infrastructure
- Essential medicines lists
- Product quality
- Staff qualifications
- Training and continuing education
- Record keeping
- Regulation and inspection

Building/infrastructure. All participating retail drug shops in accreditation and franchising enterprises should arrange for the prominent display of signs and the logo of the enterprise. Some programs require owners to paint their shops with specific colors. Standards for the shops' interior and storage areas must include level of cleanliness and specifications for shelving, counters, and other physical requirements.

Essential medicines lists. National health authorities usually have an established list of essential medicines for primary health care centers, which can form the basis for a program list. If shops are to stock an expanded list of medicines, such as common antibiotics, close work with public health and regulatory authorities will be necessary to meet their regulations and standards and change the regulation, if necessary. For example, the program may need to train retail drug shop dispensers in the rational use of medicines and treatments for common illnesses and regularly supervise and monitor dispensers' performance to meet standards to dispense certain medicines. An understanding of how essential medicines are distributed is also required. In addition to keeping accurate records on essential medicines, the program should get a baseline estimate of how many and what types of unregistered health products are being sold.

Product quality. All programs require participating shops to purchase their medicines and supplies from approved sources of supply. Franchisees must purchase from the franchisor, while accredited shops need to purchase from licensed wholesalers. Programs should provide owners and dispensers with training in pharmaceutical procurement

and inventory management. Adhering to program standards and training is very important.

Staff qualifications. Although the ideal dispensers at retail drug shops are trained pharmacy providers, the program will need to consider local labor markets and other factors. Different programs may adopt various minimum certification requirements for dispensers that depend on their education, in-service training, the drugs they will dispense, and the level of skills that are generally available in the labor market. For example, in Tanzania, because of the shortage of pharmaceutical personnel, ADDO dispensers are required to be trained nurse assistants at a minimum. The program may want certification by a recognized board or authority. Most accredited programs insist that all dispensers display their accreditation certificate at work and may require them to wear identification cards with photographs.

Training and continuing education. Improvement programs need to provide training for both dispensers and owners. Data from focus group discussions can help develop training and continuing education programs that will encourage owners to join the program and improve their services and profitability. A professional organization, such as a school of pharmacy, or a regional training center may provide training. Programs ideally provide periodic continuing education and require participation for reaccreditation or ongoing franchising approval. Some programs tie continuing education topics and requirements to the results of supervisory visits.

Conveying good business practices to shop owners as well as what sort of price markups are commonly applied throughout the distribution system, from wholesalers to products for sale to consumers, is helpful. A simple price survey can compile pricing data.

Record keeping. Standards should include a record of drugs sold, with an emphasis on prescription medicines. Other data collected may include basic demographic information about customers, expired medicines, and medicine purchase and sale prices. Programs generally use standardized forms for recording all required information and train owners and dispensers in filling them out.

Regulation and inspection. Designing and implementing regular supervision and inspection helps motivate owners and dispensers to maintain the required standards, ensures a consistent level of quality across the network, and inspires customer loyalty. Inspection needs to cover all drug shops, not just accredited shops, to prevent nonaccredited shops from selling prescription medicines and undermining the incentive for accredited shops to maintain standards. All owners need to know that they will be inspected regularly and that they will suffer sanctions for violations.

Incentives. In a comprehensive program, a balance is necessary between standards, with which shop owners must comply, and incentives, which can motivate drug shop

owners to participate in an improvement program, whether for accreditation or as part of a franchise. Make these incentives clear when recruiting owners to join the program.

Financial management. The most powerful retail incentives for shop owners are those that improve profitability, give the shops a competitive edge, and are exclusive to the shops. Shop owners can benefit from a more complete understanding of distribution systems and pricing methods. They also need to know the financial dimensions of related incentives, including—

- Legal approval to sell a range of prescription drugs
- Training for owners and dispensers
- Access to financing to purchase stock or implement building improvements
- A marketing campaign that promotes brand recognition and encourages consumers to buy drugs from network shops
- Access to convenient and reasonably priced wholesale services
- Reassessment of taxes and license fees, combined with fair and even-handed enforcement and collection, to accurately reflect shop revenue

Business ethics. Fulfilling a community social mission may motivate some owners. They may find that owning a business that provides a valuable service to the local population can give them status and a sense of personal satisfaction. Formative research will indicate whether this type of incentive will attract potential participants to the network. Over the long term, however, shop owners will remain in the network only if the financial benefits of participating are greater than the perceived costs. If their participation increases sales, customer volume, and technical skills while improving access to quality medicines without significantly increasing medicine costs, then the owners will be more likely to continue their participation.

Monitoring and supervision. Monitoring the performance of the drug shops participating in the network may be the most important supporting element of the program. It can foster a consistent level of excellence in the products and services at each shop. Monitoring or supervision activities that reinforce tangible improvement and practical training are less likely to be perceived by owners as burdensome or intrusive. Monitoring and supervision efforts in which inspectors, owners, and dispensers work together to identify problems and find solutions are more effective than efforts focused exclusively on identifying errors or noncompliance. At an accredited drug shop in Uganda, the drug seller said, “We used to run away from the inspectors because they used to come and close our shops and remove the medicines that we were not supposed to have. . . . Now that the National Drug Authority allows us to have antibiotics and other medicines, we don’t

keep these medicines hidden away or run from the inspectors like we used to do.”

Marketing and communications

The last major step for developing the program requires planning ongoing communication with stakeholders, including shop owners and customers, who can help market the program and educate consumers. The program needs to motivate shop owners to join, to maintain established standards, and to monitor their own performance. Local monitors of the Accredited Drug Shop program in Uganda reported that owners and sellers in accredited shops were now watching out for and reporting unlicensed shops to authorities. The program also needs to motivate consumers to recognize the program’s quality brand and purchase their medicines through “branded” shops. Educating consumers on what constitutes quality in retail drug shops and why visiting a branded shop can make a difference to their health is important to success.

Develop and implement a communication plan for general consumer awareness and the program’s brand by carrying out a market analysis, developing key communication messages for different groups of customers, and identifying and implementing communication activities using print and other media, such as radio announcements and billboards.

Sustaining the quality of drug shops and services

As a comprehensive drug shop improvement program that uses accreditation or franchising measures is developed, a foundation should be laid to sustain the shops over the long term. If the program is successful on a small scale, pressure will arise to not only sustain the current operations but also to expand the program model. It is logical to assume that problem areas experienced during a pilot program will loom larger during scale-up. Consider sustainability within the context of growth, and prepare the program for the future by following through on carefully planned actions. These actions may not guarantee the program sustained success and growth, but they will put the program in a strong position to face future challenges. The following actions will help sustain the program—

- Touch base with stakeholder groups periodically and use their feedback to make program adjustments.
- Review lessons learned from the training program once a year, and revise materials as needed.
- Put reporting mechanisms in place to help track performance, and give feedback and support in a timely manner if performance fails to adhere to standards.
- Closely monitor the financial performance and stability of individual shops, including increases in

Box 32-2 Drug Shop Provider Association tool kit

As part of a project funded by the Rockefeller Foundation, Management Sciences for Health developed a tool kit to facilitate the expansion of ADDO associations in Tanzania; however, the tools can be adapted for use in any context. The tool kit was finalized through a consultative stakeholder workshop. It includes seven operational and management tools, which are available in English and Kiswahili—

- Roles, responsibilities, and benefits of ADDO provider associations
- How to form and register an ADDO provider association
- Basic components of a model constitution for ADDO provider associations
- How to plan and manage activities for ADDO provider associations
- How to mobilize financial resources for ADDO provider associations

- Institutional networking and coordination mechanisms for ADDO provider associations
- How to document, monitor, and evaluate activities

In addition, the tool kit includes additional promotional and orientation materials—

- Advocacy guide for the national-, regional-, and district-level stakeholders
- Promotional banners
- Presentation slides for provider association orientation
- A DVD produced by a local consultant, MediaNet, that ADDO providers can view to become familiar with the association concept

The tool kit is available in Appendix C of the project report: <http://www.drugsellerinitiatives.org/DSI-PDF-Documents/upload/40-Rockefeller-ADDO-Association-Final-Report-MSH-Dec-2010.pdf>.

profitability and the timeliness of meeting payment schedules.

- Develop solid wholesale operations or link to reputable established operations that will allow shops to more easily access affordable, quality pharmaceuticals, pass on savings to the consumer, and stay financially stable.
- Continue to use communication activities to influence consumer behavior and encourage shop owners and dispensers to adhere to standards.
- Solicit long-term support for networks of drug shops by encouraging providers and medical authorities to recognize the vital role that retail drug shops play in ensuring access to quality pharmaceuticals and services in areas that would not otherwise be served.
- Promote the establishment and strengthening of owner and dispenser associations as a mechanism to increase product and service quality and promote sustainability. [Box 32-2](#) provides information on a provider association tool kit.

[Country Study 32-4](#) describes how multiple national and international stakeholders contributed to the successful expansion of the ADDO program in Tanzania.

Management Sciences for Health (MSH) has put together a website (<http://www.drugsellerinitiatives.org>) whose purpose is to share initiative experiences and tools of drug sellers and others to provide a resource for those with an interest in improving access to quality pharmaceutical services and products provided by drug sellers in other coun-

tries. A drug seller initiative tool kit is a major component of the website. The tool kit identifies program components, such as regulation and monitoring, and then links tools and resources related to those components from experiences in Tanzania and Uganda. Stakeholders interested in initiating a drug seller initiative are encouraged to adapt the tools and resources for their own use. ■

Country Study 32-4 Multistakeholder contributions to ADDO program expansion

Many people in rural Tanzania seek health care and medicines from retail drug shops, called *duka la dawa baridi*, for reasons such as convenience. Historically, the TFDA authorized DLDB to provide nonprescription medicines. However, a 2001 assessment showed that many shops sold prescription medicines illegally and that the drug sellers were generally unqualified and untrained. In response, the SEAM Program collaborated with TFDA to develop and launch the ADDO program in 2003. The goal was to improve access to affordable, quality medicines and pharmaceutical services in retail drug outlets in areas where few or no registered pharmacies exist. To achieve this goal, SEAM took a holistic approach that combined training, accreditation, business incentives, and regulatory enforcement with efforts to increase consumer demand for quality products and services.

By the end of the SEAM Program in 2005, the TFDA had accredited more than 150 shops in Ruvuma. Results of the pilot in the Ruvuma region provided proof that ADDOs could improve access to quality medicines and pharmaceutical services. The next year, the Danish Agency for International Development Assistance

(Danida) funded an independent evaluation of the program and confirmed SEAM's findings. Based on the SEAM and Danida evaluations, the Ministry of Health and Social Welfare approved a plan to roll out the ADDO concept to mainland Tanzania.

As the program has taken off, many have recognized the potential of ADDOs not only to increase access to essential medicines, but also to serve as a platform for community-based public health interventions, such as improving child health. As a result, numerous organizations and programs have played a role in expanding both the services that ADDOs provide and their geographic reach—about 1,300 ADDOs are currently serving eight regions.

To be successful, nationwide scale-up of initiatives such as the ADDO program in Tanzania requires creative partnerships and solid commitment to productive collaboration. The following timeline illustrates the range of partners who have contributed to the success of Tanzania's ADDO program.

Tanzania ADDO timeline

2003	The SEAM Program and TFDA design and launch the ADDO program in the Ruvuma region.
2005	SEAM and TFDA evaluate the pilot program in Ruvuma.
2006	Danida sponsors an independent evaluation of the ADDO program in Ruvuma.
2006	The government of Tanzania, through the Ministry of Health and Social Welfare, approves a TFDA plan to roll out ADDOs throughout the Tanzanian mainland.
2006	The U.S. Agency for International Development, through MSH's Rational Pharmaceutical Management (RPM) Plus Program, funds the ADDO rollout in the Morogoro region using resources from the U.S. President's Emergency Plan for AIDS Relief.
2006	The government of Tanzania funds rollout in the Mtwara and Rukwa regions.
2006	The RPM Plus Program collaborates with the Basic Support for Institutionalizing Child Survival Project to add a child health component to ADDO services.
2006	The National Malaria Control Programme adopts the ADDO concept as part of its national strategy to increase access to malaria treatment.
2007	Tanzania's National Health Insurance Fund initiates a plan that allows members to fill prescriptions at ADDOs.
2007	MSH's Strengthening Pharmaceutical Systems Program uses President's Malaria Initiative funds to provide subsidized artemisinin-based combination therapy (ACT) through ADDOs.
2007	The Global Fund to Fight AIDS, Tuberculosis and Malaria agrees to fund ADDO rollout in six to eight high-impact malaria regions to improve access to ACTs for children under five; Danida also contributes funding for rollout.
2007	The Bill & Melinda Gates Foundation funds the East African Drug Seller Initiative to work with TFDA to review and revise the existing ADDO model to make nationwide scale-up more cost-efficient and to help ensure the long-term sustainability of ADDOs.
2008	The Gates Foundation provides the East African Drug Seller Initiative with supplemental funding to evaluate ADDO rollout in Tanzania and long-term sustainability in existing ADDO regions.
2008	The Prime Minister's Office for Regional Administration and Local Government mandates local governments to incorporate ADDO program implementation into their planning and budgets.
2009	The Rockefeller Foundation funds MSH to develop a strategy to promote program sustainability and quality through the establishment of ADDO owner and dispenser associations.
2009	Local governments in Arusha, Iringa, Kagera, Kilimanjaro, and Tabora mobilize to obtain funds to introduce ADDOs.
2009	The government of Tanzania starts rolling out ADDOs to six of the eight Global Fund- and Danida-supported regions and developing a strategy to open ADDOs in urban areas.
2009	The Clinton Foundation funds initial implementation activities in Shinyanga and Dodoma.
2009	A government of Tanzania regulation is revised to phase out unaccredited drug shops (<i>duka la dawa baridi</i>) by January 2011.

SUMMARY

Although prescribers play an essential role in the choice of medicines, the role of the consumer is equally important. Public knowledge, attitudes, and perceptions regarding the use of medicines influence the decision whether to seek health care, from whom, and whether to follow the proposed treatment. In some countries, most medicines can be bought directly over the counter, often from unauthorized sources, often in response to aggressive commercial marketing, and often through illegal sales of prescription-only medicine.

For consumers to use medicines appropriately, they need to know how to take them, what to avoid, and what negative effects to watch for. Communication is needed at a general level to give people a better understanding of what medicines are, how they act in the body, what their risks and benefits are, and what their role is in health care. At a more specific level, interventions are needed to tackle particularly serious problems of misuse. Relevant strategies, based on known facilitating factors and possible constraints, must be developed and implemented.

An increased focus on treating chronic diseases in developing countries, including HIV/AIDS, has resulted in research designed to promote treatment adherence. A major concern regarding poor adherence to treatment for infectious disease is the development of antimicrobial resistance; poor adherence is also costly in terms of the patient's quality of life, the subsequent increase in health care expenditure, and reduced productivity. Components to address in promoting adherence include—

- Communication between providers and patients
- Inadequate counseling
- Lack of resources for medicines and treatment
- Complexity and duration of treatment
- Availability of information

Strategies to encourage appropriate medicine use by the consumer can be public or patient centered, but they should always be culturally specific. A public-centered approach provides the community, or target populations within the community, with information on the role of medicines and on how to make appropriate health-seeking decisions at times of illness.

Seven steps toward more effective communication strategies are—

1. Describe medicine use and identify problems
2. Prioritize problems
3. Analyze problems and identify solutions
4. Select and develop intervention
5. Pretest intervention
6. Implement intervention
7. Monitor and evaluate intervention

Developing interventions in collaboration with the people whose medicine-use patterns have been targeted for change helps ensure that the cultural and social context in which beliefs and practices have developed is taken into account. A variety of approaches and resources improves the chance of the intervention's success and expands its capacity and reach.

33.1 The need to encourage appropriate medicine use

Although the prescriber's role in promoting rational medicine use is important, the patient, community, and cultural context cannot be ignored. The knowledge, attitudes, and education of the public in relation to disease etiology and treatment are critical determinants in the decision to seek health care, the choice of provider, the use of medicines, and the success of treatment—the patient or caregiver, therefore, is the final determinant of appropriate medicine use. Patients should be actively involved in the therapeutic encounter and treatment.

Often, the patient or caregiver decides whether to go ahead with a treatment, a choice frequently influenced by the views of family, close friends, and the community. People make a series of decisions before choosing a treatment.

First: People who are ill have to believe that their health status has changed and that something is wrong with them or that they need to take action to prevent illness. To some extent, a person's culture defines this perception. In the case of children, the knowledge and experience of the caregiver are critical determinants. This decision can be complicated by the lack of observable symptoms for some conditions.

Second: People or caregivers have to decide whether this change of health status is significant enough for them to seek help or whether the symptoms or potential health threat will go away without taking any action.

Third: After they decide to get help, people choose where to seek help: a hospital, a primary health care center, a private physician, a pharmacist, a market vendor or retail drug seller, a traditional healer, a relative, or

some other community member. They may decide, rightly or not, that the symptoms are minor or that they have sufficient familiarity with the required treatment to take care of themselves with either a modern pharmaceutical or a traditional remedy.

Fourth: When they have a prescription or have received a recommendation for products from a pharmacy or drug shop, patients decide whether to buy the medicines, whether they are going to buy all or some of the items recommended, and which medicines to buy. Cost considerations may require a choice of which items to buy and which to ignore, and knowledge can help patients make rational choices within the context of medicine promotion and advertising, some of which may be unethical.

Fifth: Patients decide whether and when to take the medicines, how to take the medicines, whether to continue if side effects occur or symptoms disappear, and what to do with medicines that they do not use.

Consumers also need education on medicines and treatment because pharmaceuticals play such an important role in health care and because public education provides individuals and communities with information that enables them to use medicines in an appropriate, safe, and judicious way. Inappropriate medicine use has serious health and economic consequences for both individuals and the community. For example, development of antimicrobial resistance from the inappropriate use of antibiotics not only can harm an individual patient but also can harm the community when certain antibiotics become ineffective. Appropriate medicine use by consumers is an integral part of successful national pharmaceutical policies.

The 1978 Declaration of Alma-Ata, which focused on the need for primary health care, states that “people have the right and duty to participate individually and collectively in the planning and implementation of their health care,” a principle that should be a cornerstone of national public health and hence of pharmaceutical policy. The World Health Organization (WHO) considers public information and communication on medicine as key elements in national pharmaceutical policy and as a prerequisite for consumers to be able to make sound decisions about health care. Despite the progress by some countries, however, governments seldom allocate the necessary human and financial resources for public education on medicine. Moreover, many training programs for health care providers do not adequately cover patient counseling, communication, and appropriate use of medicines. These topics are frequently given little priority—to be tackled only when the other elements of pharmaceutical policy are in place or when the training curriculum has an open slot.

Problems

Irrational medicine use includes overuse, underuse, and inappropriate use (see [Chapter 27](#)). Various factors contribute to these problems: lack of adequate regulatory systems, shortages of essential medicines, lack of objective medicine information for prescribers and consumers, poor communication between prescribers and patients, exclusion of patients from the information needed to become partners in therapy, and considerable influence of medicine promotion on both prescribers and consumers.

Most developing countries have public health problems of medicine misuse, including the following—

- Widespread availability of prescription medicines from informal sellers, market stalls, or unlicensed drugstores—WHO data indicate that two-thirds of antibiotics are dispensed without a prescription through the informal private sector (WHO 2011a).
- A culture of self-medication and lack of knowledge about the importance of following treatment guidelines (such as taking a full dose or course of therapy), which is integral to controlling antimicrobial resistance.
- Globalization and expansion of the private sector as a source of medicines, with a corresponding commercialization of pharmaceutical supply and promotion.

Benefits

Improving public understanding about medicines will not resolve all these issues, but—together with other activities to promote rational use—it will contribute to the development of better medicine use.

At an individual level, the benefits of improved public understanding include—

- Better knowledge of how to take medicines when needed
- Better appreciation of the limits of medicines and a lessening of the belief that “there is a pill for every ill”
- More balanced partnership between consumer-patients and health care providers
- More critical attitude toward advertising and other commercial information, which often fail to give objective information about medicines

At the community level, the benefits include—

- More understanding and support for pharmaceutical policy and measures to improve medicine use
- More efficient use of medicines and less waste of resources

- Improved confidence in health services and health care providers
- Increased success of measures to deal with public health problems
- Development of expectations about receiving quality medicines and pharmacy-related services
- Protection of the effectiveness of essential antibiotics by decreasing development of antimicrobial resistance

Communication is needed at a general level to give people a better understanding of what medicines are, how they act in the body, what their risks and benefits may be, and what role they play in health care. At a more specific level, interventions are needed to tackle particularly serious problems of misuse. Campaigns for the wiser use of specific medicines (for example, in malaria control programs) have proved effective in reducing morbidity and mortality and in reducing needless expenditures. Other campaigns have tackled particular medicine-related problems. For example, WHO launched Make Medicines Child Size to advocate for and address treatment issues specific to children. [Box 33-1](#) provides more information on medicines and children.

33.2 Promoting treatment adherence and appropriate medicine use by patients

WHO defines adherence as “the extent to which a person’s behavior—taking medication, following a diet, and/or executing lifestyle changes, corresponds with agreed recommendations from a health care provider” (WHO 2003, 3). The concept of adherence requires a trusting relationship between the patient and the health professional in which the patient agrees with the provider’s recommendations.

A major concern regarding poor adherence to treatment for infectious disease is the development of antimicrobial resistance to the first-line medication, resulting in reliance on second- or third-line medicines that are expensive and may have higher levels of adverse drug reactions (see [Chapter 35](#)). Poor adherence is also costly in terms of the patient’s quality of life, the subsequent increase in health care expenditure, and lost productivity (WHO 2003).

The scale-up of antiretroviral therapy (ART) in developing countries has brought greater attention to adherence among patients who must take antiretroviral medicines (ARVs) for the rest of their lives. Other conditions requiring long-term treatment adherence include noncommunicable, chronic diseases, such as diabetes, high blood pressure, and mental disorders. This point is important because WHO estimates that, globally, deaths from noncommunicable diseases will increase by 15 percent between 2010 and 2020—and over 20 percent in Africa, the eastern Mediterranean, and Southeast Asia (Holloway and van Dijk 2011). Many studies have shown that in developed countries, adherence

to medicine regimens among patients with chronic diseases is mediocre, and the situation in developing countries is assumed to be worse because of the greater constraints to accessing affordable medicines and weaker health systems overall (WHO 2003). Poor adherence is a problem with any treatment regimen, but achieving a high rate of adherence and sustaining it over the long run is extremely difficult (Gill et al. 2005).

Reasons that patients do not follow prescribed short-term or chronic disease treatment include—

- Lack of ready access to care (for example, distance to clinic) or patient-unfriendly schedules (for example, limited hours of operation)
- Lack of appointments
- Poor communication between providers and patients
- Inadequate counseling
- Lack of resources for medicines and related treatment visits (for example, cost of travel)
- Complexity and duration of treatment, particularly in cases of chronic disease
- Lack of access to information

Communication between providers and patients

Patients are better able to adhere to their medication regimens when they have a strong relationship and enhanced communication with their health care provider (Osterberg and Blaschke 2005, WHO 2003). Lacking a trusting relationship, patients may hesitate to ask providers to clarify either their basic health condition or the treatment proposed. This hesitancy can be linked to fears of appearing foolish, to differences in social status and language, or to lack of encouragement by providers. Patients who have developed a trusting relationship with their health care provider, whether at a clinic or a drug shop, may be more likely to listen, to ask questions, and to follow advice.

Prescribers’ and dispensers’ communication skills can be weak: they tend to use complex terminology that patients cannot easily understand; they frequently lack knowledge of behavioral theory and practice; and they may have limited awareness of the scale, problems, and causes of patient nonadherence to treatment. The low priority given to communication skills in medical, paramedical, and pharmacy schools undoubtedly contributes to this situation. Fortunately, some medical and pharmacy schools—notably in Australia, Canada, Europe, and the United States—include communication techniques in their basic curricula, teaching behavioral theory and using role playing and video as learning tools. Audiovisual feedback to students markedly enhances their acquisition of such skills, and basic communication training should be an integral part of any prescriber’s or dispenser’s education and refresher training. These types of courses are gradually being incorporated into

Box 33-1**Pharmaceutical issues to consider in treating children****Product-related issues**

Ability or willingness of children to swallow tablets and capsules and tolerate liquids: Generally, as children age, their ability and willingness to swallow tablets and capsules increases; however, age cannot be assumed to be a direct correlation. Liquid preparations are often preferred for younger children, but some treatment programs have reported that small children have difficulty swallowing large volumes of liquids (for example, zidovudine) and that the syrups taste bitter.

Limited product stability: Some products (for example, stavudine liquid) have a fixed expiry after reconstitution, thus making losses caused by expiration more of a problem and quantification of needs concomitantly more complex.

Fixed-dose combinations (FDCs): FDCs formulated for adults may not be suitable for use in children because the doses of one or more of the medicines combined into the product may not be appropriate for the child's age, weight, or body surface area. Using FDCs or portions of an FDC in children can therefore result in (a) underdosing, leading to treatment failure, resistance, or both, or (b) overdosing, which increases the potential for side effects. Some FDC products are not recommended or licensed to be cut or split by the manufacturer, for example, because the active constituents may not be evenly distributed throughout the preparation.

Losses through spillage or use: Losses from spillage or from sugary liquids and suspensions sticking to the bottle or oral syringe need to be considered when dispensing and monitoring adherence to liquid-based therapy.

Product availability of low-dose tablets or capsules and FDCs: Pediatric formulations for HIV/AIDS and tuberculosis (TB) are not readily available. The lack of pediatric dosage forms of most anti-TB and antiretroviral medicines necessitates using adult pills that must be broken into halves or quarters or crushing pills and

creating suspensions, which can result in wasted product and inaccurate measurement. The development of half-sized, scored pills would help provide practical treatment alternatives for children.

Treatment-related issues

Less detailed standard treatment guidelines (STGs) for children (mainly for HIV/AIDS treatment): Many countries have now developed STGs for ART; however, the focus is mainly on adults. The recommendations for children are generally less detailed, especially with regard to addressing product-related issues.

Complex quantification because a treatment regimen is not automatically translatable to specific products or dispensing quantities: For children, the product prescribed depends on dosage needed (such as a portion of the adult dose), the ability or willingness of the patient to swallow the product, and tolerance to a formulation. The selection will also depend on the range of products available for prescribing. The dose, and therefore the quantity to be dispensed, depends on the child's age, weight, or body surface area.

Adjustments needed for continuing growth and weight gain in children receiving long-term treatment: Once a child has started on long-term treatment, the dose will increase as the child gains weight or grows in height. Programs have reported that some uninformed providers have not changed the doses for children on ARVs to take their growth into account, which can result in resistance to treatment.

Access and adherence to treatment reliant on caregiver: Programs may need to use different approaches to promote adherence to and completion of a full course of treatment to a caregiver, especially when the caregiver is elderly or if the child is accompanied by different caregivers on each visit. The time that it takes to dispense medicines to children and their caregivers is typically much longer.

training programs in developing countries; for example, as part of a countrywide antimicrobial resistance containment initiative, the University of Zambia revised its medical curriculum to include antimicrobial resistance and rational medicines use (Joshi 2010).

Adherence to treatment is linked to the clarity of the prescriber's explanation: patients often feel that instructions are unclear or nonexistent. The timing and clarity of a message

powerfully affect how the consumer receives, understands, and retains it. Patients remember the first instructions presented the best; they recall instructions that are emphasized; and the fewer instructions given, the greater the proportion they remember. Thus, a message must not only be clear; it must also be succinct and then organized and delivered in a way that allows the patient to understand and process the information completely.

Although adherence to treatment depends on a patient's acceptance of information about the health threat itself, the practitioner must also be able to persuade the patient that the treatment is worthwhile. Adherence to treatment is linked to the patient's perception of the practitioner's friendliness, empathy, interest, and concern. Finally, in most circumstances, it is essential not only to specify the patient's precise actions (for example, taking two pills twice a day) but also to suggest how the patient can insert that action into the daily routine (for example, taking them at breakfast and dinner). To accomplish this, the health care provider must understand the patient's circumstances; for example, some patients may not be able to afford more than one meal a day or may have an atypical schedule, such as working at night and sleeping during the day.

A more fruitful patient-provider interaction can be encouraged if providers increase their sensitivity, patient and consumer organizations actively promote such interaction, and relevant campaigns are carried out to empower patients.

Inadequate counseling

WHO estimates that the average amount of time that a dispenser spends with a patient is less than one minute and that only about half of patients receive instructions on how to take the medicines they receive (Holloway and van Dijk 2011). Providers sometimes attribute lack of interaction with patients to the pressures of work and a lack of adequate staff. To help correct this problem, two things need to happen. First, health care facilities need to examine their patient care routines to increase efficiency and add time for more patient interaction. For example, many health centers and outpatient departments see all their patients during a few morning hours. One possibility to consider is extending this

period so that each individual can receive more time with the prescriber and dispenser. Another possibility is to train staff to make better use of the time available and to ensure that patients do not fall into an "information gap": if the provider does not have the time to explain the treatment to the patient and ensure that the patient fully understands the instructions, the dispenser or nurse should receive training to do this. Second, health care providers must prioritize and effectively communicate critical information to patients under less-than-ideal circumstances. Staff must be encouraged to understand that effective communication with patients is not an unrealistic ideal but a core aspect of clinical practice.

Another common problem is a lack of space for confidential counseling. Pharmacy staff often must use a dispensing window that is crowded with customers to give information to one patient. The Rational Pharmaceutical Management Plus Program helped facilities in several countries, including Kenya and Ethiopia, to construct private dispensing booths where dispensers can counsel patients privately. Although the booths were constructed primarily to provide confidentiality to patients on ART, all patients, no matter what their condition, benefit from the dispensing booths.

[Country Study 33-1](#) shows how an emphasis on counseling for ART in Kenya improved medication counseling for all patients at the facility.

Lack of resources for medicines and treatment

Patients in developing countries are more likely to pay out of pocket for the medicines they need—over 70 percent of medicine expenditures in low-income countries consist of consumer payments (Holloway and van Dijk 2011). When the patient bears part or all of the cost, he or she may not buy the medicine at all if it is too expensive. When more

Country Study 33-1

Medication counseling training for ART dispensers in Kenya

Beginning in 2003, the government of Kenya initiated ART for HIV-infected patients at four health facilities serving the Coast province. When the program began, pharmacy staff received training on rational medicine use specifically for ART and on how best to offer medication counseling to ART recipients. One sensitive issue for an ART program is ensuring patients a confidential location within the pharmacy to receive their medicines and counseling. Therefore, new booths at pharmacy windows were constructed to create private counseling areas that provide a welcoming and secure atmosphere. The staff members saw the confidential nature of the booths as a valuable addition: "Before, when I was

dispensing pessaries to a patient there would be four heads listening."

When the pharmacy team later evaluated the ART program's first six months of operation, they felt that one of their main successes was using their training and the enabling environment of the booths to improve the quality of medication counseling, not only for ART, but also for their other patients. Several of the dispensing staff reported that they were applying their training on ART medication counseling to those patients taking diabetic or hypertensive medicine.

Source: RPM Plus Program 2004.

Figure 33-1 Improving adherence to treatment

than one medicine is prescribed (in some countries, the average number of medicines per prescription is five to six), the patient may be able to afford only one or two of the products listed and may choose the less important, relatively cheaper ones, such as vitamins, or buy only a partial treatment.

Providers need to know the approximate prices of medicines they prescribe, select the cheapest available generic medicines that are compatible with quality and therapeutic needs, and keep the number of products prescribed to a minimum. If the provider prescribes more than one medicine, he or she should indicate the most important ones to the patient.

Other economic factors may influence a patient's ability to access medicines. The patient may have enough money to buy the medicine but not enough to pay for the clinic visit. If the health care facility is too far away, the patient may not have enough money to pay for transportation. A lack of food can also affect treatment adherence; for example, in Tanzania, patients reported taking their ARVs only once a day instead of twice, because that was the only time they had food (Hardon et al. 2006). In some DOTS programs, food baskets provide incentives for clients to come in and take their medications.

Box 33-2 DOTS strategy for TB treatment

TB was the first disease for which an adherence strategy was developed and implemented on a large scale—DOTS, which originally stood for directly observed treatment, short-course. DOTS is considered one of the most cost-effective of all health interventions. The aspects directly related to patient adherence include using the most effective standardized, short-course regimens and FDCs to facilitate adherence; supervising treatment in a context-specific and patient-sensitive manner; and identifying and addressing physical, financial, social, cultural, and health system barriers to accessing TB treatment services.

Effective DOTS programs can help minimize the emergence of antimicrobial resistance to medicines; however, TB strains that are resistant to conventional therapy have been documented in almost every country. Countries that have the highest proportion of multidrug-resistant (MDR)-TB cases are in Eastern Europe, including Azerbaijan and Belarus (WHO 2011b). DOTS-Plus, designed to respond to MDR-TB, is a supplementary treatment strategy that builds on DOTS but focuses on the rational use of second-line TB medicines to treat MDR-TB cases.

Complexity and duration of treatment

The longer and more complex the treatment, the greater the likelihood that the patient will not follow it. Adherence to short-term treatments (less than two weeks) can be improved by clear instructions, special “reminder” pill containers and calendars, and simplified medicine regimens (see [Figure 33-1](#)). Adherence to long-term treatments is more difficult to achieve; the DOTS program was designed to increase adherence to onerous TB treatment ([Box 33-2](#)). Fixed-dose combinations of multiple medicines in one tablet or capsule simplify a treatment regimen as does prepackaging treatments, such as blister packs of artemisinin-based combination therapy. Although no single intervention is useful on its own, combinations of clear instructions, follow-up of patients missing appointments, patient self-monitoring, social support, cues for when to take the medicines, rewards, and group discussions are useful.

Availability of information

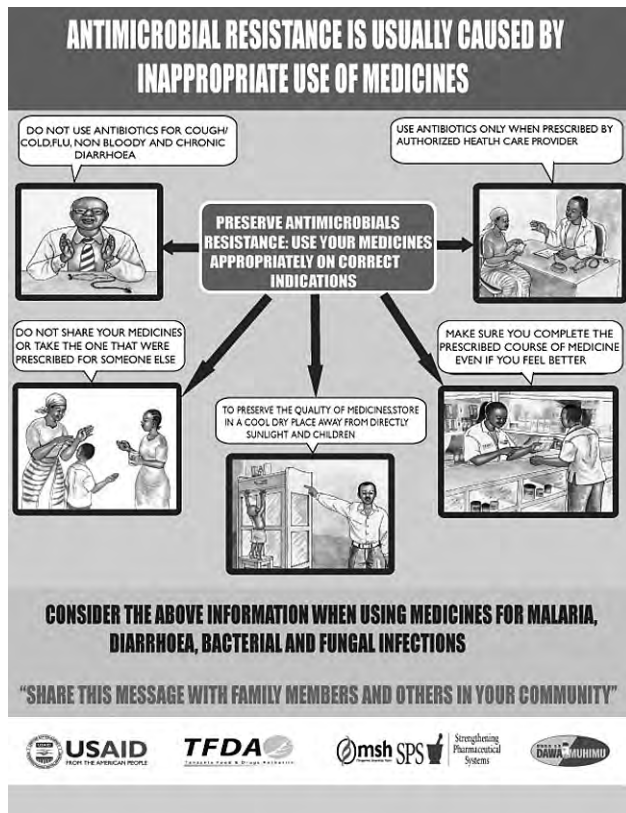

The availability of printed information in simple language to supplement a medicine's label may increase treatment adherence. (Labeling is covered in [Chapters 30](#) and [34](#).) Such patient information leaflets need well-written text in the local language, effective graphic design, large print size, and clear layout to enhance legibility; a question-and-answer format may stimulate consumer involvement.

In many parts of the world, producing leaflets for individual patients is not feasible. High rates of nonliteracy in some countries also limit the value of such information. Yet simple instructions for the most commonly used and misused medicines could be printed on inexpensive paper. Simple booklets or posters for display in retail outlets and health centers can provide consumer information on the most common medicines. Even nonliterate patients can obtain information from such publications with help from family or community members. [Figure 33-2](#) shows a poster used in Tanzania, translated from Swahili, to inform accredited drug-dispensing outlet customers about antimicrobial resistance.

Pictograms can provide reinforcing information about medicines. A setting and rising sun or moon to represent different times of the day for taking medicine have been used in a number of countries, although an evaluation in Bangladesh found that dispensers had to be trained in their use. The U.S. Pharmacopeia developed a series of pictograms for use on medicine labels (see [Annex 33-1](#)). The International Pharmaceutical Federation also has a pictogram project (http://www.fip.org/www/index.php?page=pp_sect_maepsm_pictogram).

A study in South Africa showed that images that had been developed locally were interpreted correctly more often than the U.S. Pharmacopeia images (Dowse and Ehlers 2004); therefore, each country needs to develop its own

Figure 33-2 Consumer education poster used in accredited drug-dispensing outlets in Tanzania

symbols using culturally recognizable objects. Pretesting is important, because patients need to understand the symbols without explanation. Research has shown that culturally appropriate icons can improve how well patients understand medicine labels and adhere to treatment but that inappropriate icons can be more confusing than words (Shrank et al. 2007).

33.3 Monitoring adherence in health care facilities

One particular challenge is how to measure and quantify adherence rates. No consensus exists for measuring adherence, and research reflects the variety of methods in practice (WHO 2003). A study of twenty-four health care systems serving more than 86,000 AIDS patients in East Africa showed that facilities used a wide range of methods to calculate treatment adherence. Fourteen different operational definitions of treatment defaulting existed, ranging from one day to six months following a missed appointment (Chalker et al. 2010).

Methods to measure adherence rates are subjective or objective: subjective measures include reporting by

patients and health care providers, who tend to overestimate adherence. Objective measures include counting doses of medicine at clinic or home visits, but this method tends to overestimate adherence and does not reflect other adherence information, such as timing of doses and missed doses. Special medicine-bottle caps that record when a dose is removed are expensive and generally are used only for clinical trials. Relying on pharmacy records to see when prescriptions are filled and refilled is another method that is objective, but it does not indicate medicine use once the prescription has been filled. Directly observed treatment by a health care worker is the cornerstone of adherence for TB, but this approach is not practical for many long-term treatment regimens. Other objective methods use clinical monitoring, such as testing for blood sugar for diabetes or CD4 counts or viral load for HIV/AIDS.

The International Network for the Rational Use of Drugs Initiative on Adherence to Antiretrovirals has developed and validated a set of indicators that can be used to monitor adherence to ART either at the facility or HIV/AIDS program level. The indicators measure treatment adherence and defaulting by using routine pharmacy records and patient interviews to look at appointment keeping and days covered by dispensed medicine over a period of time. The indicators correlate with increases in patients' CD4 counts and weight (Ross-Degnan et al. 2010). The initiative published a manual and tools to measure adherence that offers a step-by-step guide on how to design and carry out a national or facility survey or a program adherence survey. The manual and tools can be downloaded for adaptation and use (<http://www.inrud.org/ARV-Adherence-Project/Adherence-Survey-Tools-and-Manual.cfm>).

33.4 Addressing determinants of adherence

Causes of poor adherence vary and are not well understood. WHO has defined five "dimensions" of adherence illustrating that adherence is not the responsibility of the patient alone (WHO 2003). They are (a) social and economic factors, (b) patient-related factors, (c) health care team and system factors, (d) therapy-related factors, and (e) condition-related factors. For example, patients may not have the money or transportation to access treatment, or they may have to wait for hours to pick up their medicines. Some patients, especially those with HIV/AIDS or mental illness, may feel stigmatized. Prescribers may not explain treatment clearly, or the treatment regimen may be difficult to follow or cause adverse reactions. A study in Ethiopia and Uganda showed that a positive and confidential partnership between patients and health care providers enhanced patients' satisfaction and feelings of trust in the treatment and helped overcome adherence barriers (Gusdal et al. 2009).

Strategies to increase patient adherence include the use of FDCs and prepackaged patient packs to simplify treatment (Country Study 33-2). WHO and the International Union against Tuberculosis and Lung Disease recommend FDCs to ensure proper treatment of TB (Blomberg et al. 2001). Another intervention often incorporated as part of DOTS is the use of incentives or enablers to positively influence the behavior of both providers and patients. An enabler might be a transportation voucher that helps the patient get to the treatment facility; an incentive could be a monetary bonus for a private provider who refers suspected TB patients to an accredited testing facility (Box 33-3). ART programs are instituting interventions to increase adherence, such as reducing waiting time, tracking appointment keeping and following up with patients, and using peer counselors as support (Gusdal et al. 2011). A TB program in Cape Town uses text messaging on cell phones to remind patients to take their medicines (Green 2003).

Interventions to promote adherence should address barriers at all levels of the health care system and not just focus on the patient alone. Like interventions to improve rational medicine use, a single-factor intervention probably has limited effectiveness compared with an approach that takes multiple factors into account. Box 33-4 shows some proven interventions related to the five dimensions of adherence.

The HIV/AIDS pandemic has focused attention on expanding the role of pharmacy staff in providing a full range of pharmaceutical care services to the patient, includ-

ing medication counseling and adherence monitoring. However, as discussed in Chapter 51, the lack of trained health professionals in many countries makes adequately monitoring rational medicine use difficult, especially for chronic disease medications. This gap in human resources makes using other personnel, such as drug sellers, that much more crucial (see Chapter 32). In addition, educating patients as well as the entire community about the importance of adherence and medicine use and exploring the effectiveness of community-based interventions (see Chapter 31) become much more important.

33.5 Communicating with consumers about appropriate medicine use

Strategies to encourage appropriate medicine use by the consumer can be public or patient centered, but they should always be culturally specific. A public-centered approach provides the community, or target populations within the community, with information on the role of medicines and on how to make appropriate health-seeking decisions at times of illness.

Principles of public communication

The following principles should guide public education in appropriate medicine use—

Country Study 33-2 Using prepackaging to improve rational use of medicines

According to WHO, about half of patients who receive medicines fail to take them correctly, including taking less or more medication than necessary, taking antimicrobials for nonbacterial infections, and inappropriately self-medicating, often with prescription medications (WHO 2004b).

Several studies have shown that prepackaging medicines (particularly antimalarials) in daily doses can improve adherence, safety, and cost-effectiveness.

- One Ghanaian study showed that prepacking antimalarials into daily doses decreased costs by reducing the number of medicines prescribed, the amount of syrup consumed, and the number of injections given (WHO/TDR 1998). Prepackaging also improved adherence and reduced waiting times for treatment; moreover, patients found the packaging to be acceptable.
- A systematic review of fifteen studies of the effectiveness of FDC pills and unit-of-use packaging,

such as blister packs, found that although more rigorous research was needed, both approaches are likely to improve adherence in a range of settings in both developed and developing countries (Connor, Rafter, and Rodgers 2004).

- A third study, conducted in the Brong Ahafo region of Ghana, examined the extent to which district health teams could reduce the burden of malaria in areas with severe resource constraints (Yeboah-Antwi et al. 2001). By prepackaging antimalarial medicines into unit doses, the teams were able to improve adherence by about 20 percent in both adults and children. In addition, the prepackaging intervention reduced costs to patients by 50 percent and decreased waiting time at dispensaries and medicine waste at facilities.

Sources: Connor, Rafter, and Rodgers 2004, WHO 2004b, Yeboah-Antwi et al. 2001, WHO/TDR 1998.

Box 33-3**Improving the efficacy of the DOTS strategy through the use of enablers and incentives**

Treatment success in the 2009 worldwide DOTS cohort of 5.8 million patients was 86 percent on average, edging closer to the 90 percent target for 2015. However, treatment success was below average in the European region (67 percent) (WHO 2011b). WHO estimates that between 1995 and 2010, 6.8 million lives were saved because of the DOTS strategy.

To help improve the effectiveness of the DOTS strategy, many TB control projects and programs worldwide have adopted measures called *enablers* and *incentives* to motivate health care providers and patients. An enabler is something given to the patient or treatment provider that makes participation possible, practical, or easy. For example, providing bus tokens makes it easier for people to get to their appointments. An incentive is a stimulus designed to encourage stakeholders to behave in a certain way, such as providing food baskets to patients who show up to their appointments.

Unfortunately, the weak evidence base about enablers and incentives makes assessment of their effectiveness difficult. However, their potential role has been described in literature reviews, surveys of experiences, and mapping workshops.

Some examples of successful motivators include the following—

- In rural Bangladesh, patients sign a contract and pay a deposit of about 3.50 U.S. dollars upon initiation of TB treatment. At completion of therapy, patients receive back 37.5 percent of their original deposit, and the community-based supervisor receives the remainder. The “deposit” scheme was associated with significantly better TB treatment adherence and case detection compared to the national average.
- Targeting homeless and other vulnerable populations, the Czech Republic offers vouchers worth 4 to 5 euros for purchasing goods after TB diagnosis. As a result, case detection is five times higher among the homeless population receiving the incentive.
- Patients received travel support to attend a TB clinic in Romania for one year. During the pilot program, adherence to treatment increased to 95 percent, then fell back to 80 percent when the program ended.

Source: RPM Plus Program 2005.

- Medicine use should be viewed within the context of the society, community, family, and individual. Public communication on medicines should recognize cultural diversity in concepts of health and illness or notions about how medicines work. The different expectations surrounding conventional and traditional medicines need to be considered, as do preferences for injections or for tablets of a particular color because they are considered more potent. Social factors such as poverty, disadvantage, and power relations can also influence medicine use.
- School curricula should include education in the appropriate use of medicines, with different messages and educational approaches used for students of different ages (see, for example, Cebotarenco and Bush 2008).
- Public communication should encourage informed decision making by individuals, families, and communities on the use of medicines and on nonmedicine solutions.
- Public communication should be based on the best available scientific information about medicines, including their efficacy and side effects.
- To facilitate informed choices on medicine use, public communication should be accompanied by supportive legislation, such as regulating pharmaceutical advertising and promotion and controls on medicine availability. In addition, governments should ensure that over-the-counter medicines have adequate labels and include accurate and easily understood instructions.
- Nongovernmental organizations (NGOs), community groups, and consumer and professional organizations have important roles to play in public communication programs and should be involved, when possible, in the planning and implementation of communication activities.
- Effective public information about medicines requires a commitment to, and an understanding of the need for, improved communication between health care providers and patients. Educational and training curricula for providers should reflect this commitment.

Developing public communication strategies

Effective communication involves a process that is modified as new information on its effectiveness and need for

improvements become evident and new communication methods and technologies become available (see [Figure 33-3](#)).

Public communication can aim to influence people's thinking in many ways, including—

- Organizing campaigns to promote the values and benefits of essential medicines
- Empowering the consumer to understand what a correct prescription should look like and to know what questions to ask a health care provider
- Providing young people with a general knowledge base about the actions and use of medicines on which they can draw as adult consumers
- Targeting a particular problem related to medicine use, such as home injections and the reuse of needles
- Working through pharmacies to offer information on specific medicines and treatment categories, as in the comprehensive information programs developed by the national corporation of Swedish pharmacists and the pharmaceutical society of Australia

Providing information is much easier than changing behavior. Many studies show that knowledge does not necessarily influence action. Changing people's behavior generally requires a long-term strategy undertaken after a careful analysis of the situation and identification of priority problems, with knowledge of the societal context in which the strategy will be carried out. Identification of target groups and pretested, culturally specific materials are necessary. These materials should always be evaluated for their effect not only on knowledge acquired but also on actual behavioral change. Repeat messaging is useful.

The steps shown in [Figure 33-3](#) are discussed in the following sections.

Step 1: Describe medicine use and identify problems.

Investigating how medicines are prescribed, dispensed, and used is the foundation for the communication process. Such an investigation should address the following issues—

Information already available: Reports of studies or from annual reports of organizations working in related fields can provide information about the problem.

Box 33-4

Selected areas of intervention to improve medication adherence

Social and economic

- Ensuring affordable prices for treatment and medicines
- Preparing family members to be supportive
- Providing other forms of social support
- Combating illiteracy
- Providing food and/or transportation vouchers
- Organizing peer and community support groups
- Creating patient organizations

Health care team and system

- Ensuring reliable pharmaceutical supply systems
- Improving communication between patients and health professionals
- Creating awareness and knowledge about the value of adherence
- Making convenient appointments for the patient
- Giving simple instructions about the treatment regimen
- Tracking patient appointment keeping and following up on no-shows
- Prescribing the simplest regimen possible

Condition

- Screening and treating patient depression or substance abuse

- Addressing condition-related stigma; for example, providing confidential pharmacy dispensing booths
- Educating the patient about the disease or condition and its treatment

Therapy

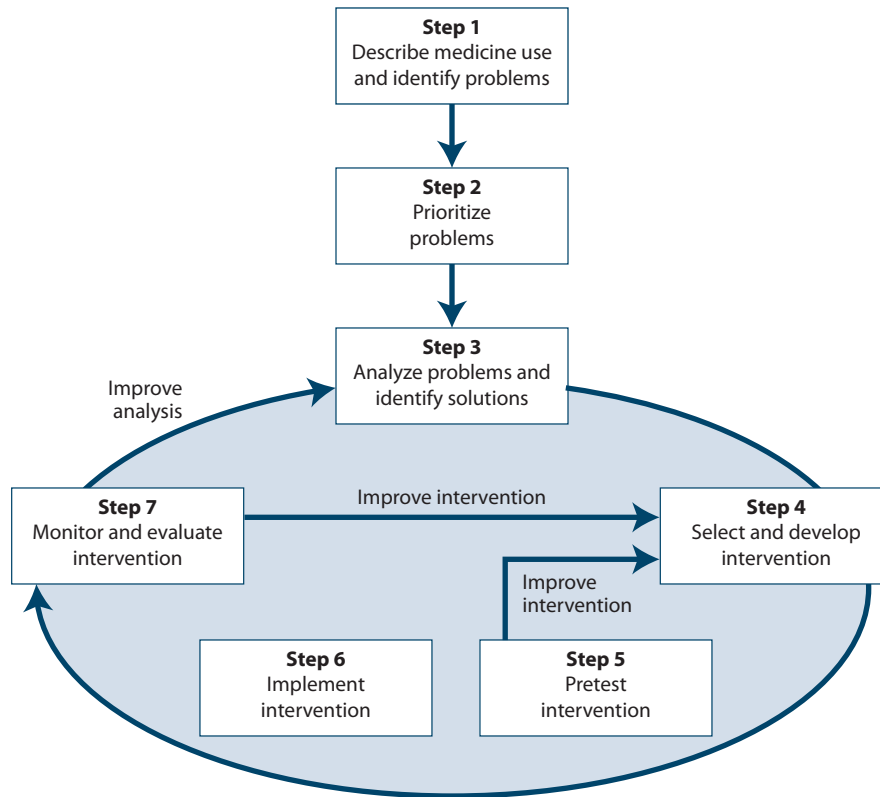

- Developing and prescribing FDC medicines
- Using prepackaging or course-of-therapy packaging
- Providing alternative medicines that are extended release or have a long half-life
- Minimizing adverse drug reactions

Patient

- Providing more information and skills related to self-management of treatment
- Addressing poor motivation and self-efficacy
- Providing adherence counseling
- Supporting behavioral changes
- Providing memory aids, such as special pill boxes or telephone reminders
- Providing treatment incentives and reinforcements

Figure 33-3 Steps in an effective public communication intervention

Source: Chetley et al. 2007.

New information needed: If it is not already available, information is needed on sources of medicines and on how health services and medicines are used in the community. The more data obtained on audience characteristics, the better: demographics, socioeconomic and literacy status, language patterns, community decision making and leadership processes, characteristics of prescribers and users, and local beliefs and practices relating to disease etiology and the use of medicines are all useful.

Communication networks: What sources of information about medicines, including nonmedical sources, are most credible to the target audience? What channels of information reach users most effectively? Do mass media channels play a role? What role can new technologies (for example, mobile phones) play?

Communication development: What resources exist in research, education and training, production and distribution of information, and social mobilization?

Researchers can combine quantitative and qualitative research methods to obtain the necessary data. Quantitative methods, such as household surveys, provide useful information on levels of knowledge and on the practices and beliefs prevalent in a population: they measure what is hap-

pening. Qualitative methods, such as focus group discussions and in-depth individual interviews, yield substantial information about specific behaviors, as well as the reasons and motivations underlying them: they explore how and why things are happening. These methods, described in Chapter 28, generate many ideas and provide language for communication materials. A handbook is also available on how to investigate consumers' use of medicines (Hardon, Hodgkin, and Fresle 2004).

Step 2: Prioritize problems. Policy makers or health professionals can prioritize medicine-use problems, but involving stakeholders through focus group discussions, for example, can increase community support for the process (Hardon, Hodgkin, and Fresle 2004). Questions to ask when prioritizing problems include the following: How many people are affected? Is the problem common or rare? How serious is the resulting adverse effect? Does the problem cost a lot of money? Does the community recognize the problem as serious? Will a community-based intervention solve the problem or does it require a different type of intervention, such as regulation? (Hardon, Hodgkin, and Fresle 2004). Once these questions are answered about the identified problems, the problems can be rated based on preselected criteria.

Step 3: Analyze problems and identify solutions.

Initial research and prioritization of problems explore the causes of the problems, define the behaviors to be adopted or changed or knowledge to be acquired, and describe constraints and facilitating factors that will affect the planning process and the feasibility of possible objectives. Objectives for the analysis include identifying how stakeholders view the problems and possible solutions and identifying factors that can facilitate interventions (Hardon, Hodgkin, and Fresle 2004). All stakeholders, including community members, should have the opportunity to consider potential solutions to the problems. The target audience for the solution may be the entire population in the case of a broad-based national program; more often, however it will be a subsection of the community, such as schoolchildren, mothers of young children, the elderly, community leaders, or women's organizations. Problem analysis should also provide insight into the cultural context of behavior and beliefs and indications of useful language and expressions.

Step 4: Select and develop intervention. A critical part of the planning process is to clarify what the intervention

should achieve. The intervention plan defines objectives and outlines how to reach them. The plan should include the elements discussed below.

Realistic and well-defined communication objectives:

Clear objectives make it easier to formulate activities that are likely to achieve the objectives and measure achievements. These objectives should focus on specific problems and target the people exhibiting the problem behavior. General campaigns may raise awareness, but they are unlikely to result in significant behavioral changes.

Approaches to change: Approaches can include either a campaign approach of short, high-intensity programs that focus on single issues (for example, injection misuse) or longer-term, sustained efforts integrated with other primary health care and educational activities (such as a literacy reader on medicine use, lesson outlines for the primary or secondary school curriculum, or routine health center education sessions).

The communication strategy may use a persuasive or social marketing approach to influence the target

Country Study 33-3**Using social marketing to promote the rational use of medicines and health commodities**

Social marketing takes the concepts of commercial marketing and applies them to social issues. In a social marketing campaign, the needed product is made widely available and affordable to the target populations, and product availability is accompanied by a campaign to create demand by raising awareness of the product, often by using brand identification, and by promoting the use of the product to encourage some healthy behavior. Social marketing approaches use research to gain an understanding of the target audience and base marketing strategies on the population's perceptions, wants, and needs.

Social marketing is commonly used to promote the use of condoms and other reproductive health commodities, oral rehydration solution, nutritional supplements for children, water purification, insecticide-treated bed nets (ITNs), and voluntary counseling and testing services for HIV/AIDS.

PSI has long been involved with social marketing programs that promote ITNs in malaria-endemic areas, and since 2003, the organization has introduced social marketing of prepackaged treatment for malaria in Cambodia, Madagascar, Nigeria, and Myanmar. Because people most often treat malaria at home with products purchased in the private sector, where the quality of medicine is not assured and the level of knowledge and

training in the vendor is low or nonexistent, focusing on these outlets to improve people's access to and proper use of antimalarials is important, especially in rural settings.

A special challenge with antimalarials comes with the shift to artemisinin-based combination therapy (ACT) as the recommended first-line treatment. PSI's social marketing campaign is designed to disseminate information on the new treatment regimen and emphasize the importance of adherence. Its PSI prepackaged medicines use blister packs that include country-specific, easy-to-follow instructions that are appropriate for people with low literacy. Packaging distinguishes between different age groups and the packs are color coded to facilitate adherence. In addition, retail outlets receive the products at a highly subsidized price, which is especially important in making the expensive ACTs affordable. Product branding focuses on the target population; for example, the children's product in Nigeria is called KidCare®, and the promotional materials include the tag line "Correct Malaria Medicine for Your Child." Initiatives are now ongoing to provide subsidized ACTs through private- and public-sector outlets in the additional countries of Democratic Republic of Congo, Kenya, Rwanda, Sudan, and Tanzania.

Sources: PSI 2005, n.d.

Box 33-5**Questions to ask when you get a new prescription medicine**

- What is the name of the medicine, and what is it supposed to do?
- Is this the brand or generic name? (Is a generic version available?)
- When do I take the medicine—and for how long?
- Should I take this medicine on an empty stomach or with food?
- What should I do if I forget a dose?
- What foods, drinks, medicines, dietary supplements, or activities should I avoid while taking this medicine?
- What precautions should be taken?
 - By children
 - During pregnancy
 - When breast-feeding
 - While driving or operating machinery
 - If taking other medicines
- What are the possible side effects, and what do I do if they occur?
- When should I expect the medicine to begin to work, and how will I know if it is working?
- Will this new prescription work safely with the other prescription and nonprescription medicines I am taking?
- How should I store this medicine at home?

Source: National Council on Patient Information and Education, “Talk about Prescriptions” Planning Kit for October 2005. <http://www.talkaboutrx.org/questions_new_prescrip2005.jsp>

audience. Social marketing, often criticized as a top-down approach, can be an effective communication strategy, particularly in specifically targeted campaigns that take into account community needs, perceptions, and values (see [Country Study 33-3](#)). Alternatively, giving people the information and the problem-solving skills necessary to make their own decisions is ideal in the long run but much more difficult to implement and evaluate. With disadvantaged groups, it can also involve consciousness-raising and promoting awareness that they are empowered to make decisions and control their own lives. For example, consumers can be encouraged to act with authority and ask questions of the health care provider (see [Box 33-5](#)).

Communication channels to deliver messages: Ideally, a communication program should combine different channels, including interpersonal channels, to maximize exchange. Each channel has its own strength: what matters is that it be cost-effective and appropriate to the audience and the message. Possibilities include—

- Printed materials—posters, leaflets, textbooks, comics
- Mass media and electronic media—radio, television, newspapers, CD-ROMs, DVDs, the Internet, mobile technology, short-message service (SMS)
- Folk media—community theater, puppets, singing groups, and other such media (important traditional channels in many countries)
- Interpersonal (or face-to-face) encounters—health workers, schoolteachers, community leaders, shopkeepers, community organizations

[Country Study 33-4](#) discusses a neighbor-to-neighbor communication strategy to improve the use of anti-malarials in a district in Kenya.

Collaborating institutions: Collaborating with a wide range of institutions—NGOs; consumer organizations; religious, women’s, youth, or social solidarity organizations; schools; development agencies such as WHO and the United Nations Children’s Fund (UNICEF); and professional associations—enhances visibility, potentially increases impact, and can be used to promote rational use concepts and the national pharmaceutical policy. Religious groups provide a substantial proportion of health care and are potential partners in many countries. [Country Study 33-5](#) illustrates a public education campaign launched through a collaboration of several French consumer and professional organizations.

Monitoring and evaluation (see Step 7 below): Milestones (for example, number of manuals produced or number of workshops completed) can help chart progress toward the objectives of the communication plan.

Timetable, budget, and source of financing: For each activity, the plan should define when it is to occur, who is responsible for it, and the funding source. A common method of displaying such information is a Gantt chart (see [Chapter 38](#)).

Step 5: Pretest intervention. Although frequently overlooked, pretesting materials is essential and saves time and money. Pretesting also often produces surprising results; for example, a patient may completely misunderstand a picture, particularly if it uses a stylized design in a society that is relatively inexperienced in interpreting graphic images.

Pretesting can help answer the following questions—

Country Study 33-4 Neighbor-to-neighbor education on antimalarials in Kenya

The Bungoma District Health Management Team in Kenya implemented a “neighbor-to-neighbor” (*jirani kwa jirani*) education program focused on caretaker purchase and consumption of antimalarial medicines. Forty government health workers received a one-day orientation on the approach and copies of two illustrated brochures explaining proper malaria treatment and recommended medicines, which they distributed in 112 villages. The health workers also organized thirty contests where village residents presented songs, dramas, or poems they had created to promote the use of effective antimalarial medicines.

About six weeks after launch, the neighbor-to-neighbor intervention had reached 53 percent of households in the intervention area through a brochure, song contest, or both. In addition, respondents in the intervention area, especially those with low education levels, were more likely than those in the comparison area to know the appropriate government-recommended antimalarial medicines and to report intention to use them, and people living in the intervention area were also twice as likely to have bought and taken the correct dose of the first-line antimalarial medicine, sulfadoxine-pyrimethamine.

Source: Tavrow and Rennie 2004.

- Does the target audience understand the materials?
- Do they feel that the materials apply to them?
- Do they find the materials attractive?
- Is anything offensive or culturally inappropriate?
- Is the message convincing? If not, why not?
- Do changes need to be made in the message or its format?

The WHO guide to improving consumers’ medicine use (Chetley et al. 2007) points out that pretesting is also a way to open dialogue with the target audience on key issues, confirm research about the medicine use problem, and gather opinions on the planned intervention.

Step 6: Implement intervention. Unless other interventions have already been implemented and evaluated, the intervention usually serves as a pilot study, which makes evaluating the success of the intervention important, as well as gathering information on how it worked, so changes can be made later (Chetley et al. 2007).

Before beginning, ensure that all materials and people are ready, channels of distribution are organized, and everyone involved is fully informed about program goals and strategies. In addition, the monitoring and evaluation plan should be in place. Delays in program implementation will have implications for future planned activities.

Step 7: Monitor and evaluate intervention. Monitoring relates to how well the activities are being implemented as the intervention progresses, and evaluation assesses how well the objectives are being achieved (see [Chapter 48](#)). Monitoring and evaluation processes need to be planned at the beginning of a project, not addressed at the end of the intervention.

Once the program starts, a clear system of monitoring should be used to assess whether—

- Training has been sufficient and effective

- Target audiences are receiving program materials and messages
- Target audiences are using the materials and understanding the messages (in the case of radio programs, such an assessment might include a program log with transmission times, and tapes and listener interviews to determine whether the messages were understood)
- The program is on schedule (if not, why not?)

Monitoring produces feedback on how well the communication is working. It allows assessment and definition of what changes can or should be made as the intervention progresses. In face-to-face communication, for example, good communicators automatically monitor whether they are having the desired effect and then vary their style and content accordingly if necessary (Chetley et al. 2007).

Evaluating communication interventions is more challenging. An evaluation to determine whether the activities met program objectives should distinguish between attitude change, knowledge acquisition, and behavior change. One may occur without the other, but most educational interventions target more than one.

All study designs must measure change using key outcome measures that relate to the communication objectives (Chetley et al. 2007). One should—

- Review the intervention’s communication objectives
- Identify in advance what behaviors are likely to be influenced because of the intervention and what changes in knowledge and attitudes are expected
- Limit the number of outcome measures: do not measure all possible changes
- Measure more than one dimension: decide whether the design will measure changes in attitudes, changes

in knowledge, or changes in medicine-use behavior, or any combination of these dimensions

- Choose outcome measures that can be clearly defined and reliably measured

Pre- and postintervention quantitative research are needed to measure effect on behavior. Defining some clear quantitative indicators, such as the percentage of respondents who self-treat a specific condition correctly or who never reuse disposable syringes, is also useful. Measures that can determine impact include—

- Exposure to project messages and materials
- Proportion of knowledge change
- Change in consumer satisfaction
- Change in medicine sales patterns
- Proportion of reported behavior change

- Use or adaptation of the program by other groups as a model in developing their own projects

When possible, compare results with those from a control group not exposed to the intervention.

Reassessment of procedures requires feedback on the following questions—

- What problems occurred in developing and implementing the program?
- Was the intervention acceptable to stakeholders?
- What factors outside the project (for example, change of legislation, increase or decrease in available medicines, support from the ministry of health) may have contributed to its success or lack of success?
- What factors within the project may have contributed to its success or lack of success?

Country Study 33-5

The INN—A medicine's true name: Promoting the use of International Nonproprietary Names

Concerned about the effect of what they viewed as advertising of prescription medicines disguised as “information” in Europe, several French organizations—Association Mieux Prescrire, Fédération Nationale de la Mutualité Française, and Union Fédérale des Consommateurs Que Choisir—collaborated on a public education campaign to encourage patients to recognize the International Nonproprietary Names (INNs) of medicines and use them in their dealings with health care professionals. The INN system allows health care professionals and patients to identify a medicine by its active ingredient and avoid potentially serious adverse

effects caused by overdose when different brand names of the same generic medicine do not convey the product's active ingredient.

Launched by the Medicines in Europe Forum in France in 2005, the campaign targets consumers, patients, and health care professionals. The campaign has created a series of leaflets that it encourages pharmacies, surgeries, clinics, and hospitals to display. The information sheets were reprinted in each issue of *La revue Prescrire* and multiple press releases were sent to the media.

The text of two of the eleven leaflets follows.

The INN on drug packaging: practical and safe!

Anthony hands his prescription to the pharmacist.

“My doctor uses the INN—the international nonproprietary name—on prescriptions,” says Anthony. “Could you give me a product where I can clearly see the INN on the box?”

“There you are. On this product the INN is clearly visible on the box, and it is also printed on each blister—the small plastic wells holding the tablets, under the aluminum film . . . That way, if you leave home with only part of the blister pack, you'll still know what drug it contains.”

Anthony is happy: with the INN clearly visible at all times, he is sure of taking the right medicine at the right time.

Placing the INN on drug packaging reduces the risk of error.

Ask your doctor and pharmacist to explain the INN system.

A holiday trip ends in hospital

Marcelle and René are on a package tour to Thailand. But they have forgotten to bring their medicines with them, including their “blood pressure” drugs. It's not a problem for Marcelle. She knows the international nonproprietary name (INN) of the beta-blocker she has to take every day: metoprolol. The doctor in Bangkok has no trouble prescribing the right treatment for her. René remembers only the trade name of his medication, Avlocardyl®, and the Bangkok doctor has never heard of it. The same drug is marketed in Thailand, but under a dozen different trade names, none of which resembles Avlocardyl. The doctor prescribes another antihypertensive drug, but René reacts badly to it and has to be hospitalized. If only he'd known the INN. . .

The INN: one drug, one name, everywhere in the world

Box 33-6**Key components of a communication plan**

- Communication objectives (awareness; increased knowledge; behaviors to be influenced, adopted, or changed); keep in mind that these may be phased or cumulative and may each involve different channels of communication.
- Intended audience(s) (include extent to which you will involve audience in program planning).
- Likely constraints (for each audience).
- Likely facilitating factors (for each audience).
- Approaches to change: power/sanctions, logic/facts, appeal/emotion, incentive/reward, facilitate/remove obstacles, fear or danger/emotion or combinations of these.
- Communication channels: a communications program should use a combination of channels, known as media mix, to maximize exchange; possibilities include visual aids: posters, flyers, pamphlets, brochures, video; mass media: radio, television, newspapers; folk media; mobile technology and SMS; interpersonal or face-to-face.
- Method for pretesting of materials or intervention.
- Collaborating institutions: collaborating with a wide range of institutions in communication activities enhances visibility, potentially increases impact, and acts as general advocacy for rational-use concepts and the national pharmaceutical policy.
- Monitoring and evaluation: this should include reporting and publications.
- Timeline (plan of activities).
- Budget, with identification of secure source of funding or potential funders to be approached.

Source: Chetley et al. 2007.

- What improvements could be made?
- What are the most important lessons for the future?

Fully documented communication activities are easier to monitor and evaluate, and help future program planners learn from the experience. Even when communication activities are carried out on a large scale, obtaining reports on them is often very difficult, particularly in developing countries. This difficulty leads to unnecessary duplication, loss of experience gained, and waste of resources. For example, a WHO study of twenty-eight developing and thirteen developed countries showed that public education interventions on rational medicine use were poorly documented (Fresle and Wolfheim 1997). In addition, most of the planning of the interventions was unstructured, with poorly defined objectives and broadly defined target groups, such as “general public.” Also, the interventions generally suffered from a lack of consistent funding and little government or donor commitment, making it difficult for them to gain momentum and show success.

In summary, the preceding steps can be used for small educational interventions or large national programs. No single approach is the solution to all health communication problems; selecting from a tool kit of possibilities, based on an analysis of the situational context and the most appropriate approach to apply, is increasingly recognized as the best way to develop effective communication interventions (Chetley et al. 2007). [Box 33-6](#) lists the key components of a communication plan.

Even if resources are sufficient only for a small-scale educational intervention, knowing why people act as they do is

still important: no human behavior takes place in a vacuum; it is always “rational” within a given personal framework. Many beliefs about health care do not match a biomedical model, and recognition of both strengths and weaknesses of local traditions is needed. The credible channels of communication in a community should always be used to provide information. Materials must be pretested, because the perception of professionals will not be the same as those of a layperson whose formal education may be limited or non-existent. Above all—and particularly when resources are limited—it is necessary to prioritize interventions in terms of the risk the problems pose to public health and then focus on the major problem behavior and target the main risk groups.

[Country Study 33-6](#) illustrates innovative public education campaigns that focus on rational medicine use in three countries.

33.6 Facilitating and constraining factors in public communication

Many factors, which vary according to a country’s level of development and health care infrastructure, affect public communication activities both positively and negatively. Factors that can facilitate public communication include the political will to increase medicine education and information, an understanding of people’s health-seeking behavior, and expanded coverage by mass media. On the other hand, public education can be constrained by a lack of coherent policies on both medicine use and public education; com-

mercial interests; professional interests; weak infrastructure; lack of resources; and economic, social, and cultural influences.

Facilitating factors

Facilitating factors stimulate, provide, or promote a fertile environment for public education. Identifying these factors can improve public communication campaigns.

Increased awareness of the need for public education on medicines. The democratic process, the growth of orga-

nized consumer and public interest groups, especially in developing countries, access to information through the Internet, and the movement for individuals to take more responsibility for their own health care stimulate public interest in and demand for medicine and health information. Awareness of the level of patient nonadherence to treatment regimens has also grown along with the increasing emphasis on chronic conditions, including AIDS, in developing countries.

Increased networking allows government health services, NGOs, and community-based groups to share their public

Country Study 33-6

Innovative public education campaigns to improve medicine use

Ghana

The Pharmaceutical Society of Ghana introduced a television serial broadcast nationwide called “Let’s Talk about Drugs,” which focused on different medicine-use issues. Instead of a doctor or pharmacist answering questions or giving a presentation, the show dramatized issues brought up at the pharmacy and interspersed those dramatizations with local facts. Episodes focused on issues such as patient rights, irrational use of antibiotics, and generic medicines. A panel of pharmacists responded to questions called in by viewers—and the response was overwhelming. The pharmaceutical society had requests to translate the program into different local languages and to adapt it for radio broadcast.

Indonesia

A survey in Indonesia indicated that mothers who bought medicines for use at home were not knowledgeable enough to ensure safe and effective use. Generally, mothers knew only the brand-name products marketed for particular symptoms, and as a result, household medicine consumption patterns showed that multiple brand names with the same active ingredient were being used concurrently, which wasted money. In addition, the population knew little about contraindications or side effects from the medicines they had in their homes. The Department of Clinical Pharmacology at Gadjah Mada University designed an educational strategy called Cara Belajar Ibu Aktif (CBIA) (Mothers’ Active Learning Method). The CBIA model used interactive discussions with small groups of six to eight people held in the context of regular meetings of women’s grassroots organizations or other gatherings. Although mothers were the target population, teenagers and fathers also participated. Participants brought in all the medicines they had at home and worked with a tutor with a set of

thirty to forty medicines to learn important facts about the active ingredients, the differences between products for adults and children, and how to interpret the package information. For example, the participants learned that brand names in different forms, such as syrups or tablets, have the same active ingredient, but syrups often cost ten times more. Also, brand names with “forte” or “plus” on the package are often more expensive, but the amount of active ingredient may be only slightly higher. In field tests, participants with CBIA experience were significantly more knowledgeable, and the number of brand-name medicines used in their households dropped dramatically. After journalists attended some of the sessions, stories about CBIA appeared in national newspapers and a popular women’s magazine.

Nepal

A survey showed that mothers in Nepal were giving either inappropriate or inadequate antimicrobial home-based treatment to children for acute respiratory infection, as well as giving children antimicrobials to treat common colds; retail drug sellers had the same level of knowledge about appropriate medicine use as the mothers. A community-based education campaign used a child-to-child education program administered by teachers, using street theater performances in front of mothers’ groups, followed by interactive group discussions with the mothers run by community health volunteers. In addition, community leaders and drug retailers were trained by paramedics on appropriate medicine use for acute respiratory infection. The main messages of the community education campaign were that young children with signs of severe infection must be taken to a health facility immediately and that medicines should be taken only on the advice of a health worker.

education experiences, so groups can learn from the experience of others.

As a response to both regulatory requirements and consumer pressures, some pharmaceutical companies are moving toward providing improved and user-friendly written patient information. In addition, some professional bodies (notably pharmacists) in Europe, the United States, and Australia have developed training programs for their members to promote communication skills and interaction with consumers. Many universities have also added such courses to their medical and pharmacy curricula.

Knowledge of social and behavioral theory. Research in the last decade has greatly expanded the knowledge base underlying health- and medicine-seeking behavior, particularly its cultural dimensions. Anthropologists have studied how medicine consumption is culturally mediated (van der Geest, Hardon, and Whyte 1990).

Expanded coverage by mass media and information technology. Communication technology has created powerful mechanisms to convey educational messages. Many people have access to radio and television, which open up new opportunities to reach large audiences, including non-literate populations, with health-related messages. SMS and mobile technology have further expanded coverage. With new information technology such as the Internet, some health professionals and patients have greater access to information from online databases, websites, and e-mail (see Chapter 50). These resources have many potential benefits, including rapid access to objective information and low-cost sharing, pooling, and comparative evaluation of different communication methodologies.

Constraining factors

Implementers of public communication strategies need to recognize and evaluate inhibiting factors, because solutions vary according to the particular situation of each country. The successes and failures of others can help in developing a framework for effective action (see References and Further Readings).

Lack of coherent policies for both medicine use and public education. Many countries need to strengthen their national policies on medicine use and to incorporate public education in them. Without a clear policy, public communication cannot take place in a cohesive manner and receive adequate support. A fragmented approach can confuse the public with conflicting and competing messages.

The weak state of public education on medicines in many countries is partly the result of a lack of political commitment to public education in general. Within health services, public education is often a low priority and is consequently poorly financed and staffed. Sometimes NGOs fill this void; however, they usually depend on donor agencies for funding that can be withdrawn or reallocated. In some instances,

public education on medicines is a sensitive issue, because it may lead to community challenges of commercial and other vested interests. To improve the situation, a multisectoral approach involving key stakeholders both inside and outside the health sector is crucial.

Commercial interests. Commercial interests do not always match public interest. Particularly in developing countries, where control of pharmaceutical promotion may be nonexistent, weak, or unenforceable, industry may contribute to inappropriate medicine use by conducting promotional activities based on inaccurate information.

In retail drug outlets, where many people seek health care and buy pharmaceuticals for self-medication, the shop owner may or may not have any health care training or experience, and the counter attendants are typically untrained. Because the objective of these businesses is to make a profit, the drug sellers generally sell the medications that the customer requests, without providing any information. However, increased recognition that informal drug sellers play an important role in the public's rational use of medicines has led to the decision that they should also be a target of education campaigns. Chapter 32 covers drug seller initiatives to improve dispensing services.

Professional interests. Resistance to change within professional groups can constrain public education. Prescribers tend to hold influential and powerful positions, and they may not perceive the need for, or the importance of, public education. In turn, they often do not fulfill their professional role of providing advice on the appropriate use of medicines on either a personal or an organizational basis.

Public education can appear to conflict with existing values and power relationships, for example, by leading the public to challenge the traditional prescriber-patient relationship. Professional groups may oppose public education if they perceive it as a threat rather than a challenging opportunity arising from a new relationship with the community.

Weak infrastructure. Lack of infrastructure within the health system for implementation of pharmaceutical policies, including access to medicines and public education, can be a major constraint. Any effort to educate the public on appropriate medicine use can be undermined if necessary medicines are inconsistently available in the public or private sectors. Consumers then face the dilemma of reconciling public educational messages that motivate appropriate behavior with the reality of product availability in the public sector and the private-sector marketplace.

Lack of resources. Effective public education requires sufficient funding and the allocation of trained staff to enable targeting of population groups through appropriate strategies. Public education on medicines requires an extensive program to train health workers and other field staff in communication skills and appropriate medicine use.

Social, economic, and cultural factors. Lack of involvement and participation of the target groups often leads to problems. Support for public education programs may be withdrawn prematurely because of a failure to recognize that bringing about behavioral change is a slow and long-term process.

33.7 Understanding the importance of communication about appropriate medicine use

A need exists for consumer education in appropriate medicine use. Such programs—whether run by government, development organizations, NGOs, community groups, or professional bodies—merit support and encouragement. Public education should form an integral part of both national pharmaceutical policy and prescriber training. Policy makers, professional bodies, prescribers, dispensers, and educators have important advocacy and technical roles.

The reasons people decide to change (or not to change) their behaviors are almost always emotional; therefore, merely informing or educating about the change is necessary although not sufficient to prompt behavior change.

According to WHO (Chetley et al. 2007), research has shown the following—

- Combining strategies—such as education and communication with regulation—produces better results (see Chapter 29).
- Combining communication methods—face-to-face communication with mass media—produces better results.
- Using any single communication approach—print or radio or face-to-face communication—is rarely effective.
- Researching, planning, pretesting, and monitoring and evaluation are required.
- Involving the target audience is essential and leads to more practical and effective interventions.
- One-off communication interventions are not very effective, and their effect is not sustainable.

In addition, a coalition of resources improves the chance of the intervention's success and expands its capacity and reach. Smaller-scale programs can provide valuable experiences, and they may later serve as development models for more comprehensive strategies. Finally, and perhaps most critically, health care practitioners must be convinced of their core educational role. They must learn how to perform that role effectively and work to alter the all-too-common perception of patients as passive recipients of treatment.

Whether planning a campaign for promoting generic use of medicines (Chapter 29) or a national pharmaceutical

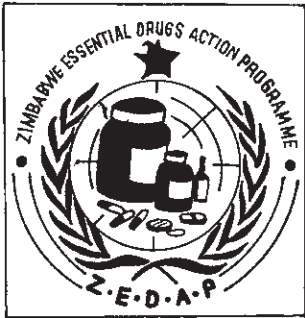

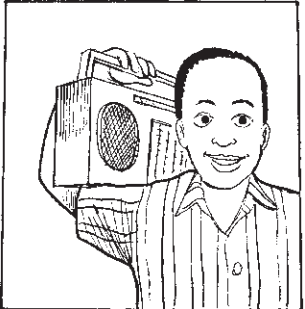

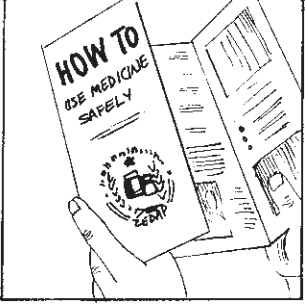

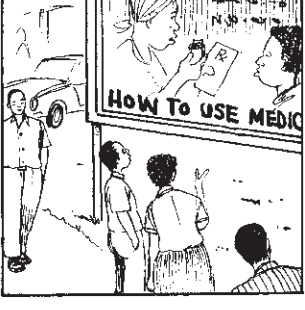

policy (Chapter 4), or when starting a health insurance plan (Chapter 12), standard communication elements should be considered. These may involve a good logo, radio spots, a flyer or visual aid, a poster, and possibly folk media (Figure 33-4). Although every campaign does not need all of these elements, using several of these components helps vary the message's delivery. The communications elements described in Figure 33-4 can be used in such campaigns. ■

Figure 33-4 Hints for selecting communication methods for public communication campaigns

	<p>A Good Logo</p> <ul style="list-style-type: none"> • is simple, not cluttered • is immediately understandable and explicit, not abstract • is related to the key program benefits and is a symbol of key data • is easily reproducible • works in different sizes and settings • dramatizes the overall tone of the change approach • is positive and uplifting
	<p>An Effective Radio Spot</p> <ul style="list-style-type: none"> • presents one idea • begins with an attention getter • is direct and explicit • repeats the key idea at least two or three times • asks listeners to take action • makes the audience feel part of the situation • maintains the same tone as the overall approach
	<p>A Useful Flyer or Visual Aid</p> <ul style="list-style-type: none"> • carries the information most likely to be forgotten • uses visuals, not only words, to tell the story • shows people doing key behaviors • uses attractive images • is concise • maintains same tone as overall change approach • is organized so that it favors a logical action sequence • is designed for easy use as a visual aid • matches graphic and language skills of a specific audience
	<p>An Effective Public Poster</p> <ul style="list-style-type: none"> • dramatizes a single idea • attracts attention from at least 10 meters away • uses visuals to carry the message • is memorable • models the behavior whenever possible • shows the product's benefit to the audience • is consistent with the tone of the overall change approach
	<p>Folk Media</p> <ul style="list-style-type: none"> • use local drama groups and musicians, who are often powerful vehicles for sharing health-related messages • include traveling health fairs with puppet shows, musical acts, distribution of printed materials, and appearances by local celebrities • stimulate interest in national and local programs, for example, through fairs that travel from village to village

ASSESSMENT GUIDE

- What are the problems related to current medicine prescribing, dispensing, and use, and what are the critical factors underlying these problems?
- What medicine prescribing, dispensing, and use practices are priorities for an intervention?
- What solutions are feasible to address the medicine prescribing, dispensing, and use problems that stakeholders support?
- Do public communication campaigns on medicine use already exist?
- What is the purpose of the campaign? What is it trying to achieve?
- Is medicine education included in the primary and secondary school curricula?
- What media are being used (for example, print, face-to-face, radio, theater)?
- What materials exist for public communication activities? How were these materials pretested? What evaluations of public education campaigns have occurred?
- Who is the audience for the campaign or the materials? What does this group know about the targeted medicine-use problem?
- What percentage of the public health or pharmaceutical budget is allocated to public communication on rational medicine use?
- What amount is spent on public communication campaigns on medicine use, and what percentage does this represent of the total amount spent on public health education campaigns?

Besides a focus on low-literate audiences, content also includes writing for policy makers, providers, field workers, and others targeted for training or advocacy efforts.

Organizations related to medicine use and safety for consumers

Ask about Medicines

<<http://www.askaboutmedicines.org>>

Ask about Medicines was an independent campaign to increase people's involvement in decisions about their use of medicines. Posters, action packs, leaflets, public relations tool kits, and fold-out medicine charts are available for free download at the website.

International Medication Safety Network (IMSN)

<<http://www.intmedsafe.net/Contents/Home.aspx>>

IMSN is a network of safe medication practice centers that aims to improve patient safety by minimizing preventable harm from medicine use. Its website includes contact information for members, position papers, and links to tools and resources from its member centers.

International Network for the Rational Use of Drugs (INRUD)

<<http://www.inrud.org/index.cfm>>

Established in 1989 and consisting of twenty-four groups from around the world, INRUD's goal is to "design, test, and disseminate effective strategies to improve the way drugs are prescribed, dispensed, and used, with a particular emphasis on resource poor countries." Its website provides details of its activities, bibliographies on the rational use of medicines, and a variety of resources available without cost.

- INRUD Bibliography on medicine use. <<http://www.inrud.org/Bibliographies/INRUD-Bibliography.cfm>>

National Council on Patient Information and Education

<<http://www.talkaboutrx.org>> Multiple campaigns on medicine, including “Educate before You Medicate,” “Be MedWise,” and “Your Medicine Information: Read It and Heed It.” Posters, leaflets, radio spots, information folders, activity sheets.

U.S. Food and Drug Administration (FDA)

<<http://www.fda.gov/Drugs/ResourcesForYou/Consumers/default.htm>> The FDA has a website that provides information and resources on medicines specifically for consumers.

WHO’s website on Rational Use of Medicines

<http://www.who.int/medicines/areas/rational_use/en> WHO’s work on the rational use of medicines advocates twelve key interventions to aid in avoiding the health hazards and waste of resources resulting from the misuse of medicines. Its website explains these interventions and provides information resources, training courses, and publications.

ANNEX

Annex 34-1 Information sources 34.17

SUMMARY

Prescribers, dispensers, and users of medicines all require information on medicines. The sources of this information can be classified as primary (articles or papers on original research), secondary (reviews of the primary literature), and tertiary (formulary manuals, standard treatment manuals, textbooks, and review articles, or pharmaceutical product information approved by drug regulatory agencies). Promotional literature has limited utility because it provides biased information designed to promote sales of commercial products.

The skills required to evaluate medicine information sources can be provided by a medicine information center (MIC); ideally, every country should have one. An MIC can be established in an accessible hospital or university department. The center should provide information proactively as well as respond to queries. The

center requires trained staff with access to both text and computer information sources.

MIC activities include sending staff out to provide information; developing, producing, and disseminating a drug bulletin based on modern communication principles; and teaching.

Funding the center may be difficult, but diversified funding should be sought whenever possible. Funding from pharmaceutical companies may appear to affect the center's impartiality and should generally be used only for capital projects. Other problems that may affect the center include—

- Inadequate information sources
- Lack of acceptance
- Inadequate communication systems
- Lack of political will to establish or sustain the center

34.1 The important role of medicine and therapeutics information

Access to clinically relevant, up-to-date, user-specific, and objective information is required to make appropriate decisions for medicine prescribing, dispensing, and use. A health care system can provide access to the highest-quality medicines, but if those medicines are not properly used, they may have negligible, or even harmful, effects. Although access to good information about medicines does not guarantee appropriate decisions and use, it is a basic requirement for good decision making.

Medicine information comes in many forms, both printed and electronic, and the need for medicine information varies among different types of health care providers and patients. For example, physicians and pharmacists need access to the full range of information about generic and brand-name medicines, indications and contraindications for use, medicines of choice and therapeutic alternatives, dosing, precautions for use, drug interactions, side effects, adverse effects, clinical features and treatment of overdose, dosage forms and strengths, and cost of a course of treatment. Patients need basic instructions for using prescribed and self-care medicines. In addition, consumers increasingly expect, and are being provided with, more comprehensive medicine information as they become more involved in decisions regarding their own treatment and care (Chapter 33). This trend has accelerated with the growth of the Internet and the huge repositories of information that are easily accessible (see Box 34-1).

Identifying and accessing needed medicine informa-

tion resources are important activities for a pharmaceutical management program. When limited funds do not allow the program to provide systemwide access to necessary information resources and individual practitioners are unlikely to be able to purchase information themselves, a centralized medicine information service should be considered.

The primary role of an MIC is to give clear and definitive information on medicines and promote their appropriate use. A secondary role of the center is to keep up-to-date with pharmacological and therapeutic advances and disseminate relevant information when it becomes available. This activity is particularly important to support a hospital's drug and therapeutics committee and the work it does in maintaining its formulary, treatment guidelines, and formulary manual (Chapter 17).

34.2 Types of medicine information

Information falls into three categories depending on its source—primary, secondary, or tertiary. Primary sources are the foundation on which all other medicine information resources are based. They provide original thinking and results of original research. Primary literature can be found as published articles or unpublished reports that provide detail on the research and its findings. Published information has typically gone through a peer-review process to assess scientific soundness and merit. Publications or reports would provide information on medicine-related subjects, such as clinical pharmaceutical trials, case studies, and pharmacological research.

Secondary sources are more difficult to define because interpretations vary as to what exactly they are. In essence, however, secondary resources function as a guide to or review of the primary literature and include, for example, indexing and abstracting services (for example, PubMed), commentaries on primary literature, review articles, drug bulletins, and meta-analyses or systematic reviews, such as Cochrane evaluations. Secondary sources are typically easy to access and use and to link to the primary literature.

Tertiary sources draw from primary and secondary literature and provide “processed” information that represents the interpretations and conclusions of the individuals or organizations doing the development. They are convenient and easily used but at the same time carry the risk of being less than objective. Examples include textbooks, general reference books, and pharmaceutical compendia. Obtain the most current edition available when using secondary or tertiary sources.

A selected list of medicine information sources that can be accessed online appears in [Annex 34-1](#). All information sources have limitations, and medicine information users should recognize both their advantages and disadvantages.

Evaluation of information sources

Evaluating information sources is an important skill (see [Box 34-2](#)). The *Teacher’s Guide to Good Prescribing* (Hogerzeil et al. 2001) contains a useful section on assessing literature. *Studying a Study and Testing a Test* (Riegelman 2004) is a valuable primer on evaluating medical literature.

Primary sources. Evaluating primary literature is difficult. The most reliable evidence comes from reports on randomized controlled clinical trials. Appropriate evaluation of these trials requires considerable time and experience, but they are by far the best source of objective information. To use primary literature effectively, the user needs a certain level of knowledge about research methodology and statistics. Keeping up with the volume of published information is also difficult. Thousands of journals are published regularly, with each containing many articles. Even if reading is limited to journals in a specific area of interest and expertise, the amount of information may preclude staying abreast of the latest findings. Therefore, many readers simply trust the journals’ peer-review processes and assume that the process will identify any problems with the studies.

In judging published primary literature, the reader cannot assume that the results of a study or a research paper

Box 34-1

Medical products and the Internet

The Internet provides people with quick and easy access to vast amounts of information on practically any subject. It is a valuable source of health information on topics such as diseases, conditions, therapies, medical products, and health and medical organizations. The quality of information, however, varies, and consumers as well as health care professionals must be careful when using the Internet as a source of health information.

The World Health Organization (WHO) created a guide on medical products and the Internet to help people obtain reliable, independent, and comparable information. The guide has five key points—

1. The Internet is a valuable source of information, but the consulted source should be known and trusted. Consumers need to judge whether or not the information is reliable, complete, and up-to-date.
2. Determining and verifying the source of a website can be difficult, so consumers should look for the following—
 - Clear indication of the name and contact address of the website owner

- Clear indication of funders, services, or other support to the website
 - Whether advertising or sponsorship is a source of funding
 - Intended audience (consumer, health professional, other)
 - Date of the last information update
3. When searching for and evaluating products, such as pharmaceuticals, if information sounds too good to be true, it probably is. Information should include active ingredients, other ingredients, side effects, interactions, how to use a product, how to store it, and contact information.
 4. Consumers need to be cautious about buying medical products on the Internet. They can be illegal, risky, poor quality, a waste of money, and lacking in safety and efficacy assurance. Instructions for use may be inadequate.
 5. Although the Internet can be a good source of information, consumers should not substitute it for an actual consultation with a health care provider.

Sources: WHO 2001, 1999.

Box 34-2 Evaluating information sources

Questions to ask when reviewing original clinical articles

- In which journal was the article published? What is the reputation of the journal? Is it known to have high standards for the acceptance of articles? Are articles peer reviewed?
- Who is the author, and what is his or her affiliation?
- Does the article report the results of a properly designed clinical study, or is it based on case reports or observations? If a clinical study, what was the sample size, and how were participants selected? Were controls used? Was the study prospective or retrospective? Is the report adequately referenced?
- Are reasonable conclusions drawn?
- Who funded the study? Does any potential exist for conflict of interest?

Questions to ask about bibliographic, abstracting, or indexing services

- What journals or information resources are covered by the service, and are these resources the ones that are essential for the particular purpose?
- What is the lag time between the publication of a journal and its inclusion in the service?
- How easily can the service be used? Are key words indexed? Are subject headings used?
- If abstracts are provided, who develops the abstracts, and how accurately do they reflect the primary source?

Questions to ask about consensus-generated documents

- How is consensus defined, and how are the individuals participating in the consensus definition process selected?

- How good is the consensus-generation process?
- Are references provided and accessible?
- Is the consensus process open to public review and comment?
- Is the information based on evidence published in peer-reviewed literature, or is it simply a compilation of use patterns reported as being accepted by the medical community?
- When was the consensus document published, and how frequently is the information updated?
- Who published the information, and what kind of reputation does the publisher have?

Questions to ask about secondary and tertiary references written by individuals or groups of individuals

- Who is the author, and what are his or her qualifications?
- Who is the publisher, and what is its reputation?
- Who paid for the development of the information? Does it come from a special-interest group? If the publication is reporting proceedings from a conference, who organized the conference, and do the organizers have a special interest?
- Has the information been peer reviewed? How good is the peer-review process?
- When was the information developed, and how current is it?
- Are references included in the article, or can the references be accessed by other means?

are valid simply because it has been accepted for publication. However, considering the source of a study or paper is useful when determining quality. A number of respected medical and pharmacy journals whose high standards for acceptance and publication make it unlikely that a research article containing erroneous, fraudulent, or misrepresented data would survive the editorial and review process. [Annex 34-1](#) lists some English-language journals that have strong editorial policies and peer-review processes that include conflict-of-interest disclosure requirements to minimize the possibility of biased or unsupportable conclusions being reported. One way to monitor such problems is to read the

letters to the editor published in journals. If questionable conclusions survive the peer-review process, some reader will undoubtedly write to the journal editor and state his or her observations or concerns. Reputable journals readily share this type of correspondence, often allowing the authors of criticized articles the opportunity to respond.

Information published in journals without a strong review process needs to be more carefully scrutinized. “Throw-away” or controlled-circulation publications, provided free of charge, often by a special-interest group (a pharmaceutical manufacturer, for example), require careful review to determine what biases, if any, exist. Determining who is

publishing these types of journals and what the peer-review process is, if any, for acceptance of an article is a good idea. In addition, note conflict-of-interest declarations.

Clinical trial databases and unpublished reports (known as gray literature) are also considered primary literature. Although not always readily available, this type of information can provide valuable insights. For example, some companies or researchers may elect not to publish results because the findings were negative. This decision presents an ethical problem in that negative findings, although potentially detrimental to the financial success of a particular product, are valuable in making evidence-based decisions on the use of

a medicine. Finding information on clinical trials has been facilitated in recent years through the creation of clinical trial registries that are available online. For example, the Duke University Medical Library has a guide to searching the gray literature and clinical trials, including those on pharmaceutical company websites (<http://guides.mclibrary.duke.edu/content.php?pid=224463&sid=1861375>). The reader needs to carefully interpret unpublished data, however, because there may be negative underlying reasons why the data have not been published in peer-review journals.

Secondary and tertiary resources. Secondary and tertiary information resources are essentially derivations of

Box 34-3

The Cochrane Collaboration

The Cochrane Collaboration was established in 1993 in England to support the systematic, up-to-date review and synthesis of scientific research, which can be used to help people make well-informed decisions about health care. The collaboration is based on the ideas of Scottish doctor Archie Cochrane, who said in 1979 that health professionals should have an updated critical summary of all relevant randomized clinical trials (RCTs) to provide evidence-based care that is proven effective.

The Cochrane reviews are prepared mainly by health care professionals who follow an established methodology. The reviewers systematically study all reports of RCTs for treatment of a specific problem while focusing on identifying the benefits and risks of different interventions. The group often uses a technique called meta-analysis, which combines the results of different RCTs to get around problems of small sample sizes that can lead to statistical errors. After extensive peer review, the documents are published and updated periodically.

Cochrane reviews cover treatments for many different diseases. Specific groups of reviewers focus on particular subjects, such as eyes and vision, arthritis treatment, and neonatal health. An example of a Cochrane review is *Co-trimoxazole Prophylaxis for Opportunistic Infections in Children with HIV Infection*, published in 2006. The review found a significant reduction (33 percent) in mortality in HIV-positive children one to fifteen years of age taking co-trimoxazole versus a placebo. Co-trimoxazole is cheap and effective against a wide range of organisms that commonly cause opportunistic infections in children with HIV. The reviewers concluded that the use of co-trimoxazole prophylaxis was beneficial for HIV-infected children in Zambia, and whether this conclusion can be extrapolated to other resource-poor settings must be decided.

Although the Cochrane Collaboration has centers in Australia, Canada, Denmark, England, Italy, and the United States, it is beginning to influence far-reaching health policies in developing countries. Through its Developing Country Network, it encourages people from these countries to become reviewers and to register all RCTs throughout the world, so that the information is available and useful to researchers and the public. For example, the African Trials Register involves tracking down all controlled trials conducted in Africa by searching global and regional databases and hand-searching African journals. This project intends to ensure that trials conducted in Africa are documented so they can be used in Cochrane reviews.

The collaboration publishes its reviews in the Cochrane Library, primarily through CD-ROM and the Internet. Free access to abstracts and summaries of the reviews are available to the public, but most full-text documents require a subscription. Access to the reviews is steadily improving for people in low- and middle-income countries through free national subscriptions or global initiatives promoting free access to health care information, such as the HINARI Access to Research in Health Programme (<http://www.who.int/hinari/en>). Since it was established, the information disseminated by the Cochrane Collaboration is having a “significant impact on education, practice, research and policy” (Volmink et al. 2004).

E-mail: secretariat@cochrane.org

Web: <http://www.cochrane.org>

Sources: Grimwade and Swingler 2006, Volmink et al. 2004.

the primary literature. Some review articles summarize the results and conclusions of a number of reports from the primary literature (usually with comments by the reviewer). Systematic reviews of data from multiple trials addressing the same research question (meta-analyses) are particularly useful. The Cochrane Collaboration (see [Box 34-3](#)) undertakes this type of work.

Bibliographic, abstracting, or indexing services provide listings or compilations of published articles. Some list the addresses of the principal authors; others contain abstracts of articles, along with key words or subject headings to help users find the articles or references for which they are looking. Examples of such services include PubMed, Embase, International Pharmaceutical Abstracts, Index Medicus, Excerpta Medica, and the Iowa Drug Information Service. Different systems cover different journals and may, for instance, omit letters to the editor. A lag period exists between initial publication of a primary source and its inclusion in such secondary sources. Not relying entirely on one secondary source is therefore important.

Drug bulletins can be valuable in helping prescribers and supply system managers determine the relative merits of new medicines and keep up-to-date. Drug bulletins can have a variety of sponsors, such as government agencies, professional bodies, university departments, philanthropic foundations, and consumer organizations. They are published in many countries, sometimes free of charge, and many are highly respected because of their unbiased information. Examples in English are *Drug and Therapeutics Bulletin* (United Kingdom), *Medical Letter on Drugs and Therapeutics* (United States), and *Australian Prescriber* (Australia). *Prescrire International* is available in both French and English. National drug bulletins appear in many other countries, including Bukina Faso, Nepal, and Pakistan. The main advantages of national drug bulletins are

that they can select topics of national relevance and use the national language.

Tertiary references, written by individuals or groups, are often developed with the input of consultant authors and reviewers and may be widely peer reviewed. In general, the more thorough the review process is, the more sound the information is likely to be. In many countries, the most widely available tertiary resources are formulary manuals and standard treatment manuals produced by the health system. These important resources are discussed in [Chapter 17](#). [Box 34-4](#) also lists selected tertiary sources.

Probably the most widely accepted secondary and tertiary information sources are those that report the consensus of experts, a process that involves a high level of scrutiny and feedback. A consensus statement is the closest one can come to agreement among experts. In most instances, consensus is defined as having addressed and considered all dissenting views so that, at a minimum, all disagreements have been publicly stated and considered. The consensus documents developed by the U.S. National Institutes of Health, such as the *NIH Consensus Development Conference Statement on the Management of Hepatitis B* from 2008, are good examples of this approach to information development.

Manufacturer-provided medicine information

Information provided by pharmaceutical companies is so commonly available and widely used that it warrants a separate discussion. This information can be technical, such as product labeling approved by a country's regulatory agency, textbooks, and journal reprints, or promotional information. Promotional information seeks to show how one company's product is better than another's or how a new product can treat a serious or not-so-serious medical condition. Although both technical and promotional information are ultimately intended to increase sales, the two differ greatly in

Box 34-4

Basic references for a medicine information library

- *Martindale: The Complete Drug Reference*
- National formulary or essential medicines list
- PubMed
- Price reference (specific for the country or region)
- *International Drug Price Indicator Guide*
- Textbook of internal medicine (such as *Harrison's Principles of Internal Medicine* or the *Oxford Textbook of Medicine*)
- Tropical medicine reference (in countries where appropriate)

Box 34-5**Medicine information and promotion: Educating medical and pharmacy students about medicine promotion**

Understanding the relationship between health professionals and medicine promotional information produced by the pharmaceutical industry is important. Research has shown that doctors who rely more on industry promotional information tend to prescribe less appropriately, prescribe more often, and adopt new medicines more quickly; therefore, medical and pharmacy students need to be educated about recognizing medicine promotion and responding appropriately.

In 2005, an international cross-sectional survey, Educational Initiatives for Medical and Pharmacy Students about Medicine Promotion, examined the extent to which students are educated about the pharmaceutical industry and medicine promotion. The results are based on a survey of 228 pharmacy and medical school educators from sixty-four countries.

In the survey, nearly three-quarters of educators reported that education about medicine promotion is part of their required curriculum but that most students devoted less than one-half day to this topic. The regional breakdown is illustrated in the table below.

The survey reported what survey respondents felt were the main objectives of their medicine promotion curriculum—

- Of educators from all regions, 70 percent or greater, except the eastern Mediterranean (56 percent), said

the main objective of their curricula was to teach critical appraisal of medicine promotion.

- Of educators from all regions, 70 percent or greater said that the main objective was to increase students' use of independent resources.
- Only 14 to 26 percent of the educators felt that the main objective was to decrease students' use of medicine promotion.

Many pharmacy and medical educators have recognized the need for education about medicine promotion, but they frequently mention a lack of integration into the main curriculum and inadequate time allocation as barriers to a successful program.

In some cases, students themselves are taking an active role in opposing the influence of medicine promotion. In 2002, the American Medical Student Association launched its PharmFree campaign, which educates medical students about the influences of the pharmaceutical industry on medical training and the problems with using biased industry-based information to choose which medicines to prescribe. The association encourages students to refuse any gifts from pharmaceutical representatives as a way to show that they are not influenced by them, and they encourage the use of sources such as the *Medical Letter* to get unbiased evaluations of new medications.

Educators' report of the role of medicine promotion in international pharmacy and medical school curriculum

Role of medicine promotion	Europe (%)	Americas (%)	Western Pacific (%)	Africa (%)	Eastern Mediterranean (%)	Southeast Asia (%)
Promotion is part of curriculum	81	83	67	86	70	91
Promotion is part of <i>required</i> curriculum	75	64	81	85	65	56
One-half day or less spent on promotion	30	32	39	25	20	20
Ten or more hours spent on promotion	40	34	32	50	45	44

terms of source and presentation. The information provided by pharmaceutical manufacturers varies considerably from country to country, depending on a government's regulatory requirements and its ability to effectively monitor and enforce those requirements. [Box 34-5](#) covers an initiative to increase medical and pharmacy students' knowledge of medicine promotion.

Technical information. The information developed as part of a new medicine approval process by a country's drug regulatory authority has been thoroughly reviewed and should accurately reflect a product's basis for approval. It defines what information manufacturers are required by law to include with their product—that which is affixed to a bottle or package (the labeling) and more detailed

information that needs to accompany the product (package insert). Approved product information guides prescribers, dispensers, and patients on use of a particular medicine and defines what the manufacturer can legally say (advertise) about its product. This information includes, for example, the medicine's approved indications for use, precautions, potential adverse effects, and dosing, as well as the product's strength, composition, and packaging and storage requirements. In addition, more and more countries are providing information for the patient in easy-to-read language on how to use the product correctly. Because this information is approved by the drug regulatory authority, it carries significant impact both clinically and legally.

Many health professionals and patients regularly use references that compile government-approved product

information or brief descriptions of a product's physical characteristics and use that are based on approved product information. In the United States, the most common reference of this type is the *Physicians' Desk Reference*, where pharmaceutical companies pay to include their products (making it marketing focused). In the United Kingdom, the Association of the British Pharmaceutical Industry *Data Sheet Compendium* is commonly used; and in many other countries, the country-specific or regional edition of *MIMS (Monthly Index of Medical Specialties)* provides brief sets of information for products marketed in that country or region. The limitations of these types of publications must be kept in mind, particularly related to what is included (older, less-profitable products are more likely to be excluded) and the information omitted because of

Box 34-6 WHO ethical guidelines for medicine promotion

Since 1967, WHO has been concerned about improper pharmaceutical advertising. A new statement on ethical criteria for medicine promotion was adopted in 1988. At the 1997 Roundtable on WHO's Ethical Criteria for Promotion of Medicinal Drugs, participants agreed that inappropriate medicines promotion remained a problem both in developing and developed countries. The movement for a major project on pharmaceutical promotion originated at the May 1999 meeting of the WHO/public-interest nongovernmental organization, Roundtable on Pharmaceuticals.

Promotion of pharmaceuticals should support the national pharmaceutical policy. The WHO ethical criteria state that advertisements should be consistent with the approved scientific data sheet and should be fully legible. Advertisements to the public should be for non-prescription medicines only. Medical representatives should have appropriate training and should present information in an accurate and responsible manner, without offering incentives to prescribers or dispensers. They should make unbiased information on products available.

Under the criteria, free samples may be provided in modest quantities to prescribers. The criteria also state that providing free samples of nonprescription medicines is difficult to justify from a health perspective. When a pharmaceutical company sponsors a symposium or scientific meeting, its involvement should be clearly stated in advance at the meeting and in any publications.

The criteria recognize that postmarketing surveillance is important but caution that it should not be misused as

a disguised form of promotion. The criteria also define standards in packaging and labeling, patient information, and promotion of exported medicines. Many, but not all countries and some companies have adopted these criteria as a guide for marketing practices.

Copies of the ethical criteria are available from WHO offices and have also been published in full in the *WHO Essential Drugs Monitor* 17 (1994).

Other helpful resources related to pharmaceutical promotion include—

- Health Action International has a website devoted to medicine promotion (http://www.haiweb.org/03_other.htm). It includes downloadable resources related to promotion to consumers, promotion in health education, and drug industry sponsorship.
- The organization Healthy Skepticism (<http://www.healthyskepticism.org>), formerly the Medical Lobby for Appropriate Marketing, is a nonprofit advocacy group that initially focused on revealing harmful medicine promotion activities in developing countries but now documents information from all countries. Its online library of medicine promotion information includes more than 19,000 items.
- *Understanding and Responding to Pharmaceutical Promotion: A Practical Guide* (WHO/HAI 2010) is designed to summarize medicine marketing and promotion issues for medical and pharmacy students (http://www.haiweb.org/10112010/DPM_ENG_Final_SEP10.pdf).

Box 34-7**Questions to ask about manufacturer-supplied information**

- Has the information been approved by the country's drug regulatory body?
- Are references to the medical literature provided or available? Do they come from peer-reviewed journals?
- Was the information unsolicited, or was it provided in response to a request or question?
- Does the information contain negative references to the use of other medicines that might be substitutes or therapeutic alternatives to the medicine in question? If so, are such negative references warranted?
- Do the claims for the medicine's effectiveness appear overly positive, sensational, or one-sided?
- Is the information balanced with the negative outcomes related to the use of a medicine (such as side effects or adverse effects)?
- Are cost comparisons included?
- Does the information included in the product insert or the labeling reflect current medical practice and standards?
- Are references dated and current?
- Is the information in a language suitable for the consumer?

space limitations. They are not comprehensive information sources.

Promotional information. Promotional materials developed by a pharmaceutical company typically present only favorable views of the sponsor's products, and the materials may not furnish adequate information to make good prescribing decisions. Although most countries have regulations defining acceptable pharmaceutical marketing, in practice, governments often have difficulty controlling what information companies provide. A multinational advocacy organization, Healthy Skepticism, monitors misleading advertisements, as does Health Action International. WHO has developed ethical guidelines for pharmaceutical promotion (see [Box 34-6](#)).

This does not mean that manufacturers' information is universally bad and should not be used at all, because manufacturers can supply very timely and useful medicine information. However, health care professionals or patients using manufacturer-supplied sources need to recognize the potential for bias and make a judgment about the materials' value (see [Box 34-7](#)).

34.3 Setting up a medicine and therapeutics information center

A medicine and therapeutics information center is a vital part of efforts to promote appropriate medicine use. In a small country with limited means, this center may be a small office in the national hospital with a shelf of books and WHO publications and where a hospital pharmacist is responsible for answering queries. Ideally, however, countries should develop formal MICs as part of their national health programs. An MIC should work closely with the national essential medicines program, provide support for development and maintenance of formulary and standard

treatment guidelines, and be involved in the production of national medicine-related materials.

To be successful, an MIC requires a stable location and environment, a philosophical commitment to providing needed medicine information, physical space to house the center, basic information references, staff, and equipment to support information access and dissemination.

An MIC and a poison control center are two different services, although they are often combined. Poison control is usually an emergency service requiring rapid response. A medicine information service deals with both urgent requests for therapeutic information and requests that require a more detailed review and synthesis of information.

Philosophical commitment

An MIC should be both reactive and proactive. Reactive or passive duties include providing information for people who call or come to the center with questions. Although this function is important, it certainly should not define the limits of a center's activities. A center's effect will be greater if it functions proactively by reaching out with medicine information for people who need it, in a format that is convenient and effective. This task will be easier if a medicine information service is based on a cooperative model, involving all health care disciplines and using existing resources to the greatest extent possible. The center not only should be driven by the needs and expectations of its users but also should work to create demand and raise expectations.

Site identification

Ideally, an MIC is in or near a major hospital or other major health care facility. Location within a hospital, university, or other academic institution provides a network of medical disciplines that can support and enrich the work, allowing

MEDICINE INFORMATION SHOULD BE RESPONSIVE TO CLIENTS' NEEDS

better access to medicine information and to libraries, research facilities, expertise, and academic and educational activities. Possible alternative sites include a facility within or adjacent to a medical or pharmacy association or a relevant governmental agency (such as the ministry of health, drug regulatory authority, pharmaceutical approval unit, or quality-control laboratory).

A secure location in one or two rooms allows space for office work, space for storage of references, and space for visitors to use the MIC's resources. Involving several institutions in the support of an MIC may be necessary. In some countries, a mutual agreement exists that the MIC at the university provides services on behalf of the ministry of health. In turn, the government covers some recurrent expenses.

Staffing and equipment requirements

An MIC needs dedicated staff who will not be diverted to other activities and duties and who can provide dependable coverage for the center's stated business hours. This need translates into one or two full-time employees, including a full-time clinical or hospital pharmacist who specializes in clinical pharmacology, therapeutics, or toxicology. Additional staffing may be required if activities other than information, such as pharmacovigilance, are part of the center's mission.

The training and experience of the staff must be clinically based. The user population for any information service is primarily clinicians, and expertise in pharmacotherapy is essential to communicate effectively with them. When an appropriately trained person is not available, every effort

should be made to train someone to fill the position. Other relevant professionals—medical, paramedical, or non-medical—and specialists in information communication techniques may be required to help develop materials and provide specific information and services. When medicine information specialists are not available, a medical doctor with some training in clinical pharmacology should be considered to head the center. Ideally, the center should have qualified administrative staff to help establish, maintain, and update the information access and dissemination processes.

Proper photocopying, communications (including Internet access), and computer equipment are important in establishing a viable medicine information service. A computer, CD-ROM/DVD drive, printer, and appropriate software programs are highly desirable because access to electronic medicine and therapy databases is critical. However, small centers can provide important medicine information services using basic texts and other printed references if electronic access is not possible.

Basic information resources

The latest editions of the textbooks listed in [Box 34-4](#) could form the core of a basic library for an MIC, along with journals and newsletters, WHO materials, and computer databases (see [Annex 34-1](#)). Although the most flexible and efficient of these resources are the computer databases, cost may limit their availability. Print resources, if kept up-to-date, can adequately cover basic information needs. Some print and electronic databases can be accessed free of charge.

Although subscriptions to medical and pharmacy journals and newsletters are expensive, some basic subscriptions should be considered if the funds are available. Many scientific journals are now available via open access or are free of charge. A list of many such journals can be found at the Directory of Open Access Journals (<http://www.doaj.org>). Because acquiring and updating information is costly, establishing a link to a medical library is very important. The addresses of organizations that produce widely accepted medicine newsletters or bulletins, which are inexpensive and useful sources of information, can be obtained from the International Society of Drug Bulletins (ISDB).

Electronic access to information is critical for an MIC because most databases and journals are online. If Internet access is unavailable or unreliable, however, or if the costs of online access are prohibitive, CD-ROMs might be an alternative resource. Databases to consider including in an MIC include—

- PubMed (online)
- British National Formulary (online)
- Cochrane Library (online and CD-ROM)
- DrugDex (online)
- Poisindex (online and CD-ROM)
- Martindale: The Complete Drug Reference (online and CD-ROM)
- AHFS Drug Information (online)
- International Pharmaceutical Abstracts (online)

- Embase (online)
- Iowa Drug Information Service (online, CD-ROM, and microfiche)

34.4 Managing a medicine information center

An MIC should provide a variety of services, from responding to patients' and doctors' queries to making proactive efforts such as publishing newsletters or drug bulletins, participating in clinical activities, and organizing formulary and treatment guideline committees (see [Country Study 34-1](#)). MIC staff members are also likely to be involved in training health professionals and regularly evaluating the performance of the center's staff. Although MICs tend to be small units, each one should have a well-developed annual plan.

Proactive outreach

Health care professionals in both the public and private sectors often have little time or funds to spend on medicine information resources. An MIC can fill this gap, but the service must be effectively marketed.

Medicine information professionals need to work to build credibility and improve perceptions of their accessibility and value to health care providers, specifically, and to the health care system overall. This can be done by—

Country Study 34-1 Therapeutics Information and Pharmacovigilance Center in Namibia

As the Namibian government began rolling out anti-retroviral therapy, an assessment identified lack of a source of information about medicines and lack of a monitoring system for adverse drug reactions as critical gaps in Namibia's ability to deliver AIDS treatment. To fill this gap, the Rational Pharmaceutical Management Plus Program conceptualized a model that integrated medicines information and pharmacovigilance activities into one service unit called the Therapeutics Information and Pharmacovigilance Center (TIPC). Although most countries separate these activities, this integrated model was driven by the potential synergies between the two services, opportunities for leveraging resources, and human resource constraints. The model placed the TIPC under the Namibia Medicines Regulatory Council with existing Ministry of Health and Social Services committees serving as the advisory body.

The TIPC provides unbiased therapeutics information and serves as the official reference center for medicine

safety monitoring in Namibia. It provides broad-based medicine-safety services, such as how to avoid potential drug interactions, and communicates point-of-care therapeutic information to health care providers and the public through a hotline, fax, and e-mail. Anyone can request medicine or therapeutics information by filling out a form on the TIPC website. The TIPC also publishes the *Namibia Medicines Watch*, a drug bulletin for health care providers and consumers.

The center implemented a nationwide system for spontaneous reporting of adverse drug reactions in 2007, through which it collects reports from health care providers and the public of adverse effects of medicines. The TIPC has also collaborated with partners to conduct trainings for health care workers in therapeutics information and pharmacovigilance and basic research methods.

Source: SPS Program n.d.

- Building alliances with the most influential clinicians, providing them with particular information they request, and involving them as consultants and reviewers
- Ensuring that they are readily accessible by telephone or in person and providing responses to queries promptly
- Making an extra effort to find answers for clinicians who have raised unusual medicine-related questions
- Participating in national essential medicines list committees, hospital drug and therapeutics committees, and standard treatment guidelines committees
- Preparing short, problem-oriented, practical bulletins on medicine-use problems specific to the country, district, or hospital
- Making patient rounds with doctors and other clinical staff
- Providing in-service training to health facility staff
- Making short presentations to outpatient groups
- Making presentations to community organizations

Drug bulletins

The development, production, and dissemination of newsletters or drug bulletins that address relevant medicine information issues often help develop the market for an MIC. These periodicals should promote rational medicine therapy and appear at regular intervals, ranging from weekly to quarterly, depending on their purpose and on the capacity of the MIC. Drug bulletins should provide impartial assessments of medicines and practical recommendations, based on a comparison of treatment alternatives and on the consensus of the main specialists in the field.

Drug bulletins are more likely to be effective if they take the following principles into account (see [Figure 34-1](#))—

Understanding the reasons for prescribing behavior: As mentioned in [Chapter 29](#), providing information alone does not change undesirable behavior. Understanding the reasons for the behavior is a necessary first step in developing appropriate messages.

Being oriented toward decisions and actions: Prescribers need information that is immediately useful in their daily work.

Emphasizing and repeating only a few key messages: If too many ideas are brought up in the bulletin, none will be absorbed. A few messages that are the focus of the bulletin and are repeated are more likely to be retained.

Capturing attention with headlines and visually appealing illustrations: An effective bulletin grabs the reader's attention with attractive graphics that emphasize key messages.

Keeping text brief and simple: Although readers of the bulletin may be well educated and knowledgeable, a bulletin should provide immediately accessible information.

Referencing the best research and having respectable sponsorship: The bulletin should be affiliated with a credible organization or institution such as a medical society or medical school. Key messages in each issue should be supported by a few well-chosen and respected references. Three references to the *Lancet*, *New England Journal of Medicine*, *British Medical Journal*, or *Journal of the American Medical Association* are better than twenty references to unpublished reports.

Being relevant: Materials in the bulletin should relate to clinical issues that affect the target audience and should discuss medicines that are available in the audience's country or health system.

The ISDB produces a regular newsletter, organizes regional workshops for international editors of bulletins and newsletters, and provides a forum for the exchange of high-quality information and ideas related to promoting effective dissemination of information. [Box 34-8](#) includes information on starting or strengthening a drug bulletin.

Training

Training in the management of an MIC or a medicine information service is necessary for key personnel, as is training on medicine information retrieval, literature evaluation, publication development, and sustainability planning and funding. In addition, communications skills, including ability to write succinctly using language appropriate for the target audience, are critical. A large medicine information service should ideally have a career structure similar to those of academic or educational institutions. All staff members should have the opportunity for additional training and advancement within their own capabilities. When appropriate, professional staff should be encouraged to undertake relevant research activities.

Evaluation

Ongoing monitoring and evaluation is particularly important for services such as an MIC, where resources are limited and getting the most out of the available funding is essential. Monitoring should be built in from the start and should include documenting the questions asked, responses provided, references used, complaints and compliments received, timing of responses, and services provided (such as new medicine evaluations). The queries should be analyzed, and the results summarized in the annual report. In addition, periodic input from users of the medicine information service should be sought through personal contacts, questionnaires, or focus groups.

This information can help the center's manager make good decisions about future programs and budgeting. For example, if a certain inquiry has been made several times by

DRUG INFORMATION PROGRAM

PHARMACOKINETICS IN DAILY PRACTICE (third in a series)

ORAL METRONIDAZOLE: A First Consideration in Anaerobic Infections

Time (hours)	Oral Dose (µg/ml)	IV Dose (µg/ml)
0	0	0
0.5	6.5	9.0
1	7.5	8.5
2	8.5	8.0
3	8.0	7.0
4	7.5	6.0
6	6.0	5.0
8	5.0	4.0

Metronidazole may well be the drug of first choice in the treatment of many patients with anaerobic infections. Surprisingly, the oral form of this agent reaches serum levels quite comparable to those achieved with intravenous use.

Oral metronidazole achieved the same serum levels as the intravenous preparation when 500mg was administered via each route in a crossover study. Data from Mattila et al.¹

Oral versus intravenous use
 Unlike most commonly used systemic antibiotics, **metronidazole is almost completely absorbed when given orally.** As a result, comparable serum levels are attained with either oral or intravenous therapy using the same dose and interval (see graph).⁷ Patients with a variety of serious anaerobic infections, including intra-abdominal abscess, peritonitis, endomyometritis, and pelvic abscess have been successfully treated by the oral route with metronidazole.^{8,10} **Intravenous therapy offers no advantage in patients able to take and absorb oral medication.** Patients begun on intravenous metronidazole because of impaired g.i. function may be switched to the oral form of the drug as soon as their clinical status permits feeding.

different individuals, the question may be a good topic for an article in the medicine information newsletter or bulletin. If the same complaint about MIC service is made repeatedly, perhaps a review of the center's operations is in order. If a certain textbook or database is not frequently used, perhaps it should be replaced by another one.

Sources of help

Funding for the establishment of an MIC may come from government resources, donors supporting essential medicines projects, professional associations, university or other training programs, nongovernmental organizations, or a combination of several of these funding sources.

Several programs allow developing countries to more easily access health and medicine information and re-

sources. For example, the International Pharmaceutical Federation's Pharmabridge program helps provide books, journals, and electronic resources to those who need them in developing countries (<http://www.fip.nl/pharmabridge>). WHO's HINARI Access to Research in Health Programme also allows developing countries to use a large collection of scientific and medical literature (<http://who.int/hinari/en>). WHO also has "blue trunk libraries" that have over 100 books arranged by topic, including essential medicines (www.who.int/ghl/mobile_libraries/bluetrunk/en). Blue trunk libraries are available in English, French, Portuguese, and Arabic. Collaboration between centers in developing and developed countries is very valuable and enables the exchange of information and staff for teaching and training. The ISDB is also a useful channel for support.

Box 34-8

Starting or strengthening a drug bulletin

Drug bulletins are a fundamental tool for promoting rational use of medicines, and locally produced bulletins are an effective approach to providing reliable and unbiased comparative information on medicines and therapies for prescribers, patients, and the public within the context of local needs and uses. The information should focus on using medicines safely and correctly and help people make better decisions about medicines.

WHO and the ISDB have worked together to develop guidelines called *Starting or Strengthening a Drug Bulletin: A Practical Manual*, which shows global experiences related to developing drug bulletins.

The objectives of the ISDB and WHO manual include—

- Illustrating what makes bulletins independent
- Reflecting the diversity found among drug bulletins
- Helping people make choices about what is appropriate for their bulletin
- Showing useful methods and models and helping people learn from the successes and failures of others
- Helping people decide whether to set up a bulletin, how to set up a bulletin, or how to strengthen their existing bulletin

The manual has sections on planning, production, and the editorial process, as well as a detailed discussion of books and journals that are good references for bulletins.

How drug bulletins provide unbiased information on pharmaceuticals in Kyrgyzstan

According to WHO, an underlying factor in irrational medicine use in Kyrgyzstan is the lack of access to inde-

pendent medicine information. Working closely with the National Drug Committee, Kyrgyzstan's drug information center has taken on the important role of providing independent medicine information to health care providers. The center publishes a quarterly drug bulletin to disseminate unbiased and updated pharmaceutical information and to promote rational medicine use and information on health reform. Previously addressed topics include medical errors related to the name of medicines, medicine interactions, and modified-release preparations of pharmaceuticals.

How drug bulletins provide unbiased information on pharmaceuticals in Nicaragua

In Nicaragua, *Boletín AIS-COIME* is produced by a national nongovernmental organization, AIS-Nicaragua. It distributes free copies of its twelve-to-sixteen-page bulletins to all doctors working in public hospitals and primary health care units, pharmacy and medical students and teachers, nongovernmental organizations, and some private pharmacies. The bulletin is produced by a small team of three to four people and some volunteers. The team works together in a small room with access to a fax, photocopier, store, library, and meeting room. The country's drug information center provides them with information and reviews and helps with distribution of the bulletin.

ASSESSMENT GUIDE

Medicine information center

- Does a medicine information unit or center exist? If so, how is it funded and staffed?
- Does the medicine information unit or center (or another independent body) provide regular information on medicines to prescribers and dispensers?
- How many issues of independent drug bulletins are published each year?
- What percentage of prescribers receives copies of independent drug bulletins?
- What level of financial support did the medicine information center receive?
- How many queries did the medicine information center respond to in the past year?
- What current information resources are available? Which are most frequently used?

Local medicine information resources

- Has a national essential medicines list or formulary been officially adopted and distributed country-wide?
- Does a national publication (formulary bulletin or manual), revised within the past five years, provide objective information on medicines?
- Does a national therapeutic guide exist with standardized treatments for common diseases?
- What percentage of advertisements violates regulations on the ethical promotion of medicines, and how many sanctions have been implemented?
- What percentage of prescribers and dispensers has direct access to a (national) medicine formulary and standard treatment guidelines?

Funding issues

The source of funding may affect how an MIC functions. No matter how it is financed, the integrity of the unit is paramount. No special interests should be able to influence what information is or is not given out.

Obtaining initial capital funding from the sources listed previously may be possible. These organizations often provide funds for the purchase of items such as computers or photocopiers. For sustainability, it is wise to purchase a two- or three-year maintenance contract for such equipment as part of the initial capital costs.

Obtaining an adequate level of recurrent funding, particularly for staff salaries and journal, online database, or CD-ROM subscriptions, can be more difficult. Therefore, while establishing the center, every effort should be made to secure recurrent funding. For example, if a donor provides the start-up capital, the government may be persuaded to commit funding for a full-time pharmacist at the center. If a hospital is located near the center, it could be a source for long-term funding. In some countries, implementing user fees may be possible; however, this approach should be taken gradually, after the MIC has been accepted by users and they have given their input in determining services and fees.

Pharmaceutical companies may be willing to support a center, but this support should be considered cautiously. If medicine information critical of a sponsoring company's product is disseminated, the company may withdraw support. In general, funding from a pharmaceutical company should be used for discrete projects, such as replacement of a photocopier. Remember, however, that even the perception

of bias toward a sponsoring company's products can harm an MIC's reputation.

Medicine information professionals in developing countries inevitably become fund-raisers to maintain activities. For example, in Cameroon, a consortium of donors was mobilized to share support for the drug bulletin. ■

SUMMARY

Poor product quality, adverse drug reactions (ADRs), and medication errors greatly influence health care systems by negatively affecting patient care and increasing costs. Most of the statistics documenting the issues and highlighting the importance of pharmacovigilance come from developed countries, therefore low- and middle-income countries likely have greater problems because of the poorer state of their health system infrastructure, the unreliable supply and quality of medicines, the lack of adequately trained essential health care staff, and their limited access to communication and information technology.

Three areas of pharmacovigilance include—

- Product quality
- Adverse drug reactions
- Medication errors

Product quality problem reporting systems are covered in [Chapter 19](#) on quality assurance. This chapter focuses on the importance of ADRs and medication errors and actions to take to minimize their impact. An ADR is a harmful response caused by the medicine after the patient has received it in the recommended manner; whereas, adverse drug events (ADEs) result from either the medicine itself or the medicine's inappropriate use or medication error.

Health professionals may still think of pharmacovigilance strictly in terms of identifying and reporting previously unknown and serious ADRs related to new products; however, pharmacovigilance activities are related to every sector of the pharmaceutical management framework: selection, procurement, distribution, use, management support, and the overarching policy and legal framework. Likewise, pharmacovigilance

activities are carried out at the facility, national, and international levels and require collaboration among a wide range of partners with differing responsibilities. National governments are responsible for ensuring that medicines sold in their countries are of good quality, safe, and effective. An important component of a country's ability to monitor pharmaceutical safety is a national pharmacovigilance system that is supported by the drug regulatory authority. However, some countries have not included pharmacovigilance as part of their legal framework. Public health programs, such as those for treating HIV/AIDS and malaria, may have separate pharmacovigilance systems, while hospitals usually have the capacity to design and implement facility-based medication safety activities.

The major components of a pharmacovigilance system are data collection, which can be passive, active, or mandatory, and data analysis and reporting. When ADEs occur, they must be analyzed and reported and their significance must be communicated effectively to an audience that has the knowledge to interpret the information, including the national pharmacovigilance center, if one exists, and the World Health Organization (WHO) Programme for International Drug Monitoring. Based on the results of the analysis, actions should be carried out to reduce adverse drug events and thereby improve patient care. To encourage continued participation in the process, interventions should be shared with the data reporters. Follow-up data collection and analysis can then measure the effectiveness of the interventions.

The use of medicines involves a trade-off between benefits and the potential for harm. Pharmacovigilance can help minimize harm by ensuring that medicines of good quality are used rationally.

35.1 What is pharmacovigilance and why is it important?

WHO defines pharmacovigilance as “the science and activities relating to the detection, assessment, understanding and prevention of adverse effects or any other medicine-related problem” (WHO 2004, 1). Terms related to the science of pharmacovigilance are defined differently in different settings and by different organizations. The terms used in this chapter are defined in [Table 35-1](#).

More and more evidence is showing the huge effect of poor product quality, ADRs, and medication errors on health care, but estimating the actual scale of this effect

is almost impossible because most cases go undetected. Much of the documented evidence available on medicine quality and ADEs comes from industrialized countries. For example, in a bellwether report, the U.S. Institute of Medicine (IOM 2000) estimated that 7,000 or more people die each year from medication errors and ADRs and that the total costs may be between 17 billion U.S. dollars (USD) and USD 29 billion per year in hospitals nationwide. A follow-up report estimated that more than 1.5 million Americans are injured every year by medication errors in hospitals, nursing homes, and doctor's offices (IOM 2006). ADEs also are costly in terms of loss of trust in the health care system by patients.

Table 35-1 Definitions of terms related to pharmacovigilance

Terms	Definition	Example
<i>Harm occurred</i>		
Adverse drug event	Harm caused by the use of a drug	Heart arrhythmia from discontinuing atenolol (whether or not it was considered an error)
Adverse drug reaction	Harm caused by the use of a drug at normal doses	Skin rash from nevirapine
<i>Harm may have occurred</i>		
Medication error	Preventable event that may cause inappropriate use of a drug or patient harm	Failure to renew prednisone order on transfer to medical ward
<i>Harm did not occur</i>		
Potential adverse drug event	Circumstances that <i>could</i> result in harm by the use of a drug but did <i>not</i> harm the patient	Receipt of another patient's ampicillin, with no resulting effect

Source: Adapted from Nebeker, Barach, and Samore 2004.

Compared with that in high-income countries, the situation in low- and middle-income countries is likely more urgent because of the poorer state of health system infrastructure, the unreliable supply and quality of medicines, and the lack of adequately trained essential health care staff.

Three areas of pharmacovigilance include—

- Product quality
- Adverse drug reactions
- Medication errors

Quality issues relate to pharmaceutical products that are defective, deteriorated, or adulterated because of poor manufacturing practices, inadequate distribution and storage, poor labeling, or tampering. Counterfeit products would fall under this category, for example, as would medicines that have lost their potency after being stored at high temperatures. These quality assurance issues, including product problem reporting systems, are covered in detail in [Chapter 19](#). In addition, pharmaceutical donations have

sometimes expired or are close to expiration or have been stored under conditions that adversely affect their quality. See [Chapter 15](#) for more information about ensuring the quality of medicine donations.

This chapter focuses on the importance of ADRs and medication errors and actions to take to minimize them.

Adverse drug reactions

An ADR is a harmful response in the patient caused by the drug itself given in the recommended manner (dose, frequency, route, administration technique). Examples include allergic reactions, effects from withdrawal, or reactions caused by interactions with other medications. WHO defines a serious ADR as any reaction that is fatal, life-threatening, or permanently or significantly disabling; requires or prolongs hospitalization; or relates to misuse or dependence (WHO/UMC 2000).

When a new medicine is being developed, it goes through several phases of testing, first with animals, then with human

Table 35-2 Determining ADR probability using indicators

Probability scale: indicators	Yes	No	Don't know
1. Are there previous conclusive reports on this ADR?	+1	0	0
2. Did the ADR appear after the suspected drug was administered?	+2	-1	0
3. Did the ADR improve when the drug was discontinued or a specific antidote was administered?	+1	0	0
4. Did the ADR reappear when the drug was readministered?	+2	-1	0
5. Could alternative causes (other than the drug) have caused the ADR on their own?	-1	+2	0
6. Was the drug detected in the blood (or other fluids) in a concentration known to be toxic?	+1	0	0
7. Was the ADR more severe when the dose was increased or less severe when the dose was decreased?	+1	0	0
8. Did the patient have a similar ADR to the same or similar drugs in any previous exposure?	+1	0	0
9. Did any objective evidence confirm the ADR?	+1	0	0
Total score = _____	Possible = 0–4 Probable = 5–8 Definite = >9

volunteers, for safety and efficacy. However, when a product is approved, it may have been tested in only thousands of patients—many fewer than are likely to use the product once it is approved for sale on the market. Therefore, the information on effects generated in premarketing studies is incomplete relative to the full complement of likely users, making postmarketing surveillance an important tool for completing the safety and efficacy profile of a drug product (Ahmad 2003).

Because it includes so many more people than are included in the premarketing surveillance process, postmarketing surveillance should be able to detect rare but serious adverse reactions; chronic toxicity; effects in sensitive groups, such as children, pregnant women, and the elderly; and interactions with other pharmaceuticals, herbal medicines, or food. Often, however, linking an ADR with a specific medicine is difficult; for example, an ADR can occur long after a medication is administered, which makes confirming the cause a challenge. See [Table 35-2](#) for ways to analyze probable causality.

Medication errors

The National Coordinating Council for Medication Error Reporting and Prevention defines medication error as “any preventable event that may cause or lead to inappropriate medication use or patient harm while the medication is in the control of the health care professional, patient, or consumer” (<http://www.nccmerp.org/aboutMedErrors.html>). Errors can be harmless or detrimental to the patient. A study

Box 35-1 Medication error caused by sound-alike products

Nurses and pharmacists at a hospital reported two cases where RECOMBIVAX HB (hepatitis B vaccine, recombinant) was given to newborns instead of Comvax (hemophilus B conjugate vaccine with hepatitis B vaccine). When a telephone order was misunderstood, the wrong product was administered to the patients. Nurses in the unit felt this same error had probably occurred other times without anyone noticing. A safe medication practice to prevent sound-alike product name errors is to transcribe and read back verbal orders. Face-to-face verbal orders should be accepted only in emergencies or when the prescriber is physically unable to write the order.

Source: ISMP 2003.

of thirty-six health care facilities in the United States showed that nearly one in five doses of medication was given in error, and 7 percent had the potential to cause patient harm (Barker et al. 2002).

Medication errors are caused by faulty systems, processes, and conditions that lead people to make mistakes or fail to prevent mistakes ([Figure 35-1](#)). For example, stocking wards in hospitals with certain concentrated solutions, even

Table 35-3 Dangerous abbreviations

Abbreviation	Intended meaning	Common error	Preferred term
U	Units	Mistaken as a 0 (zero) or a 4 (four), resulting in overdose. Also mistaken for cc (cubic centimeters) when poorly written.	Write <i>unit</i> .
µg	Micrograms	Mistaken for mg (milligrams), resulting in a one-thousand-fold overdose.	Write <i>mcg</i> .
Q.D.	Latin abbreviation for every day	The period after the Q has sometimes been mistaken for an I, and the drug has been given QID (four times daily) rather than daily.	Write <i>daily</i> .
Q.O.D.	Latin abbreviation for every other day	Misinterpreted as QD (daily) or QID (four times daily). If the O is poorly written, it looks like a period or an I.	Write <i>every other day</i> .
SC or SQ	Subcutaneous	Mistaken as SL (sublingual) when poorly written.	Write <i>subcutaneous</i> or <i>subcut</i> .
T I W	Three times a week	Misinterpreted as three times a day or twice a week.	Write specific days for administration, for example, MON., WED., and FRI.
D/C	Discharge; also discontinue	Patient's medications have been prematurely discontinued when D/C (intended to mean discharge) was misinterpreted as discontinue, because it was followed by a list of drugs.	Write <i>discharge</i> or <i>discontinue</i> .
HS	Half strength	Misinterpreted as the Latin abbreviation HS (hour of sleep).	Write <i>half strength</i> .
cc	Cubic centimeters	Mistaken as U (units) when poorly written.	Write <i>ml</i> or <i>mL</i> or <i>mls</i> for milliliters.
AU, AS, AD	Latin abbreviation for both ears; left ear; right ear	Misinterpreted as the Latin abbreviation OU (both eyes); OS (left eye); OD (right eye).	Write <i>ear</i> .
Lack of a leading zero (.X mg) or Use of a trailing zero (X.0 mg)		Decimal point is missed, resulting in a dosage error of tenfold or greater.	Always lead with a zero before a decimal point (0.X mg). Never follow a whole number with a decimal point and zero (X mg).
@	at	Mistaken as zero.	Write <i>at</i> .
MS, MSO4 MgSO4	Morphine sulfate, magnesium sulfate	Confused for each other.	Write <i>morphine sulfate</i> or <i>magnesium sulfate</i> .
IU	International Unit	Mistaken as IV (intravenous) or 10 (ten).	Write <i>international unit</i> .

Source: <http://www.nccmerp.org/dangerousAbbrev.html>.

though they are toxic unless diluted, has resulted in deadly errors. Other problems can result from illegible handwriting, use of dangerous abbreviations (Table 35-3), overlooked interactions with other medicines, and verbal miscommunications and sound-alike or look-alike products. Box 35-1 describes a case where the wrong medicine was administered to babies because of a misunderstood verbal order.

Medication errors, by definition, should be preventable through education and effective systems controls involving pharmacists, prescribers, nurses, administrators, regulators, and patients.

Adverse drug events

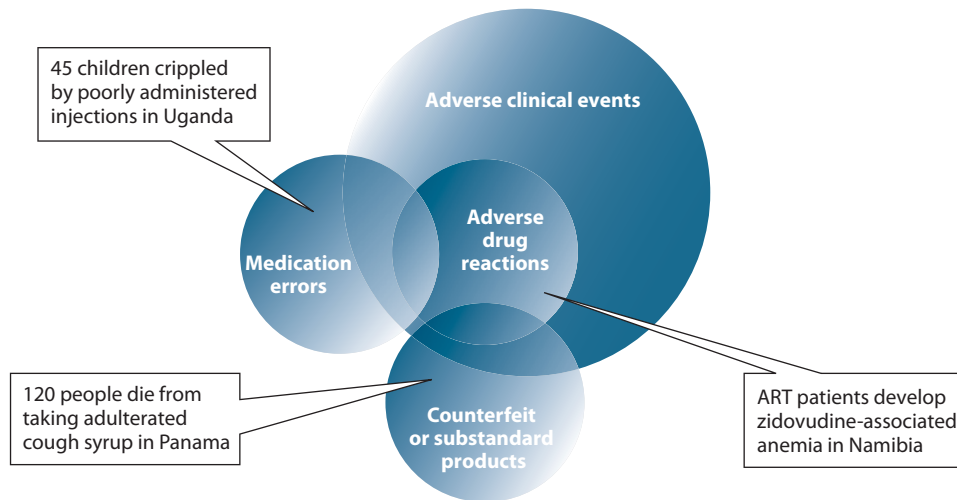

An ADE is a harmful response that is caused by a drug or the inappropriate use of a drug. Therefore, an ADR is always an

ADE, but an ADE might include the result of an overdose because of a dispensing error or some other error occurring during the medication-use process. (See Figure 35-2.)

Medication-usage patterns strongly influence the incidence of ADEs. For example, injectable medications are more commonly used in developing countries, and they are more likely to be associated with ADEs (WHO/UMC 2002). In addition, self-medication, lack of regulatory control over the sale of medicines, and irrational prescribing all contribute to the incidence of ADEs.

ADEs are preventable when they are the result of a medication error (discussed below) or nonpreventable, as would be the result of an unknown allergy. A potential ADE could include an error that may or may not reach the patient but does not cause harm, such as a dispensing error that was discovered and avoided at the last minute. The documentation

Figure 35-2 Relationship of medication safety terms

Sources: SPS 2009, figure 1, adapted from Barker et al. 2002; Ferner and Aronson 2006; Nebeker, Barach, and Samore 2004.

of ADEs and ADRs is important—especially in new products—where such postmarketing information can result in changes to the recommended usage, product packaging or labeling, or even a recall. Identifying and documenting potential ADEs is useful because this can identify problem areas that might be corrected, such as a communication problem within the health facility or two medicines with similar names being stored next to and therefore confused with each other.

35.2 Designing a pharmacovigilance system

Health professionals may still think of pharmacovigilance strictly in terms of identifying and reporting previously unknown and serious ADEs related to new products; however, pharmacovigilance activities are related to every sector of the pharmaceutical management cycle. Figure 35-3 shows examples of the relationship between pharmacovigilance and pharmaceutical management.

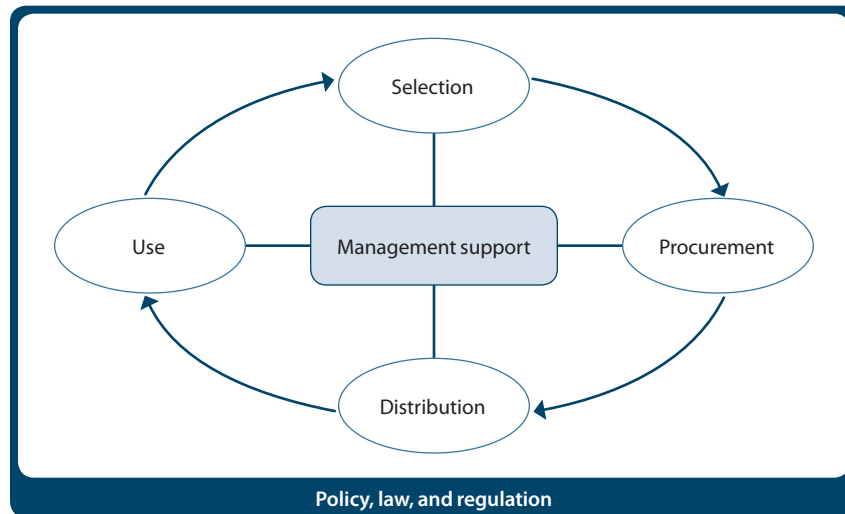

Although many national pharmacovigilance programs are largely based on ADE reporting, a comprehensive system should encompass monitoring of medication errors and therapeutic ineffectiveness (related to poor treatment adherence, antimicrobial resistance, product quality problems, inappropriate use, or interactions); product quality problems; and communication of such information to health care professionals and consumers for risk-benefit decision making (SPS 2009). For example, as a pharmacovigilance system matures, it may expand from a program based strictly on passive ADE surveillance that relies on voluntary reports from health care providers or consumers to incorporate active surveillance methods to address

priority safety concerns, such as the use of registries, sentinel sites, and follow-up of defined patient cohorts. Other system expansion efforts can include establishing a link between pharmaceutical quality assurance and ADR monitoring and developing mechanisms to communicate medicine safety information to health care professionals and the public.

A country's pharmacovigilance system should incorporate activities and resources at the facility, national, and international levels and foster collaboration among a wide range of partners and organizations that contribute to ensuring medicine safety. Figure 35-4 illustrates the components of a comprehensive, ongoing pharmacovigilance system with functions for monitoring, detecting, reporting, evaluating, and documenting medicine safety data as well as intervening and gathering information from and providing educational feedback to the reporters—prescribers, health care workers, other health care professionals, and consumers. When the information has been collected, evaluators, such as epidemiologists or pharmacologists, should analyze it to determine the adverse event's severity, probable causality, and preventability.

Significant data must be communicated effectively to a structure or entity that has the authority to take appropriate action, whether at the facility, national, or even international level. The entity may be a hospital's drug and therapeutics committee, the national pharmacovigilance center, if one exists, or the WHO Programme for International Drug Monitoring. The final function in the framework is appropriate action. If data are collected, analyzed, and reported, but no one takes any action based on the data, the system is irrelevant. The risk reduction action may be regulatory (withdrawing marketing authorization, recalling a medica-

Figure 35-3 Pharmacovigilance and the pharmaceutical management framework

Pharmacovigilance activity	Detection within the pharmaceutical management framework	Prevention
Product quality	<ul style="list-style-type: none"> • Most product quality issues are detected in the <i>distribution</i> portion of the pharmaceutical management cycle. • Physical inspection is done at the time of receiving the product from the supplier and at other points of <i>distribution</i> to the patient. • Complaints about efficacy occur during <i>use</i>. 	<ul style="list-style-type: none"> • Prequalify suppliers during <i>procurement</i>. • Establish a pharmaceutical quality assurance program. • Establish a <i>policy and legal framework</i> that addresses pharmaceutical quality. • Enforce laws and regulations related to product quality.
ADRs	<ul style="list-style-type: none"> • <i>Management support</i> functions, such as surveillance and monitoring systems, during <i>use</i> are the primary methods for detecting ADRs. 	<ul style="list-style-type: none"> • Consider ADR information during the <i>selection</i> process to make formulary decisions and establish standard treatment guidelines. • Report ADRs to the appropriate parties at the facility, national, and international levels. • Train health professionals about ADRs. • Communicate with patients about ADRs.
Medication errors	<ul style="list-style-type: none"> • Errors can be detected in all phases of the pharmaceutical management cycle: ordering, storing, labeling, compounding, dispensing, transcribing, prescribing, administering, and monitoring. 	<p>Prevention strategies should focus on all processes—</p> <ul style="list-style-type: none"> • Promote a culture of safety through a nonpunitive environment for reporting events. • Improve availability of drug information. • Train and educate staff. • Consider past and potential errors when selecting products or a formulary. • Issue prescribing guidelines. • Establish dispensing and administration procedures and safeguards. • Establish monitoring guidelines. • Improve written and oral communication. • Involve patient and family in care plan.

Source: CPM/MSH 2011.

tion); managerial (revising a hospital formulary, instituting distribution controls); or educational (teaching prescribers about medicine-medicine interactions or proper product handling). To encourage continued participation in the process, interventions should be shared with the data reporters as part of a feedback loop. Follow-up data collection and analysis will then measure the effectiveness of the interventions.

The outcome of a pharmacovigilance system should be decreased medicine-related problems with the ultimate effect being a reduction in morbidity and mortality.

As mentioned, pharmacovigilance activities are carried out at the facility, national, and international levels and require collaboration among a wide range of partners with differing responsibilities (Table 35-4). To plan for this information system, basic questions must be answered about

Figure 35-4 The pharmacovigilance framework

Source: CPM/MSH 2011.

whether the data flow will be separate for each area of pharmacovigilance or combined, who will be responsible for the data collection and reporting at each level of the health system, and whether vertical public health programs will be separated or integrated. For example, will the responsibility for pharmacovigilance fall under the drug and therapeutics committee (or pharmacy and therapeutics committee) at the facility level? How will pharmacovigilance drive decisions for formulary selection and treatment guidelines, changes in policies and procedures at different levels, and product approval and pharmaceutical regulation? These questions may be easier to answer if the country has a national pharmacovigilance system in place—or individual facilities developing their own systems may need to create the best information management system based on their own organization.

Pharmacovigilance activities at the facility level

Medication safety monitoring is an important part of high-quality health care in health facilities, especially hospitals. A U.S.-based study showed that ADEs in hospitalized patients resulted in significant health and economic consequences (Classen et al. 1997). Monitoring and reporting of medication errors and ADRs are important aspects of a hospital's safety system; consequently, most evidence of ADEs comes from hospitals, because the risks associated

with hospital care are high and strategies for improvement are better documented. But many ADEs occur in other health care settings, such as physicians' offices, nursing homes, pharmacies, and patients' homes. However, underreporting of ADEs is a critical problem in all health care settings.

Even if a country lacks the infrastructure for coordinating national pharmacovigilance activities, hospitals usually have the capacity to design and implement a facility-based pharmacovigilance system. Effective systems for pharmacovigilance and promoting safe medication practices generally fall under the purview of the drug and therapeutics committee.

Hospital-based reports of ADRs make important contributions to clinical experience and improving the understanding of pharmacotherapy. In addition, the assessment of ADEs gives facilities the information necessary to reduce medication errors and improve health care for patients.

Pharmacovigilance activities at the national level

National governments are responsible for ensuring that medicines sold in their countries are of good quality, safe, and effective. An important component of a country's ability to monitor pharmaceutical safety is a national pharmacovigilance system that is supported by the drug regulatory authority (see [Chapters 6 and 19](#)).

Table 35-4 Roles and responsibilities of partners in pharmacovigilance

Partner	Responsibilities
Government	<ul style="list-style-type: none"> • Establish national pharmacovigilance system • Develop regulations for medicine monitoring • Provide up-to-date information on adverse reactions to professionals and consumers • Monitor effect of pharmacovigilance through indicators and outcomes
Industry	<ul style="list-style-type: none"> • Provide quality medicines of assured safety and efficacy • Assess and share ADRs that are reported
Hospitals	<ul style="list-style-type: none"> • Promote the incorporation of pharmacovigilance into procedures and clinical practice
Academia	<ul style="list-style-type: none"> • Teach, train, conduct research, and develop policy about pharmacovigilance • Include pharmacovigilance in curriculum
Medical and pharmaceutical professional associations	<ul style="list-style-type: none"> • Provide training and awareness to health professionals regarding pharmacovigilance
Poisons and medicines information centers	<ul style="list-style-type: none"> • Provide information on medication safety and pharmacovigilance • Collaborate with national pharmacovigilance centers, if applicable
Health professionals (including physicians, nurses, pharmacists, dentists)	<ul style="list-style-type: none"> • Detect, investigate, manage, and report ADRs, medication errors, and product quality concerns • Counsel patients about ADRs
Patients and consumers	<ul style="list-style-type: none"> • Understand to the extent possible their own health problems and participate in the treatment plan by following medication instructions • Report adverse reactions to health professionals as well as concomitant use of other medications, including traditional medicine
Media	<ul style="list-style-type: none"> • Create awareness in the community about the safe use of medicines

National pharmacovigilance centers are responsible for—

- Promoting the reporting of ADEs
- Collecting case reports of ADEs
- Clinically evaluating case reports
- Collating, analyzing, and evaluating patterns of ADEs
- Promoting policies and interventions that help prevent medication errors
- Determining what case reports constitute true adverse reactions to medications
- Recommending or taking regulatory action in response to findings supported by good evidence
- Initiating studies to investigate significant suspect reactions
- Alerting prescribers, manufacturers, and the public to new risks of adverse events
- Sharing their reports with the WHO Programme for International Drug Monitoring (WHO/UMC 2006)

A national pharmacovigilance system can be housed in a national pharmacovigilance center or in a tertiary or research-oriented hospital. In the traditional model, a pharmacovigilance system was strongly centralized and consisted of one national center collecting reports from health professionals around the country. Many countries are moving toward a more decentralized system with a national center functioning as a focal point for regional or facility-based centers (WHO/UMC 2000).

Pharmacovigilance activities as part of public health programs

Depending on how their public health systems are organized, countries may have public health initiatives that are disease-specific and operate separately from the primary health system (for example, HIV/AIDS, tuberculosis, malaria, vaccinations), also known as vertical health programs. Such vertical programs depend on good pharmacovigilance practices (WHO/UMC 2006). Monitoring ADRs is especially important when treatment is being scaled up, such as antiretroviral therapy (ART) for HIV/AIDS, or if a change is being made in the standard treatment guidelines, such as switching to artemisinin-based combination therapies for malaria.

The major aims of pharmacovigilance in public health initiatives are the same as those of the national pharmacovigilance system. The structure and organization of the existing national systems will help determine how the public health program pharmacovigilance efforts should be designed. In some cases, the country may not have a national pharmacovigilance system. In that case, the public health program's system takes on additional importance and may provide a model for the eventual establishment of a national system. In Kenya, as ART programs scaled up and developed facility-based ADR monitoring systems, the Ministry of Health recognized the importance of national-level coordination and added pharmacovigilance to its responsibilities—a good example of a bottom-up approach to incorporating pharmacovigilance into the health care system.

WHO has a good resource on using pharmacovigilance as a tool in public health treatment programs (WHO/UMC 2006).

Pharmacovigilance activities at the international level

The patterns of how people access and use pharmaceuticals are changing because of globalization, free trade, and increased use of the Internet (WHO 2004). These changing patterns require that pharmacovigilance activities around the world become more closely linked and therefore better able to respond to how medicines are being used in society.

At the international level, WHO initiated its Programme for International Drug Monitoring in 1968 to pool existing data on ADRs from ten countries. With its Uppsala Monitoring Centre, the WHO program now works with national pharmacovigilance programs in almost 100 countries (UMC 2010). The Uppsala Centre maintains the database of ADR reports—one of the largest in the world with more than 5 million case reports. The Uppsala Centre established standardized reporting by all national centers and facilitates communication between countries on medicine safety issues.

The Institute for Safe Medication Practices (<http://www.ismp.org>) has established a forum for individual health care providers and consumers in any country to confidentially share information on ADEs. Although the system was established for U.S.-based reporting, the institute welcomes reports from anywhere in the world. Health care professionals and consumers can submit reports and associated materials in confidence. After removing the identifiers, the information is shared with the U.S. Food and Drug Administration, the manufacturer, and others to inform them about pharmaceutical labeling, packaging, and nomenclature issues that may promote errors by their design.

Major components of a pharmacovigilance system are data collection, which can be voluntary or nonvoluntary, and data analysis and reporting.

35.3 Data collection

Passive data collection

Passive reporting of ADRs and medication errors (also known as voluntary case reporting) requires health care providers to be active participants in a culture of safety. Programs relying solely on voluntary, spontaneous reporting methods reveal only the tip of the iceberg, and calculated medication event rates are more an indication of reporting rates than actual occurrence rates. However, voluntary reporting should always be encouraged, because it helps

establish a team approach to improving patient care and reducing risks.

Barriers to voluntary reporting of medication events are—

- Fear of punishment by supervisors or fellow workers (in the case of an error)
- Fear of liability for the provider or facility
- Failure to recognize that an incident has occurred
- Unclear or cumbersome methods for reporting
- Poor track record of improvements by the institution
- Lack of time

The objective of a successful monitoring system is to learn from and correct sources of error rather than to punish offenders. In addition to driving out fear, facilities should try to improve error tracking through education programs that promote voluntary reporting and by communication to staff about the improvements resulting from medication events reported.

Mandatory data collection

Many country regulations require manufacturers and distributors of pharmaceuticals to report information on ADRs that they gather during postmarketing surveillance to health authorities. In addition, facilities seeking accreditation may be required to have an ADE collection system in place as part of the process to receive official recognition. Some countries require health care professionals to report ADEs, but the effectiveness of such legislation is unknown (WHO/UMC 2000).

Active data collection

Active data collection of medication events is carried out as a focused and structured activity and includes trigger tools, patient chart audits, and direct observation methods. Using a consistent methodology for active data collection provides more reliable calculated medication event occurrence rates and evidence of trends.

Trigger tools provide clues that an ADR occurred. Triggers are identified from either computerized reports or manual review methods to identify alerting orders, laboratory values, or clinical conditions. Further research into these triggers may help identify ADRs that have occurred or that are currently evolving—

Laboratory triggers are identified from defined parameters indicating an ADR might be associated (serum glucose under 50, white blood cell count below 3,000, platelets below 50,000, toxic drug levels, and the like).

Medication order triggers are prescription orders for antidotes or reversal agents such as dextrose 50 percent 50-mL injection, glucose tablets, diphenhydramine,

steroids, naloxone, epinephrine, or sudden change or stoppage of a patient's medication ("discontinue digoxin, quinidine, potassium chloride").

Clinical triggers are patient conditions often associated with ADRs, such as rash, falls, lethargy, or apnea.

Trigger detection methods yield more data than voluntary reports (Jha et al. 1998), and more sophisticated methods combine composite triggers (such as laboratory tests and medication orders) for better yields (Schiff et al. 2003).

Whereas trigger tools can help identify the patients and medications most likely implicated in an event, *chart review* is used to identify potential ADRs, medicine interactions, and medication errors. These reviews can be conducted prospectively, concurrently, or retrospectively. Retrospective reviews are often more convenient for data collection, although the time lapse since the event makes in-depth investigation difficult. Medical records classified by codes, such as ICD-10 (International Classification of Diseases, Tenth Revision) codes that indicate an ADR, provide a method to identify suspicious charts.

A prospective study might focus on recording any possible adverse event in every patient receiving a new medicine. For instance, the Ghana National Centre for Pharmacovigilance developed a simple form for facilities to document and report ADRs in pregnant women associated with a change in recommended treatment from chloroquine to sulfadoxine-pyrimethamine to prevent malaria (Doodoo 2005). Combined with their demographic information, the information collected on this cohort of patients can provide an effective way of identifying previously unrecognized ADRs (WHO/UMC 2000). Prospective and concurrent reviews can also detect potential adverse events before they happen or as they are evolving, so that patient harm can be avoided or minimized.

Direct observation provides an abundance of useful data on medication errors and helps to identify weaknesses in the medication-use process. Observers can be placed at any point in the medication-use process, but medication administration is often one of the most problematic areas and easiest to observe. If the data collection method is consistent, the resulting error rates are reliable and allow improvements to be measured. An example follows of the steps that could comprise data collection using direct observation of the medication administration process—

1. The observer follows randomly selected nurses as they administer medications to patients on a hospital ward. The observer collects data for a specified number of medications using preprinted forms. [Figure 35-5](#) shows an example of an observation audit tool.
2. The observer verifies each medication on the original physician order in the patient chart, noting discrepan-

cies between the written order and the actual practice observed in terms of medication, dose, frequency, route, and so on.

3. The data are used to calculate error rates for a specific focus area, such as the ward or the facility. Rates or trends may help identify problematic procedures or areas for additional training.

A study comparing three methods for detecting errors—direct observation, chart review, or voluntary adverse event reporting—showed that direct observation was far more efficient and accurate in detecting medication errors (Flynn et al. 2002). Direct observation can also be used as a training and orientation tool for new employees by ensuring that new employees have a minimal level of competency and understand the facility's medication administration process.

Data collection tools

ADR and medication error data are usually collected by filling out a standardized form, thereby providing convenience and consistency. Data collection tools should be adapted from standards of practice and procedures, and the data fields on the form determined by how the data are eventually summarized and used. Ideally, if a country has a national pharmacovigilance program, the reporting form is standardized for use in all settings throughout the country.

For ADR data, identifying specifics about the patient is important. These include concomitant therapies and conditions, the patient's reaction to the medicine, and the medicine suspected of causing the reaction together with the manufacturer and batch number, if available. WHO gives guidance on what to include on a data collection form (WHO 2002) (see also [Box 6-2](#) on adverse drug reaction monitoring in [Chapter 6](#)).

For medication error data, collecting information that can be analyzed for improvements to the medication-use system is important. Systems may have separate forms for tracking product quality problems, ADRs, and medication errors, or systems may use one form and process. [Figure 35-6](#) shows a sample ADE reporting form that also combines reporting for product quality problems in Zambia.

35.4 Data analysis and reporting

After the ADR data have been collected, they should be analyzed to determine severity, probable causality, and preventability. Specific algorithms and classification systems have been developed for these analyses—

Severity (impact on the patient's health): [Table 35-5](#) shows a classification for determining the severity of ADRs. It addresses both ADEs associated with medication error

Figure 35-5 Nonvoluntary data collection tool for pharmacovigilance

Medication Administration Audit Tool					
Date: _____	Unit: _____	Name of Evaluator: _____			
Checklist for medication administration	Patient #1		Patient #2		Comments
	Met	Not met	Met	Not met	
1. Washes hands before start of medication administration process, before and after each patient contact, and before preparing injectable medications.					
2. Performs and charts necessary pre-administration assessments for specific medicines (pulse, blood pressure, nausea, etc.).					
3. Notes allergies and compares to medicines to be administered.					
4. Correctly identifies patient. Compares name and/or ID# on MAR with patient ID band. Cannot use room number for identification.					
5. Correct medication (removes medications and verifies correct medication with the MAR).					
6. Correct dosage (including accurate measurement of liquids).					
7. Correct route of administration.					
8. Correct time of administration (administers within 1 hour before or after time ordered; considers relationship to meals and/or food; waits appropriate time between ophthalmic medicines, inhaled doses, etc.).					
9. Explains purpose of each medication; answers questions about the medication.					
10. Stays with patient until each medication has been safely swallowed.					
11. Properly administers medications (preps IV port, appropriate IV compatibility, administers over correct time interval).					
12. After medication administration, initials time of administration for each medication and signs appropriate document.					
13. Correct disposal of pharmaceutical waste; disposes of narcotics and dangerous drugs with applicable documentation.					
14. Maintains the security of the medications at all times (locked medicine cabinet or locked medication room door).

Table 35-5 Severity index for medication errors

Category	Description
Category A	Circumstances or events that have the capacity to cause error (note that these are <i>potential, not actual</i> , errors).
Category B	An error occurred but the error did not reach the patient (an “error of omission” <i>does</i> reach the patient).
Category C	An error occurred that reached the patient but did not cause patient harm.
Category D	An error occurred that reached the patient and required monitoring to confirm that it resulted in no harm to the patient or required intervention to preclude harm.
Category E	An event occurred that may have contributed to or resulted in temporary harm to the patient and required intervention.
Category F	An event occurred that may have contributed to or resulted in temporary harm to the patient and required initial or prolonged hospitalization.
Category G	An event occurred that may have contributed to or resulted in permanent patient harm.
Category H	An event occurred that required intervention necessary to sustain life.
Category I	An event occurred that may have contributed to or resulted in the patient’s death.

Source: NCC MERP n.d.

and those not associated with error, so it can be applied to all medication events.

Probable causality (likelihood that the medicine’s use or lack of use contributed to the ADR); [Table 35-2](#) illustrates how to calculate the Naranjo Probability Score, a common method for determining whether a particular medicine was actually related to the ADR.

Preventability (Was an error associated with the event?):

[Box 35-2](#) is an algorithm used to help determine if the ADE was caused by a medication prescribing error, and therefore, preventable.

For ADEs that are considered preventable, identifying where the primary error occurred and what aspects contributed to the system breakdown is useful; therefore, analysis and reporting should facilitate this activity by identifying and targeting problem-prone areas, such as specific steps in the process (prescribing practices), medication types (injectables), disease states or patient types, employees (new employees, interns), patient care areas (surgery), and time of the day (night shift). For example, if data indicate that ADEs are caused by nurses giving the wrong dose of injectable medications, then focused activities for improvement should be developed. These activities might include educational activities and procedural changes, such as independent double-checks of all injectable medications. After implementing the interventions, the error rate can be checked for improvement.

Medication event data are organized on manual or electronic spreadsheets, which help summarize and sort data for reporting at the facility or regional level. National and international programs often use Internet-based ADR or medication error databases to collect and share data. (See [References and Further Readings](#).)

ADRs should be reported to the national ADR program, if one exists, as well as to the pharmaceutical manufac-

Box 35-2 Determining whether a medication error occurred

- Was the drug involved appropriate for the patient’s clinical condition? (NO = Preventable)
- Was the dose, route, or frequency of administration appropriate for the patient’s age, weight, or disease state? (NO = Preventable)
- Was required therapeutic pharmaceutical monitoring or other necessary laboratory tests performed? (NO = Preventable)
- Was there a history of allergy or previous events to the drug? (YES = Preventable)
- Was an interaction (medicine–medicine; medicine–food; medicine–herbal) involved in the ADR? (YES = Preventable)
- Was a toxic serum drug concentration (or laboratory monitoring test) documented? (YES = Preventable)
- Was poor compliance involved in the ADR? (YES = Preventable)
- Was the error considered preventable because of deviations in procedures or standards of practice? (Yes = Preventable)

Source: Adapted from Schumock and Thornton 1992.

turer; the latter is especially important if the ADR has not been reported previously in the literature or is not included on the product’s label. Reporting the results of ADR and medical error analysis to the organizational body within a hospital or facility that has responsibility for medicine safety, such as the drug and therapeutics committee, is also important.

Country Study 35-1 shows how a research hospital in India established an ADR reporting system.

35.5 Taking actions for improvement

When ADEs occur, they must be analyzed and reported, and their significance should be communicated effectively to an audience that has the knowledge to interpret the information. National or even international actions that can result from the appropriate reporting of ADEs include—

- Pharmaceutical manufacturers sending out “Dear Doctor” letters to alert health care providers of newly discovered adverse reactions
- Pharmaceutical manufacturers revising medicine package inserts that reflect the new information
- Pharmaceutical manufacturers or national regulatory authorities instigating a medicine recall

At the clinical level, actions concerning serious or recurring ADEs include—

- Changing the medication formulary if necessary
- Implementing new prescribing procedures
- Implementing new dispensing procedures
- Modifying patient-monitoring procedures
- Educating professional staff (face-to-face; in-service education; bulletins; reports of collected ADRs)
- Educating patients

Most important at the clinical level, however, is taking action to improve medication safety and decrease medication events by developing a culture of safety in the health care organization (see Box 35-3). For example, the organization’s leadership should maintain a clear commitment to safety by emphasizing that safety takes priority over production or efficiency; employee job descriptions and performance evaluations should include a component for participation in safety initiatives that are supported by recourses, rewards, and incentives; and the response to a problem should focus on improving system performance.

Country Study 35-2 illustrates the standard operating procedures and possible actions for addressing recurring ADRs in an ART program in Kenya. In a report on preventing medication errors, the Institute of Medicine (IOM 2006) urged that doctors, nurses, pharmacists, and other health care providers communicate more with patients about the risks, contraindications, and possible adverse reactions from medications and what to do if they experience an ADE. In addition, patients should be encouraged to take a more active role in their own medical care and should be given plenty of time to consult with health care providers about their medications (see also WHO’s patient safety initiative, <http://www.who.int/patientsafety/en>).

In summary, the use of medicines involves a trade-off between benefits and potential for harm. Pharmacovigilance can help minimize the harm by ensuring that medicines of good quality are used rationally and that the expectations and concerns of the patient are taken into account when

Country Study 35-1 Implementing an ADR reporting system in India

ADR monitoring and reporting systems are uncommon at the local level in developing countries. Although India has a national ADR monitoring center in New Delhi, Kasturba Hospital, a 1,400-bed, tertiary care teaching hospital in Manipal had never had an ADR program before 2001. It established an ADR monitoring center not only to improve medication safety practices in the district, but also to provide a link between the region and the national center. The Kasturba Hospital program was launched and is maintained by the pharmacy department using established ADR-reporting centers in India as models.

The Kasturba Hospital system relies on physicians and pharmacists working together. When a physician detects an ADR, he or she fills out the reporting form and sends it to the pharmacy department, where a pharmacist follows up on the ward with an investigation of the incident.

Pharmacists may also report ADRs on their own. When the documentation is complete, the pharmacist analyzes the causality, preventability, and severity of the ADRs using various scales, then issues the results quarterly. Physicians who report ADRs may be given information on how to manage the reaction, and if it involves an allergy, the pharmacist counsels the patient and provides an alert card for the patient to give his or her health care provider. In the first year of the program, 142 ADRs were reported, including several rarely seen reactions, among them cisplatin-induced hiccups. As a result of the new program, the Kasturba Hospital staff saw an increase in the awareness of the importance of ADR monitoring and reporting and improved interactions between the physicians and the pharmacists.

Source: Mohan, Rao, and Rao 2003.

Box 35-3 Safe medication practices

- Encourage staff to report ADRs, errors, and unsafe conditions.
- Change the safety culture from punitive to participatory.
- Standardize abbreviations, and develop a list of dangerous abbreviations, acronyms, and symbols to avoid.
- Write or print clearly.
- Review medication orders for appropriateness before dispensing and administration.
- Clarify medication orders that are not clear or do not make sense for the patient's clinical condition.
- Provide health care providers with access to drug information.
- Read back and receive confirmation on all verbal and telephone orders.
- Identify look-alike and sound-alike products and take action to avoid mix-ups (for example, physically separate storage, clearly differentiate appearance, purchase alternatives, use generic versus brand name or vice versa to differentiate from sound-alike product).
- Label all medications in a standardized manner according to hospital policy.
- Dispense medications labeled for a specific patient and in the most ready-to-administer dosage form.
- Follow the five "rights" of drug administration: right patient, right drug, right time, right dose, and right route.
- Verify patient identification against labels and orders prior to medication administration.
- Develop a list of problem-prone or high-risk medications and implement strategies to minimize the risk.
- Standardize or limit the number of drug concentrations available in the organization.
- Remove high-risk medications from patient care areas (for example, concentrated electrolytes).
- Involve patients in their care: tell them the name of the medicine and its purpose before administration.

health care providers are making decisions about therapy. WHO (2004) lists the best ways to achieve these goals—

- Serving public health and fostering a sense of trust among patients in the medicines they use that also extends to confidence in the health service in general
- Ensuring that risks in medicine use are anticipated and managed
- Providing regulators with the necessary information to amend the recommendations on the use of medicines
- Improving communication between the health professionals and the public
- Educating health professionals to understand the effectiveness and risk of medicines that they prescribe. ■

Country Study 35-2

Standard operating procedures for aggregating ADR data and taking appropriate action in an ART program in Kenya

The Coast Provincial General Hospital in Mombasa, Kenya, was one of the first public facilities in the country to offer ART to AIDS patients. Hospital administrators and program managers realized the importance of monitoring and reviewing ADRs related to the use of these new, powerful antiretroviral medicines to ensure optimal treatment outcomes and patient safety. The ART program staff designed and implemented standard operating procedures for ADR monitoring for all staff involved with the ART program.

All ART patients' ADRs are reported on an ADR form. The forms are reviewed, compiled, examined for trends, and reported, and appropriate actions are taken in response to the ADR report. Actions can be taken at the individual patient level or, in the case of a noted trend, at the system level. A summary of the procedures for aggregating the individual ADR data follows.

Pharmacist in charge of the ART program—

1. Reviews the *ART ADR Forms* and *ART ADR Reports* and prepares the *ADR Summary Report* at the end of each month
2. Looks for unusual trends
3. Reviews the *Actions Taken* section of the reports submitted to ensure that appropriate actions have been taken as decided by the ART Eligibility Committee based on the outline in the following table
4. Presents the *ADR Summary Report* to the ART Eligibility Committee at the first meeting of each month
5. Reports on unusual trends
6. Reports on inappropriate actions taken

The ART Eligibility Committee—

1. Reviews the *ADR Summary Report* and, if necessary, the raw data
2. Decides to take appropriate actions in response to *ADR Summary Reports* or unusual trends or inappropriate actions taken (possible actions are outlined in the following table)
3. Forwards the *ADR Summary Reports* and presents the findings to the Scientific Committee

The Scientific Committee reviews the *ADR Summary Report* and decides on appropriate action to be taken.

Suggested trends and actions for the data fields appearing on the *ADR Summary Report* and the *ART ADR Form* appear in the following table. This table is not all inclusive; it merely provides a starting point for the ART Eligibility Committee, Scientific Committee, and Steering Committee to use when evaluating the *ART ADR Reports*.

ADR actions on an aggregate level

Trends	Possible actions
An increase in suspected or probable ADRs associated with a specific age group, gender, pregnancy status, drug class, or particular medicine	<ul style="list-style-type: none"> • Notify the Scientific Committee. • Medicine may be used cautiously in particular groups with extra patient monitoring (lab or clinic visits) required. • Medicine may not be given to particular groups. • Medicine may be removed from treatment plan. • ADR may be reported to the Pharmacy and Poisons Board by the Steering Committee on the recommendation of the Scientific Committee. Pharmacy and Poisons Board may inform the manufacturer. • ART Eligibility Committee or Scientific Committee will investigate possible causes of this increase and take appropriate corrective or preventive actions.
Serious ADRs associated with ADR probability category definite or probable <ul style="list-style-type: none"> • not listed in the product labeling or <ul style="list-style-type: none"> • occurring in medicines less than five years since first approved by the Pharmacy and Poisons Board 	<ul style="list-style-type: none"> • Notify the Scientific Committee. • Medicine may be used cautiously with extra patient monitoring (lab or clinic visits) required. • Medicine may be removed from treatment plan. • ADR may be reported to the Pharmacy and Poisons Board by the Steering Committee on the recommendation of the Scientific Committee. Pharmacy and Poisons Board may inform the manufacturer.
Appropriate actions not being taken in response to suspected ADRs as decided by the ART Eligibility Committee	<ul style="list-style-type: none"> • Organize a training session. • Discuss with individual prescribers.

ASSESSMENT GUIDE

National activities

- Does the country address pharmacovigilance as part of its pharmaceutical legislation?
- Do any national policies and practices exist that are related to pharmacovigilance?
- Who is responsible for overseeing national pharmacovigilance activities?
- Does a national pharmacovigilance center exist? If so, where is it housed?
- Does the national pharmacovigilance program have a relationship with WHO's Programme for International Drug Monitoring?
- Does a national ADR monitoring and reporting system exist? If so, how many reports were submitted during the previous year? What is done with the reports?
- Is a system in place to report product quality problems? In the previous year, how many reports were submitted on medicine product problems?
- Are reports of medical errors collected and analyzed at the national level?
- Are the three areas—ADRs, product quality problems, and medication errors—combined in one reporting stream or separate streams?
- How is important information about ADRs communicated to health professionals? To the industry? To the media? To consumers?
- Is pharmacovigilance included in university curricula for health care professionals?

Public health program activities

- Do the country's public health programs (for example, HIV/AIDS, tuberculosis, malaria) have their own ADR reporting systems? If so, what is the reporting structure?
- Do the public health programs integrate their pharmacovigilance activities with national-level activities?

Facility activities

- Does the facility track information on ADRs in patients? Request an example of a recent report. Is reporting passive (voluntary) or active (nonvoluntary)?
- Does the facility track medication errors?
- What committee oversees the pharmacovigilance activities, and when did it last review a pharmacovigilance report?
- Does the facility have a culture of safety, that is, do employees feel comfortable reporting information on medication errors and ADRs? How many voluntary reports did the facility have in the last year?
- To whom are ADRs and medication errors reported? What is the mechanism?
- Does the organization have an internal mechanism to analyze and address problems with medication safety? Give examples of recent actions.

CHAPTER 36

Pharmaceutical supply systems assessment

Summary 36.2

- 36.1 Reasons for assessing pharmaceutical systems 36.2
Diagnosing emergent problems and analyzing options • Planning pharmaceutical management projects and formulating policies • Monitoring changes • Comparing the performance of different systems
- 36.2 Structure of the assessment 36.5
Prerequisites for assessment • Assessment approaches • Time frame and assessment costs
- 36.3 Defining the scope of the assessment 36.9
Functionality of the pharmaceutical system • Private-sector capacity • Political mapping
- 36.4 Defining the information targets 36.14
Quantitative and qualitative data • Performance indicators • Defining information targets for a specific assessment
- 36.5 Methods for collecting information 36.15
Document review • Key informant interviews • Data collection from retrospective record review • Data collection by prospective field observation • Other methods for collecting qualitative information
- 36.6 Planning and managing the assessment 36.18
Data analysis • Preparing the assessment report • Presentations and workshops • Using the assessment results
- References and further readings 36.19
- Assessment guide 36.21

SUMMARY

Pharmaceutical system assessments are useful to diagnose problems, plan major projects and interventions, monitor progress, and compare the performance of one system with that of another. Recent years have seen a growth in demand for such assessments because of the Global Fund to Fight AIDS, Tuberculosis and Malaria's policy to conduct procurement and supply management (PSM) assessments as a grant condition.

To produce useful results, all assessments should be structured. Two approaches may be useful—

- Comprehensive structured assessment, which generally involves a full-time, dedicated team using structured survey instruments to gather data through site visits, but may be done as a self-assessment exercise by managers
- Limited assessment, which uses interviews and document reviews

Four major categories of issues should be addressed in a comprehensive pharmaceutical sector assessment—

1. The functionality of the entire pharmaceutical system
2. The capacity of the private sector
3. “Political mapping” to understand the important actors and their attitudes and the feasibility of successfully implementing changes in the pharmaceutical system

4. Total operating costs of the existing pharmaceutical system and projected costs of potential alternative options

Special-purpose assessments, such as the Global Fund's PSM reviews, may be more limited in scope.

Specific information objectives should be set in advance, incorporating quantitative as well as qualitative data, performance indicators, and special-purpose analyses. The most important methods for collecting information are likely to be document review, key informant interviews, collection of data from existing records, and prospective observation.

Key issues in planning and managing the assessment are listed in this chapter, but readers should obtain one or more of the manuals mentioned throughout the chapter and in References and Further Readings for full details on organizing and conducting an assessment. When the data are in hand, they must be analyzed efficiently, and a user-friendly report should be produced, supplemented by presentations using graphic aids to help key decision makers absorb the findings. The assessment results must be used in developing new policies and procedures for the pharmaceutical system; otherwise, the process is a waste of resources.

36.1 Reasons for assessing pharmaceutical systems

High-level commitment to pharmaceutical sector improvements can be stimulated by discontent among health staff and the public about medicine shortages, concern in the ministry of finance about rising pharmaceutical expenditures, or publicity about poor pharmaceutical quality. Too often, however, the pressure resulting from this commitment leads to hasty assessments and inadequately developed plans for change. Sustainable improvements in the pharmaceutical sector depend on high-level national commitment to improvement, technically sound plans based on an accurate situation assessment, and the technical and financial resources to implement proposed changes.

This chapter proposes comprehensive structured assessments for accurately diagnosing problems in the pharmaceutical supply system, identifying their root causes, prioritizing the problems, analyzing options to determine feasible interventions, developing short- and long-term action plans, and providing indicators for monitoring

progress. When a comprehensive structured assessment is carried out with full government commitment by an appropriate expert team (local or international), it enables the government to formulate a sound strategy for improving access, rational medicine use, and medicine quality. [Figure 36-1](#) illustrates an options analysis framework.

A comprehensive assessment can be an invaluable input to the development of a national medicine policy ([Chapter 4](#)) or a strategic plan for pharmaceutical sector development ([Chapter 38](#)). It also provides government officials with a basis for coordinating donor involvement (see [Chapter 14](#)). Assessments may be required as a condition precedent for grants or other types of donor support, such as the PSM assessments that the Global Fund requires. The assessments discussed in this chapter do not take the place of an ongoing monitoring program ([Chapter 48](#)) or a management information system that tracks and reports on performance ([Chapter 49](#)). When good management information systems and monitoring programs are in place, the need for special-purpose assessment decreases, as does the effort and expense required to carry out an assessment when one is indicated.

Figure 36-1 Options analysis framework

Source: CPM/MSH 2011.

Proposals for pharmaceutical sector assessments sometimes meet with resistance. Decision makers may believe that action is needed instead of another study. Managers may think they already know the nature and causes of problems. Government officials responsible for donor coordination may be weary from the seemingly innumerable visits from representatives of donors and technical assistance organizations who ask the same questions but leave little behind. And some donors may prefer action to research.

In such situations, the general nature of the problems may be evident, but the true causes are often not so clearly known, and the full range of solutions that could produce sustainable improvements has not been considered. An assessment is needed—but an assessment of a different nature from those previously experienced.

Accurate systematic assessment is a prerequisite for planning changes in the pharmaceutical sector and, in particular, in the pharmaceutical supply system. Pharmaceutical sector assessments can serve any of four main purposes—

- Diagnosing emergent problems in the system and analyzing options
- Planning a project or formulating a pharmaceutical policy
- Monitoring change in the pharmaceutical system
- Comparing the performance of the supply system with that of other systems

Diagnosing emergent problems and analyzing options

Accurate diagnosis and action are urgently needed when major problems exist: medicines are out of stock in the rural health facilities, patients and politicians are complaining, and money is short. The assessment in such cases must be

done quickly, but it still needs to yield a thorough understanding of where the various subcomponents in the pharmaceutical system are functioning and where they are not, what factors are involved, and what sorts of interventions might be feasible and effective to address the problems. [Country Study 36-1](#) shows how a rapid assessment approach was applied to help countries under pressure to scale up HIV/AIDS services analyze their pharmaceutical management situations and options.

Planning pharmaceutical management projects and formulating policies

Systematic assessments should be done before all major pharmaceutical management projects and certainly as part of the process of developing a national medicine policy (or making any significant legal or policy changes related to pharmaceuticals). In addition, the Global Fund requires grantees to develop PSM plans as a condition for funding. When a project is being planned, the preproject assessment should define precisely the problems to be addressed, the interventions and expected outcomes, and the resource requirements in terms of capital, equipment, infrastructure improvements, recurrent expenditures, and technical assistance.

Monitoring changes

After an intervention is undertaken or a policy put into place, it should be assessed periodically to measure progress toward achieving objectives and to determine whether strategy changes are warranted. At the end of the project, another assessment should look at process and outcome to determine the extent of change in the system, whether the reforms appear to be sustainable, and whether additional inputs are needed.

Country Study 36-1**Assessing pharmaceutical and commodity management for VCT, PMTCT, and ART programs: Ethiopia, Namibia, and Rwanda**

With the increased focus of governments and donors to effectively scale up HIV/AIDS-related programs at the national level, supply systems for voluntary counseling and testing (VCT), prevention of mother-to-child transmission (PMTCT) of HIV, and antiretroviral therapy (ART) programs must work effectively. Governments and donors need to identify specific intervention options that will promote better commodity management practices among the VCT, PMTCT, and ART programs they support.

The Rational Pharmaceutical Management (RPM) project of Management Sciences for Health developed a rapid assessment approach for pharmaceutical management systems that identifies areas of improvement and provides intervention options for government agencies and donors to guide the scale-up of HIV/AIDS programs. Two phases result in a set of findings and recommended options for strengthening pharmaceutical and commodity management of HIV/AIDS services.

Phase 1: Situational diagnosis

- A country team gathers background information and reviews country data, reports, and strategic program plans for VCT, PMTCT, and ART.
- In-country, the team identifies local stakeholders' contributions to the pharmaceutical sector and maps the flow of medicines and commodities specifically for HIV/AIDS services, from the international level to the user level.
- Interviews are conducted with a variety of stakeholders, including government policy makers, pharmaceutical experts, central procurement units, central medical stores, donors, national AIDS commissions, stakeholders in the laboratory sector, pharmaceutical manufacturers (if any), pharmaceutical regulatory and professional agencies, private-sector wholesalers or distributors, and staff at service delivery sites.

Phase 1 provides critical information on the national policy and legal framework for pharmaceuticals. The assessment team looks at the availability of standard national treatment guidelines related to HIV/AIDS, staffing policies, quality assurance, distribution systems, inventory management and control procedures, availability of essential products, national practices for rational medicine use, and monitoring and evaluation systems. This

phase culminates in the identification of key strengths and weaknesses of the overall pharmaceutical system, as well as potential areas for improvement related to HIV/AIDS services.

Phase 2: Options analysis

- Assessors use Phase 1 data to select study areas and indicators and to generate options analysis matrices.
- In collaboration with country counterparts and donors, the team chooses study sites.
- Data are collected in-country over a period of two to three weeks. Data collection addresses pharmaceutical management system weaknesses and improvement options related to staff capacity, infrastructure, product selection, procurement, distribution, medicine availability, storage conditions, inventory control and management practices, medicine use, and management information and reporting systems.
- After analysis and interpretation of findings, the team compiles a full report with all assessment findings and the feasibility of improvement options.
- Local stakeholders attend an options analysis workshop where results are presented, priorities are proposed, and options are selected. The options constitute the basis upon which RPM Plus prepares its developmental action plans for improving pharmaceutical management for VCT, PMTCT, and ART programs.

Ethiopia*Assessment findings*

Warehousing and distribution systems for PMTCT products at the central level were lacking. Pharmaceutical and laboratory structures at the facility level were limited in terms of space, storage, and handling capacity, thereby compromising product security and safety and patient confidentiality.

Assessment response

- Evaluated different options for the distribution of PMTCT supplies and started negotiations with PHARMID (a parastatal import and distribution company) to serve as a warehousing and distribution agent to PMTCT delivery sites.
- Conducted engineering and infrastructural assessments in more than ten target facilities and designed a renovation plan to ensure minimum operational

conditions. In five sites, renovations have been initiated to expand space, improve shelving, and ensure safety and security of PMTCT products.

- Developed standard operating procedures for the management of PMTCT supplies and providing training to pharmacy staff.

Namibia

Assessment findings

Inadequate capacity and information hampered procurement planning and quantification. Inventory control systems in the supply chain were weak.

Assessment response

- Developed and implemented systems to strengthen the procurement, storage, inventory control, and distribution functions of the central and regional medical stores
- Facilitated the quantification of rapid HIV test kits and antiretroviral drugs

- Developed standard operating procedures for pharmaceutical management for VCT, PMTCT, and ART programs in Namibia

Rwanda

Assessment findings

A lack of capacity existed to quantify and coordinate national needs for PMTCT and ART services.

Assessment response

- Facilitated links between the ministry of health, the central medical stores of Rwanda (CAMERWA), and VCT/PMTCT facilities
- Helped CAMERWA establish systems to collect data that will make quantification for procurement more accurate
- Developed standard operating procedures for VCT/PMTCT and ART sites to facilitate operation and scale-up

Source: MSH/RPM Plus 2004.

Comparing the performance of different systems

An assessment may be needed to compare the effectiveness of one pharmaceutical management system with that of others. For example, an assessment might address two vertical distribution systems (such as essential medicines and HIV/AIDS-related products in the ministry of health) to ascertain how well each is functioning and whether opportunities exist for integrating them. Or the goal might be to compare the strengths and weaknesses of the public and private pharmaceutical sectors to determine what potential exists for collaboration.

36.2 Structure of the assessment

Every pharmaceutical system assessment should have a formal structure; otherwise, any observations, conclusions, and recommendations are wholly subjective, and the opinion of one expert (or assessment team) may be radically different from that of another expert or team that has visited the same offices and talked to the same people. García-Núñez (1992, 49) stresses the need for structure in assessment and project evaluation: “A person who visits a project and conducts a casual assessment of project activities is not conducting an evaluation. He/she is merely making observations. Individual unsubstantiated assessments should not be used as tools for decision making. Evaluations have to be conducted according to specific guidelines and procedures. Without a recognized frame-

work from which to draw conclusions, evaluation results are not credible.”

[Country Study 36-2](#) gives an example of an assessment using unstructured methods that failed to produce the necessary results; many others can be drawn from recent history around the world.

The primary questions to be answered when structuring a pharmaceutical system assessment are—

- What issues should be addressed in the assessment?
- What potential information sources exist?
- What information should be collected?
- What methods will be used to collect the information?
- What sort of team will do the assessment?
- What is the time frame and cost for the assessment?
- How will the study be managed?
- How will the results be presented for use by decision makers?

To fit the structure of the assessment to a specific purpose, many different combinations of answers might be appropriate. In some cases, the structure is defined and standardized by the funding agency. The rest of the chapter explores options that can be considered.

Prerequisites for assessment

Assessment approaches range from self-assessment by health system managers to assessment by a team of local

Country Study 36-2 Unstructured assessments

In one African country, several teams of international experts were given the responsibility of assessing the status of the public pharmaceutical supply system and quantifying resource needs for a World Bank loan. All the teams were experienced in the pharmaceutical management field, but none of the teams used a structured assessment approach—each team leader was free to develop his or her own methodology. The team responsible for identifying needs for equipment and infrastructure forgot to consider cold-chain equipment. Thus, the budget allocated for cold-chain equipment in the eventual project was a pure guess. The team assigned to evaluate treatment patterns and develop algorithms for morbidity-based quantification developed a treatment manual that was useless for quantification. Another team was assigned to look at the potential for private-sector collaboration in the public system; the team prepared a nice report on the issues that might be assessed but did not actually do the assessment. When decisions had to be made concerning what type of logistics system would be supported, no data were available on private-sector capacity. This gap was still in evidence five years later, when the country and the World Bank were again trying to figure out a way to salvage a viable pharmaceutical system.

experts to assessment by a full-time team of local and external experts doing extensive site visits. The approach should be tailored to the scope of the assessment and the quantity of data and quality of analysis needed for decision support. Four prerequisites for success exist with any of the approaches discussed in this section—

- Government commitment to the process
- A qualified assessment team
- A clear definition of objectives and procedures
- An unbiased approach

Government commitment. For a systematic assessment to be successful in public-sector programs, government commitment and active involvement are essential. If the study team is denied access to essential data or if key informants are never available, producing useful results will be difficult. Even if a report is produced, the likelihood of fruitful follow-up is greatly reduced without active senior-level commitment to using the assessment results for making policy decisions and instituting strategies for improvement.

Top management support must be translated into allocating both human and financial resources by making sure that operations staff members cooperate with the assessment and that health system staff assigned to the assessment actually participate fully in the process. Project budgets should include funding for scheduled assessments or for particular projects, at least a baseline and endline assessment.

Qualified assessment team. The team doing the assessment must be familiar with the intricacies of pharmaceutical systems in general and the local pharmaceutical sector in particular. The team also must be familiar with national administrative structures, the national health system, and local development experience. The team principals must be motivated and qualified to collect and analyze data and present the results in an organized fashion. The team should receive training to ensure the accuracy and validity of data collection and analysis. Outside experts are not always essential, but they can supplement local expertise by offering experience in comparable countries, a broader view, and an independent perspective.

Clearly defined objectives and procedures. Various assessment approaches and methods are discussed here; all have their place, but no matter which combination of methods is used, the goals, procedures, data to be collected, scope of the study, participants, and time frame should be clearly defined before the assessment begins. Once established, the structure should be followed within the bounds of normal constraints.

The assessment should be tailored to fit the purpose. The assessment may be broad in scope, to design a major essential medicines project, or it might have a limited focus, such as determining how many vehicles are needed for pharmaceutical distribution in a single region. Even in the latter example, the assessment should be structured broadly enough so that all potential options are identified (including contracts with the private sector).

The team should have a plan on how to analyze the data collected and how the assessment results will be presented to decision makers as well as disseminated to other stakeholders.

Unbiased approach. The assessment should be undertaken without preconceived notions as to what the findings will or should be. When a total lack of bias is not possible, all parties to the study should clearly understand what preconceptions exist.

A biased assessment may not identify the real causes of problems or consider all options for solution. For example, if an assessment is begun with the premise that all pharmaceutical services in the health system must be provided by government, it will probably overlook or downplay the potential for private-sector and nongovernmental organization (NGO) participation.

Assessment approaches

The two most common approaches to pharmaceutical system assessment are comprehensive structured assessment and limited assessment.

Comprehensive structured assessment. A comprehensive structured assessment gathers information from all levels of the pharmaceutical system. A specific team is responsible for making field visits to offices, warehouses, and health facilities and gathering multiple types of information through document review, interviews, data collection from records, and prospective observation. Preprinted survey instruments are used to collect data, which helps

ensure that a standard set of information is collected at each field site.

The survey instruments are structured questionnaires and data collection forms; they may be designed for a specific assessment or adapted from manuals (see for example, MSH/RPM 1995, WHO 2007). This type of assessment is often done as a rapid, intensive exercise by a full-time, dedicated team in cooperation with pharmaceutical system counterparts, but it can also be done as a self-assessment exercise by managers in the health system.

Limited assessment. Limited assessments rely primarily on interviews and document review, with limited field visits and little if any primary data collection from records or

Country Study 36-3 Developing and testing a procurement system assessment in India

In 2008, the Indian government recognized that agencies procuring health commodities for central and state health projects lacked consistent practice standards. To improve states' efficiency in procuring health commodities for public and World Bank projects, MSH's Center for Pharmaceutical Management (CPM) developed a tool incorporating international best-practice standards to serve as a basis for identifying strengths and weaknesses of procurement agencies or departments. CPM piloted the assessment tool at the Tamil Nadu Medical Services Corporation (TNMSC), which procures for both government- and World Bank-sponsored programs.

The specific assessment tool modules included the following—

- General requirements
 - Physical resources
 - Organization, structure, and functions
- Transparency
- Procurement cycle management
 - Bidding documents
 - Pre- and postqualification of suppliers
 - Advertisement and sale of bid document
 - Communication during the bidding process
 - Receipt of bids and bid opening
 - Bid evaluation
 - Contract award
 - Contract administration
- Support and control systems (audit)
- Record keeping
- Human resources and personnel
- General risk assessment
- Private-sector supplier assessment

The tool format included columns for standards, compliance rating (range of zero for noncompliant to three for fully compliant), assessor observations and comments, and instructions for the assessor.

Five important points were kept in mind when conducting the assessment—

1. The correct composition of the assessment team is critical.
2. Advance communication is necessary.
3. Assessment is an iterative process—not just the physical application of the tool.
4. Willingness of the agency to share the information and introduce improvement is a must.
5. The assessment tool must remain dynamic.

The TNMSC did not meet the minimum total combined score for each of the assessment modules that was required to immediately start national or international procurements. A thorough analysis revealed that the TNMSC had significant weaknesses pertaining to transparency, record keeping, information technology, and quality assurance, but at the same time, it exhibited many strengths, including the capability to follow World Bank guidelines for procuring nonpharmaceutical commodities. The assessment team debriefed TNMSC management and discussed the broader strengths and weaknesses. The TNMSC team stated its readiness to close gaps identified by the assessment and adhere to guidelines for World Bank procurements.

For more information on the assessment or to receive a copy of the tool, contact cpm@msh.org.

Source: Heltzer, Shrivastav, and Clark 2008.

prospective observation. The assessment may be done by a small dedicated team or by a working group from the pharmaceutical system. The assessment normally has a scope of work and should follow a predefined assessment plan; however, because the scope is constrained and time is not needed to prepare and validate survey instruments, a limited assessment can usually be completed more quickly and less expensively than a comprehensive structured assessment. [Country Study 36-3](#) describes a limited assessment of the pharmaceutical procurement system in India.

In some cases, a limited assessment obtains a great deal of information; the constraint is that the information tends to be whatever is provided by the officials interviewed. When a structured survey instrument is not used, the quantity and type of data obtained may not be consistent from site to site, which may hamper efforts to compile a valid picture of the whole system. The self-assessment option requires less incremental funding, but the usefulness of the results will depend on the willingness of officials to document and report problems.

Time frame and assessment costs

The financial and human resources required for an assessment obviously depend primarily on the assessment approach. A locally managed self-assessment can be done in two or three months at low incremental cost, although a few thousand dollars (or the equivalent) would probably be needed to cover travel costs, meeting expenses, forms, and communication costs.

A typical limited assessment involves two to six person-weeks for site visits, plus another person-week or so to develop a report ([Box 36-1](#) shows an example of an assessment timetable used in Rajasthan, India). Costs depend on how many experts are involved, but an average might be 25,000 U.S. dollars (USD) to USD 50,000 to cover all costs.

Time requirements and costs for a comprehensive structured assessment vary considerably, according to the number of levels in the pharmaceutical system and the size of the country. An experienced two-person team of experts might be able to manage a structured field-visit survey of public-sector pharmaceutical programs in a small country with three weeks on site, one week beforehand for preparation, and two to three weeks after for analysis and report writing. This schedule assumes that local officials and counterparts are active supporters and participants and that the health system has no more than three levels to be covered: central, provincial, and district. In the same country, one more experienced person plus a counterpart would be needed to cover the private sector in detail, and an additional person would be needed if the public-sector system had more levels.

Larger countries and more complex pharmaceutical systems require more effort for a thorough assessment; this effort can be managed by adding more team members or more field time for existing members, but in any case, costs will increase because of the logistics of sending data collectors to multiple districts across a large country. If the principal assessment team includes international experts, which costs more, the total cost of a comprehensive struc-

Box 36-1 Sample pharmaceutical assessment timetable

April 23 (Monday) a.m.	Assessment team arrives in Jaipur
April 23 p.m.	Meet with local NGO partner to discuss selection of districts and sample size
April 24	Adapt data collection forms and develop tracer drug list
April 25–27	Train field investigators and adapt questionnaires
April 26	Pilot instruments and make final adaptation of questionnaires
April 27	Photocopy and translate final data collection forms into Hindi
April 28 a.m.	Distribute forms and final instructions; review timetable for data collection in each district
April 28 p.m.	Field investigators leave for field
April 29–30	Data collection starts
May 1–4	Quality control teams leave for field
May 4–14	Use data collection forms at Jaipur SMS Hospital (state hospital and tertiary referral center)
May 14–15	Data collection complete
May 15–18	Input data and analyze

tured assessment of all sectors of a pharmaceutical system in a medium-sized country may still cost up to USD 250,000. Costs can be reduced by contracting with local companies for elements such as data entry, although a large-scale assessment is still going to be an expensive exercise. Nevertheless, a project or development loan to be based on the assessment might be worth tens of millions of dollars, making the expense worthwhile.

If only government budgetary resources are available, mounting a comprehensive structured assessment with external consultants may not be practical. However, multi-lateral or bilateral agencies may be prepared to support the assessment (and possibly provide experts). For example, the U.S. Agency for International Development (USAID) recognized the need for a comprehensive pharmaceutical assessment and options analysis in Uganda to frame its activities for a new system-strengthening project. Even if no donors are prepared to provide financial support or experts, advice and information may be available from international agencies such as the World Health Organization (WHO) and the United Nations Children's Fund (UNICEF); however, people with expertise in the area need to be involved for the assessment to prove valuable.

36.3 Defining the scope of the assessment

The issues that should be addressed in an assessment depend on its purpose; the issues that can be realistically addressed depend on the availability of information, the capacities of the assessment team, and the time frame allowed to collect information (discussed in the previous section). Issues of importance to the pharmaceutical system fall into one of three general categories—

1. Functionality of the pharmaceutical system
2. Private-sector capacity, including faith-based and other NGOs
3. Political situation and attitudes of major players and interest groups in the pharmaceutical sector

Understanding and solving widespread problems in a pharmaceutical system require a broad assessment covering all three categories. If the assessment is looking at only one vertical program or one aspect of the system (for example, HIV/AIDS commodity management in mission hospitals, see [Country Study 36-4](#)), the scope will be narrower, but many of the issues discussed in this section still need to be considered, if on a smaller scale.

Functionality of the pharmaceutical system

A comprehensive pharmaceutical system assessment needs to look at several subcategories of functions. Historically,

assessments focused mainly on the public-sector system; however, an inclusive view of access to pharmaceuticals in a country should encompass a range of operations, such as manufacturing, wholesaling, retailing, and providing health care services in both the public and private sectors, and the relationship between the different sectors. The Strategies for Enhancing Access to Medicines (SEAM) Program conducted comprehensive pharmaceutical sector assessments in six countries that included the private sector ([Country Study 36-5](#)). The functions of a pharmaceutical system can be categorized in many ways; the following list is drawn mainly from the indicator manuals discussed in Section 36.4—

Policy, legislation, and regulation: Are policies, laws, and regulations consistent, comprehensive, and current? Are they enforced?

Budget and finance: What sources of funds are available? Are the funds adequate to purchase all necessary medicines and to manage the pharmaceutical system effectively? Are the funds that are available effectively managed?

Medicine selection: How are medicines selected for use in the system? Do consistent policies and procedures exist, or is the choice up to each purchaser and prescriber?

Pharmaceutical procurement: Does an effective procurement system exist that gets good prices and manages to purchase medicines in the quantities and time frame needed?

Pharmaceutical logistics and availability: Are medicines well managed at storage facilities and available at the points where they are needed? Are major losses caused by expiration or theft?

Geographic accessibility: Are the locations of pharmaceutical products and services close enough for the people who need them to get access?

Affordability: Can the health system afford to procure and distribute adequate supplies to provide access to target users? Are users able to pay for pharmaceutical products or services?

Medicine use: Do prescribers, dispensers, and patients use medicines rationally, or do major problems exist with irrational use?

Acceptability (or satisfaction): Do users find pharmaceutical products and services acceptable to them?

Product quality assurance: Are the products that are purchased and used in the supply system of good quality? Are quality assurance programs adequate to ensure good product quality?

System management: Are management procedures fully transparent with clear lines of accountability? (See [Country Study 36-6](#).) Does each level of the system have adequate quantities of well-trained managers and operations-level staff? Are modern human resources

Country Study 36-4 Information targets for an assessment in Tanzania

The following list is an excerpt of information targets set for a structured field-visit assessment of five missionary hospitals in Tanzania in 2006; the goal of the assessment was to collect information on existing needs and gaps in HIV/AIDS commodity management to develop a plan of action for strengthening pharmaceutical management systems for HIV/AIDS commodities in the mission sector. The complete set of information targets (and the structured survey instruments used to collect the data) can be obtained from MSH's RPM Plus Program.

- *Policies and guidelines for HIV/AIDS services delivery:* availability and implementation of guidelines for prevention of mother-to-child transmission, voluntary counseling and testing, and clinical management of HIV and AIDS; health sector strategy for HIV/AIDS; national policy on HIV/AIDS
- *Capacity and training of human resources:* numbers of staff from different cadres dispensing anti-retrovirals (ARVs); number of staff trained in antiretroviral therapy commodity management; frequency of supportive supervision visits
- *Infrastructure supporting HIV/AIDS commodity management:* functionality of equipment (for example, refrigerator, dispensing trays, computers); availability of communications equipment (for example, telephone, fax machine, e-mail, Internet); number of burglar-proofed doors and windows; number of lockable cabinets; availability of cold room
- *Standard operating procedures (SOPs) that support HIV/AIDS commodity management:* availability and implementation of specific SOPs, such as requesting and ordering ARVs, medication use counseling for

ART, stock count discrepancy report for ARVs, disposal of ARVs

- *Supply procedures that support HIV/AIDS commodity management:* criteria used for medicine selection; pharmaceutical ordering process; data elements used to quantify needs; storage procedures for ARVs; procedures to manage medicine donations
- *Management information systems:* availability and use of records, such as ART Chart to Track the Expiry of ARV Drugs, Adverse Drug Reaction Form, Patient Log Book/Register; use of automated report systems (for example, computers, fax sheets, e-mail)
- *ART prescribing and dispensing practices:* number of reference books available in the pharmacy; adverse drug reaction monitoring and reporting system in place and functional for ARVs; mechanisms used to monitor ART adherence; adequate materials for labeling and packaging available
- *Monitoring and evaluation:* system in place for monitoring and evaluation at the pharmacy; list of indicators routinely tracked; percentage of ARVs whose physical count exactly match the records in the bin cards; current stock available and number of days that ARV medicines by type were out of stock during the last quarter
- *Commodity financing supporting HIV/AIDS services:* total budget of the hospital; percentage of budget spent on pharmaceuticals (current and previous three years); patient fees for any health service and how much

Source: Rutta, McCollum, and Mwakisu 2006.

management and training programs in place? Are salaries adequate to promote good performance?

Total operating costs: Do managers have information on the total costs associated with purchasing and inventory management needed to consider options for change in terms of their impact on total costs? (See [Chapter 40](#).)

Monitoring and management information: Are effective monitoring programs in place at each level of the system? Does an effective management information system allow managers to track supplies and funds throughout the pharmaceutical system?

Assessment guides at the end of each chapter of this book contain suggestions about the information needed to answer these types of questions and, more important,

to understand why problems exist and what can be done about them.

When defining the scope of a particular assessment, one must determine what information will likely be available in that pharmaceutical system from government documents, records, and reports; from interviews with system managers and staff; and from officials in related government offices and ministries. If the assessment is to address the private sector in a meaningful way, a method is needed to obtain information about the current state of the private pharmaceutical sector—the current types and levels of service provided to clients in various parts of the country, the capacity for providing services to the public sector, the attitude toward public-private collaboration, and the constraints that would need to be resolved to establish a working

Country Study 36-5 Applying access indicators to the pharmaceutical sector in six countries

WHO and MSH organized a joint consultative meeting to identify an operational definition of access and propose testable indicators to measure it. Workshop participants developed a framework comprising seventeen key indicators to represent the four dimensions of access and the one cross-cutting characteristic. The SEAM Program used the framework to conduct an overall assessment of the pharmaceutical supply systems in six resource-limited countries: Brazil (State of Minas Gerais), Cambodia, El Salvador, Ghana, India (State of Rajasthan), and Tanzania. Local private, not-for-profit, and academic organizations collaborated in the adaptation of data collection instruments, sample selection, data collection, and analysis.

Select data came from public- and private-sector health care facilities—

- Public health facilities (clinics and hospital out-patient departments)
- Private not-for-profit clinics and hospitals (NGOs)
- Private for-profit facilities (hospitals and clinics)
- Private retail drug outlets (pharmacies, chemical sellers)

To gather data on these indicators, SEAM used prescription-dispensing records to measure the quality of medicine-dispensing activity from the previous year, interviewed patients as they exited facilities to gather information on their perceptions and experiences, and conducted an exercise where simulated patients went to private retail pharmacies and drug outlets to obtain information about the quality of the services provided. An example of the indicator results follows.

Country Study 36-6**Pharmaceutical sector transparency assessments in four Asian countries**

WHO's Good Governance in Medicines initiative has created a tool for assessing the level of transparency in three functions of the public pharmaceutical sector—registration of pharmaceutical products, selection of essential medicines, and procurement. Assessors interview at least ten key informants for each function (at least thirty interviews for the country). The key informants, chosen using strict criteria, represent the public and private sectors, including civil society organizations.

When the interviews are complete, a rough quantification is used to characterize the level of transparency for each function—registration, selection and procurement—using a zero to ten scale. The interpretation represents the following degrees of vulnerability to corruption.

0.0–2.0	2.1–4.1	4.1–6.0	6.1–8.0	8.1–10.0
Extremely vulnerable	Very vulnerable	Moderately vulnerable	Marginally vulnerable	Minimally vulnerable

WHO used this methodology to assess four Asian countries: the Lao People's Democratic Republic (Lao P.D.R.), Malaysia, the Philippines, and Thailand. The assessment

results showed that the four countries shared a number of strengths and weaknesses. For example, all four had information systems for the registration process of pharmaceutical products, an official national list of essential medicines, and SOPs for transparent procurement. A common weakness was the lack of a conflict of interest form or guidance for the members of committees responsible for registering pharmaceutical products or selecting essential medicines.

The following table lists the vulnerability scores calculated for the four assessment countries. WHO notes that the scoring indicates vulnerability to corruption based on procedures at the time of the survey and not that one country's system is more corrupt than another. The scoring system is meant to help countries monitor their progress in improving transparency and good governance practices. Assessment results will provide a starting point for countries to develop and implement a national strategy promoting good governance in regulation and procurement of medicines.

Source: WHO 2006.

Vulnerability scale scores in four-country assessment

Function	Lao P.D.R.	Malaysia	Philippines	Thailand
Registration	5.6 Moderate	6.8 Marginal	6.8 Marginal	7.0 Marginal
Selection	6.1 Marginal	5.7 Moderate	6.1 Marginal	8.0 Marginal
Procurement	6.9 Marginal	7.1 Marginal	8.5 Minimal	7.1 Marginal

relationship. Information access varies from country to country; access largely determines how detailed an assessment is feasible and sensible.

Private-sector capacity

Many countries are incorporating private-sector services into the public pharmaceutical system, particularly when problems in the public system seem intractable (Quick et al. 2005). Of course, private entities of all sorts—nongovernmental, faith based, for profit—operate in the pharmaceutical sector of any country, but the level of their intersection and relationship with the government vary. Any assessment that is done in the context of major problems in the public pharmaceutical system should investigate private-sector capacity and the potential for public-private collaboration

of the sort outlined in [Chapter 8](#). Note that such assessments should encompass NGOs as well as the for-profit private sector.

The public sector may not have much reliable information on hand about the private sector, and establishing communication may be difficult if a history of mutual suspicion and hostility exists between the private and public sectors. For some countries, reports compiled by international companies that specialize in selling industry information can be obtained, but this information is expensive, not always detailed and current, and available for only a limited number of nonindustrialized countries. Most countries have associations that represent manufacturers, distributors, and pharmacies, but getting more than general information about the market and the member companies from these sources may be difficult.

Country Study 36-7

Data collection methodology for a pharmaceutical sector assessment in Tanzania

The Ministry of Health sponsored an assessment of the pharmaceutical sector in Tanzania to evaluate the situation in both public and private sectors and the viability of potential strategies for improving consumer access to essential medicines.

The pharmaceutical sector assessment, led by the Strategies to Enhance Access to Medicines (SEAM) Program, was based on two distinct sets of data collection efforts. First, a team of consultants worked with local counterparts to conduct key informant interviews, carry out site visits, and review documents (for example, policy documents, legislation and regulation relative to pharmaceuticals and public sector procurement, study reports, and financial reports).

Second, SEAM surveyed a sample of 104 facilities, including public, nongovernmental, and private hospitals; pharmacies; zonal medical stores; health centers; dispensaries; and *duka la dawa baridi*, or retail drugstores. The survey was conducted in six districts: Dodoma Urban, Njombe, Tanga Urban, Karagwe, Kilimanjaro Rural, and Masasi. Within each subsector, a representative sample included each relevant type of facility, focusing on outpatient care. Sampling issues for surveys were addressed and resolved in collaboration with local counterparts. Key issues considered included the existing information about the distribution of facilities and population, in particular the information's level of detail.

The following tasks were performed at each type of facility—

1. Public-sector facilities and private not-for-profit hospitals and clinics that also provide medicines to outpatients
 - Inspect and determine availability of a set of tracer essential medicines
 - Obtain prices charged for medicines (if relevant)
 - If possible, obtain prices paid by facility to its suppliers
 - Review inventory control record or bin card for tracer set of essential medicines

- Conduct interviews of relevant staff to fill in facility survey form
- Conduct patient or client exit interviews (minimum of ten patients)
- Review medical records or prescriber logs to collect prescribing data (thirty consultations)
- Obtain or purchase twenty units of a designated tracer essential medicine (for testing purposes)

2. Private for-profit hospitals and clinics

- Inspect or determine availability of a set of tracer essential medicines
- Obtain prices charged for medicines (if relevant)
- If possible, obtain prices paid by facility to its suppliers
- Review inventory control record or bin card for tracer set of essential medicines
- If possible, review medical records or prescriber logs to collect prescribing data (thirty consultations)
- Conduct interviews with relevant staff to fill in facility survey form
- Purchase twenty units of a designated tracer essential medicine (for testing purposes)

3. Private drug outlets (pharmacies and other types of drug outlets)

- Obtain a list of medicinal product names (brand or the manufacturer if generic) that are available for sale
- Determine availability of a set of tracer essential medicines
- Obtain prices for a set of tracer essential medicines; if possible, obtain prices paid by pharmacy or drug outlet to its suppliers
- Conduct questionnaire-based interview of drug outlet attendant
- Observe and record simulated patient or mystery client scenario
- Purchase twenty units of a designated tracer essential medicine (for testing purposes)

Source: CPM 2003f.

In most situations, the best option for assessing the private sector's capacity to play an increased role in the pharmaceutical system and contribute more to national medicine policy objectives is by conducting a special survey of the various components of the sector (including associations and their member companies). The SEAM

Program conducted detailed assessments of the private pharmaceutical sectors in six countries. [Country Study 36-7](#) describes the methodology used in Tanzania; the other assessment reports describe the methodologies used in the other five countries (see <http://www.msh.org/seam>).

Political mapping

An assessment aimed at making significant changes in the pharmaceutical system needs to define the consequences of potential changes. The assessment should also determine which politically powerful individuals and groups are likely to support potential changes, which will be actively opposed to change, and which will be basically indifferent. This process, called political mapping, is also useful in evaluating the feasibility of successfully implementing options for change.

Defining the best sources of information to map interest groups, political feasibility, and attitudes is not always simple. In most countries, the assessment team will be able to assemble at least a rudimentary map of political issues; likely consequences of various options for change; supporters and opponents of change; and individuals, organizations, companies, and interest groups that are prominent in pharmaceutical management (public or private). Truly reliable political mapping requires the active cooperation of senior managers (or ex-managers) in the government who are knowledgeable about the various political issues and interest groups but who have no personal stake in the outcome of the assessment.

Political mapping is an essential component of pharmaceutical system assessment; for example, in most countries, the private pharmaceutical sector is hardly a monolith—often important differences in attitudes and interests exist between local and international manufacturers, manufacturers and distributors, chain and independent pharmacies, and so forth. As noted previously, NGOs are another part of the private sector that involves people with unique views, and the various NGOs active in the country are likely to have differences in interests and attitudes.

The mapping process, if done accurately, helps define the causes of problems in the pharmaceutical system, examine the likely consequences of various changes and interventions, and determine which options are feasible and sustainable. Brugha and Varvasovszky (2000) describe stakeholder analysis, and political mapping computer software called PolicyMaker is available to help organize and interpret information (<http://polimap.books.officelive.com>). Williams, Durrheim, and Shretta (2004) take a political mapping approach to decision making regarding malaria treatment policy.

36.4 Defining the information targets

When the issues to be addressed and the assessment approach and time frame have been determined, the next step is to define the specific set of qualitative and quantitative data targeted for collection. In many cases, these data are collected in the form of standard performance indicators and are later organized into tables that provide insight into the pharmaceutical system.

Quantitative and qualitative data

Quantitative data describe the what, where, and when of a situation—for example, the percentage of a list of essential medicines that is available in a sample of health facilities. Qualitative data provide insights into why and how the situation is as it is—for example, why key informants believe that essential medicines are not more widely available. Quantitative methods can be used to give precision to qualitative ideas. Therefore, qualitative research is often used initially to identify problems and define the scope of options and issues, whereas quantitative data can then define the magnitude of the problem and measure the changes over time. In-depth interviews, structured observation, and focus group discussions are qualitative methods that can be used to explore behavior, attitudes, practices, and causal factors. Some of the data collected by these methods may be quantified, but the analysis itself is a qualitative one.

Although a comprehensive assessment should include both qualitative and quantitative elements, collecting a valid sample of quantitative data from a widely varied sample can sometimes be more time consuming and involve more work than conducting a series of focused qualitative informant interviews (which are more informal than focus group discussions); therefore, many reports on country pharmaceutical systems contain very little quantitative data and many unsubstantiated observations from informants. When an assessment does not gather quantitative data for analysis and comparison, the magnitude of problems or how much a situation has changed over time is difficult to know. At the same time, qualitative information is essential to understanding quantitative data, the reasons that specific weaknesses and constraints exist, and what strategies might be effective in overcoming the problem.

As noted, a properly structured assessment gathers and interprets both quantitative and qualitative information; problems with imbalance usually result when an assessment has no formal structure. [Chapter 28](#) discusses issues related to quantitative and qualitative data; for more information, see the starred entries in References and Further Readings.

Performance indicators

Performance indicators are standardized measurements that theoretically mean the same thing in every country; for that reason, they are widely used to compare the performance of different businesses, economies, and societies. A well-known set of indicators in international development is published annually by the World Bank in the *World Development Report*; the 1993 edition focused on health issues (World Bank 1993). In addition, the United Nations has drafted more than sixty indicators to measure progress toward the Millennium Development Goals, such as “the percentage of children under 5 years with fever being treated

Box 36-2**WHO pharmaceutical monitoring indicators for three levels of the pharmaceutical sector**

WHO has developed a core indicator package to monitor and evaluate country pharmaceutical situations. By repeating the assessment at regular intervals, WHO supports ministries of health in assessing the current pharmaceutical situation and giving them access to information that they can use to determine priority areas for intervention, track progress, plan programs, assess program effectiveness, coordinate donors and raise funds.

The core indicator package has three levels of assessment.

Level I: *The Questionnaire on Structures and Processes of Country Pharmaceutical Situation* measures structures and processes at the level of national governments, including policies, regulations, quality-control measures, essential medicines lists, supply systems, financing, access, production, rational use, and intellectual property rights legislation. WHO's plan is to distribute the questionnaire every four years to all member states. WHO uses this questionnaire to assess the global pharmaceutical situation, evaluate progress achieved toward goals set in the WHO Medicines Strategy, and make plans and set targets for WHO work for the next four years.

Level II: *The WHO Operational Package for Monitoring and Assessing Country Pharmaceutical Situations* is a practical and cost-efficient survey tool used by ministries of health to assess outcomes, including access, quality and safety, and rational use of essential medicines, at public health facilities and their pharmacies; central and district warehouses; or private, NGO, and mission pharmacies, as appropriate to country situation and households. The tool provides an evidence base for prioritizing health programs, developing and implementing plans, tracking progress, coordinating donors, and raising funds. More than forty member states have used this tool at least once to date.

Level III: A series of detailed survey packages to assess specific aspects of the pharmaceutical sector, such as medicine prices, the supply system, or traditional medicines. A country may implement a Level III survey to learn more about a specific area of the medicine sector after the results of the Level II survey have pointed to an area as needing more analysis.

Sources: WHO/TCM and DACP 2006; WHO 2007.

with antimalarial drugs" (see the indicator website at <http://unstats.un.org/unsd/mdg/Default.aspx>).

Performance indicators should be the foundation for ongoing monitoring in the pharmaceutical system (see [Chapter 48](#)) and should be a fundamental part of any pharmaceutical system assessment. Indicators to assess and monitor public pharmaceutical systems are a relatively recent development, and the optimal indicators to measure system performance have not been fully determined. WHO has developed pharmaceutical indicators to measure important aspects of a country's pharmaceutical situation at three different levels (see [Box 36-2](#)). Several other sets of performance indicators for pharmaceutical management systems have been developed; [Box 36-3](#) discusses four of them and lists performance indicator resources and tools for specific public health programs.

Defining information targets for a specific assessment

Three principles guide the setting of information targets for a specific assessment—

- Get all the information needed for the purpose, within time limitations, but do not gather data that are un-

necessary (doing so wastes time and effort in two phases of the process—collection and analysis).

- Make sure that the data used in producing analyses and recommendations are as reliable as possible, and determine which data are likely to be reliable and which are not.
- Define information targets based on what is available, and do not try to collect information that is nonexistent or impossible to retrieve.

[Country Study 36-4](#) shows some of the information targets for a pharmaceutical system assessment done in Tanzania in 2006.

36.5 Methods for collecting information

The basic methods of obtaining information in a pharmaceutical system assessment are—

- Document review
- Key informant interviews
- Collection of data from existing records
- Prospective studies

Box 36-3**Examples of indicators in pharmaceutical management**

Working in collaboration with USAID, the International Network for the Rational Use of Drugs, the Harvard Drug Policy Research Group, and the Pan American Health Organization Essential Drugs Program, MSH's Drug Management Program developed and field-tested an initial list of thirty-three indicators plus methods for data collection in 1993. Under the auspices of the USAID-supported Rational Pharmaceutical Management project, this indicator set and manual were further tested and revised to include forty-six indicators for the rapid assessment of pharmaceutical systems. The manual that documents this rapid assessment method also provides practical guidelines for organizing and completing a structured field-visit assessment (MSH/RPM 1995).

In 1994, the WHO Action Programme on Essential Drugs published a manual that proposed a set of thirty-one background information indicators, fifty structural indicators, thirty-eight process indicators, and ten outcome indicators, primarily for countries to assess themselves on issues related to national medicine policy. The indicators were field-tested in twelve countries in 1995 and 1996. WHO published the second edition of the indicators in 1999 (Brudon, Rainhorn, and Reich 1999).

The Australian Department of Health and Ageing adapted the WHO indicator format to develop

pharmaceutical policy indicators focused on medicine use. The second edition of the indicator manual was published in 2004 (Quality Use of Medicines and Pharmacy Research Centre 2004). This set has sixty-seven process indicators, fifty-seven impact indicators, and six outcome indicators. The indicators are used to monitor the implementation and effect of Australia's National Strategy for Quality Use of Medicines.

WHO and MSH organized a joint consultative meeting to identify an operational definition of access and propose testable indicators to measure it. Four dimensions of access emerged as being of particular relevance to essential drugs, vaccines, and other health commodities—physical availability, affordability, geographic accessibility, and acceptability (or satisfaction). In addition, the quality of products and services was identified as a cross-cutting dimension. Workshop participants developed a set of seventeen key indicators to represent the four dimensions of access and the one cross-cutting characteristic (CPM 2003g). The SEAM Program used the resulting framework to conduct an overall assessment of the pharmaceutical supply systems in six resource-limited countries: Brazil (state of Minas Gerais), Cambodia, El Salvador, Ghana, India (state of Rajasthan), and Tanzania (<http://www.msh.org/seam>).

This chapter summarizes these methods (see also [Chapter 28](#); INRUD 1996, WHO 2007, MSH/RPM 1995).

[Country Study 36-7](#) illustrates the methodology used to assess the public and private sectors of the pharmaceutical system in Tanzania.

Document review

Most countries have conducted studies of problems in the pharmaceutical sector and have made attempts to correct them. When donors have been involved in improving pharmaceutical services, many relevant reports are likely to exist. Government agencies can provide budget reports and, in many cases, files of technical reports by various agencies on the pharmaceutical sector. Contacting international agencies such as WHO, UNICEF, or the World Bank, bilateral donors, and technical assistance organizations to obtain copies of relevant documents is also useful.

A review of the literature should be one of the first steps in any assessment. Failure to include this important step inevitably results in a waste of time and money to regather data that are already available and reinvent analyses and recommendations that duplicate those already made. Worse, interventions that have been unsuccessful in the past may be tried again, with similar lack of success.

Key informant interviews

Interviews are one of the quickest ways to learn about urgent problems, if the assessment team is able to identify the people who are most knowledgeable about the situation and if these people are prepared to discuss the situation frankly. Interviews may be misleading, however, if the informants are not fully frank because of fear of retribution or if they have some vested interest in hiding or distorting information. Nevertheless, interviews are essential for insight into the political and administrative processes, which are major determinants of whether assessments will lead to real action.

Interviews may be conducted with or without structure. In the unstructured format, the interviewer relies on personal experience to ask relevant questions and to ensure that

important issues are not overlooked, which means the interviewer should be knowledgeable and well trained. In the structured approach, the interviewer uses a written survey form listing the important questions and the qualitative and quantitative information to be solicited.

Each format has advantages and disadvantages. The unstructured interview allows a free flow of conversation and may promote a more revealing interview, but it is subject to bias. Overlooking important issues is also easy when the interview is unstructured, and collating and analyzing responses from a series of such interviews are difficult, particularly if different interviewers are involved. The structured interview is usually more formal but is more likely to ensure that all important issues are addressed by each interviewer and that the responses are ordered in a manner that facilitates analysis. An interviewer using a structured format can combine both approaches by asking more probing questions to investigate an issue more thoroughly, but then return to the interview guide once the probing has finished.

Data collection from retrospective record review

A record review is a critical step in all structured assessments and should be done at each site where reasonably well-organized, complete, and current records exist. Where records are totally disorganized and badly out-of-date, the information gained may not be worth the effort, and other methods will be needed.

Relevant records include government publications on budgets and expenditures, drug regulatory inspection reports, patient medical records, pharmacy dispensing records, records of procurement and accounts payable to suppliers, warehouse ledgers, bin cards and computer records, and accounting and finance records. Private-sector records to review may include company financial reports, balance sheets, sales and stock data, and customs and import data.

Data collection by prospective field observation

When needed information cannot be obtained from a retrospective review of records, it may be possible to use

prospective observation to obtain the information. For example, one method of reviewing prescribing practices in a health facility is to examine clinical charts and dispensing records. If these records are not available, the team can observe patient encounters directly and record the prescribing in that manner (a patient exit survey).

Some types of data are best obtained by prospective methods. For example, to determine whether private pharmacies are selling prescription-only medicines without a prescription, the best method is a simulated purchase survey, where local data collectors visit a sample of pharmacies and actually attempt to purchase prescription medicines (see Boyce and Neale 2006b).

Other methods for collecting qualitative information

Other common methods for obtaining useful data include focus groups and household surveys, although both methods can be complex, technically demanding, and costly. These techniques, however, can be important tools in determining why attitudes and practices exist in one group or another (see [Chapter 28](#)), and sometimes they can be piggy-backed onto other household surveys or reports from previous efforts can be used, such as national demographic and health surveys (see <http://www.measuredhs.com>).

36.6 Planning and managing the assessment

The key issues in planning most assessments are—

- Defining the assessment approach
- Defining and locating financial resources
- Defining management and technical responsibilities
- Developing a draft workplan

After these issues are resolved, the assessment leader and the team develop a management plan. The plan must cover these issues—

- Making logistics arrangements
- Preparing a system overview
- Selecting sites to be visited
- Selecting indicator medicines
- Defining data collection methods
- Developing and refining data collection forms
- Selecting and training data collectors
- Revising the workplan to its final form

These issues are relevant to most comprehensive structured assessments, and they are covered in great detail in *Rapid Pharmaceutical Management Assessment* (MSH/RPM 1995) and the *WHO Operational Package for Assessing, Monitoring and Evaluating Country Pharmaceutical*

Situations (WHO 2007), which are available without charge. Any country or supply system that is planning a pharmaceutical assessment should get these manuals to aid in its planning and execution.

Given proper preparation, the actual data collection process may go relatively smoothly and produce reliable data for evaluation. However, one can safely assume that the assessment will not proceed entirely according to the workplan, no matter how well it was thought out. Minor frustrations will occur, such as unavailability of some key team members, weather-related delays for some site visits, and unexpected absence of key informants. These can be worked around, as long as the assessment team maintains its flexibility and sense of humor. Major problems such as widespread work stoppages can shut down the entire public health system and require postponement of the assessment, if it has not started, or interrupt the study until facilities reopen.

The following are vital issues to consider when analyzing situations and options—especially for fast-track assessments—

- Ability to quickly identify and mobilize the lead team of assessors, once a country need has been identified
- Continuity of the team throughout the different phases of the approach and their solid understanding of the methodology
- Experienced, knowledgeable assessors to facilitate interviews with national policy makers and officials, interpret policy data, and develop and analyze improvement options
- Full engagement of local stakeholders throughout the different implementation phases
- A logistics system to support scheduling, recruitment, and training of data collectors and then data entry and analysis

Data analysis

When a large amount of quantitative data is available on costs, purchases, medicine consumption, and use patterns, it must be organized to facilitate analysis. [Chapter 40](#) is devoted to the issue of analyzing data to understand and control costs in the pharmaceutical supply system; most of the analytical techniques in that chapter can and should be incorporated into assessment information targets, if necessary data are available. Several other chapters offer suggestions for organizing data to facilitate analysis during an assessment (see [Chapters 28, 48, and 49](#)).

To avoid confusion and haste at the end of an assessment, one should collate and prepare assessment data for analysis as they are collected (see [Chapter 48](#)). If a computerized program such as Epi Info (see [Chapter 50](#)) or even an Excel spreadsheet is used for collating survey results, data should

ideally be entered at the end of each day by team members or a local data-entry person, or if teams are operating simultaneously in different parts of a country, then data should be collated at the end and entered into a system. Both team members and counterparts should play an active role in examining data that are recovered and considering what sorts of additional analyses may be appropriate beyond those prescribed in the assessment workplan.

Preparing the assessment report

Chapter 49 discusses how to interpret data from a pharmaceutical management information system. The issues are similar for interpreting results from assessments. No matter how well the assessment was designed, planned, and executed, the data obtained may not be totally reliable. Part of the job of the study team is to determine what sorts of biases, inaccuracies, or inconsistencies may exist and what precautions are necessary in interpreting the data. The report itself must be presented in a way that helps the decision makers who need to use the information; a clear outline and executive summary of not more than two pages, which includes a statement of the next steps, are important. The methodology and detailed results can be mentioned in the text and appended to keep the document concise for interested but nonspecialist readers.

Presentations and workshops

Many key decision makers may not have the time to read the whole report. Presentations and workshops are excellent ways to convey important results directly and may be useful before the final report is written, providing feedback for clarification. Charts and graphs are important visual aids to organize the presentation and ensure that key points are covered. Actual examples of graphic presentations of findings from a medicine use assessment are found in Chapter 28.

Using the assessment results

An assessment should be seen as only one of several steps involved in planning and implementing pharmaceutical system changes. The assessment may be part of the development process for a donor project proposal, a national pharmaceutical sector restructuring exercise, or a national five-year development plan.

If the assessment is leading to a donor project proposal, the assessment team should be aware of this goal from the outset. If possible, the prospective donor should contribute to the assessment design. As mentioned, some donors, such as the Global Fund, have standardized assessment protocols. To encourage a sense of involvement, the prospective donor might also be given an opportunity to participate at various

points in the assessment and report-writing process. The assessment team should be sure to collect all background information that may be needed. The content and format of the assessment should be compatible with what is needed for a project proposal. Depending on donor requirements, the assessment report may serve as a project proposal with little or no editing.

If the assessment is part of a national restructuring or planning exercise, key government officials must be involved from the beginning, as well as stakeholders from the private sector and the community. People are much more committed to implementing solutions that they have helped develop.

The whole assessment process will have been wasted if the report goes on a shelf and is not used to effect changes in policies and procedures. Follow-up may be tied to the development of national medicine policies, revisions in legislation and regulation, and consideration of public-private collaboration.

After the assessment is complete, a workshop to bring stakeholders together and work through the assessment results and related options will define next steps and stakeholder roles and responsibilities. The assessment results may suggest revised policies and procedures in pharmaceutical selection, procurement, distribution, and use. The assessment and subsequent stakeholder options workshop should guide the development of strategic plans for pharmaceutical systems (see Chapter 38) and monitoring programs, program planning, and management information systems. Country Study 36-8 looks at examples of how assessment results were used to address issues in pharmaceutical management for TB medicines in several countries. ■

Country Study 36-8

Using assessment results to improve TB pharmaceutical management in three countries

The RPM Plus Program's indicator-based *Pharmaceutical Management for Tuberculosis Assessment Manual* (PMTB) helps users, primarily national tuberculosis (TB) programs, conduct studies that—

- Provide data on TB pharmaceutical management practices
- Identify ways to improve the national TB pharmaceutical management system, thereby promoting an uninterrupted supply of quality TB medicines
- Build country-based research capacity

Findings from an assessment can provide the basis for policy dialogue, strategic planning, program monitoring, and intervention design.

The PMTB has been used in Armenia, Azerbaijan, Cambodia, China, Congo (Brazzaville), the Dominican Republic, Ethiopia, Georgia, Moldova, India (Uttar Pradesh), and Romania. Highlights from Ethiopia, China, and Cambodia follow.

Field-testing of the PMTB in Ethiopia and impact of findings on policy

In 2004, RPM Plus field-tested the PMTB tool in Ethiopia to evaluate TB medicine availability and use. Key assessment findings included the following—

- Inventory records were not regularly updated, resulting in discrepancies between stock records and actual stock.
- Standard treatment guidelines (STGs) differed slightly from recommendations of WHO: for example, STGs for Category I patients included injections instead of tablets.
- Health care providers gave incorrect medicines 10 percent of the time.
- Of intensive-phase patients, 76 percent were observed taking their medicines (a primary element of the DOTS strategy).
- Only 32 percent of patients had adequate knowledge about how to take their medicines.

Following the assessment, Ethiopia's TB and Leprosy Prevention and Control Program took specific measures to address some of these problems, such as—

- Recruiting a logistics officer to oversee the details of TB medicines and supplies management
- Incorporating information on logistics management into the newest national TB program manual
- Providing training to pharmacy staff on how to

manage TB medicines and commodities, and supporting supervision to reinforce their training

- Using new methods to record and report on the consumption of TB medicines and stock status
- Conducting pharmaceutical supply management assessments throughout the year to monitor progress and identify areas that still need improvement
- Revising STGs to align with WHO recommendations

Using PMTB findings to introduce new pharmaceutical management systems in China

After adapting the PMTB tool to the Chinese setting, RPM Plus used the tool in two provinces—Shandong and Henan. On the basis of the findings, Henan province was chosen to update its TB pharmaceutical management system. In 2006, three sets of SOP manuals were prepared for use at provincial, prefecture, and county levels, and training in procedures was completed for thirty personnel. The SOPs have been modified in line with feedback to make them more user-friendly in the Chinese context. With positive results in seven pilot facilities in Henan since July 2006, the plan is to expand the new system's implementation to the rest of the province and throughout China, reaching more than 3,500 TB facilities.

Using the PMTB to evaluate policy change in Cambodia

The Japan International Cooperation Agency used the PMTB methodology and questionnaires to conduct TB pharmaceutical management assessments in Cambodia during 2003–04 and 2005–06. The first assessment established a baseline and illustrated key problems in pharmaceutical management, such as medicine availability and rational medicine use. The second assessment measured any improvement in TB pharmaceutical management practices after switching the national TB program's policy from an eight-month to a six-month treatment regimen and evaluated whether any change occurred in TB medicine availability in the private sector.

A comparison of findings from the two surveys revealed improvement in a few areas and highlighted the need for further interventions emphasizing the following areas: periodic supervision, on-the-job training for drug storekeepers and TB service providers, further expanding community DOTS, strengthening public-private collaboration, and exploring the possibility of procurement and use of four fixed-dose combination TB medicines or patient kits.

ASSESSMENT GUIDE

- What are the reasons that the pharmaceutical system is being assessed?
- What issues should the assessment address?
- Have any assessments of the pharmaceutical system been conducted in the past?
- Who is sponsoring the assessment? Who is actually conducting the assessment?
- If the assessment covers the public sector, is the government committed and involved in the assessment process?
- What other stakeholders should be involved in the assessment?
- What information related to the pharmaceutical system will likely be available for review?
- Is the scope of the assessment comprehensive (covering the entire system—both public and private sectors)? Or is the scope more focused (for example, one sector or one vertical program)?
- What are the qualitative and quantitative information targets to be collected as part of the assessment? Are the information targets based on standard performance indicators?
- What methods will be used to collect the information?
- What is the time frame and cost for the assessment?
- What are the qualifications of the assessment team?
- Who will analyze the results?
- How will the results be presented for use by decision makers?

SUMMARY

Although management means different things in different contexts, all managers are responsible for the activities and accomplishments of their organization. Good management is about ensuring reliable operations that serve clients, staff, and other stakeholders in their efforts to reach common goals. As a result of the manager's actions, the organization successfully and consistently does what it is supposed to do.

Managers must balance their time among the four activities of crisis management, routine administration, control and supervision of operations, and long-term program development. They are called upon to fulfill the roles of—

- **Leader:** providing direction, motivating staff, maintaining liaison with other organizations
- **Coach:** using a coaching style of interaction to improve employee performance
- **Communicator:** maintaining networks of formal and informal contacts, disseminating information, serving as spokesperson
- **Decision maker:** allocating resources, deciding on program change and development, solving problems, negotiating

Organizations need good leadership to move toward a better future and good management to make sure that current operations run smoothly and efficiently, and produce the intended results. Leading means enabling others

to face challenges and achieve results under complex conditions. By using their adaptive skills, managers who lead are able to achieve results even when conditions are very difficult and resources scarce.

Effective managers require technical, analytical, and interpersonal skills. They set priorities based on the urgency, relevance, effect, future consequences, and growth of competing issues. They follow systematic processes for decision making and problem solving. Necessary skills can be acquired through formal management training programs and practiced in formal and mentoring situations.

The management process, which is at the hub of the pharmaceutical management framework, consists essentially of three basic functions—

- **Planning** (see [Chapter 38](#))
- **Implementation**
- **Monitoring and evaluation** (see [Chapter 48](#))

Improvements in pharmaceutical systems involve change; leading well requires continuously adapting to changing conditions in the environment and helping others to do the same. To manage change effectively, managers who lead must understand the forces driving internal and external change, the sources of resistance to change, and the principles for successfully managing change.

37.1 Managing and leading a pharmaceutical program to produce results

Part III of this manual, Management Support Systems, takes a look at the knowledge, values, practices, and skills required to manage organizations, finances, information, and people and to successfully lead change efforts to improve current operations. The preceding sections on selection, procurement, distribution, and use presented the technical core of the pharmaceutical management framework. Management support systems form the hub of this framework ([Figure 37-1](#)). This chapter explores the requirements for creating a strong hub for pharmaceutical management.

Failing programs and organizations have demonstrated that neither abundant resources nor excellent technical skill can guarantee success. If management or leadership or both are not well executed, the organization will not be able to fulfill its mission or will do so with unnecessary effort and significant waste of resources. Although managing and leading are critical organizational functions, they are often taken

for granted. This chapter provides new and experienced managers with a practical framework for assessing and improving their own and others' management and leadership practices and skills.

Managing for performance

As a prerequisite to receive funding, an increasing trend in performance-based development aid requires health programs to establish and meet measurable objectives (see [Chapter 14](#)). Such results, in pharmaceutical management as in any other specialized area of management, must be directly linked to improved delivery of services to the population, always with a view toward improved health for all people in the country or in the population served by the public health program.

Achieving results in pharmaceutical management by meeting program objectives requires action by individual staff members as they work together as a team toward common objectives. Establishing individual performance-based

Figure 37-1 Pharmaceutical management framework

Source: CPM/MSH 2011.

objectives is a participatory process in which managers and staff members set goals that are then used to periodically assess performance. Using performance-based objectives provides the link between overall program implementation activities and individual staff performance. Section 37.3 covers monitoring individual objectives in more detail.

To provide the desired level and quality of services, organizations or programs need to make sure that—

- Management systems are well designed, fully operational, and maintained by appropriately trained people. Management systems are the structures, processes, and procedures that managers develop to help staff do their work. Managers use systems to inform, organize, and track progress in performing these tasks.
- The work climate is positive and promotes staff motivation and dedication to produce intended results. Work climate refers to the prevailing mood of a workplace or what it feels like to work there. It is the environment related to staff motivation, including working conditions, managerial support, acknowledgment, and encouragement.
- The organization or program is able and prepared to continually adapt to changing circumstances, which includes the ability to anticipate and adapt to changing conditions in the internal or external environment. This capacity relies on staff resilience, empowerment, optimism, openness to learning, creativity, and ability to communicate with partners from other ethnic, social, gender, and organizational groups.

The manager's role is to make sure that these three conditions are met in the workplace. A positive work climate,

strong management systems, and openness to learning all foster an organization's capacity to respond to a changing world (Figure 37-2).

Managers and leaders

People often refer to one person or another as a good manager or a good leader. Such statements are usually intuitive, and when pressed to describe the difference between leading and managing, many people find it hard to do so. What exactly is the difference? *Managing* means organizing the internal parts of the organization to implement systems and coordinate resources to produce reliable performance. *Leading* means enabling others to face challenges and achieve results under complex conditions. Modern organizations and the increased understanding of how people function have led to a different concept of management methods. Table 37-1 contrasts the attitudes and style of traditional and modern methods.

People who manage well are good at planning and organizing. They make sure that processes and procedures, staff, and other resources are used in an efficient and effective manner. Good management is about ensuring reliable operations that serve clients, staff, and other stakeholders in their efforts to reach common goals. As a result of a good manager's actions, the organization successfully and consistently does what it is supposed to do—it is trustworthy to its clients, supporters, and suppliers. Trustworthiness helps the organization maintain its funding flows, goodwill from supporters, and reputation for reliable results. Although good management and the establishment of sound management systems form the foundation for the organization's work, they do not always guarantee the desired results.

Figure 37-2 Leading and managing for results model

Source: MSH 2005a.

Managers with new tools and systems often get the same outcomes as before, unless they *lead* others to use these systems well, periodically adapt tools and systems to meet changing needs, and manage the organizational context.

Leading well requires continuously adapting to changing conditions in the environment and helping others do the same. By using their adaptive skills, managers who lead are able to achieve results even when conditions are very difficult and resources scarce. They make sure that they are always well informed about opportunities and threats. They continually inquire into their own, their organization's, and their staff members' strengths and weaknesses. They are able to develop a compelling vision, get key stakeholders to buy into that vision, and then focus organizational efforts on achieving it. They mobilize people, resources, and goodwill around the vision and keep everything moving in the right direction. They inspire and encourage staff to overcome obstacles that obscure the vision, recognize the contributions of everyone, celebrate successes, and learn from mistakes.

Pharmacists as professional leaders

Pharmacy professionals, because of their technical training and unique expertise in systems management, have much to offer in public health policy making and leadership, especially as part of the global effort to increase access to medicines and scale up major public health programs, such as antiretroviral therapy. Although representatives from all health professions—medical, nursing, pharmacy, health administration—should be involved with public health planning and implementation, often the pharmacy profes-

sion does not play as strong a leadership role as it could in public health decision making, whether at the national, regional, or facility level. Although pharmacy staff are valued for their role in supply management, the contributions of the profession to patient care and to promoting the rational use of medicines is often unrecognized and under-resourced, and the pharmacy staff members' clinical skills are often underused. The International Pharmaceutical Federation recommends that "governments and international organizations with a focus on health should recognize the unique contribution pharmacists can make, through their technical expertise, to improving access to medicines for people in developing countries" (FIP 2005). More important, however, pharmacy professionals, themselves, through their professional organizations as well as through individual efforts, should work toward strengthening their role as leaders at all levels of the health care system, mentor the next generation of leaders in the profession, work to improve access to medicines through use of ancillary dispensers, and, when appropriate, position the pharmacy profession at the forefront of public health policy development and implementation.

37.2 What makes a successful manager who leads?

Organizations need both good leadership to move toward a better future and good management to make sure that current operations run smoothly, efficiently, and produce the intended results. The notion of "managers who lead" makes sure that both areas are covered.

Table 37-1 Comparison of traditional and modern managers

Traditional manager	Modern manager
Acts as authoritarian figure, critic	Acts as facilitator, coach
Is concerned about structure and procedures	Is concerned about objectives and results
Tries to succeed alone	Succeeds through the success of the team
Pushes staff to focus on manager's needs and concerns	Encourages staff to focus on the program's needs and concerns
Gives little feedback	Gives positive feedback and constructive negative feedback
Is critical; discourages individual initiative	Is supportive; coaches staff to take initiative
Uses threats to control staff	Uses encouragement and support to motivate staff
Uses one-way, top-down communication	Uses two-way communication
Is secretive	Shares information
Knows all the answers	Recognizes the expertise of other team members
Holds decision-making authority; makes decisions single-handedly	Involves staff in decision making
Decides not only what should be done but also how it should be done	Allows staff to participate in deciding what should be done and defining how they can best do it
Resists change; views change as a threat	Welcomes change as a source of improvement
Is concerned with punishing people for doing a bad job	Helps people do a better job
Creates fear, which discourages staff from asking questions and making suggestions	Creates a sense of security; staff ask questions and make constructive suggestions

Sources: Adapted from Ivancevich et al. 1994; Rees 2001.

The tasks of a manager

Managers in every part of the world have something in common: their days are filled with four quite different sets of tasks, all of which require their attention—

- Crisis management
- Routine administration
- Control and supervision of operations
- Long-term program development

Crisis management—or “fighting fires”—can consume entire days or sometimes entire weeks: an overdue proposal to a donor, a shipment of emergency medicines stuck at the port, an outbreak of meningitis in one part of the country, a break-in or robbery at the regional store in another part of the country. Many such crises are actually preventable through better management of activities, but learning to respond quickly and decisively—and not to overrespond or to overcommit scarce resources—is an important part of becoming an effective manager.

Routine administration includes the whole range of day-to-day activities involved in receiving reports, managing staff, making decisions, and generally conducting the business of the organization or program. These activities are necessary but can often be managed more efficiently through delegation and other skills described in other management support chapters.

Control and supervision of operations is the formal or even legal responsibility of the manager. He or she must ensure that the work is done in compliance with national or institutional regulations and requirements. Controlling and supervising is a true balancing act. Too much supervision and too much control will discourage employees from developing initiative and resourcefulness, which creates a fearful and demoralized workforce. Too little control and too little supervision nearly always produce unnecessary crises and leave employees feeling abandoned, create opportunities for leakage and graft, and risk noncompliance, thus leaving the manager and the organization vulnerable to sanctions.

Long-term program development concerns a task that is important, even critical, to long-term survival and program success. Because it is never urgent at any particular moment, long-term program development always receives less attention than the urgent and important tasks. Nevertheless, failure to plan and implement needed changes often increases the number of management “fires” and makes even routine administration less efficient and more time-consuming than it should be. Unfortunately, many managers are so consumed by the first three tasks that they make little time for long-term program development.

An effective manager who leads must balance attention to these four tasks—responding promptly to crises, efficiently handling routine administrative work, and exerting the

right amount of control and supervision while still attending to the long-term growth and development of the program or organization.

The practices of a manager who leads

A study of successful public health managers who lead (MSH 2005b) showed that, despite differences in style and personality, they all did similar things: they continually scanned, they focused, they aligned and mobilized, and they inspired. These are the particular practices of good leaders. They also planned, organized, implemented, and monitored and evaluated. These are the practices of good managers. Effective managers who lead constantly and consistently use these eight practices to produce intended results. The leading and managing practices described in the leading and managing framework (Figure 37-3) offer specific practices to improve organizational performance and sustain performance over time.

The skills of a manager who leads

Most health program managers have climbed up through the ranks and have been promoted because of their technical skills and knowledge. Technical skills, therefore, are rarely an area of weakness. Nevertheless, any health program manager has to have a certain minimum amount of practical and theoretical knowledge as well as a set of practical skills in the professional discipline relevant to his or her job. These skills may relate to pharmaceuticals, medicine, logistics, accounting, epidemiology, public health, infectious diseases, and so on.

Because all managers have responsibility over budgets, they have to be familiar with the basics of financial management, such as preparing, managing, and monitoring budgets; assessing value for money in people and projects; and doing a cost-benefit analysis. They should also be able to read, understand, and manipulate financial data pertaining to their program or organization.

Managers who lead need another set of skills, however, unrelated to their level of technical expertise in their area. The following skills become increasingly important as the scope of a manager's authority, influence, and responsibility increases—

Priority setting: Focusing attention and action among multiple options and interests

Managing time: Making good use of time to align personal and organizational goals

Problem solving and decision making: Using analytical abilities, pragmatism, and other tools to resolve complex problems and make the right decision in a variety of contexts

Coaching: Mastering a comfortable coaching style and using it strategically to improve performance

Communicating: Communicating both orally and in writing and relating to a broad range of people within and outside of the organization

Negotiating: Arriving at understandings and agreements with a broad range of people inside and outside the organization or program

Managing change: Adapting to and thriving in times of internal or external change

In addition, computer skills have become indispensable. Managers who lead should be comfortable using word-processing, spreadsheet, database, presentation, and other software applications that are relevant to their work. They should be able to use the potential of the Internet to its fullest, for both research and communication. The skills listed here are discussed in more detail in Sections 37.4 and 37.5.

The values of a manager who leads

Values guide the manager who leads as he or she makes choices about how to serve staff, clients, and partners. Positive leadership has a strong ethical component that is missing from negative leadership. Those who lead with an eye on the common good are sustained by their values; positive leaders communicate their values frequently, and those values are visible in all their actions. In contrast, negative leadership draws on people's fears. It uses reward and punishment and depends on including some people and excluding others in the exercise of power and authority and in the distribution of rewards.

Managers who demonstrate positive values gain the respect of their staff, and they easily attract others to join them in pursuit of a vision of success as they display these values in their everyday life—

Integrity and commitment: People respect leaders for their ethics and personal commitment. People who are honest and ethical are credible to others who value integrity. A manager who leads who strongly believes in serving a greater good can avoid the temptations that often come with power.

Respect and trust: Respecting others means being willing to listen to their points of view and their needs. Respect builds trust over time, and trust is the foundation for developing productive relationships. Successful managers who lead nurture respectful work relationships with subordinates, colleagues, and superiors. They create new connections to broaden their own network and spend time improving existing relations that are problematic.

Courage: One job of leaders is to set an example for taking calculated risks that do not endanger the organization, its mission, or individuals. People who lead do not give up if they fail; they find the courage to reengage. Supported by their networks of trusting relationships, they find

Figure 37-3 Leading and managing framework: Practices that enable work groups and organizations to face challenges and achieve results

Source: MSH 2005a.

support and courage to take necessary chances, make tough decisions, and face criticism or personal failure. By example, they encourage others to take calculated risks as well.

Openness to learning: Effective managers who lead are open to learning and inspire others to do the same. Their open minds are evident in their eagerness to continually learn and acquire knowledge and information. They initiate approaches to learning with others. This openness to learning and anticipation of the need to change allows a nimble response when the time comes to change old habits or long-standing practices.

The attitudes of a manager who leads

Effective managers who lead are recognizable by their mind-set. A *mind-set* is a habitual way of interpreting and responding to situations, which results from beliefs that are shaped by personal history and the surrounding culture. Such beliefs may be about the power of an individual to change a situation, the innate goodness or trustworthiness of others, or the assumption that the value of a person depends on his or her position in society.

For example, if a manager believes that people have something to contribute, he or she will find ways to encourage participation and shared learning. If a manager believes that individuals can make a difference, he or she will look for opportunities for thinking and working creatively together to achieve common goals.

By changing his or her view and interpretation of a situation, or by questioning deeply held beliefs, a manager may see new avenues for action that were hidden before. Therefore, being flexible enough to change one's viewpoint may reveal new possibilities for action and for success. These capacities are particularly important for managers who lead. These "leader shifts" are fundamental to effective leadership. Each of the following five leader shifts represents a series of changes in perspective that occur when people deepen their understanding of themselves, others, and the environment—

- From a belief in heroic actions to a preference for collaborative action that builds on the strength of a group of individuals to produce sustainable results
- From a state of despair or cynicism, where problems and obstacles appear to be insurmountable, to a place of hope and dreams, where multiple possibilities present themselves to make things better
- From a tendency to blame others for problems or failure to take the initiative, taking ownership of challenges, and working together to do something about them
- From frantic days filled with unrelated activities carried out for their own sake to purposeful work directed toward achieving results that matter
- From a preoccupation with oneself and ways to satisfy one's own needs to a concern with the greater good and a sense of responsibility toward others and society as a whole

These shifts are not easy to make or sustain, because a person's own needs, habits, and worries can interfere at any time. By being mindful of these issues, managers who lead can make corrections when they see that they are becoming busy but unproductive or are being drawn into a state of despair. They can stop themselves when they feel the urge to blame someone else or when their own needs begin to overshadow the greater good.

37.3 The management cycle and leading and managing practices

Program management activities are cyclical. To move from idea to result, the manager has to complete a set of activities through a series of phases: the planning phase, the implementation phase, and the monitoring and evaluation phase. This loop is continuous, because each evaluation contains the seeds for a new plan, and each plan is only as useful as it is feasible and implemented. Implementation is only successful if program goals and objectives are met, which is determined through monitoring and evaluation.

To make sure that the activities related to the management cycle are well managed and led, the manager draws on a particular set of management and leadership practices for each phase of the cycle (Figure 37-4).

Planning phase

In this phase, all major decisions regarding the use of human, financial, and other resources have to be made. During this phase, indicators are established that will allow later monitoring and evaluation. Although all managing and leading practices are required during this phase, the most critical practices are—

- *Scanning* to ensure that relevant and critical information about the current situation, key actors, strengths, weaknesses, threats, and opportunities is available, understood, and analyzed
- *Focusing* to set priorities among the many competing needs and interests and to identify key stakeholders and major variables, so that the best program approaches, broad goals, and strategies can be established
- *Planning* to set specific objectives and targets, determine implementation strategies, define activities and tasks, assign responsibilities, and allocate the resources needed to implement the plan and reach objectives

Figure 37-4 The management cycle

In all health programs, three main levels of planning exist, differing in purpose, time frame, and level of detail—

1. *Strategic planning*: This is planning with a long-term focus, usually more than five years and possibly as much as twenty-five years into the future. Such plans are concerned with the overall effectiveness and direction of the program or organization, and they establish or confirm a common vision of what the organization or program is meant to achieve. National development plans, national health policies, and national pharmaceutical policies are forms of strategic planning.
2. *Program planning*: This is planning with a medium-term focus, and it seeks to establish major objectives, activities, and resources needed for a specific program or organization over a three- to five-year period. Essential medicines program master plans and most large, multiyear project proposals are forms of program planning.
3. *Work planning*: This is planning with a short-term focus (usually six to twelve months), indicating for each major objective the specific target outputs, required tasks, individual responsibilities, schedule, and budget. Work planning also includes operational planning, such as that required to produce a national formulary manual, renovate a medical store, or conduct a major educational campaign on rational medicine use. Strategic plans and program plans that lack workplans are of little practical use.

To maximize the chance of success, those who will be involved in implementing a plan must be involved in formulating the plan. For strategic plans, senior ministry or program officials may have to be involved. For program plans or annual workplans, the staff of the program, department, and units involved should participate in plan formulation.

[Chapter 38](#) describes in detail the planning process, the three levels of planning, and various planning methods.

Implementation phase

During the implementation phase, the plans are put into action. This phase usually requires most of a manager's time and energy. The work that is done during the planning phase provides the foundation for implementation; the better and more realistic the plan, the more likely that this phase will start well. The true test of a good plan is in its implementation: can the manager transform money, information, people's energy and skills, and other resources into the intended outcome?

The following managing and leading practices are particularly important during the implementation phase—

- *Aligning and mobilizing* to make sure key stakeholders are engaged and all possible resources are fully mobilized toward the planned activities
- *Organizing* to make sure that the right resources are available and usable at the right time at the right place and that people have the skills to use them
- *Implementing* to ensure the smooth progress of activities, coordinate with others, solve problems, remove obstacles, and make timely decisions
- *Inspiring* to create and support the commitment that sustains and nurtures people's efforts over time, especially when they are encountering setbacks or problems in their work

The effective functioning of the various management systems is especially important during the implementation phase. Specific aspects of implementation are discussed in other chapters of this manual, including—

- *Organizational structure for pharmaceutical supply* ([Chapter 8](#)): alternative models for pharmaceutical supply, centralization versus decentralization of pharmaceutical supply systems
- *Human resources management* ([Chapter 51](#)): staff selection, job descriptions, support and supervision, communication, delegation, motivation, and discipline
- *Financial management* ([Chapter 41](#)): budgeting, cash planning, costing, accounting, financial control, and reporting
- *Information management* ([Chapter 49](#)): information needs, information systems, and use of information for decision making

Monitoring and evaluation phase

The next phase in the management cycle is monitoring and evaluation. Although closely related, monitoring and evaluation are two distinct activities.

Monitoring starts during the implementation phase and is, in fact, an integral part of it. *Monitoring* is the process of observing implementation activities and comparing actual performance with plans. Objective indicators, developed during the planning phase, help track performance against targets. Objectives should be SMART—specific, measurable, appropriate to the individual or unit, realistic, and time-bound. They should also be written down. Objective indicators may specify performance levels for ongoing activities or plans to complete new tasks.

Examples of individual performance objectives within an essential medicines program would be—

- For the training officer: ensure that ongoing education programs contain a module on rational medicine use

- For the chief supplies officer: ensure that stock record-keeping is properly maintained
- For the district pharmacist: ensure that appropriate data, such as consumption rates for individual medicines, overstocks, and shortages, are collected and used for decision making

Methods of monitoring these performance activities may include carrying out random stock and record checks or requiring submission of quarterly reports on pharmacy data.

Monitoring allows the manager to take action when a discrepancy occurs. Program monitoring is done through supervisory visits, routine reporting, the use of sentinel reporting sites, and special studies (see [Chapter 48](#)). In addition, the staff members or units and supervisors should review individual progress on a regular basis. The review should assess progress toward each target, identify implementation problems, make any required changes in the targets, and suggest additional inputs required to achieve the targets. Actions may include providing corrective feedback, reallocating staff or other resources, adjusting plans and targets, or requesting additional information.

Evaluation is a periodic assessment of progress toward achieving long-term objectives and goals. Whereas monitoring is concerned with whether activities are being implemented as planned, evaluation is concerned with the overall relevance, effectiveness, efficiency, sustainability, effect, and future of the program. Evaluation builds on information gathered for monitoring purposes, but it requires additional information. Evaluation methods are also useful in pharmaceutical sector assessment for project planning (see [Chapter 36](#)).

In this phase, all the leading and managing practices are required. If the monitoring activities show that progress is being made, and if evaluation indicates that objectives and goals have been reached, the practice of inspiring becomes easier because nothing inspires people as much as being successful. The manager who leads needs to acknowledge all contributions to the success.

[Chapter 48](#) describes monitoring and evaluation methods, the use of indicators, common pitfalls, and ways of using the monitoring system to improve performance.

37.4 Skills for managers who lead

For most people, training is a significant motivator, and most people look for opportunities to develop and grow professionally and personally. Skill development, whether self-directed or imposed, requires awareness, willingness to learn, training, and practice. Part of the planning phase requires an assessment of whether staff members have the required skills to implement the plan. If training is needed,

adequate resources (time and money) need to be reserved for this purpose.

Those concerned with pharmaceutical management policy increasingly recognize the need to support the strengthening of management and leadership skills. This reinforcement can be done on the job through coaching programs, by giving people assignments that challenge them to go beyond their current skill level, through continuing education schemes, or by participating in formal training programs.

A promising approach to management and leadership skill development is the enrollment of complete work teams in management and leadership development programs. In these programs, which can be face-to-face or Internet based, natural work teams select a real work challenge and learn the skills, practices, and values that will help them overcome the challenge and produce intended results (MSH 2005b).

Setting priorities

Priority setting is the skill of focusing attention and action among multiple options and interests. Devoting time to one problem or decision means that another must wait. All phases of the management cycle require priority setting, and the practice of *focusing* makes this possible.

In the *planning phase*, the manager has to decide what to plan for and what not; in the *implementation phase*, the manager has to make choices about how staff members use time; and in the *monitoring and evaluation phase*, the manager has to decide what to monitor and what to evaluate, because resources will never be enough to monitor and evaluate everything.

Managers are constantly faced with questions about which decision should be made first and which problems should be solved first. How much time and effort should be allocated to a specific problem or decision? What tasks should be delegated to other staff? To set priorities, managers need to ask themselves several questions—

Urgency: Many issues seem urgent, but which ones really have a critical requirement with an absolute deadline or time limit?

Relevance: Which issues are most central to long-term strategic plans and goals?

Impact: Which issues are likely to have the greatest impact on major program activities?

Future consequences: Which issues present the greatest threat to or the greatest opportunity for the future of the program?

Growth tendency: Which issues will get worse if they are not addressed sooner rather than later?

In general, issues should receive high priority if they are urgent, are likely to significantly affect future activities, or are

likely to become worse if left unattended. The dilemma is that these high-priority issues are usually also the complex issues that require complex responses that cannot be addressed by the manager alone, whereas the simple, less urgent, or unimportant issues can be easily done and checked off a to-do list, thus giving the illusion of progress and successful action, yet having little or no significant impact.

An important principle for setting priorities is *management by exception*. With this approach, the manager expects staff to handle all decisions, problems, and activities, except for those that are of special importance, have long-term consequences, or are unusual in some way. This system allows the manager to focus on those issues that really need his or her attention. Management by exception is similar in some ways to the 80-20 rule in ABC analysis (see [Chapter 40](#)). It allows managers to focus on the most important areas. Management by exception can be applied to a variety of management tasks—

- Program development efforts should focus on the key aspects of pharmaceutical policy implementation that present the greatest difficulties.
- Routine reports should be reviewed to identify districts, facilities, or activities that are doing exceptionally badly (so that corrective action can be taken) or exceptionally well (so that they can be acknowledged and learned from).
- Follow-up supervisory visits should be made to regional depots, districts, or health units that are known from routine reports or other information to be having the most problems.

Management by exception and the key priority-setting questions apply mostly to the allocation of human resources. [Chapter 38](#) discusses setting priorities for financial and other tangible resources as part of the planning process.

Managing time

Staff time and personal time are resources that need to be managed. Wasting time diverts a manager from important tasks. The most frequent time wasters include—

- Random activities (“busy-ness”) that do not contribute to specified objectives
- Failure to set priorities
- Absence of deadlines
- Unnecessary or badly structured meetings
- Visitors arriving without appointments
- Telephone or e-mail interruptions
- Too little or too much information
- Attempts to do too much in too little time
- Overemphasis on easier, more routine work at the expense of harder tasks

- Long breaks and social chat
- Inability to say no

To avoid wasting time, the following techniques may be useful—

- Be clear on your own and your team or organization’s vision.
- Identify measurable results as milestones toward the vision.
- Clarify objectives by writing them down.
- Establish in the morning at least one good outcome for the day (“this will be a good day if I accomplish . . .”) and then focus your attention and effort on achieving it.
- Keep a log of how days are spent, and review it.
- Reserve the best time of the workday to concentrate on the most important task.
- If necessary, negotiate with your supervisor to take work to a quiet place—the unoccupied office of someone on leave, a nearby library, or home—when an assignment must be finished.

Time is one resource that is equally available to everyone and distributed in a finite way; only twenty-four hours are available in a day. When time is frittered away, it is lost forever. A manager who makes good use of time to align personal and organizational goals is investing well in his or her own future as well as the future of the program.

Decision making and problem solving

Decision making is a skill that requires a combination of analytical thinking, pragmatic considerations, and intuition. Many tools are available that can help in this process. Successful management requires prompt, thoughtful responses to the problems that inevitably arise when plans are put into action. This is the art of effective implementation. Some managers are very good at both decision making and problem solving; others defer decisions, avoid problems, or make impulsive responses that create new problems.

Although they are different in some respects, decision making and problem solving can both be approached through a seven-step process, which requires the management and leadership practices of scanning and focusing—

1. Review the basic objective.
2. Define the decision to be made or the problem to be solved.
3. Assess the situation to determine the cause of the problem.
4. Identify alternative solutions.
5. Compare the alternatives, using defined criteria.
6. Select and implement the best decision or solution.
7. Follow up and adjust.

Decision making and problem solving can go wrong at any of the seven steps, but some of the following common mistakes can lead to bad decisions or unworkable solutions.

Losing track of the original objective or solving the wrong problem: The basic problem must be clearly identified. Managers may be presented with a problem of inadequate financing for pharmaceuticals when the real problem is that the procurement unit is wasting money by not following the essential medicines list. Or considerable time and money may be invested in renovating and reorganizing the central warehouse to improve the supply system when the real problem is that staff members are not adequately trained or motivated.

Failure to properly assess the situation or the causes of the problem: If the causes of a problem are thoroughly understood, the solution is often obvious. It is therefore important to identify what additional information is needed to adequately understand the situation. If a stockout of amoxicilline occurs, for example, the manager needs to know whether it is because the medicine was not ordered, not shipped, not delivered, or consumed more rapidly than expected.

Failure to identify all relevant alternatives: Managers who act too quickly may achieve poor results because they have not considered the options or consulted key stakeholders who could have pointed out previously unnoticed issues. Similarly, managers who avoid decisions and problems may do so simply because they have not made the effort to identify reasonable alternatives.

Lack of clear criteria for selecting among alternatives: If what is to be accomplished is clear, the criteria for choosing among alternatives will be easier to define. Sometimes cost is a major factor; sometimes it is time.

Failure to follow up and adjust: Things seldom work out exactly as expected. Managers must be willing to adjust their actions on the basis of experience. Lack of follow-up, leaving people to their own devices when new behaviors are needed, laziness, carelessness, or stubborn unwillingness to adjust to experience are likely to waste resources.

One effective way for managers to improve decision making and problem solving is to ask staff to go through these steps themselves before coming to the manager. They should present the manager not only with a question or a problem but also with a list of alternative courses of action, a recommended course, and the reasons for the recommendation. The manager can then make the final decision. With staff members doing the basic problem solving, the decision is likely to be better and require much less time and effort.

Managers who maintain control by acting as if or believing they are the only source of answers and solutions may resist this approach. But as the quality of decisions—and

with it, program performance—improves, the manager will soon appreciate the benefits of the new approach.

Coaching

Coaching is a conversation in which the coach is committed to the development and success of the person being coached. A coach helps the other person clarify her commitments and intended results, see new possibilities and actions, and expand her range of behavior choices. Coaching also helps the person understand his own contribution to recurrent problems and see the consequences of choices made. Ultimately, coaching is intended to help the other person think more clearly and see new ways of achieving intended results. However, for a person to be coached, he or she has to want to learn and change, be open to feedback from others, and be willing to take responsibility for his or her own actions.

A coach does not evaluate and judge, blame, criticize, scold, or give solutions. An effective coach builds a relationship of trust and support, cares about the person being coached and has his or her growth in mind, listens well, and asks questions to clarify and illuminate a goal or challenge. Some of the questions a coach might ask are—

- What are you committed to achieving?
- What have you achieved so far?
- What obstacles are you facing?
- Why do you think you are stuck?
- If it could turn out exactly as you dreamed, how would it turn out?
- What actions could you take to overcome your obstacles?
- What support do you need from others?
- How can I support you?

Coaching is a good vehicle for the manager to give the underperforming person a warning and a chance to improve. Sometimes poor performance is simply a matter of mismatched expectations or the complete absence of feedback. When no feedback or no adverse reaction results from poor performance, the staff member may conclude that performance is either up to standards or does not matter. Perhaps current policies, procedures, and flow of resources support and reward mediocre performance. And finally, staff may not have the skills to do well.

The manager should prepare for the coaching conversation before meeting with the staff member. Preparation will help the manager avoid being sidetracked from the planned conversation in case strong emotions surface (such as crying, shouting, making threats). Review what happened, separating feelings and thoughts from facts or observations, and then reach a decision with the person that reengages him or her in the task at hand.

By mastering a comfortable coaching style and using it strategically to improve performance, the manager who leads will be able to deal more effectively with difficult personnel issues.

Communicating

The manager who leads is the central focus for receiving and disseminating information. He or she needs to be able to communicate orally and in writing to various stakeholder groups, including not only staff members, peers, and bosses, but also people outside the program or organization.

Disseminating information to staff members helps them in their work. Insecure managers trying to protect their jobs sometimes purposefully withhold relevant information from subordinates. Sadly, by failing to support subordinates in their work, the manager increases the chances that the program will perform poorly, which in turn reflects badly on the manager.

Good communication will permit the manager to build a network of formal and informal contacts. This network is an invaluable source of information for scanning so that the manager can monitor changes, opportunities, problems, or misunderstandings that may affect the work. Networking is especially important in formalized relationships, such as those between ministries (finance and health, for example) or between programs and their donors.

Feedback is an important part of communication. If staff members do not know whether they are performing below standards, they cannot take corrective action. Often, managers avoid giving feedback about poor performance because it makes them uncomfortable. After all, giving someone bad news is not easy. Such avoidance can be devastating for individuals, however, and in the end, an unnecessary delay makes the conversation even more awkward and uncomfortable than it needs to be. The easiest way to give feedback is to alert the person ahead of time; seek a quiet place where the conversation cannot be interrupted, disturbed, or overheard; and review the things that go well, the things that need improvement, and finally, the things that need to stop. If the manager provides feedback in the right manner, an employee will be able to hear it without becoming defensive. Feedback can also become a motivator for change and improve the quality of information submitted to the manager.

Communication skills require an acute awareness of how messages are being transmitted, such as tone of voice, phrasing, and even use of words. Using simple and descriptive language and avoiding jargon are important. Simple and clear language that avoids confusion or double meanings is especially important when communicating with people from other cultures—whether professional, ethnic, or socioeconomic. Many potential misunderstandings are entirely preventable by paying more attention to language.

Senior-level managers often have to serve as spokespersons and present program needs and activities to higher officials, to donor organizations, or to the community. For such written or oral communication, the manager needs to think through the purpose and desired outcome of the report or presentation. Is it for information only or is some sort of action expected? Before composing a written communication, whether for oral presentation or for a report, the manager needs to consider the following questions—

- What is the purpose of the communication?
- Who is the audience?
- What is the expectation that the audience will retain?
- What is the audience, or selected parts of the audience, expected to do as a result of the communication?

Presenters of PowerPoint slides need to follow a few simple rules—

- Use only a few slides and use them as a presentation guide.
- Avoid reading the exact text from a slide.
- Use no more than five lines of five to six words each per slide.
- Distribute dense tables or long lists of statistics as handouts rather than putting them on slides.
- Practice the presentation with people who are likely to give honest feedback.

Negotiating

Negotiations usually happen either to create something new that neither party can produce on its own or to resolve a problem between two parties. Therefore, negotiating is a critical skill for managers who lead. Whatever the reason for the negotiation, managers need to be able to reach understandings and agreements with a broad range of people inside and outside their organization or program.

Each negotiation involves two factors: the substance of the negotiation (what is being negotiated) and the relationship between the two parties. To deal with the substance of the negotiation, the manager needs to present and defend his or her own point of view to establish his or her voice in the negotiation. But the manager also needs to establish and nurture the relationship with the other party in the negotiation. Different negotiating circumstances and partners require different tactics, and the manager has to decide which is more important—the relationship or the substance of the negotiation; sometimes they are equally important.

Pharmaceutical system managers often have little power within their larger organizations, which makes negotiation skills especially important for them. The basis for their power lies mainly in their knowledge and information. Managers need to plan their negotiations carefully by rec-

ognizing good opportunities to open a negotiation, thinking about the best timing for negotiations, and presenting good evidence to support the case.

Planning for a negotiation requires three steps related to the leading and managing framework (see [Figure 37-3](#))—

Step 1. Characterize the substance of the negotiation. This step requires the practice of scanning.

- Find out as much as possible about what each party brings to the table (for example, skills, information, experience).
- Recognize factors that make each party vulnerable and plan how to deal with them.
- Develop alternatives to a negotiated agreement.
- Seek fresh perspectives from others.
- Anticipate reactions from the other party to the presented viewpoint and proposals.

Step 2. Attract the other party to the table, which requires the practice of aligning and mobilizing.

- Make sure the other party sees that entering into the negotiation will be of value, and that this value will not be available otherwise.
- Make negotiation unavoidable by showing that no one has an alternative to a negotiated agreement or that not negotiating will result in an undesirable change for the other party.
- Level the playing field by establishing authority and credibility. When the negotiator is lower in status than the other party, getting explicit authorization from a superior is helpful.
- Build support for the agenda by using allies as intermediaries, strategic partners, and promoters of the cause.

Step 3. Make the personal connection, which requires the practices of scanning, focusing, aligning, and mobilizing.

- Invest time and energy in relationship building, participation, and staying engaged.
- Get everyone to take ownership of the problem by pointing out the negative consequences for all of not reaching agreement.
- Take a critical look at your own situation in order to separate fact from fiction or belief.
- Be open to listening to the other person's situation, appreciating his or her feelings, ideas, and need to save face. Look for links between the two situations.

As an example, a hospital pharmacist negotiating for a budget increase to add a computerized information system might need to—

1. Look into what competing priorities for resources the hospital administrators are juggling.

2. Enlist the support of colleagues in other departments, such as clinicians and nurses, whose performances are affected by service in the pharmacy.
3. Present the case for how a computerized pharmacy system will provide information to clinicians on patient adherence levels and adverse drug reactions and information to administrators, who need to compile monthly reports on patient treatment for donors and the ministry of health. Present the case that the computer will not only make a measurable difference in pharmaceutical service quality, but also will help the hospital meet overall performance objectives.

It is important to recognize, however, that sometimes the other party is playing by different rules and is unwilling to engage in a fair negotiation. The power imbalance between the two parties may simply be too great, turning the negotiation into a win-lose battle. Managers need to recognize this situation and be prepared to cut their losses (and try to do better next time).

37.5 Managing change

Leading is by definition related to change, because leaders take their followers to a place in the future that is different from the current situation. Improvements in managing pharmaceutical systems involve changes in policy, organizations, and individuals. Successful development is in many respects the management of change, and an organization that does not change eventually fails.

Change occurs at different levels and magnitudes, from restructuring the entire supply system to simply introducing a new dispensing register, or from launching a comprehensive national medicine policy to changing generic labeling requirements. Strategic planning may lead to major changes, whereas annual workplans generally involve smaller operational changes.

Effective management of change depends on an understanding of forces for change, resistance to change, and principles for successful change management.

Forces for change

Forces for change may come from within or outside the organization. Internal forces include pressure from individuals genuinely seeking to improve the program, from ambitious individuals pursuing their own ends, or from individuals and groups who are dissatisfied.

Sources of external pressure for change can include parts of the government or society, groups working globally, or specific donors. Such external pressure may arise from economic factors, political forces, or philosophical differences.

External pressure may also arise from trends toward democratization, decentralization, or privatization.

Managers who do not recognize and respond to change forces risk being overwhelmed by them. Many directors of medical services and program managers have lost their positions because they failed to appreciate the need for change and did not exert leadership in managing change.

Resistance to change

Resistance to change is a normal human response that is more likely to interfere with the change process if the change is imposed without any consultation with those most affected by it. Common sources of resistance to change include—

Personal self-interest: People resist change when they perceive it as a threat to their status, power, or personal finance; in short, when the change represents the loss of something that is significant. This situation includes instances where vested interests are being threatened. Anyone who is benefiting from the current situation is likely to resist the proposed change.

Bureaucratic inertia: Bureaucracies develop structures, policies, and procedures of their own: “We’ve always done it this way.” The response to change can be to subvert it with innumerable delays, diversions, and other barriers.

Habit: People resist change in organizations, but they also resist changing themselves. Most people find comfort and safety in the familiar.

Fear and uncertainty: Change generally involves some risk. Although things are supposed to get better, they could become worse if the change is unsuccessful.

Conformity and peer pressure: If new warehouse procedures or computerization of procurement systems is seen as a threat to jobs, co-workers may pressure colleagues to undermine the changes.

Rejection of outsiders: Changes are sometimes designed, proposed, or advocated by outsiders to the system and may bring in new managers or staff. Changes associated with outsiders are often resisted, regardless of the potential benefits of the changes themselves.

Understanding the sources of resistance to change can help identify ways of reducing this resistance, described below in the section on principles for managing change.

Changing management systems

Improving the performance of essential medicines programs often means developing and implementing new management systems or strengthening existing ones and developing the capacities of staff. Examples include the

process for selecting essential medicines and publishing the results; the committee structure, procedures, and forms used for tendering and other procurement activities; and the inventory control system and delivery schedule for distribution.

Effective management systems are rarely developed by people sitting behind a desk, and management systems never implement themselves. Too often, new management systems are designed in isolation and implemented without adequate testing. To increase the chance that the proposed changes are implemented, four key steps are necessary—

Step 1. Assessment of needs: What are the management needs? The procurement system for a program that buys medicines only from a few established international low-cost suppliers is likely to be quite different from one that buys through open international tender.

Step 2. Interactive system design and testing: In an interactive design process, those responsible for developing new systems work closely with operational staff. For example, new district systems can often build on innovations developed by an individual district or several health facilities. Procedures, recording systems, or reporting forms can be tested and revised at selected sites.

Step 3. Implementation training: Training based on general management concepts often has limited impact. But implementation training is an indispensable part of management development and should be as practical as possible and include a visit to facilities that have already implemented the new systems.

Step 4. Focused supervision: Training alone will not ensure implementation of new systems. Considerable follow-up supervision, focused on those units that are having the greatest difficulty, is often needed.

The concept of interactive system design is especially important. Staff members tend to resist centrally designed systems that fail to consider local needs or practical constraints. Most important, experienced operational staff members have clever ideas and solutions of their own to contribute. Interactive system design should not be seen as a totally democratic process in which everyone’s ideas are adopted. Instead, it is a creative but pragmatic process in which the most demonstrably useful ideas are incorporated into the final design.

Phased implementation

When new management systems, reporting forms, or other major changes are introduced, the manager needs to make sure that all affected parties are aligned and mobilized around the proposed change. For example, introduction of a new standard treatment manual or ordering system would begin with a national workshop for key staff

from provincial hospitals, followed several months later by provincial-level workshops for key district staff within the province. Finally, each district would hold workshops for its staff.

Phased implementation has the following advantages—

- It is more practical than introducing changes at all levels and all sites at the same time.
- It allows some real-world testing and revision of new systems before national implementation.
- It allows the public to adjust to new ideas and provides some flexibility in the timing of expansion to other levels. This gradual introduction is especially important when the proposed change has political ramifications, such as the introduction of user fees.
- It allows time for training and follow-up at one level before moving to the next level; when the new system has become fully functional at the initial level, facilities at that level can serve as training sites for the next level (see [Country Study 37-1](#)).
- Senior medical and administrative staff at one level who have become familiar with the new system become more effective advocates and supervisors at the next level.

Phased implementation may start at the central level and move to the provincial or state, district or regional, and local

levels; it may also be geographical, thereby completing the introduction of new systems in one area, province, or state before moving to the next.

Force field analysis

Force field analysis is a technique for identifying driving forces, those forces that push toward an objective, and restraining forces, those that stand in the way. The balance of these forces determines the point of equilibrium.

Implementing change or solving problems involves unbalancing the forces and shifting the equilibrium. The analysis has three steps—

1. *Diagnosing*: Identify all driving and restraining forces.
2. *Unfreezing*: Find ways to reduce restraining forces, strengthen driving forces, or find new driving forces.
3. *Refreezing or redefining*: Reestablish the equilibrium at the new target point.

Force field analysis uses a brainstorming technique, which is ideal for management teams. It enables a logical, systematic review of any problem or change situation, facilitates a comprehensive discussion of factors and possibilities, and is a highly participatory planning method that enhances teamwork. See [Box 37-1](#) for more information on force field analysis.

Country Study 37-1

Using learning sites to phase in the implementation of antiretroviral therapy programs in Kenya

An antiretroviral therapy (ART) learning site is a health facility where the facility managers, ART program staff, and partners collaborate to apply, integrate, and maintain best practices in ART pharmaceutical management system and services. The facility staff then serve as leaders and mentors, and the facility serves as a practicum site for training and promoting high standards for health commodity management.

The Coast Provincial General Hospital (CPGH) in Mombasa was the first facility in Kenya that integrated comprehensive HIV care and treatment into existing services, and CPGH became Kenya's first ART learning site as the country began scaling up ART. CPGH's package of services included clinical, pharmaceutical, laboratory, psychosocial, and community linkages.

Arranging site visits to and mentoring relationships with the learning site is an effective strategy to prepare staff who are about to start providing ART pharmaceutical services. The objective is to give pharmacy staff hands-on experience in managing inventory and dispensing

antiretroviral medicines, quantifying consumption, and medication counseling and to familiarize them with tools and record keeping. The learning site experience also allows the pharmacy staff members to exchange information on their challenges and lessons learned and to give them a reference point as they make changes at their own sites.

Pharmacy staff from Coast province and other provinces that used CPGH as a resource strengthened their own facilities and then became pharmaceutical management learning sites modeled on CPGH. In addition, the two national teaching and referral hospitals, Kenyatta National Hospital and Moi Teaching and Referral Hospital, adopted the CPGH model for ART pharmaceutical services. Eventually, the success of the learning site model resulted in Kenya's National AIDS/ STD Control Program adopting it in support of the country's goal of providing universal access to HIV care and treatment. Its decentralization strategy for HIV services is anchored in learning sites.

Box 37-1
Force field analysis

Force field analysis is a technique for analyzing the forces in an environment that can drive or restrain change. Force field analysis involves the following steps—

1. Write the objective at the top of a flip chart.
2. Draw a line down the middle of the sheet.
3. Brainstorm and list on the right-hand side all the restraining forces: those factors in the situation that will have a negative influence on the achievement of the objective.
4. On the left-hand side, list all the driving forces: those that will have a positive influence on the achievement of the objective. (It is important to put down only those factors that are actually present in the current situation, not what would be desirable in the future.)

After the force field has been fully set out, strategies for creating change can be developed.

5. Draw a line under the list in the left-hand column and write “Action Points.”
6. Analyze the array of forces that has been constructed. Consider how the positive ones can be strengthened or augmented and, more important,

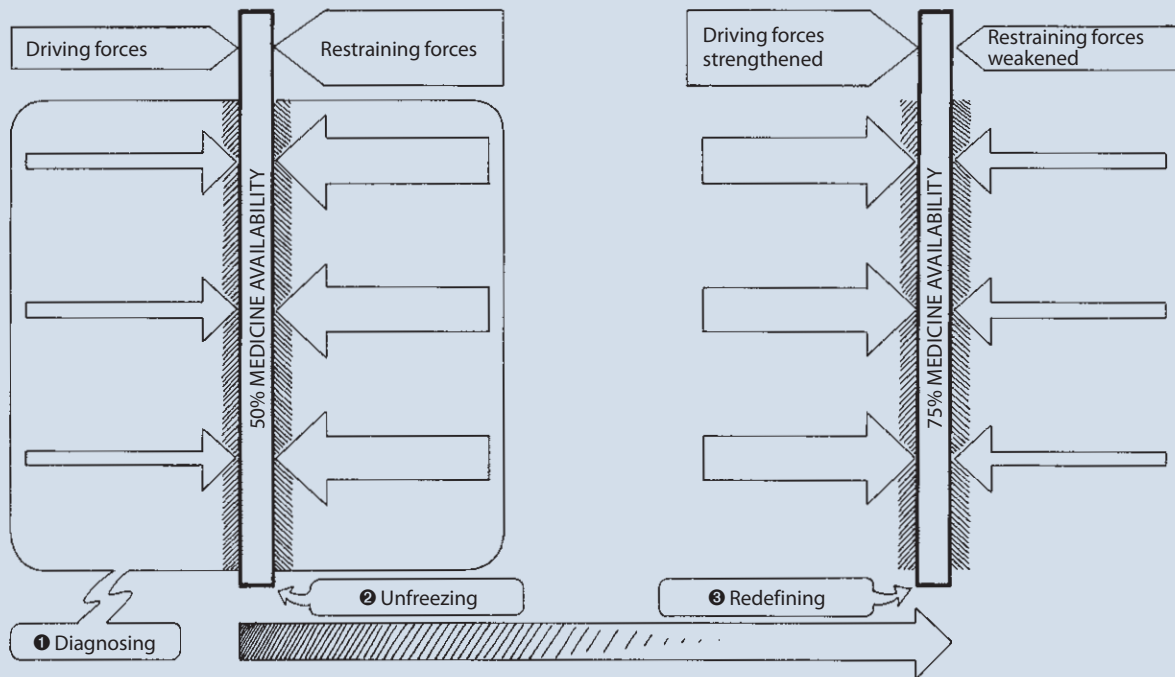

how the negative ones can be eliminated or counteracted. The questions to be asked at this stage are—

- Can any of the restraining forces be reduced?
- Can any of the driving forces be strengthened?
- Can any new driving forces be found?

7. In light of the foregoing analysis, list action points that will be helpful in achieving the objective.

In the accompanying figure, the objective is to move from a current level of 50 percent pharmaceutical availability (vertical bar on the left) to a level of 75 percent pharmaceutical availability (bar on right). The first step is diagnosis—identifying driving and restraining forces. Below are some of the forces that might come out.

Driving forces	Restraining forces
<ul style="list-style-type: none"> • Political pressure to solve medicine availability problem • New pharmaceutical management leadership • Up-to-date essential medicines list • New training on rational use of medicines 	<ul style="list-style-type: none"> • Interference in procurement process • Poor quantification practices • Lax storage and distribution system • Overprescription by health workers

Principles for managing change

Success depends on the magnitude and circumstances of the change as well as on the organizations and people affected by it. It is important to understand the responses people have to change and provide support and encouragement that are appropriate to where people are in their own process (see Figure 37-5). The following suggestions are useful in overcoming resistance to change and in managing change only when a manager has a clear sense of direction and purpose—

Know yourself: Managers should recognize their own reactions to change and their strengths and limitations.

Learn how others feel: Using both direct and indirect channels of communication helps managers assess reactions to change and adjust the change process.

Know the organization: Any organization has both a formal structure of reporting relationships and informal channels of influence. Understanding the organization, often with the help of others, is important to planning and managing change.

Generate “ownership” through participation: The seeds of success or failure for change are sown even before the change has been fully planned or implemented. Involving potential supporters and implementers early in the process generates a sense of ownership.

Use reason: Make the case (as in a legal argument) for the proposed change by pointing out the pros and cons of the change, showing the consequences of not addressing it.

Debunk myths: Directly (but tactfully) challenge myths stemming from long-held beliefs, wrong or outdated ideas, or misinformation passed on by others.

Share the credit: Part of generating a sense of ownership among staff involves sharing the credit. Leaders who capture the credit for themselves are likely to find themselves alone at a critical point in the process.

Look for win-win strategies: Change is more likely to succeed if every interest group benefits in some way. Generic medicine substitution can benefit both customers and retail pharmacists if the pharmacist is allowed to make a higher mark-up on a much less expensive medicine.

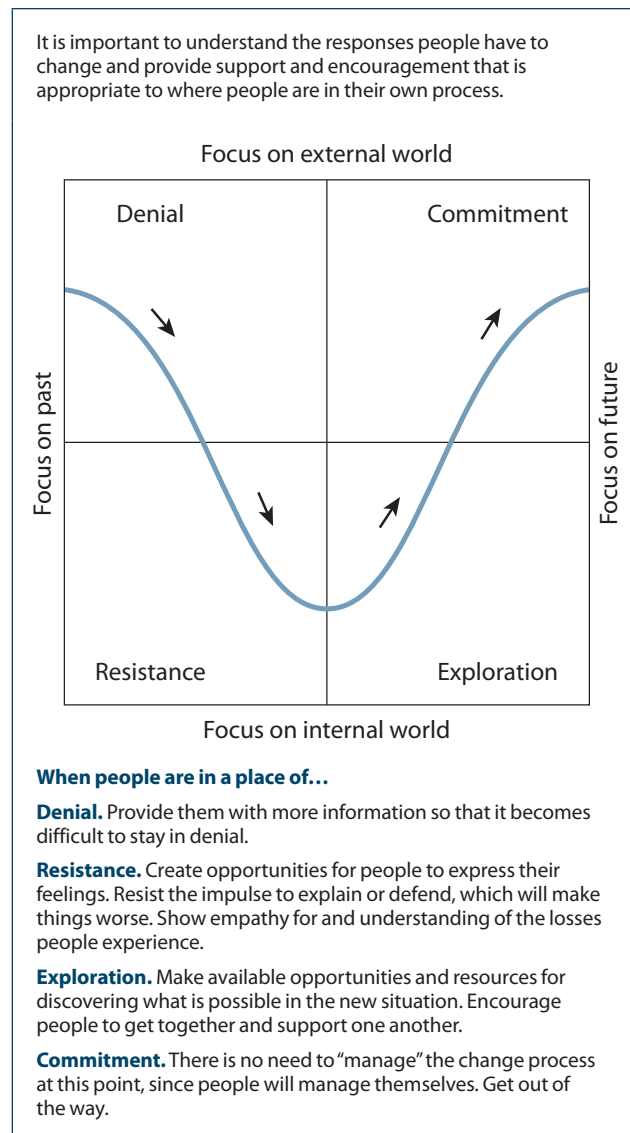

Develop a sense of timing: People often expect and want policy and program changes when the leadership changes. New governments and new managers provide an opportunity for change.

Share information and educate: Much of the resistance to change comes from fear and uncertainty. These can be reduced by clear and open communication with staff.

Recognize that people take in information in different ways: Some need to see numbers presented in graphs or tables. Others prefer to see pictures or hear quotations.

Tell a compelling story about the vision and show how the changes are inevitable.

Figure 37-5 Working with people’s responses to change

Source: Scott and Jaffe 2010.

Describe the vision in a variety of ways: Provide opportunities for people to “try on” the new vision for themselves.

Facilitate and support: Fear and anxiety can also be reduced if managers listen, show concern, and support staff in their effort to understand and adapt to change.

Be persistent: Change does not happen immediately. Successful change often occurs slowly, step-by-step. A gradual approach, with occasional retreats (two steps forward, one step back), is sometimes the best way to succeed.

Reinforce the desired new behaviors or practices: Provide resources and rewards (which may include publicity, public recognition, awards, extra resources, or

opportunities for growth) to those who apply the new behaviors or practices.

Use force sparingly: Threats of firing, reassignment, loss of privileges, or other forms of coercion may be necessary to manage specific individuals or groups. Such measures should be used selectively, and only when other approaches have not worked; threats that are not carried out soon become hollow. ■

ASSESSMENT GUIDE

Tasks, practices, skills, values, and mind-sets

- How do managers divide their time between crisis management, routine administration, control and supervision, and long-term program development?
- To what extent do managers use the eight management and leadership practices?
- Are the managers up-to-date on their technical skills?
- To what extent are the managers financially literate and computer literate?
- What are the strengths and weaknesses of senior managers with respect to the essential management and leadership skills (setting priorities, managing time, problem solving and decision making, coaching, communicating, negotiating, managing change)?
- To what extent do managers set priorities based on the urgency, relevance, impact, future consequences, and growth of issues? Do they manage by exception?
- How frequently do managers have contact with operational staff? Do they involve staff in planning, decision making, and problem solving?

- Do managers and staff members jointly set performance targets and use them to monitor performance?

Management cycle

- Can managers articulate the management and leadership practices for each of the three phases in the management cycle?
- What levels of planning take place—strategic planning, program planning, work planning?
- Does the planning process involve staff members who are responsible for implementation?
- Are new management systems designed with input from operational-level staff? Is implementation phased? Are staff trained in the use of new systems?
- Does regular monitoring take place? Are monitoring results used to make corrective adjustments?
- Are evaluations focused on the program or project's relevance, effectiveness, efficiency, sustainability, and impact?

Glossary

Activity: An action aimed at achieving a particular objective.

Delegation: The assignment by a manager of an activity, task, defined scope of authority, or responsibility to a staff member under the manager's supervision.

Evaluation: A periodic assessment of progress toward achieving long-term objectives and goals. Monitoring and evaluation are the third phase in the management cycle.

Force field analysis: A planning technique used in change management to identify driving forces, those forces that favor a particular change, and restraining forces, those that stand in the way of change.

Goal: The general aim toward which the organization or program is striving.

Implementation: The second phase in the management cycle; the process of putting a plan into action by organizing and directing the work. It involves managing people, money, information, and other resources to achieve intended results.

Indicator: Criterion used to measure changes, directly or indirectly, and to assess the extent to which the targets and objectives of a program or project are being attained. Indicators should meet the criteria of clarity, usefulness, measurability, reliability, validity, and acceptance by key stakeholders.

Information system: The system of records kept at offices, storage facilities, and clinical facilities; forms that are used to communicate supply needs, consumption data, and other information; reports that summarize the data from records and forms for planning and evaluation purposes; and procedures that coordinate the use and flow of these documents.

Management by exception: A technique in which the manager

expects staff to handle all decisions, problems, and activities, except for those that are of special importance, have long-term consequences, or are in some way unusual.

Management cycle: The process consisting of the three interconnected phases of planning, implementing, and monitoring and evaluating.

Mission (or mission statement): A brief general description of the type of organization, its main purpose, and its values.

Monitoring: The ongoing process of reviewing the degree to which program activities are completed and objectives are being met, to allow for corrective action to be taken during implementation. Monitoring and evaluation are the third phase in the management cycle.

Objectives: Results that a program or workplan seeks to achieve. A well-formulated objective fits the SMART mnemonic: specific, measurable, appropriate to overall objectives or goals, realistic in terms of available resources, time-bound (there is a deadline).

Participatory management: The process of involving staff in management processes to bring more information, creativity, and experience to planning, decision making, and problem solving, often resulting in better conclusions and better implementation efforts.

Performance target: An objective or desired standard of performance for an individual or unit that is written, specific, measurable, appropriate to the individual or unit, realistic, and time-bound; is in line with overall program goals and objectives; and is used to periodically assess progress.

Planning: The first phase in the management cycle; the process of analyzing the current situation, assessing needs, establishing goals, setting objectives and targets, and determining the strategies, responsibilities, and resources needed to achieve the objectives. Three levels of planning are strategic, program, and work planning.

Program plans: Medium-term plans (three to five years) that specify major objectives, activities, and resources needed for a specific program or organization; examples include master plans and multiyear-project plans.

Sentinel sites: Selected units or facilities from which more detailed information is collected for monitoring purposes, on a more frequent basis than from other units.

Strategic plans: Long-term development plans concerned with the overall effectiveness and direction of a program or organization.

Strategy: A broad plan of action for fulfilling a program's basic purpose and achieving its main goals.

Supervise: To oversee; to provide direction; to guide and instruct with immediate responsibility for performance.

SWOT analysis: An assessment of the internal strengths and weaknesses of an organization or program, as well as external opportunities and threats.

Targets: Measurable, time-limited, intermediate progress points toward objectives; also called milestones.

Task: Specific work to be performed as part of an activity and within a certain time.

Workplans: Short-term plans (usually six to twelve months) that list for each major objective the target outputs, required tasks, individual responsibilities, schedule, and budget.

SUMMARY

Planning is the process of analyzing the current situation; assessing needs; establishing goals; setting objectives and measurable targets; and determining the strategies, responsibilities, and resources needed to achieve the expected results.

The three levels of planning differ in purpose, time frame, and focus of detail.

Strategic planning is concerned with the long-term future of an organization and its overall effectiveness and direction in light of changing external and internal environments. It includes specific strategies for achieving the organization's mission and a means of tracking progress. A national pharmaceutical policy, for example, may result from a strategic-planning process. New strategies are most useful when—

- Current strategies are not working
- A pharmaceutical sector options analysis has been completed and new strategies are required
- The political or social environment changes dramatically
- There is a crisis

Program planning follows from strategic planning and focuses on medium-term objectives. For each objective, a program or project plan should specify outcomes, responsibilities, time frame, and budget. It is best implemented through operational workplans. Essential medicines programs, for example, should have program plans.

Work planning or operational planning is short-term planning and should involve staff who will be responsible for implementation. Workplans generally specify a limited set of objectives, all major activities, individual responsibilities, timing (at least to the month), indicators for monitoring and measuring progress and results,

budget, and source of funds for each activity or task. Gantt charts are often key features and are useful for monitoring.

Some project-planning methods and tools that can be helpful include the critical path method (CPM) and project evaluation and review technique (PERT), the logical framework approach (LogFrame), and various computer software packages.

Plans may fail to achieve their intended objectives when—

- Problems, root causes, and options have not been well analyzed
- Planning is unrealistic or overly ambitious
- Existing commitments have not been considered
- Implementers have not been involved
- There is inadequate support, funds, staff, or time
- Planning is undertaken for the wrong reasons or at the wrong level
- Plans are poorly presented or overly complicated
- Implementation is not regularly monitored

Planning is a part of every person's life. Similarly, every organization and every program needs to plan in order to be effective. A good plan begins with a realistic and objective assessment of the present situation and asks where the organization or program is going, how it will get there, what resources are needed, and how progress will be monitored and measured. Planning is an essential tool for effective work and overall organizational performance, not a constraint on what can be done.

Planning is the first step in the management framework described in [Chapter 37](#). A well-formulated plan provides direction and inspiration for an organization and is necessary to coordinate implementation efforts, staff activities, and financial operations.

38.1 The planning process

Planning is the process of analyzing the current situation; assessing needs; establishing goals; setting objectives and measurable targets; and determining the strategies, responsibilities, and resources needed to achieve the expected results. Before reviewing in detail the different types of planning, it is important to consider the reasons for planning.

Why plan?

It is always possible to find reasons not to plan: “We’re too busy; we have no time for planning.” “We have no medicines

and no money; there’s nothing to plan with.” “Whatever we plan is changed by the higher-ups.” Despite such constraints, good planning is essential to the success of any program or organization. When time or money is limited, planning is even more important.

Planning is a process, not simply the creation of a product (the plan). The planning process, as well as the result, is important for achieving at least six purposes—

1. To clearly identify goals: Is the organization addressing the right goals and in the right way? It is easy to continue doing the same things in the same way, but are these the best things to be done and the best way to do them?

2. To assess current needs and problems: What is the current pharmaceutical sector situation? What are the most pressing problems? (See Chapter 36 for a discussion of assessment methods.)
3. To ensure wise use of available human and financial resources: Good planning helps coordinate the use of limited resources and avoid duplication. A plan that has been agreed on becomes a commitment of available resources and gives managers more control and a basis for saying yes or no to unexpected requests.
4. To obtain additional resources: A good plan with clear objectives and expected results is useful in building support among senior officials, board members, and others in authority for obtaining additional staff or funding, and it is usually essential for donor or other external support.
5. To provide a basis for evaluating effectiveness: Without a stated plan, assessing what the organization is achieving is difficult.
6. To align staff priorities and build a sense of teamwork: The planning process can provide a forum for staff and other stakeholders to work together on a shared vision.

Nonetheless, plans can also be used to avoid responsibility for failure, especially where they have been either ill conceived or developed without the full participation of all relevant stakeholders. For similar reasons, ensuring that planning does not become an end in itself is important.

Types of planning

Organizations engage in three types of planning that differ in purpose, time frame, and level of detail: strategic planning, program planning, and work planning (Figure 38-1). These types of planning are discussed in more detail later in the chapter.

Strategic planning. Strategic planning is concerned with the long-term future of an organization and its overall effectiveness and direction in light of changing external and internal environments. This type of planning begins with a clear statement of the mission and vision of the organization. A strategic plan might follow from a comprehensive pharmaceutical sector assessment and options analysis; in any case, a strategic plan must be based on a thorough and objective assessment of the organization's current situation—including its market, organizational strengths and opportunities, priority goals and strategies, and financial plans—and takes into account relevant experience and lessons learned from other countries or other organizations. It includes specific strategies for achieving the organization's mission and a means of tracking progress. Strategic planning takes a long-

Figure 38-1 Levels of planning: The planning pyramid

term perspective, usually five years or more, and is less detailed than program or work planning.

Program planning. Program planning, sometimes called tactical-level planning, focuses on clearly defined, medium-term objectives (up to five years) within the organization's overall long-term goals. It specifies major activities that address the objectives, responsibilities (usually by unit, not by individual), and time frame (usually by year or quarter, not by month). The time frame and level of planning are usually used for specific development assistance projects. In such instances, program planning can also serve the needs of project planning. In the context of essential medicines, program plans are sometimes called master plans. Generally, program plans should be tied to activity-specific budgets.

Work planning. Work planning, or operational planning, is short-term planning (usually one year or less). Annual workplans typically specify a limited set of objectives, all major activities, individual responsibilities, time frame (detailed at least to the month), indicators for monitoring and measuring progress and results, and activity-specific or task-specific budgets. Operational planning covers specific tasks, such as producing a national formulary manual for the first time, renovating a medical store, or carrying out a major public education campaign on rational medicine use. The annual workplan should contribute to the organizational mission and to the achievement of the organization's long-term strategies and goals. In this respect, workplans are the organization's annual building blocks.

Planning questions and terms

Whether preparing a strategic plan, a program plan, or a workplan, people engaged in the planning process address four key questions—

1. Where are we now and how did we get here?
2. Where do we want to go?
3. How will we get there?
4. How will we know when we have arrived?

Planning terminology varies considerably among organizations, countries, and programs, even though the questions are similar. What is a “goal” to one person is an “objective” or a “result” to another. Because no universally agreed-upon terminology exists, there can be no right or wrong definitions. For consistency, however, this manual uses planning terms as defined in the following paragraphs, which the reader can adapt to the local setting.

1. Where are we now and how did we get here? All planning begins with an assessment of the current situation and needs, customized for each particular context. As mentioned, [Chapter 36](#) describes pharmaceutical sector assessment and different methods for conducting an assessment.

2. Where do we want to go? Statements of intent describe the expected measurable results of a long- or short-term plan.

This description can be organized based on five levels of breadth and detail—

Mission: The mission, or mission statement, is a brief general description of the type of organization, its main purpose, and its values. The mission of an organization describes why the organization exists and provides the rationale for defining strategies and goals.

Vision: The vision statement describes where an organization wants to be in the future and creates the method for working toward that vision. The vision helps remind the organization why it is doing what it is doing and provides the big picture and the inspiration to keep it going in the face of obstacles as it strives to achieve its stated short- and long-term results (MSH 2005).

Goal: Goals describe the proposed long-term benefits the organization will bring to the people, programs, or other organizations it serves, defined in general terms. In an essential medicines program, for example, one goal might be to ensure access to safe, effective, affordable essential medicines at all public health institutions.

Objectives: Objectives are the anticipated results or outcomes defined by the organization in its long- or short-term plan, described in measurable terms, and indicating a specific period of time during which these results will

be achieved (MSH 1996). A well-formulated objective uses the SMART mnemonic—

- Specific—to avoid differences of interpretation
- Measurable—to enable monitoring and evaluation
- Appropriate—in relation to overall organizational mission, strategies, and goals
- Realistic—achievable and meaningful in terms of available human and financial resources
- Time-bound—with a specific time period for achieving them

An objective might be “to ensure that all medicines used in government facilities are prescribed according to national treatment guidelines within two years of introduction.”

Expected results: Expected results, or targets, are measurable, time-limited, intermediate progress or anticipated end points; for example, “By 2009, achieve at least 50 percent compliance with national treatment guidelines.” Milestones may also apply to process objectives; for example, “Train 600 clinicians (about 33 percent of an estimated 1,800 clinicians) in rational medicine use.”

3. How will we get there? Methods for achieving specific objectives and results can also be described by using different levels of breadth and detail—

Strategy: a broad plan of action for fulfilling a program’s basic purpose and achieving its main goals; for example, “Promote rational prescribing through strengthening formal education, continuing education, and supervision.”

Activity: a specific action aimed at achieving a particular objective; for example, “Conduct a workshop on rational prescribing.”

Task: specific work to be performed as part of an activity and within a certain time; for example, “Prepare session notes and overhead transparencies at least four weeks before workshop.”

The inputs needed for achieving the desired objectives and results are people, time, and money. Plans should therefore describe responsibilities, schedules, and budgets, with the level of detail depending on the type of plan.

4. How will we know when we have arrived? A key function of effective project management is monitoring and evaluation linked directly to the planning process. Monitoring is a continuous process that focuses on the implementation of specific activities and the achievement of targets or milestones. Evaluation focuses on achievement of objectives and expected results.

Progress toward achieving goals, objectives, milestones, and expected results should be monitored on an ongoing

basis. Formal review of program plans should take place at least annually. Progress on workplans should be reviewed monthly or quarterly.

Indicators can help measure changes directly or indirectly and assess the extent to which the results and objectives of a program or project are being attained. As described in [Chapter 48](#), indicators are an integral part of monitoring and make a useful contribution to evaluation.

Who should plan?

The test of a plan is in its implementation; to maximize the chances of success, those involved in implementing a plan should be part of formulating it. Therefore, establishing the planning team at the outset is important. For strategic planning, the team usually consists of policy makers and senior staff members, although organizations should consider involving staff members from other organizational levels and even some beneficiaries. For program and work planning, the team should include all key people in the units concerned. Stakeholders at all levels of the organization should be identified and their roles and responsibilities in the planning process delineated. Depending on the level of complexity of the planning process and the funding available, stakeholders may include ministry of health decision makers or technical staff; development partners, such as donors or technical assistance agencies; health care providers in the public and private sectors; nongovernmental organizations (NGOs) and community groups; and patient representatives.

Planning can be top-down or bottom-up. In top-down planning, major discussions and decisions start at the top. Situation assessment and other planning data are provided by operational units, but setting goals, identifying options, and choosing among options all happen at the senior level. In bottom-up planning, the process starts with each operational unit carrying out its own planning exercise and developing a plan that is then merged with others and revised to form the overall plan.

Bottom-up planning is most appropriate for operational planning, in which the purpose and major goals are already clear. Top-down planning may be more appropriate for strategic planning, in which the basic mission and goals must be defined; however, top-down planning does require input from lower levels as well as acceptance and alignment of a plan throughout the organization after it has been completed.

Planning for pharmaceutical management is too important and specialized to be left to planning experts or outside advisers alone. National planning ministries, although they often maintain population, economic, and other forecasts to estimate program growth, are not experts on pharmaceutical management and cannot fully assess alternative pharmaceutical management strategies and solutions. Nonetheless,

Country Study 38-1**Establishing a multisectoral team to plan an HIV/AIDS/TB program in Tanzania**

Scaling up national prevention and treatment programs related to HIV/AIDS requires a multisectoral planning process. The government of Tanzania submitted a proposal to the Global Fund to Fight AIDS, Tuberculosis and Malaria on the theme of integrating care and support for HIV/AIDS and tuberculosis (TB). The goal of the five-year program was to decrease morbidity from HIV/AIDS/TB and related opportunistic infections and to stabilize mortality from TB through increased access to care and support for Tanzanians benefiting from voluntary counseling and testing.

The resulting plan was unique because it included such a wide range of partners from around Tanzania—

- National AIDS Control Program
- National TB and Leprosy Control Program
- Ministry of Health facilities at the national, regional, and local levels
- Five faith-based organizations
- One parastatal organization
- Ten nongovernmental organizations
- One private-sector group
- One national association of people living with HIV/AIDS
- Two academic organizations
- Health Services of the Tanzania People's Defense Force

planning units and health information units have important roles, because they are usually adept at gathering and analyzing data and presenting the results.

Local or international expert advisers can make important contributions. They can provide a neutral outside perspective, bring skills in organizing and in analyzing perspectives from other countries, and make suggestions for practical alternative strategies that might otherwise be missed. In some cases, however, expert advisers may have their own agendas and may be unfamiliar with the circumstances of the program.

Multisectoral planning brings together organizations from different sectors, such as the ministry of health and ministry of finance in the public sector and a professional organization or community group in the private sector (see [Country Study 38-1](#)). It is appropriate for large-scale programs, such as planning and implementing an HIV/AIDS prevention and treatment program at the country level. Multisectoral planning enables participants to understand their interdependence, identify how they can contribute (and make a commitment to contributing), and agree on which functions will be managed in common. The planning process creates the partnerships through which activities will be carried out (Helfenbein and Severo 2004).

Good plans and good opportunities

Good managers are always reviewing their goals, assessing the current situation, considering current strategies, and monitoring the progress and results of their programs. The most effective managers also have a long-term strategic perspective in mind and are constantly watching for, and making the most of, opportunities to progress.

Adapting plans to changing circumstances and opportunities is important. Most enlightened senior officials and donors would prefer to hear that short- or long-term plans should be modified to make better use of limited time and money than to be told eventually that by faithfully following the original plan, opportunities were missed and resources were wasted.

38.2 Strategic planning

Strategic planning is concerned with developing a shared vision of mission or fundamental purpose. It is concerned with the overall effectiveness and direction of the program. Fundamentally, strategic planning asks the question, Is the organization doing the right things? In contrast, program planning is more concerned with the question, Is the organization doing things the right way?

Specific questions that a strategic thinker asks are—

- What are the basic values of the organization?
- Who is meant to benefit from our services?
- What are our priority goals?
- What are the most appropriate strategies for achieving our goals?
- Is the organization appropriately structured for achieving its goals and expected results?

For example, is a goal to provide free medicines for all patients appropriate given the external and internal environments? Is a more appropriate alternative goal to ensure access to medicines for all patients, with only the poorest receiving free medicines and others paying a reasonable fee?

When weighing these goals, consider whether a large, centralized government supply system is the best way to distribute medicines to government health facilities.

When is a strategic plan needed? A strategic-planning exercise is most needed and most useful in the following situations—

When current strategies are not working: Organizational directors or their superiors often accept perpetually marginal or poor results simply because “we’ve always done it this way” or “nobody has thought of a better way.” Strategic planning provides a mechanism for finding better ways. For example, if the current strategy of centralized supply is failing to ensure a regular supply of medicines, the best solution may not be a project to renovate central medical stores but a strategic planning exercise to consider restructuring the supply system.

In response to an assessment: A comprehensive assessment of the pharmaceutical sector can identify problems and their root causes. A consensus-based options analysis can result in the need for a strategic plan to address problems.

When the political or social environment changes dramatically: Changes in government or replacement of senior ministry officials may offer the opportunity or result in the demand for change. The pharmaceutical sector may be affected by prevailing national trends, such as decentralization, civil service reform, or privatization. Strategic planning can help redirect an organization to adapt to such trends and take maximum advantage of opportunities for improved performance.

When a new initiative or restructuring of programs is undertaken: The development of a new essential medicines program, the integration of essential medicines and family planning commodities, or the creation of a division of pharmaceutical services all provide opportunities and challenges for senior officials and program managers. A strategic plan can help them respond to such changes.

When a crisis occurs: Not all crises create the need for a strategic plan—some crises are short-lived and do not reflect underlying deficiencies. But a major currency devaluation, a national disaster such as an earthquake or a flood, or a debt crisis may have long-term consequences that mandate new approaches.

A national pharmaceutical policy (see [Chapter 4](#)) represents a government effort to articulate new goals and strategies for the pharmaceutical sector and often results from what is effectively a strategic-planning process.

Strategic planning involves several steps, which are outlined in [Box 38-1](#). Authors may describe these steps differently, but the basic ideas are similar.

Step 1. Create the guiding framework

Who will organize the work of the planning team? Who will be on the planning team? Who else will be consulted, and how will they be consulted? Why is a strategic plan being sought, and how will it be used? All these questions must be answered in establishing the guiding framework for strategic planning.

Box 38-1 Steps in strategic planning

Step 1. Create the guiding framework

- Create the planning team
- Identify stakeholders: the community, patients, beneficiaries, health staff members, national government, politicians, ministry of health, essential medicines program, suppliers (local industry, overseas suppliers)

Step 2. Establish mission and vision of the organization

- Define or clarify mission, long-term goals
- Define or clarify the vision

Step 3. Assess the current situation and environment

- Identify strengths, weaknesses, opportunities, and threats within the context of the organization

Step 4. Establish specific goals

Step 5. Identify strategic options

- Question everything about current structures and operations
- Think creatively

Step 6. Use defined criteria to select specific strategies

- Decide who chooses
- Establish criteria for choice on the basis of information and facts
- Avoid bias and reflexive reactions

Step 7. Transform strategies into operational plans

- Prepare the strategic plan
- Prepare program plans and work or operational plans

Step 8. Assess impact and adjust strategies

Source: Adapted from Helfenbein et al. 1994.

The planning process lays the groundwork of support for implementation and requires identifying the key stakeholders, or those individuals and organizations with an interest in the pharmaceutical sector: ministry of health, treasury, and other ministries; the pharmacy division, the essential medicines program, health facilities, and health care providers; international agencies, bilateral donors, and development banks; local industry, overseas manufacturers, and pharmaceutical suppliers; and patients, the general public, and local communities.

Having identified the stakeholders, the next question is, How will they be involved? That is, will they be full participants, contributors to selected parts of the process, or commentators on draft plans? [Chapter 4](#) describes various ways of seeking advice in formulating a national pharmaceutical policy.

Finally, responsibilities for the planning process must be assigned, a timetable established, and a budget prepared.

Step 2. Establish the mission and vision of the organization

Every organization should have a vision and a mission statement or statement of purpose that addresses at least the following questions: Why does the organization exist and who are its beneficiaries? Policy makers and program managers may assume that they know why a national pharmaceutical policy is necessary or why an essential medicines program exists. Nevertheless, it is useful to ensure that there is agreement on the mission that underlies the policy or the existence of an organization.

The mission statement for the Mission for Essential Drugs and Supplies (MEDS), a church-sponsored supply service in East Africa, for example, states—

MEDS seeks to promote health for all through the provision of essential drugs, medical supplies, training and other pharmaceutical services, guided by ethical and professional Christian values. In pursuit of this mission, MEDS has two broad objectives: to provide a reliable supply of essential drugs and medical supplies of good quality at affordable prices; and to improve the quality of patient care through training in all aspects of health and general management, with specific emphasis on the essential drugs concept and the rational use of drugs (WHO 2004).

This statement, which clearly describes the purpose and intended beneficiaries of MEDS, is made available to all MEDS staff members and the health units it serves. It mentions the quality of services, the source of funding (there will be a cost to health units), and the services provided (training as well as pharmaceutical supply).

A discussion of the purpose of an organization is needed to formulate a mission statement as well as to create a shared vision among the leadership and senior staff. For example, the following alternative mission statements for a national essential medicines program have very different implications for the management, financing, and operation of the organization—

- The purpose of the national essential medicines program is to ensure the availability, accessibility, and quality of medicines to all members of society.
- The purpose of the national essential medicines program is to provide high-quality essential medicines to the ministry of health facilities, with emphasis on ensuring access for the poor and medically needy members of society.

Mission statements may also include value statements, such as, “The national essential medicines program is based on the belief that provision of a limited list of low-cost, high-quality essential medicines is a highly cost-effective health care intervention.” Mission statements need to be communicated throughout the organization as well as to the general public and should be reviewed periodically to ensure that they remain appropriate.

Unlike the mission of the organization, which states why the organization exists, the *vision provides a picture of a desired future*. It describes where the group or the organization wants to be in the years to come and creates the method for working toward that vision. An organizational vision could come from the top level, such as a minister, executive director, or management team; however, a vision is more powerful when a team creates it and shares it. Because people usually are motivated to support what they help to create, organizations should try to create a shared vision that is developed and owned by those who will need to carry it out (MSH 2005).

An example of a vision might be, “Our pharmacy is known for consistently providing excellent medicines and service, and people come from all around to have us dispense their medicines. We make sure that people have the correct medicines at the correct time, and that they understand how to take their medicines properly. As a result, the people in our area are healthier and happier.”

Step 3. Assess the current situation and environment

Systematic assessment, as described in [Chapter 36](#), means documenting what is going well and what is not going well and why. Increasingly, this process involves objective indicators that allow comparison of pharmaceutical sector structure, process, and performance with targets, over time, and with other countries. These indicators are important and should be included in any planning process. In the context

Box 38-2**Key elements of a strategic plan for an essential medicines program**

Mission (overall goal): Improve the health of the population by ensuring the availability and proper use of essential medicines for the treatment, prevention, and diagnosis of common health problems at government health facilities.

Goal: pharmaceutical availability—ensure that safe, effective, high-quality essential medicines are available at all times at all government health facilities.

Objectives

- *Financing*—ensure that financial resources are adequate to meet basic pharmaceutical needs.
- *Procurement*—obtain a regular supply of medicines at favorable prices.
- *Quality assurance*—ensure that procured medicines meet recognized standards of quality and that quality is maintained through the distribution chain.
- *Central storage*—ensure that medicines are properly stored, with minimal expirations or other losses.
- *Delivery*—ensure timely delivery of medicines to health units.
- *Storage at health units*—ensure that medicines are properly stored, with minimal expirations or other losses.

Goal: rational use—ensure that medicines are rationally prescribed, correctly dispensed, and appropriately used by patients.

Objectives

- *Selection*—maintain an up-to-date list and information on safe, effective, affordable essential medicines.
- *Prescribing*—ensure that medicines are prescribed according to local standard treatment guidelines.
- *Dispensing*—ensure that medicines are correctly identified, labeled, and packaged and that patients are clearly instructed on medicine use.
- *Patient use*—ensure that patients consume medicines as prescribed and do not use medicines in an unsafe manner.

of strategic planning, however, situation assessment is much broader, in that it looks at the environment surrounding the pharmaceutical sector, including the political, economic, and social environment—the context in which the program is working. A broad-based assessment also identifies options for correcting problems and analyzes their feasibility and implementation costs.

A SWOT analysis considers internal strengths and weaknesses of the organization or program, as well as external opportunities and threats. (SWOT is an acronym for strengths, weaknesses, opportunities, and threats.) SWOT analysis is an essential method for assessing the internal and external environment.

For example, a particular essential medicines program's internal strengths may include a well-established medicine selection process, an efficient procurement office, and a series of regular workshops on rational medicine use. Internal weaknesses may include poor central and regional storage facilities and unreliable transport. For the same program, a growing private-sector distribution network may provide external opportunities for contracting out storage and transport functions. But decreasing government revenues caused by an economic downturn may represent an external threat to the program. In this example, SWOT analysis might suggest maintaining the government's role in selecting, procuring, and promoting the rational use of

medicines, but decentralizing warehousing, contracting out distribution, and encouraging local financing.

Step 4. Establish specific goals

The goals of a program or organization should follow from its mission and the functions central to achieving that mission. A strategic plan for the pharmaceutical sector may have goals related to pharmaceutical availability in government health facilities, rational medicine use, pharmaceutical quality, access to medicines in the private sector, the role of NGOs in expanding access and rational medicine use, control of medicines on the market, and local production. Examples of two goals are shown in [Box 38-2](#).

Step 5. Identify strategic options

Perhaps the most serious mistake in strategic planning is to consider only familiar strategies or those that have been tried in the past. The greatest benefit from planning often comes from identifying practical new options. In generating new ideas, a number of tactics can be useful—

- Talk to people with relevant experience and listen to what they suggest. Although ministries of health, private health care providers, mission health services,

and various NGOs work under very different circumstances, many of the problems they face are similar. Strategies that have been successful for one may be useful to another, perhaps with modifications or adaptations.

- Learn about other programs from published reports, project evaluations, or other local sources, and international agencies, such as the World Bank or the World Health Organization's Health Technology and Pharmaceuticals section, and independent organizations, such as Management Sciences for Health.
- Visit other programs through study tours or by arranging short visits as part of regional conferences. Often the most useful lessons—both positive and negative—come from the experiences of neighboring countries. Although some question the benefit of study tours, when the right people are sent to the right places for the right reasons, study tours can be extremely effective in opening up thinking to new ideas and stimulating alternative views of the future.
- Brainstorm within the planning team. Brainstorming helps groups be more creative at all types of planning, decision making, and problem solving. Proven to be highly successful in a wide range of organizations and cultures, brainstorming is neither a free-for-all nor a formal discussion. [Chapter 52](#) provides guidelines.
- Bring in outside expertise. Local or international advisers can be costly but may offer practical suggestions and important ideas that might have otherwise been difficult or impossible to conceive.

Identifying strategic options requires thinking creatively and questioning current strategies, structures, and operations if analysis identifies chronic deficiencies in performance or threats from actual or anticipated changes in the external environment.

Step 6. Use defined criteria to select specific strategies

After the full range of options has been identified, the most promising should be selected for further consideration and carefully evaluated. Final judgments should be based on information and facts, not on unfounded biases or reflexive reactions.

Who should be involved, and how should choices be made? Senior officials and those most central to the implementation process should participate in selecting specific strategies, using established criteria against which each option can be assessed.

Commonly used criteria are—

Potential impact: If the strategy is successful, how large an impact can be expected? For example, would shifting to international competitive bidding reduce prices by 40 to

50 percent, or by only 5 to 10 percent? Whenever possible, the potential impact should be expressed in terms of cost savings or other financial benefits.

Political feasibility: Successful strategy implementation is in large measure a political process. Judgments must be made about expected political support and opposition.

Technical feasibility: Local infrastructure capacity, available human resources, and even the state of pharmaceutical science influence technical feasibility. For example, a demand-based pull system for supplying health centers, although theoretically less wasteful than a push system, may not be feasible when most staff members have only a minimal level of education. Such a system may become feasible, however, as the general level of education and experience rises.

Financial feasibility: Many good ideas may be unaffordable. Financial feasibility may relate to recurrent operating costs or initial implementation costs (see [Chapter 40](#)) and may depend in part on donor interest.

Cost-benefit: Cost-benefit (see [Chapter 10](#) for more details) relates the cost of a particular strategy to its potential impact on cost. A total cost analysis exercise during the assessment can help determine cost-effectiveness ([Chapter 40](#)). Usually this measurement involves approximate costs and projected, rather than actual, measures of each. Even rough estimates may provide useful insights for planning purposes.

Political will and technical feasibility help define the likelihood of success. Selecting strategies involves weighing the potential impact or benefits, if successful, against the likelihood of success and the costs of success.

Step 7. Transform strategies into operational plans

When strategies have been selected, the strategic plan should be put in writing. Generally, it should cover the following points as succinctly as possible—

- Mission and vision statements of the organization
- Brief assessment of the current situation: strengths, weaknesses, opportunities, threats
- Concise description of each goal for the organization
- Brief summary of each specific strategy for achieving these goals
- Monitoring and evaluation plan, including indicators for each goal

After the strategic plan has been completed, official endorsement is beneficial and is usually required. If all concerned senior officials have been involved in the process and have accepted the plan, a letter of transmittal may be sufficient. In government settings, the plan may need to be presented to a senior ministerial management committee or

even to the cabinet. In NGOs and private organizations, strategic plans may need to be endorsed by the governing body or board of directors, which may also have been involved in the planning process.

The benefits of strategic planning are felt only when the plan is implemented. Strategic plans do not include operational detail. Turning the approved strategic plan into action requires short-term planning, such as a three- or five-year program plan or project proposal, or both.

Step 8. Assess impact and adjust strategies

As noted, the true test of any plan is in its implementation—however, the strategic-planning process does not stop with formulation of the plan, or even with its implementation. The strategic-planning process continues through ongoing monitoring and periodic evaluation.

Perform regular assessment of the plan. Are the strategies being turned into programs and workplans? Are they having the intended effect? If not, does the problem lie with the implementation process? Are different people required? Is more time required? Is the basic goal wrong? Should it be revised? Or are the strategies themselves to blame? A strategy that is good in theory but that cannot be implemented is not a good strategy.

38.3 Program planning

Most planning is done at the program, project, and operational levels. Program planning focuses on clearly defined medium-term objectives within a framework of overall, long-term strategic goals. A program plan should follow from a strategic plan, national pharmaceutical policy, or national development plan. Often, however, a program plan is based on historical expectations and assumptions about the role of pharmaceutical management within the government. In addition, if a program was preceded by a pilot project, the full-scale program plan may be developed based on the experiences from its pilot. However, the two plans are not interchangeable, because a pilot plan may not adequately address the challenges of scaling up.

A government essential medicines program, a mission essential medicines service, or any other major pharmaceutical program should have a program plan, regardless of funding sources. A well-formulated plan provides direction and a framework for month-to-month and year-to-year activities; it helps coordinate staff, finances, and other resources. In the context of national essential medicines programs, program plans provide an overview of the sector and a three- to five-year plan of action and are sometimes called five-year implementation plans.

Program plans are more specific than strategic plans with respect to objectives, responsibilities, time frame, and usu-

Box 38-3 Program-planning process

Exploration

- Step 1. Establish the planning group
- Step 2. Confirm long-term goals, strategies, and current objectives
- Step 3. Assess the current situation

Formulation

- Step 4. Specify objectives for the planning period
- Step 5. Set targets for each objective and the monitoring and evaluation plan
- Step 6. Determine the resources needed for achieving each objective

Action

- Step 7. Prepare the program plan and budget
- Step 8. Implement the plan
- Step 9. Monitor the plan

ally, budget. They are best implemented through detailed annual or semiannual operational workplans (described below).

Program-planning process

Program planning usually involves a three-stage process. In the exploration phase, a planning group is formed, existing long-term goals and strategies are reviewed, and the current situation is assessed. In the formulation phase, objectives for the planning period are specified, targets and indicators are set for each objective, and resource requirements are determined. In the action phase, the program plan and budget are prepared, implemented, and monitored. Each of these three stages has distinctive operational steps, outlined in [Box 38-3](#).

Exploration. The first step in program planning is to establish the planning group, usually the program manager and senior staff and representatives from other organizations, if the program is operating at the regional or national level. Experienced advisers may help guide the planning process. Representatives of international organizations, donors, and development banks often can provide useful input into the planning process, but they are generally not part of the planning team.

If a national pharmaceutical policy, national development plan, or other form of strategic plan for the pharmaceutical sector exists, broad objectives have already been developed. Even in the absence of such a plan, most national programs have some objectives toward which they

Figure 38-2 Five-year program plan for promoting rational medicine use

Goal: Rational use—ensure that medicines are rationally prescribed, correctly dispensed, and appropriately used by patients

Objectives/activities	Output targets (5 year)	Inputs	Budget (U.S. dollars)	Time frame				
				Year 1	Year 2	Year 3	Year 4	Year 5
<p>Selection—maintain an up-to-date list and information on safe, effective, affordable essential medicines. Essential medicines list (EML)—revise and distribute national essential medicines list every 2 years.</p> <p>National formulary manual (NFM)—prepare/revise and distribute national formulary manual at least every 4 years.</p>	<p>Two revisions of EML</p> <p>First edition of NFM completed and distributed</p>	<p>Meeting expenses</p> <p>Meeting expenses, editing services, layout, printing, implementation workshops</p>	<p>2,000</p> <p>32,000</p>	<<—>>	<<—>>	<<—>>	<<—>>	<<—>>

have been working. These should be written down and reviewed.

Assessment of the current situation can be rather limited and impressionistic, depending on the resources available to carry it out. Whenever possible, however, assessment of the current situation should be based on monitoring data, indicators, review of progress reports, and other systematic measures described in [Chapter 36](#).

Current problems and constraints can be identified from the systematic assessment. For major problems, a force field analysis (described in [Chapter 37](#)) may be useful to identify restraining and driving forces that must be considered if the program plan is to achieve its objectives.

Formulation. The next steps are to specify objectives, set targets, and determine resources needed to achieve each objective. As previously noted, objectives should be SMART: specific, measurable, appropriate, realistic, and time-bound.

[Figure 38-2](#) contains an example of a five-year program plan for promoting rational medicine use. This plan, which follows from the key elements of a strategic plan outlined in [Box 38-2](#), illustrates specific objectives that might be included.

As with problem solving (described in [Chapter 37](#)) and strategic planning (described above), one of the most critical steps in the program-planning process is identifying the full range of options. Each option should be analyzed for likely strengths and weaknesses, resource demands, and possible consequences. [Country Study 38-2](#) shows how poor information gathering led planners to an administrative obstacle in a multisectoral plan for HIV/AIDS and tuberculosis.

Action. After objectives, priorities, and activities have been established, a draft plan should be prepared, specifying responsibilities, schedules, budgets, and a monitoring

and evaluation plan with indicators, preferably according to activity. Important deadlines should be clearly identified.

First drafts of program plans usually promise too many activities in too short a time for the number of staff and amount of money available. For the plan to have any value, it must be realistic. Making a realistic plan usually means reducing the number of activities and lengthening the time frame to reflect the amount of staff time and money actually available.

The final step is to implement and monitor the plan, as described in [Chapter 37](#), and revise it as needed based on changing circumstances or priorities.

Contents of a program or project plan

A program or project plan should include—

- A summary of the long-term goal
- Major strategies for achieving the goal
- Specific objectives
- Targets for each objective
- Responsibilities for each activity
- A schedule for each objective, in chronological order (usually by year)
- A budget for each objective or area of activity

The written plan usually consists of text and tables. A table showing activities, targets, inputs with budget amounts, and time frame is most useful, as in [Figure 38-2](#).

Although budget figures can be included in the summary table, a separate budget is usually necessary. A program budget should indicate the area of activity (pharmaceutical supply or rational medicine use, for example), the type of expenditure (salary, medicine purchases, per diem,

Country Study 38-2 Identifying administrative obstacles in Tanzania

The multisectoral plan for care and support of those affected by HIV/AIDS and tuberculosis called for transferring funds to a variety of government ministries, faith-based organizations, national hospitals, NGOs, and private companies. The plan required a single institution to act as financial manager, holding the funds, transferring them to partners, and reporting on them to the donor in a timely fashion. Having this institution house the coordinating unit for technical execution of the program would also make sense.

One logical option was for the national AIDS commission, TACAIDS, to add these two functions to its existing roles of coordination and resource mobilization.

However, the founding legislation for TACAIDS precludes the commission and its secretariat from managing financial resources other than its own operating budget because it has monitoring authority over all HIV/AIDS activities and institutions in the country. Therefore, a financial manager had to be found elsewhere.

Planners should not assume, on the basis of incomplete information, that a logical or innovative option can be implemented. It is important to first become informed about regulations, legislation, and administrative obstacles that may prevent otherwise good ideas from being realized.

Source: Helfenbein and Severo 2004.

and so forth), whether the expenditure is in local or foreign currency, and the likely source of funding. [Chapter 41](#) contains more detailed information on preparing budgets.

In addition to the summary table, descriptive text is necessary to communicate the goal and rationale of the program, describe specific activities, and justify the budget.

38.4 Work planning

Work planning is the most detailed type of routine planning. A workplan is like a blueprint: it shows each of the smaller steps involved in achieving the larger goal. Effective managers use workplans to keep efforts focused on planned activities and to align and coordinate staff efforts in the achievement of longer-term goals. Workplans are not intended to limit staff members' initiative, but they should help managers and staff members say no to unreasonable and unplanned requests and discourage overly optimistic promises.

A workplan is typically prepared annually to cover a twelve-month period, although some essential medicines programs do operational work planning on a six-month cycle. Compared with program plans, workplans should be more specific with respect to outputs, individual responsibilities, precise time frame, and budget requirements.

The steps for preparing an annual workplan—which are similar but not identical to those for preparing a program plan—follow.

1. Review long-term goals and existing program plans.
2. Define specific objectives for the upcoming year.
3. Set targets for each objective, and define indicators.
4. List major activities for each objective. Prepare monitoring and evaluation plan.
5. Prepare an activity-time (Gantt) chart showing the responsibility and timing for each activity.
6. Review or prepare the annual budget.
7. Revise the plan based on available staff, time, and funds.
8. Implement the plan.
9. Monitor the plan and revise as needed.

For each objective and activity, workplans generally specify major tasks involved, measurable outputs and indicators, responsibilities for each task, timing (at least to the month or quarter), budget, and source of funds for each activity or task.

Under Step 4, considering what activities are necessary for achieving each objective is important, as is not being limited to what was done last year.

[Figures 38-3](#) and [38-4](#) illustrate two different types of activity-time charts (Step 5).

Step 7 is particularly important. When Steps 1 through 6 have been completed and a draft workplan exists, the plan must be reviewed carefully and finalized according to available staff, time, and funds. A plan that is unrealistic from the start will quickly lose credibility and have little value as a management tool. In addition, a plan may need to be revised several times while progress is being monitored (Step 9).

Work-planning process

Preparation of workplans must involve those who will be implementing them. Because this activity requires a focused effort without interruptions, moving out of the office for a day or more is often useful while preparing the workplan. Participants should be chosen on the basis of their knowledge and expertise as well as their commitment to making contributions. Brainstorming techniques (see [Chapter 52](#)) can be useful in generating ideas for specific activities and tasks. In any case, the tone of meetings should encourage the open exchange of ideas and creative thinking. Sometimes, informal discussions preceding the formal work-planning discussion can help staff members reflect on the preceding year, consider the reasons for recent successes and failures, and begin thinking about the next year.

Objectives, targets, activities, and tasks should be consistent with the definitions given earlier in this chapter. Responsibilities for each activity should be listed by unit or office, or sometimes by person or team. The time frame for each activity is usually set by year or quarter rather than by month.

Generally, workplans should be tied to activity-specific budgets that reflect all required inputs, including staff salaries, pharmaceutical costs, vehicle costs, and other operating costs. For government programs, routine, recurrent costs such as salary and utility expenses, may be part of larger divisional budgets and not readily separated. Certainly pharmaceutical costs and major additional costs should be noted separately.

Activity-time chart

At the center of an annual workplan is an activity-time (Gantt) chart, chronogram, or schedule of activities and responsibilities. A Gantt chart provides a clear, concise summary that is invaluable for communicating plans to staff, checking financial and other resource requirements, and monitoring progress.

A Gantt chart groups activities under objectives and usually contains a series of rows for each major activity. Typically, it contains columns for—

- The objectives and activities
- The person or unit responsible for each activity
- The time period in which the activity will occur

Figure 38-4 Example of an activity-time chart for a three-year program in East Africa

Output targets and performance indicators for each objective may be listed separately or included as a column of the Gantt chart. Budgets should be linked to objectives and sometimes to individual activities. Often, budgets are listed in a separate part of the workplan. However, if specific funds and funding sources are associated with each activity, columns in the Gantt chart can specify the amounts and sources of funds.

Figure 38-3 shows an example of a Gantt chart for an essential medicines program. This example is based on the first year of the program plan shown in Figure 38-2. Figure 38-4 illustrates a simpler activity-timeline with program milestones.

Monthly, weekly, and daily workplans

An annual workplan provides major deadlines and a certain level of detail. Individual units and staff members, however, often prepare their own monthly, weekly, or daily schedules or to-do lists. This activity allows individuals to translate the workplan into short-term tasks and to set priorities to ensure that the most important tasks are being accomplished.

For example, the training officer responsible for the national workshop on undergraduate curriculum listed under “Undergraduate training” in Figure 38-3 may take this activity and prepare a one-page to-do list that contains tasks and target dates for selecting the venue, sending invitations, planning the agenda, obtaining flip charts and other training supplies, and doing other important tasks. Such lists help spread work over the available time so that staff members are not left with a large number of last-minute tasks before a major event.

Using workplans to check progress

To be an effective management tool, workplans must be readily accessible and frequently reviewed by managers and staff members involved in implementing them. Wall charts of the workplan in the office and copies taped to desktops can be used as consistent reminders.

Workplans should be checked regularly. When specific activities are behind schedule, a decision must be made by the concerned manager: reorganize priorities, assign additional staff or provide extra resources to get the activity back on schedule, or accept the delay.

If an annual workplan is well formulated and consistent with long-term program objectives, the performance of a program and its staff can be assessed by the extent to which it adheres to the workplan.

38.5 Project-planning methods and tools

Several planning methods and computer-based tools exist to help managers. These include methods derived from

Figure 38-5 Critical path method (CPM) analysis of plan to upgrade central pharmaceutical supply functions

Activity	Activity description	Time (weeks)	Predecessor activity
A	Plan to upgrade central pharmaceutical supply services	6	—
B	Appoint committee to revise essential medicines list	6	A
C	Develop new procurement procedures	8	A
D	Revise essential medicines list, organize by level of care	2	B
E	Prequalify suppliers	12	C
F	Quantify pharmaceutical requirements by level of care	4	D
G	Prepare and distribute tender documents	4	F, E
H	Prepare budget proposal	3	F
I	Obtain budget approval	10	H
J	Ensure availability of funds	8	I
K	Complete tendering and place orders	8	G
L	Receive and pay for medicines	12	J, K

industrial and engineering management science, methods supported by specific donor requirements, and computer programs for project management.

Management science methods

For program and work planning, two commonly used methods from management science are the critical path method (CPM; see Figure 38-5) and the project evaluation and review technique (PERT). Although originally formulated as two distinct methods, their similarities are such that they are commonly referred to collectively as CPM-PERT. The combined method uses a network model to help planners arrange and schedule project activities.

The main steps for CPM-PERT planning are (1) identify all necessary tasks; (2) determine which tasks need to be completed before the next ones are started; (3) estimate the time needed for each task; and (4) combine the information from the first three steps into a diagram of the whole process.

The most important benefits of the CPM-PERT method are that it forces managers to estimate realistically the time

Table 38-1 The logical framework matrix

Narrative summary	Verifiable indicators	Means of verification	Assumptions/risks
Goal	Quantitative ways of measuring, or qualitative ways of judging, achievement of broad objectives	What sources of information exist?	External factors necessary for sustaining objectives in the long term
Purpose	Quantitative measures or qualitative evidence to judge achievement and impacts (estimated time)	What sources of information exist?	External factors affecting movement of purposes toward project goal
Outputs (Outputs to be produced to achieve project purpose)	Performance questions and indicators for each output—output indicators	What sources of information exist?	External factors affecting movement of outputs to purposes
Activities (Activities to be undertaken to accomplish the outputs)	Can include the needed inputs for activities	What sources of information exist?	External factors affecting movement of activities toward outputs

required for each task or activity and to think carefully about the best sequence of tasks and activities. Full-scale application of the method is most common with complex construction projects, but realistic assessment of time requirements and efficient sequencing of activities should be part of any planning effort.

Each circle on the diagram in [Figure 38-5](#) represents a task or well-defined activity that is part of the project. The number in each circle represents the expected time required to complete the task. Arrows indicate the dependencies of relationships among the tasks and show which tasks must be completed before the next can begin. Adding together all of the task times in [Figure 38-5](#) shows that 83 weeks of work must be completed; however, several tasks can be done simultaneously. For example, when task A has been completed, B and C can be started and worked on concurrently. Therefore, the earliest completion date is estimated by looking at all possible paths through the diagram and choosing the one with tasks requiring the most total time. In this example, the longest, or “critical,” path is A–C–E–G–K–L, requiring a total time of fifty weeks.

The LogFrame project-planning method

Most donors have a required series of steps that they follow to identify, plan, implement, and monitor projects (see [Chapter 14](#)). The logical framework approach (LogFrame, or LFA) is one such planning method that has broader applications. The LogFrame approach has been used by the U.S. Agency for International Development, Danida, and other donors and organizations. The World Bank (2005) has published a guidebook on the approach.

The LogFrame approach combines all the key components of a project in one place and presents them in a systematic, concise way. LogFrame also ensures a logical inter-relatedness among project elements, highlights the influence of external factors, and provides a systematic basis

for monitoring. However, the approach can lead to an inflexible project design without connection to realities in the field or changing situations. Nevertheless, if the LogFrame analysis is seen not as a final product, but rather is evaluated and updated along the way, it can provide a clear view of needs, objectives, and strategies for all involved on a continuing basis.

The written output of a LogFrame basically appears as a four-by-four matrix (see [Table 38-1](#)). Along the horizontal axis are objectives, indicators, means of verification, and assumptions; along the vertical axis are four hierarchical levels of objectives: goal, purpose, outputs, and activities. The matrix summarizes what the project should achieve; the performance questions and indicators that will be used for monitoring and evaluation; how these indicators will be monitored or where the data can be found; and assumptions, such as a secure government or the availability of funds, plus associated risks for the project if assumptions turn out to be incorrect.

Project-planning management software

A number of computer programs based on variations of CPM-PERT and other planning methods can help organize operational planning and monitoring. Planning software can be useful for generating charts and schedules of different levels of detail; for determining when too much has been planned for available human or financial resources; for summarizing tasks by objective, unit, or individual; for preparing and monitoring project budgets; and for reporting on project achievements.

In practice, simple spreadsheet programs are the most commonly used software for program planning. The example in [Figure 38-2](#) is from a spreadsheet model in which each category of essential information (such as objective or target) forms a separate column and each task or activity is given a separate row.

Computers are useful for organizing planning information, but they cannot replace clear thinking about project objectives, substitute for personal monitoring of project activities, or make planning decisions.

38.6 Progress review cycle

Planning represents the beginning of the management cycle. Plans must be implemented, and equally important, implementation must be monitored. When plans are made and implemented, determining how often progress will be monitored is important. The review cycles for strategic plans, program plans, and workplans are different, but they should be linked.

If formal evaluations of progress are carried out (see Chapter 48), they are typically done after two to three years. Such evaluations may focus on long-term strategic plans, program plans, or specific project plans.

Progress toward achievement of the objectives set forth in a program plan should be reviewed at least annually, whether the plan covers a three-year, five-year, or other period. If a strategic plan exists, progress toward achieving long-term goals is generally reviewed at the same time as the program plan is reviewed.

An annual program review should address the following questions—

- What progress has been made toward each objective and expected result or output?
- What are the implementation problems?
- What changes are needed in strategies, objectives, or specific activities?
- What activities should be deleted from the plan?
- What new activities must be added to achieve the original objectives?

Progress toward implementation of annual workplans should be formally reviewed at least quarterly, if not monthly. In general, the questions asked during annual progress reviews also apply to quarterly or monthly reviews of workplans.

38.7 Why plans sometimes fail

Good plans to guide program development and implementation require time and effort. Sometimes, however, plans exist merely on paper: they are made but never actually used. Even well-conceived, well-presented plans can remain unused.

Why are plans not implemented? If implemented, why do plans fail to achieve their intended objectives? There are many reasons, but some of the more common are—

Unrealistic or overly ambitious planning: Planning must be based on a realistic assessment of the current situation, clear objectives for the future, and a practical assessment of what is possible. Planning, particularly in groups, can sometimes become overly optimistic and idealistic. Planning should be forward thinking but should not confuse hopes and wishes with good judgment and decisions about what is possible.

Failure to consider existing resources and commitments:

Plans must be made within the context and constraints of existing commitments. Although the opportunity often exists for great progress, progress takes time. Plans that propose too much in too little time may spread everyone's efforts too thinly to accomplish any of the stated objectives or may compromise the work's quality.

Lack of involvement by the implementers: Plans are best made at the levels where they will be carried out.

Strategic plans to guide long-term policy must involve policy makers, medium-term program plans must involve program managers and key program staff members, and annual work planning must involve the people whose work is being planned. Without such involvement, plans are likely to lack both the realism and the commitment necessary for effective implementation.

Lack of support: Success also depends on support from others who are not directly involved in implementation. Such support may come from senior staff members and officials of ministries (such as treasury) and other governmental bodies, international organizations such as WHO and UNICEF, donors and development banks, local NGOs, and local professional societies. Selectively involving individuals from such organizations in preparing or reviewing a strategic or program plan can lay a good foundation for future support during implementation.

Planning for the wrong reasons: Some plans are never really meant to be implemented. Examples include plans made only for short-term political gain or to satisfy a condition for receiving a grant or a loan. Whenever possible, however, plans pushed by external needs should also suit the needs of the organization or program. If plans are sometimes made "for appearances only," staff members should understand why this is done so that the experience does not undermine their confidence in the value of good planning.

Lack of funds: Nothing is more frustrating than spending considerable time and effort in planning, only to learn that funds are insufficient to carry out the plan. Planning should be based on a realistic assessment of potential funding sources.

Lack of people or time: Although plans are made for organizations or programs, they depend on people. Ambitious plans require more people and more capable people. But

ASSESSMENT GUIDE

Strategic planning

- Does a strategic plan exist for the pharmaceutical sector (for example, a national pharmaceutical policy or national development plan)? Does it reflect the current political, social, and economic environment? Are its strategies appropriate and realistic?
- Did the strategic-planning process involve policy makers and senior staff? Which key stakeholders were involved or consulted?
- Did the strategic-planning process actively consider new strategic options, such as strategies used elsewhere or suggested by outside experts?
- Is the strategic plan written? Does it include mission and vision statements; a brief assessment of the current situation, including strengths, weaknesses, opportunities, and threats; a concise description of each goal and measurable results; and a brief summary of each strategy for achieving these goals? Has it been officially endorsed?
- Is the strategic plan reflected in program plans and workplans? To what extent are strategies having the intended impact?

Program planning

- If there is an essential drugs program or other major pharmaceutical program, is there a pharmaceutical master plan, five-year implementation plan, or other program plan?
- Does each program or project plan include a statement of the goal, strategies, objectives, targets or output, responsibilities, schedule, monitoring and evaluation plan, and budget? Does the plan include both descriptive text and summary tables?

- Are program plans implemented through annual or semiannual operational workplans?
- Have program plans been used in presenting arguments for additional funding?

Work planning

- Are workplans prepared annually?
- Do they specify objectives, activities, major tasks, measurable outputs or targets, individual responsibilities, timing (at least to the month), monitoring and evaluation plan, budget, and source of funds for each activity? Are workplans realistic in terms of available staff, time, and funds?
- Do workplan documents include activity-time (Gantt) charts? Are they used for monitoring?
- To what extent are implementing staff involved in the preparation of workplans? Do individual units and staff members prepare, based on the workplan, their own monthly, weekly, or daily schedules or to-do lists?

Planning tools

- What planning methods or computer tools (for example, CPM, PERT, LogFrame) are used to support planning efforts?

Planning as part of the management cycle

- After plans have been established, are they reviewed on a regular basis for implementation progress and problems? Are the review cycles for strategic plans, program plans, and workplans linked?
- Have formal assessments or evaluations been done? If so, have the findings and recommendations been incorporated into revised plans?

even a plan that was realistic at the time it was made may fail if key people are transferred or otherwise become unavailable.

Wrong level of planning: Some managers and staff tend to avoid planning for themselves. They prefer planning for the people below them or making recommendations to the people above them. A fundamental principle of planning, as noted above, is that plans should be developed with the active involvement of those who are central to implementing them.

Poorly presented or overly complicated plans: Often, the clearest, most useful plans are the shortest plans. For example, an annual workplan for a national essential medicines program may consist of a one-page introduction and statement of objectives, a two-page chart of

activities and time frame (Gantt chart), a monitoring and evaluation plan, a one-page budget, and one page of text describing the eight major program components. Plans that are poorly organized or overly complex or that provide excessive detail are difficult to understand, let alone implement.

Lack of follow-up and monitoring: One of the most common management failures is the failure to actually use a plan after it has been prepared. A five-year program plan such as that shown in [Figure 38-2](#) should be reviewed regularly and used to formulate annual workplans. Annual workplans and timelines such as those shown in [Figures 38-3](#) and [38-4](#) should be checked on a weekly or monthly basis. The program's monitoring system (see [Chapter 48](#)) should be linked with organizational and

program plans. Without this link, the plan loses its value in guiding implementation.

Thus, for plans to be implemented effectively, they must be realistic, they must be developed with input from the people who will implement them, they must have sufficient support, they must have adequate resources, and they must be clearly presented. ■

SUMMARY

A contract for goods or services is a legally binding agreement between a purchaser and a provider for a specified period of time. In the public sector, the purchaser is usually the government and the provider may be a private-sector company.

Some health systems contract out (outsource) customs clearance, pharmaceutical storage, procurement, and transport. In some cases, a health system may contract out pharmaceutical services through retail or not-for-profit pharmacies. Outsourcing services can, in some cases, reduce costs and improve effectiveness. The decision whether to contract out or to provide services in-house must rely on a careful analysis of the effect on the entire supply chain, including costs, performance, the capacity of the private sector to provide the goods and services in question, and the capacity of the health system to monitor the contract. Outsourcing is most likely to succeed when real competition takes place, the health system is equipped to supervise the contract, and sufficient funds are available to pay the contractor.

This chapter considers—

- *Pharmaceutical procurement contracts*: Careful preparation of specifications and enforcement of

contract terms are a must for efficient procurement.

- *Service contracts*: Such arrangements may reduce or eliminate the need to maintain government storage and transport infrastructure. In a supply agency contract, an autonomous private or parastatal agency operates warehousing and transport services on the government's behalf. In a direct delivery contract, the supplier delivers to regional or district stores and hospitals. Under a primary distributor contract, health facilities order from a contracted distributor and pay the manufacturer's contract price for the medicines plus a distribution fee. Pharmacy benefit management programs provide prescription services to designated beneficiaries, either in person at contracted pharmacies or through direct delivery (that is, via mail) from a central location.
- *Service contracting process*: The process of contracting for services has four stages: (1) identify a service that could be provided by contract and establish the feasibility of contracting out; (2) prepare detailed tender specifications and contract terms; (3) short-list suitably qualified contractors, invite formal tenders, and appoint a contractor; and (4) monitor the contractor's and the health system's performance.

39.1 Overview of contracts

A health system is responsible for ensuring a continuous supply of high-quality goods and services to its clients at an affordable cost. This responsibility does not mean, however, that the organization needs to manufacture the supplies or provide all the services itself. Nevertheless, an argument is made—especially in developing countries—that the government should be responsible for the effective and efficient functioning of the entire national supply chain, regardless of whether individual components are managed by government agencies or by the private sector. In most health systems, pharmaceuticals and medical equipment are routinely supplied by private companies. Increasingly, the storage and distribution of these goods are also being contracted out. Industrialized countries often contract out the complete pharmaceutical program to serve designated categories of patients. [Box 39-1](#) describes contracts for prescription services (pharmacy benefit programs). This chapter discusses—

- Contracts for pharmaceutical procurement
- Contracts for the direct delivery of pharmaceuticals by suppliers

- Contracts for nonsupply services such as customs clearance, warehousing, and transport
- Assessment and monitoring of the quality and cost-effectiveness of contracts

Contracting for services is also discussed in [Chapters 24](#) (port clearing), [25](#) (transport management), and [42](#) (warehouse construction).

The essential first step in contract management is to decide whether an outside contract is desirable. The authority whose budget will cover the cost of the contract must make this decision, considering its impact on the entire health system—not on only one specific component. For example, in an environment of government inefficiency, outsourcing pharmaceutical distribution to a contractor may actually save costs, but may also justify a higher expenditure, if distribution services are more effective under the contractor and stock levels improve.

Producing supply items such as pharmaceuticals and other health care goods in-house is usually too expensive or impractical. Services, however, are different, and the total cost and performance of an in-house service as compared with a contracted service needs to be assessed. Furthermore, the choice is not a one-time decision. Regular monitoring of

Box 39-1 Pharmacy benefit programs

Pharmacy benefit management companies (PBMs) have emerged in industrialized countries as a way to contain health care costs by implementing mechanisms to improve the cost-effectiveness of prescription medicine programs. A PBM contracts with employers, insurers, and others to provide benefits to those groups' members. Often the PBM is paid a fixed amount for which it must provide contracted services, either by itself or by subcontracting with others.

Full-service PBM functions can include the following—

- Establishing networks of pharmacies for use by plan members
- Processing claims electronically and maintaining a database on drug use and cost
- Encouraging the use of generic products
- Managing existing formularies, helping to establish customized formularies, or providing a national formulary

- Encouraging prescriptions for maintenance medications to be filled less frequently with larger amounts, often by mail order
- Negotiating volume-based rebates from manufacturers
- Performing drug-use reviews
- Developing disease management programs based on standard treatment guidelines and assessments of patient outcome

PBM mechanisms for decreasing costs include implementing consumer cost-sharing to encourage the use of generic drugs, requiring prior authorization for certain prescriptions, and establishing multitiered formulary copayments. Although studies have shown that some mechanisms, such as tiered formularies and prior authorization do positively affect costs and medicine usage, little information is available on how these PBM programs affect health outcomes.

Source: Abt Associates 2010.

the contracted service and annual comparison with an in-house alternative are necessary to confirm that outsourcing remains the most cost-effective option.

A *contract* for the provision of goods or services is a legally binding agreement between a *purchaser* (or buyer) and a *provider* (or seller) for a period of time specified. In the health system context, the purchaser is generally the government or a public or private health care system, and the provider a private-sector company or parastatal entity. The responsibilities and interests of the purchaser and the provider, as well as remedies to address any potential future disagreement between the parties, are defined by the contract terms and conditions. Pharmaceutical contracts should be established in a formal written document.

The contracting process usually starts with the preparation of a *tender document*, which specifies the *technical requirements* of the goods or services required and the *terms and conditions* of the contract. Tenders are then formally invited and evaluated. The service agreement becomes binding after a tender is accepted, a letter of acceptance is issued, the contract is signed by both parties, and, in some special cases, the contract is registered with the appropriate government representative. If either party subsequently fails to comply with the contract, penalties are imposed. Clear and comprehensive technical requirements and contract terms and conditions are essential; otherwise, disputes may arise and the contractor may not perform as expected. Changes to a contract should be authorized only when technical evi-

dence supports the change or when the change will not significantly affect services provided.

The design, implementation, and monitoring of contracts must also take into consideration the issue of corruption. Contracts related to pharmaceutical management, and especially procurement, are susceptible to corruption because the supply chain can be complicated and lack transparency, and because drug volumes are usually large and unit costs high, thereby making such contracts very lucrative for suppliers (Cohen 2002).

Established service contracts should be reviewed to ensure that their terms and conditions continue to address the required scope of work and that they comply with current legislation and that all parties are performing as agreed. Outsourcing may not be cost-effective if the quality of the contracted service cannot be monitored and enforced.

39.2 Critical contract terms in pharmaceutical procurement

The discussion of tender management procedures in [Chapter 21](#) introduced issues related to supply contracts. Tender specifications include many of the conditions of contract performance. Normally, by submitting a bid, the prospective seller is agreeing to the proposed contract terms (unless the seller stipulates otherwise in writing on

Figure 39-1 Contract terms must be fully specified

the tender submission). Care should be taken to ensure that the terms of the final contract match the terms specified in the tender or bid document. If any conditions are altered, the desired performance or price may be compromised or losing bidders may feel that they were disadvantaged in the contracting process and take legal action.

Although the tender documents specify the supplies and services expected, the purchaser and the provider should execute a discrete written contract. The most critical contract terms are discussed below (see also Figure 39-1).

Preparing an effective pharmaceutical procurement contract is a specialized function requiring a great deal of care. Critical details include the specification of the medicine; the quality standards required; analyses to be performed; batch records required; certificates of quality assurance that must be issued; the type of packing, documentation, lot numbering, and labeling requirements; return and disposal procedures and obligations; communication requirements; shipment and delivery agreements; the price and payment terms; and the last date of shipment. Again, the contract specifications should be consistent with those pre-

sented in the tender or bid document to ensure the fairness of the process. Failure by the supplier to comply with those requirements can cause substantial loss or extra expense to the buyer. From the supplier's perspective, if the procurement office places a verbal order and subsequently refuses to confirm it or fails to pay for an order as agreed, the supplier will suffer loss or added expense. Thus, all orders should be requested in writing and signed by the authorized contract representative.

An interpretation or clarification of the various terms and conditions contained in a tender should become part of the overall tender document to avoid any ambiguity or conflict that may arise because of different interpretations. Annex 39-1 shows a tender's sample interpretation section. Questions should be solicited from the bidders at the beginning of the bid process. All questions and corresponding answers should be distributed in writing to all prospective bidders, and written confirmation of receipt requested from each. Any additional questions that arise during the bidding process should be addressed in the same manner.

Trade terms

Trade terms are used in pharmaceutical supply contracts to define the division of costs and responsibilities during the shipment of commodities between the supplier and the buyer's stores. Trade terms were standardized by the International Chamber of Commerce in 1953 when it first published *Incoterms*; these standards are reviewed and revised approximately every decade (International Chamber of Commerce 2010). Over the years, more precise definitions and new terms have been created to establish the exact point where the seller's costs and responsibilities end and the buyer's begin. However, old terms are still in common use, so it is important that both parties understand and agree on the contract terms. [Table 39-1](#) summarizes the trade terms most commonly used for government supply programs. Procurement agencies should have a copy of the latest version of *Incoterms*.

The buyer usually specifies the applicable trade terms in the contract or tender document. The buyer must, therefore, understand the implications of various trade terms and the corresponding relative risks assumed by the buyer and the

seller in case of loss or damage. Of the trade terms listed in [Table 39-1](#), CIP (carriage and insurance paid) is generally preferable for pharmaceutical supply tenders. These terms make it easier to compare tender offers fairly and to budget for the true cost of products on the tender list. In cost-recovery programs, these terms also make it easier to determine the full replacement cost for each product. When using CIP terms, specifying precisely the final destination to which the cost of transport will be paid by the seller is essential.

In many countries, transportation routes are limited, and economical delivery of goods from overseas requires a detailed knowledge of these routes. If the chosen supplier is unfamiliar with local trade routes but the procurement office is knowledgeable about local routes, FAS (free alongside ship) or FOB (free on board) terms may be preferable, with the buyer making separate arrangements for shipping and insurance. According to FAS terms, the seller pays for packing and delivery to the place of loading. The buyer pays loading costs plus export customs and documentation charges. Under FOB terms, documentation charges are paid by the seller.

Table 39-1 Summary of common trade terms in the 2010 *Incoterms*

Category	Code	Code meaning	Explanation
Any mode of transport	EXW	Ex works. Need to state a named place.	Seller pays for expenses at factory or warehouse. Buyer assumes all onward expenses.
	FCA	Free carrier. Need to state a named place.	Seller pays packing and delivery at the named point into the custody of the carrier and cleared for export.
	CPT	Carriage paid to. Need to state the destination port.	Seller pays freight and charges to named destination port. Buyer pays expenses from this port onward, including foreign customs clearance.
	CIP	Carriage and insurance paid. Need to state the destination port.	Like CPT, but the seller also has to procure and pay for cargo insurance.
	DAP	Delivered at place. Need to state place.	Seller delivers the goods when they are placed at the disposal of the buyer on the arriving means of transport ready for unloading at the named place of destination. Seller bears the responsibility and risks to deliver the goods to the named place.
	DAT	Delivered at terminal. Need to state place.	Seller delivers when the goods have been unloaded and are placed at the disposal of the buyer at a named terminal at the named port or named destination.
	DDP	Delivered duty paid. Need to state place.	Seller pays for all transportation costs and bears all risk until the goods have been delivered and pays the duty.
Waterway transport	FAS	Free alongside ship. Need to state the loading port.	The same as FCA, with the exception that buyer pays for loading. NOT suitable for multimodal sea transport in containers.
	FOB	Free on board. Need to state the loading port.	The same as FCA, but for ocean or inland waterway freight use only. NOT suitable for multimodal sea transport in containers.
	CFR	Cost and freight. Need to state the destination port.	Seller pays all expenses up to arrival at named port of destination, and buyer pays marine insurance.
	CIF	Cost, insurance, and freight. Need to state the destination port.	Same as CFR, except seller also pays for insurance for the buyer.

In general, sea freight cost is about 10 percent, and insurance about 1 percent of the FOB cost. Some buyers require that bidders provide both CIP or CIF and FOB prices to help determine whether shipping and insurance could be managed at a lower cost by the buyer. The eventual contract may also require that the FOB portion remain unchanged but that the CIP price be adjusted for actual freight and insurance costs. By this means the buyer can collect data on actual freight charges and compare costs under the different trade terms.

Financial capability

The bidder must submit documentary evidence demonstrating to the buyer's satisfaction that the bidder has the financial capability to perform its obligations under the supply contract if its bid is chosen. Such documentation should include the bidder's financial accounts for the two most recently completed fiscal years.

Purchase quantities

The buyer may request tenders for either fixed or estimated quantities (see [Chapter 21](#)). The contract terms should specify if estimated quantities represent a guaranteed minimum purchase or if there is no guarantee of quantities in the contract. The latter arrangement is standard practice in pharmaceutical group-purchasing contracts in developed countries. From a supplier's perspective, offering a specially discounted price for a quantity that is not a guaranteed purchase would not be beneficial. Price fluctuations of raw materials used in pharmaceuticals are such that suppliers tend to build higher buffers into their pricing structures, depending on the certainty of a purchase and the period over which they are expected to keep their prices valid.

Exchange rates and price comparisons

Often, bidding documents will require that bidders use a specified currency or currencies to express their bids. However, the International Bank for Reconstruction and Development (IBRD) guidelines for procurement (2010) suggest that if bidders are allowed to state their bids in the currency of their choice, in order to compare prices, all bid prices should be converted to a single currency selected by the buyer (local currency or fully convertible foreign currency) and established in the bidding documents. Price comparisons can be based on the official rates of exchange prevailing on the day bids are opened, with the stipulation that if those rates subsequently change, the rates applicable at the time of the award of contract should be used. Table 39-2 illustrates how this rule would be applied to compare bids from four hypothetical suppliers. Whether or not the IBRD guidelines are used, the method for bid comparisons should be stated in the bidding documents.

The currency chosen for comparing bids can be a major influence on the award process. When bid evaluation is done in a currency within a high-inflation economy, price differences at the time of bid opening, the date of award, and the date of payment can be substantial. In such circumstances, requesting bids in U.S. dollars or another commonly accepted currency in international pharmaceutical trade, such as Japanese yen, British pounds, or the euro, may be advisable.

Payment currency

The contract must specify the payment currency, which should be the currency specified in the terms and conditions of the bid. The payment currency may be widely used in international trade or may be the supplier's or buyer's

Table 39-2 Bid comparison according to currency conversion rate

Supplier	Tender currency	Value of bid in U.S. dollars			
		On date of bid submission	On date of opening bid	On date of award	On date of payment
A	Euro	6.43	7.07	7.07	7.07
B	Japanese yen	6.86	6.86	7.20	7.20
C	U.S. dollar	7.14	7.14	7.14	7.14
D	U.K. pound	7.57	7.57	7.19	6.84

Source: Westring (1985).

Note: Currency conversion rates used to evaluate tenders and guide awards should be consistent with the terms and conditions stipulated in tender/bid documents. The table shows how exchange rates could vary at different times in the bid invitation, submission, award, and payment process. Considering that bidders may submit their bids at different times before the specified closing date and that the buyer may delay the time between the award and the bid opening, the fairest process is to base the value of the bid on the conversion rate prevailing on the date of the bid opening. For example, on the date of bid submission, supplier A offered the lowest price (USD 6.43), but this offer was irrelevant because supplier B had the most favorable price when the bids were opened (USD 6.86). Sellers should not be held responsible for delays experienced on the part of buying agencies in evaluating bids, which can happen if a buying agency takes several months to determine an award. Therefore, although supplier A's bid was the lowest on the date of the award, the value on the date of bid opening is the relevant one for bid selection. It would be purely speculative to attempt to anticipate changes in parity, which should be avoided in public procurement. Payment value should be based on the rate on the date of the bid opening, because that is the rate used to determine the award, and this process should be specified in the contract between the buyer and supplier. Problems can be reduced by specifying or limiting the currencies that suppliers can use when bidding.

own currency. If the buyer's currency is used, a speculative risk exists for the supplier if the local currency is not freely convertible or if the conversion rate fluctuates significantly. Many international suppliers either do not accept payment in local currency or include a "contingency factor" that raises prices.

When procurement offices can pay only in local currency, the need for a contingency factor may be avoided if the buyer is able to guarantee that payments will be converted into the supplier's currency at the exchange rate prevailing when the contract was awarded.

Validity of contract prices

The validity period is the period of time after contract signing during which contract prices apply. The length of this period depends on the type of tender and contract. If the tender establishes a specific quantity to be shipped at a certain time, the bid prices are normally valid until the final shipment has been received by the buyer and payment has been made. If the tender is based on estimated quantities with periodic orders, bid prices should be valid for a longer term. The standard in industrialized countries is one year, although shorter and longer terms are sometimes required. As discussed in [Chapter 21](#), in highly inflationary environments, it may be necessary to tender more frequently or include a price-escalation clause in the contract that adjusts prices for inflation at specific intervals (for example, quarterly). Such adjustments should be clearly specified; it may be useful to tie the adjustment to the actual rate of inflation or another economic indicator as reported by the national central bank or other authoritative source.

As previously discussed, the greater the supplier's uncertainty regarding an actual purchase against a tender, the higher the risk factor the supplier builds into its pricing. To best protect themselves in an uncertain purchasing environment, procurement agencies should consider undertaking a Pareto or ABC analysis and base their purchasing strategies on the items that comprise the bulk of their order value, rather than applying one rule for all items they purchase. (See [Chapter 40](#) for an explanation of ABC analysis.)

Payment terms

The contract must specify payment terms. Unless timely and secure payment is guaranteed, obtaining the best prices is difficult. Many public-sector systems are either periodically short of funds or have a slow payment process. Suppliers generally require such supply systems to pay by irrevocable letter of credit, submitted before any shipments are made. Public-sector systems must realize that reputable suppliers conduct a risk analysis before submitting prices and that the supplier will usually build in a larger buffer if its experience

shows that the public system has continually delayed payments.

Letter of credit. A letter of credit is an interbank document stating that a certain sum of money is available for the seller to claim from its bank as soon as it ships a consignment and presents the required documents. A letter of credit generally involves a surcharge of 1 to 2.5 percent for the buyer. However, because it reduces the supplier's credit risk, using a letter of credit can facilitate a better contract price offer. Contract agreements often allow for some price fluctuations caused, for example, by changes in freight and insurance costs. Accordingly, a supplementary payment or refund may be necessary at the time of delivery.

Deferred payment (commercial terms). The buyer and the seller may contract for payment at the time of delivery (without a letter of credit), or payment may be deferred for a period of 30, 60, 90, 120, or 180 days. Both options are forms of credit buying, and the procurement office must be careful not to contract for more supplies than it can ultimately afford. If a country defaults on deferred payment terms, it may subsequently be forced to prepay or to pay solely by letter of credit or cash on delivery.

Deferred payment allows the buyer to retain use of funds for a longer period. In addition, it enables the buyer to withhold payment if the supplier provides substandard or incomplete deliveries.

When tenders are being evaluated, the cost of various payment options should be carefully compared. Suppose two suppliers quote the same price. Supplier A requires a letter of credit to be submitted when goods are cleared from the port. Supplier B allows a credit period of 120 days from receipt of goods until payment. If the annual interest rate in the buyer's country is 12 percent, this credit period represents a 4 percent savings compared with supplier A's terms.

Quality standards

The contract terms should state that all pharmaceutical products are to be manufactured in conformity with recognized pharmacopoeial standards. The most commonly used standards in pharmaceutical procurement are the latest editions of the *British Pharmacopoeia* (BP) or the *United States Pharmacopoeia* (USP), but others, such as the *European Pharmacopoeia* (EA) or the *International Pharmacopoeia* (IP), may be appropriate in some circumstances. The major pharmacopoeias include specifications for most pharmaceutical products, both raw materials and finished products in their final dosage form, organized by generic name (international nonproprietary name, INN), not by brand name.

As discussed in [Chapter 21](#), the pharmacopoeial standards should be specified in both the tender invitation and the contract. Suppliers should be required to state the pharmacopoeial standard applicable to each product offered. The contract should specify that batch certificates and the World

Health Organization (WHO) certificate of a pharmaceutical product must be supplied for each product (see [Chapter 19](#)). In some procurement situations, it may be necessary to require that products and supplies be prequalified by WHO or approved by stringent regulatory authorities.

Manufacturing approvals

For each pharmaceutical product, tender conditions should specify that the bidder must attach the following documentation for evaluation—

- A copy of the product certificate authorizing the source facility to manufacture the particular pharmaceutical product
- A copy of the statement of licensing status, which gives the source facility manufacturing authority
- A copy of the product license as issued for the exporting country
- A copy of the product license as issued for the other countries (up to a maximum of five) in which the pharmaceutical is sold or distributed
- Copies of approval documents from WHO prequalification
- The product information
- A sample of the standard marking or label to be included on each dispensing unit
- An estimate of the percentage of capacity committed to other contracts
- A good manufacturing practices inspection certificate from the regulatory authority in the country of manufacture (although WHO provides guidelines for the certification process, countries implement it through their drug regulatory authorities; therefore, the quality of GMP (Good Manufacturing Practices) certification may be inconsistent)

Some health systems tender with commercial or nonprofit wholesale suppliers rather than manufacturers. The suppliers should provide the information and documentation (described above) required of the manufacturers.

Labeling and nomenclature

Many otherwise identical medicines are marketed under several different brand names by multinational pharmaceutical corporations and by local enterprises (see [Chapter 19](#)). To avoid confusion in the selection, procurement, distribution, and use of medicines, contract terms should require standard labeling for all products. General guidelines for labeling are as follows—

- The language for labeling should be clearly specified in the contract.

- All package labels should contain at least the following information—
 - Generic name of the active ingredients
 - Dosage form (tablet, ampoule, vial)
 - Quantity of active ingredient(s) in the dosage form
 - Number of units per package
 - Batch number
 - Date of manufacture
 - Expiry date (in clear language, not in code)
 - Pharmacopoeial standard
 - Instructions for storage
 - Name and address of manufacturer
 - “Not to be sold without a prescription” statement, if appropriate
 - “Keep out of the reach of children” statement
- The label on each ampoule or vial should contain the following information—
 - Generic name of the active ingredient(s)
 - Quantity of the active ingredient
 - Batch number
 - Expiry date
 - Name of manufacturer
- The full package label (as specified above in this list) should appear on the immediate container.
- Directions for use and precautions may be given in leaflets (package inserts). However, leaflets provide supplementary information and are not an alternative to labeling.
- For products requiring reconstitution before use (for example, powder for injection), instructions for the reconstitution should be on the label.

In some countries, unique identifiers are used to reduce theft and also to promote the essential medicines concept (see [Chapter 43](#)). However, such measures may increase cost.

Packaging

Proper packaging should be clearly specified in the tender documents and in the supply contract. General packaging guidelines are as follows—

- If pack size is important, it should be clearly specified (for example, tablets and capsules packaged in amounts of 1,000; ampoules and vials packaged in amounts of 100).
- All packaging must be suitable for the climate zone and storage conditions in the destination country.
- Tablets and capsules should be packed in sealed, waterproof containers with replaceable lids that protect the contents against light and humidity. If individual pack-

aging for tablets or capsules is required, this condition must be stipulated. Tampering evidence requirements need to be specified.

- Liquids should be packed in unbreakable, leakproof bottles or containers.
- Ampoules should preferably be one-ended and auto-breakable. Alternatively, packages should include an adequate supply of ampoule files to facilitate breaking. Light-sensitive products, such as ergometrine, should be packed in brown glass ampoules. Individual ampoules should be packed in plastic or in cardboard trays (five to ten ampoules per tray) and trays in outer cartons (for example, 100 trays per carton).
- Containers for all pharmaceutical preparations should conform to the latest edition of an internationally recognized pharmacopoeia (such as BP or USP).
- Outer cartons should be of strong, export-quality material able to withstand rough handling and the prevailing climatic conditions during transport and storage.
- If the receiving warehouse is equipped to handle pallets (see [Chapter 44](#)), the contract should require that cartons be shipped on pallets. The preferred pallet size should be specified. Additional security against theft and water damage is provided if pallets are shrink-wrapped in clear plastic.
- Each consignment must be accompanied by a detailed packing list, stating the number of cartons and the type and quantity of medicines in each carton. An outer carton should contain products with the same expiry date; this date should be printed on the carton as well as on the immediate containers. If required, outer cartons should also be labeled with a unique identifier (see [Chapter 43](#)), a commodity code, or both.
- Upon delivery, packaging becomes the property of the buyer.
- The supplier is responsible for replacing any packages and products found to be damaged at the point of delivery.

To ensure proper packing and labeling, suppliers—particularly those that are new or unknown—should be instructed to submit samples along with their bids. By assessing and visually checking the samples, buyers may avoid problems caused by poor packaging or labeling. Packaging specifications for medicine kits are discussed in [Chapter 26](#).

Shelf life and expiry date

Pharmaceutical products have varying shelf lives. The expiry date is specified by the manufacturer at the time of manufacture and can range from six months to more than five years.

Supply contracts should specify the required minimum shelf life remaining at delivery for all pharmaceutical prod-

ucts. Because of the length of time required for local distribution, it is advisable to include a general condition that, at the time of arrival, at least two years of shelf life should remain. For products with a shelf life of less than two years, at least 75 percent of the shelf life should remain upon arrival.

Because the same generic products from different manufacturers may have different shelf lives, suppliers should specify the shelf life for every product in their bids so that the procurement office can consider shelf life when evaluating bids.

Bid bonds and performance bonds

In international trade, ascertaining the reliability of suppliers is sometimes difficult. To encourage suppliers to live up to their obligations, financial guarantees may be required.

Bid bonds are earnest money or security deposits in the form of cash, certified check, bank draft, state bond, or other negotiable bank document (equal, for example, to 1 percent of the value of the offered bid) that are provided by the potential supplier at the time a bid is submitted. This security is forfeited if the successful bidder withdraws the offer or refuses to agree to the contract requirements. Bid bonds are refunded when the award is announced and all suppliers have accepted the contract terms. World Bank pharmaceutical standard bidding documents recommend the use of bid bonds and performance bonds (World Bank 2008).

Performance bonds are security deposits in the form of negotiable fiscal documents that may be required at the time a contract is awarded. Their purpose is to guarantee that the supplier fulfills the contract obligations. An amount equivalent to 5 to 10 percent of the contract price is often used for this purpose. The deposit is separate from documentation involved in the letter of credit and is returned only after goods have been received in the country and are found to meet all contractual standards and to be of acceptable quality. The World Bank specifies a performance bond set at an amount stated in the contract, posted as a cashier's check or irreversible letter of credit within twenty-eight days of contract award. The performance bond is released after the contractual requirements have been fulfilled (World Bank 2008).

Both bid and performance bonds provide protection for the buyer against supplier default. The potential financial risk, however, may drive away many potential bidders, including some reliable international companies. For example, when the banking system of the purchasing country is poorly integrated into the international banking system, retrieving a performance bond after the contract is completed may be difficult.

As an alternative to requiring bonds, the risk of supplier default can be reduced by inviting tenders only from suppliers of known reliability. It is not uncommon for

pharmaceutical procurement programs to require financial guarantees only from new or previously unreliable suppliers.

Performance bonds are particularly unappealing to suppliers in a tender that calls for “draw-down” by purchasing group members, in which the tender quantity is just an estimate and orders are placed throughout a contract period. In such cases, the supplier would presumably lose access to the performance bond funds for the entire contract period; most established pharmaceutical companies would not be interested in such a contract. Despite these reservations, performance bonds may be warranted in fixed-quantity open tenders with postqualification, where many bidders and suppliers may be largely unknown entities.

Experience

The bidder should provide documentary evidence acceptable to the purchaser—including sales figures for at least three years—to prove that it is a regular supplier of pharmaceuticals to the domestic and international markets under the specific type of tender involved.

Shipment date

For fixed-quantity contracts, the contract and the letter of credit (if used) should specify the last date by which the supplier is to ship the consignment. The implication of this requirement is that the bill of lading (the standard shipping documentation) issued by the shipping company and signed by the master of the carrying vessel must be dated on or before the last date of shipment specified in the letter of credit.

The bank that holds the letter of credit is prohibited from accepting a bill of lading dated after the last date for shipment under the contract unless the buyer has agreed to the delay and the letter of credit has been suitably extended. If orders are covered by import licenses, an extension from the appropriate office may also be needed.

In contracts based on estimated quantities with periodic orders during the contract, the contract should specify the maximum number of days between the receipt of an order by the supplier and the shipment of goods.

Patent provisions

In countries that recognize patent laws, most new pharmaceutical products were originally covered by patent for periods ranging from two to seventeen years. Since 1994, World Trade Organization (WTO) members have been obligated under the Agreement on Trade-Related Aspects of Intellectual Property Rights (TRIPS) to recognize twenty-year patent periods. During this period, no seller may manufacture or market a patented product without the consent of the patent holder.

Each country’s policy regarding patent rights is governed by legal, political, and economic considerations, both local and international. If the country is a WTO member, it may be obligated by the TRIPS agreement, or it may be restricted by intellectual property conditions within bilateral trade agreements. The Declaration on TRIPS and Public Health (Doha Declaration) gives developing countries some flexibility in adhering to TRIPS, enabling them to take steps to protect the public health of their populations. Least-developed countries have been given until at least 2016 to comply with pharmaceutical patent requirements. [Chapter 3](#), on intellectual property and access to medicines, details the issues surrounding pharmaceutical patents and the TRIPS agreement.

Purchasing countries must decide which patent laws, if any, will be recognized in the procurement contract. The simplest practice for buyers is to place the responsibility for observance of patent rights in the country of origin on the supplier. Contracts can stipulate that the supplier will indemnify the buyer against all claims that may arise on account of patent rights, trademarks, proprietary designs, or royalties.

Penalties for default

The contract should specify the remedies available to each party in case of default by the other party, and the body of law and court under which disputes will be resolved.

Contracts with domestic suppliers are, of course, subject to the laws of the buyer’s country. Contracts with international suppliers may also be written with that provision, but enforcing local law on an international supplier that has no local operations may be difficult. Even if a judgment is obtained, it may be impossible to recover damages.

Contracts are sometimes written providing that disputes will be resolved through arbitration, but this process is also unlikely to produce a favorable solution for a buyer that is injured through the default of an international supplier.

The contract should specify that the buyer will withhold payments in process and/or cancel any outstanding transactions in the event of supplier default. This remedy is suitable only in contracts in which some form of delayed payment applies and when the deliveries and payments are divided. If the contract specifies a single shipment with payment by letter of credit up front, payment will have been made by the time problems are discovered. [Annex 39-2](#) illustrates a typical contract for pharmaceutical supply.

Some countries have a system to delist suppliers who have clearly defaulted on a contract. A delisted supplier could potentially be barred from supplying a national agency for periods ranging from one to three years or more, depending on the nature of the default. Delisted suppliers must undergo a new prequalifying process to be reconsidered as a supplier.

39.3 Contracts for services

For many years, private companies and governments in industrialized countries have used outside contractors to provide specialized services at lower cost and with higher quality than the company or government can achieve in-house. Increasingly, many developing countries' governments are considering this model.

Contracting out, or outsourcing, in health care has traditionally been used for nonclinical services, such as equipment maintenance, laundry, and catering. Outsourcing might be used in the pharmaceutical supply system in many ways. [Chapter 8](#) discusses various ways in which contracts may be used to manage pharmaceutical warehousing and distribution services to the public sector, extending in some cases to total pharmaceutical service provision through the private sector. [Chapter 24](#) points out options for contracting port-clearing services, and [Chapter 25](#) discusses contracts for private-sector transport services.

Successful contracting of services can tap private-sector expertise and efficiency, yet still leave the government in overall control. In some cases, there may be additional benefits; for example, a private transport firm that is awarded the contract to deliver medicines to remote rural locations may be able to offer local agricultural cooperatives a favorable price to carry their produce on the return trip. Contracting out can also reduce the cost to the supply system of wastage and losses due to theft, by making the contractor responsible for losses. However, in considering an outsourcing option, the supply system management must also consider the overall indirect costs and benefits to the entire system, not only compare the direct costs between options. A total cost analysis can inform decisions regarding whether to outsource (see [Chapter 40](#)).

The main steps in contracting out nonsupply services are to—

- Identify a single, well-defined service
- Carry out a feasibility study, including a total cost analysis
- Specify the contract terms clearly and precisely
- Use a competitive tender to select the contractor
- Pay the contractor
- Monitor the contract

When considering service contracts, the first step is to determine whether the private sector has the capacity to provide an adequate level of service. If the capacity exists, the next step is to calculate the total cost of providing the service in-house and to establish, by means of a survey or formal tender, what the total cost of contracting or privatizing the service would be. If the private-sector service appears to be more cost-effective and is able to provide at least the same level of service, it should be seriously con-

sidered. The answers to five key questions may determine the feasibility and desirability of contracting for services (McPake and Ngalande-Bande 1994)—

1. *Will real competition take place?* Are multiple providers in the market, or do one or two companies monopolize the service?
2. *Will competition actually promote efficiency?* When the background of the bidders is not known or when the service is new in the market, it may be difficult to assess the bidders' ability to meet the terms of the contract at the price and quality required. If a contractor fails to perform satisfactorily, the health service is left with an interrupted service and with the problem of finding an alternative supplier.
3. *Can the health system effectively supervise the contract?* Are there defined procedures for supervising contracts? Are these procedures included in the terms of the contract? Does the health system staff have the necessary skills, and is the information system able to provide indicators to monitor the contractor's performance?
4. *Will funding be sufficient for the contract?* Budget constraints might make fulfilling payment obligations to contractors impossible. For example, releasing funds regularly or on time may not be possible, which would likely lead to either suspension of services by the provider or less than optimal performance.
5. *Is advocacy sufficient within the government to adopt an outsourced model and will public reaction support the initiative?* Often, many departments within the government must work together to accomplish change, particularly when actions are taken to partner with the private sector. In addition, public sentiment may interfere with the government's willingness to move ahead, especially if outsourcing will result in the loss of government jobs. An effective communications strategy must be prepared to address these critical stakeholder groups.

Before contracting out any service, an options analysis should be conducted, and these questions should be answered.

39.4 Feasibility assessment

Contracting out may be one way of solving the problems of an unsatisfactory service, but only if the process can be managed properly. If it cannot, an unsatisfactory situation may be made worse. Senior health service managers are responsible for ensuring that a contracted service is feasible and cost-effective, that the private sector can offer reliable tenderers that are able to provide good-quality service, and that the contract can be monitored effectively. This

Country Study 39-1**Public-private health services contracting experience in Cambodia**

In the mid-1990s, the Cambodian health care system was having difficulty serving an adequate level of the population, especially the poor living in remote, rural areas. Nine rural districts participated in a study comparing the traditional government model of health care with two different models using nongovernmental organizations (NGOs) as contractors. The contracts were awarded through an international competitive bid, based on the technical quality of the proposed services and price. The districts were randomly assigned to one of three models—

- Contracting out: NGO contractors had responsibility for services, including hiring, firing, wage setting, and procuring and distributing essential medicines and commodities.
- Contracting in: NGO contractors worked within the government system to strengthen infrastructure through management support. They could not hire or fire workers, and medicines were distributed through normal government channels.
- Government: Government continued managing and supplying services.

Evaluation indicators were established, and extensive data were collected before and two and a half years after the intervention started. All districts had extremely poor health service coverage at baseline. The contracts included detailed and objectively measurable service coverage and equity goals. The control (government) districts were given the same goals. For example, for immunization, the target was to increase to 70 percent the percentage of children who are fully immunized, while targeting children from the poorest 50 percent of households. The contracts specified financial bonuses for achieving coverage higher than the target and equity rates, as well as penalties if the goals were unmet.

Results showed that contracted-out districts experienced significantly better improvements in virtually every public health service that was analyzed; for example, immunization rates increased by 158 percent in those districts compared with 82 percent and 56 percent increases in contracted-in and control districts, respectively. Additionally, the contracted districts provided more than proportionate benefits to poor households.

The average annual recurrent expenditure per person was USD 3.88 for the contracted-out districts, USD 2.40 for the contracted-in districts, and USD 1.65 for the control districts. Although the direct expenditure was higher in contracted-out districts, many indirect costs were decreased; for example, people in these districts lost 15 percent less work time because of illness and time spent seeking health care, and even more important, their out-of-pocket expenses for health care were significantly reduced. Expenditures by the poorest 50 percent of people fell 70 percent, or USD 35, which is impressive. The addition of out-of-pocket expenses to the government expenditure made contracting out the most cost-effective choice.

On the basis of their experience, the study organizers concluded that successful contracting requires—

- Predetermined and objectively measurable performance indicators, with clear and detailed contract targets
- Government support at the central and local levels
- An allowance for government health care workers to be employed by the contractor for market wage rates
- Contractors to be given the maximum management autonomy to achieve specified contract targets

Sources: Bhushan et al. 2002; Schwartz and Bhushan 2004.

determination requires feasibility assessment, planning, implementation of the tender process, contract monitoring, and review. Again, the entire process must be conducted with transparency, especially if the political or business environment is conducive to corrupt practices.

Four main issues need to be considered to determine the feasibility of contracting out a service. First, the total *cost* of the existing service must be compiled and compared with the total projected cost of alternative forms of provision to determine whether contracting out is potentially cost-effective; second, a *total cost analysis* must be carried out from a broader supply chain perspective; third, the *capacity* of potential contractors to provide an acceptable quality

of service must be assessed; and fourth, the service *performance* required must be clearly defined so that satisfactory tender documents can be prepared.

Comparative cost

In the case of a new contract, the total cost of the in-house service should be accurately assessed before modeling costs with other options and before inviting any tenders. Figures can then be compared realistically with the cost of the tenders received (see also [Chapter 21](#)). Usually, two cost models of the in-house service are made, one including the capital cost of improving the service and the other excluding it. In

addition, the potential cash benefits and out-of-pocket costs associated with privatization must be considered. On the one hand, income may be generated when buildings and equipment that are no longer needed are sold. On the other hand, severance payments may have to be made to workers whose jobs are eliminated. Another approach to this issue is to require the contractor to take over existing buildings and equipment and to absorb the existing workforce.

In the case of an existing contracted service whose cost-effectiveness is being assessed, an analysis of a suitable comparable noncontracted service in another health unit or province is needed to compare the cost of the in-house service with the price of the contract.

Standard cost-accounting methods should be used, and the cost per unit of service should be computed. Costs need to be assigned to each of the service units. This determination is sometimes difficult when such data are not routinely collected or compiled, or when all expenditures are categorized by line item and not by department or service. In such cases, a special study is required. After the data are analyzed, the cost per unit of service is calculated.

Contracting out may be justified if potential contractors can provide good-quality service at a lower total cost. Keeping the cost of the existing service confidential is essential; otherwise, tenderers may be tempted to underbid those costs without carrying out a proper analysis. They may then find that they are unable to provide an acceptable service at the bid price.

Total cost analysis from the supply chain perspective

Managers tend to look at the immediate gross cost savings rather than net cost savings after considering the value of

benefits; however, a careful benefits assessment should not be overlooked. Total cost analysis ([Chapter 40](#)) is one approach to analyzing costs and benefits of structured changes in a pharmaceutical supply system.

Outsourcing options are generally considered when the regular distribution system is regarded as ineffective and inefficient or when the organization is shifting the concentration of its core business to an area of activity other than direct distribution. However, the supply chain operation is undermined if a total analysis fails to consider both the costs and benefits to the entire interlinked system, not just the individual sectors whose functions are being outsourced.

Easily measurable effects relevant to the entire system include changes in stock-holding practices and inventory management at holding points, and the amount of wastage. More difficult to measure, but important, effects are related to indirect costs and benefits, such as the level of community satisfaction with health care in terms of the availability of and access to essential medicines and out-of-pocket costs. [Country Study 39-1](#) shows how a contracted service that, at start-up, was more expensive than the in-house service ultimately resulted in cost savings.

Private-sector capacity

Capacities of the private sector can vary significantly between countries and within different regions in the same country. Some countries use a combination of public, private, and nonprofit providers to fulfill varying service needs (see [Country Study 39-2](#)). A structured survey of private-sector capacity (see [Chapter 36](#)) can be used to assess the capacity and willingness of the private sector to provide the required service. The survey will help managers determine

Country Study 39-2

Using innovative contracting to address regional challenges in Papua New Guinea

Around 2005, Papua New Guinea had nineteen provinces and one national capital district. The terrain and poor road conditions in the country made distributing pharmaceuticals and medical supplies to the provinces extremely difficult. The country had 650 health centers: half were accessible by road; 30 percent were accessible only by a combination of road and water; 18 percent had only air access; 2 percent had to be accessed by a combination of road, water, and walking. Certain provinces with especially challenging terrain had problems over the years with ineffective distribution of pharmaceutical and medical supply kits to health centers.

Many provinces did not have enough private-sector contractors with sufficient capacity to efficiently distribute to

the entire province. Although local people or small companies did the actual distribution, they did not have the management capacity to meet the contract conditions that would result from a competitive tender. Therefore, larger companies based in the capital, Port Moresby, or the port city of Lae that had the necessary organizational ability joined forces with these experienced local agents to bid for provincial distribution contracts managed by various international nonprofit agencies. Papua New Guinea's innovative contracting successfully combined the talents of the few central companies capable of competing in a tender and managing the conditions of a contract with the local expertise needed to overcome logistical and geographic challenges in the field.

whether there would be competition for the contract, what options are available, and how total costs might vary with each option.

Performance indicators to compare options and monitor contracts

Performance indicators for the service need to be identified for two reasons. First, measuring the performance of the existing service is essential in order to establish where it succeeds and where it fails. Only by doing so can the purchaser prepare a realistic tender specification for the contracted alternative. Second, performance indicators are an essential component of contract monitoring; if the contractor cuts costs, it may be at the expense of quality. After performance indicators for the type of service are identified, a checklist for their assessment is prepared. For example, indicators for the assessment of contracting for the management of essential medicines warehousing and distribution might include—

- Total costs to the public sector (see [Chapter 40](#))
- Service level to lower-level warehouses and health facilities (see [Chapter 44](#))
- Availability of indicator medicines at pharmacies and health facilities
- Average lead time for receiving orders
- Average shelf life remaining upon delivery
- Average percentage of time out of stock for indicator medicines in facilities
- Number of complaints about short shipments or incorrect items shipped
- Number of complaints about damaged or poor-quality goods received

39.5 Developing a contract for services

When contracting has been determined to be feasible and potentially cost-effective, five major steps are involved in developing a service contract—

1. Identifying qualified providers
2. Preparing and completing all internal and public communications
3. Developing and managing the tender for services
4. Adjudicating and awarding contracts
5. Monitoring performance

Identifying qualified providers

A short list should be prepared of contractors adequately qualified to tender for the contract. Depending on the size of the contract and on local tendering regulations, this list

may be developed by informal inquiry, through structured interviews and inspections, or by means of a prequalification tender process. This step can be incorporated into the survey of capacity previously discussed. For example, a first step in identifying potentially qualified providers might be through an invitation to submit an expression of interest (EOI). Each EOI response would include information from the provider as to its ability to meet the contract requirements.

A formal set of procedures for identifying and evaluating potential contractors produces more objective results than information gathering that is more subjective and informal. Formal qualification procedures increase the transparency of the contracting process and promote the fair evaluation of all prospective contractors, while decreasing the likelihood of corruption. Questions to consider and to require supporting documentation for include the following—

- Does the company have established experience in providing this type of service?
- Is the company financially sound, and are its accounts satisfactory?
- Does the company's financial accounting comply with government procedures?
- Does the company have the necessary infrastructure and equipment?
- Are sound management systems in place?
- Are internal quality-control measures in place?
- Does the company manage any other government contracts?
- Does the company's management information system produce useful reports on services provided?
- Does the company have an adequate number of trained staff persons to handle the proposed contract?
- Can the company provide documentation of its performance according to the indicators deemed critical for the type of service?
- Are other clients satisfied with services received?
- Do any conflicts of interest, such as family member associations with key government officials, exist that could compromise the initiative or create public concern?

When a short list of qualified service providers has been prepared, the contract can be formally tendered.

Developing the service contract and managing the tender

After the decision to contract out a service has been reached, tender specifications and provisions of the service contract must be drawn up. The tender documents and provisions of the service contract should clearly specify the duties of both contracting parties. The issues to be covered include—

Scope of the service: This section must include a detailed description of the service required and the anticipated workload. For example, in the case of a transport contract, it should include a full definition of the routes, the delivery points, the delivery schedule, and responsibility for loading and unloading. The contractor must agree to work as part of the national or provincial health system and to be supervised by the relevant authorities.

Performance standards and service quality: This section should define the performance and quality standards that have been set for the service, including matters such as service level, response rates, security measures, documentation, and maintenance standards. The duties of the contractor in maintaining and monitoring quality standards should be defined. Restrictions on assignment of the contractor's duties in the event of a change of ownership must be clearly defined to avoid any potential interference with service during such transitions.

Contract management: This section should define the client's and the contractor's responsibilities for overseeing the contract, assessing and monitoring performance, and reporting and payment procedures. Subcontracting requirements or prohibitions should be defined clearly.

Staffing: The contract may specify the qualifications and skills required for key positions needed to manage the contract and how many workers should be assigned to the contract, although the contractor usually has total responsibility for the selection, discipline, and termination of staff. The contract terms should specify how issues such as staffing increases, overtime, working on holidays, and so on will be addressed. In some service contracts, contractors may try to cut costs by paying very low wages. This practice contributes to high staff turnover and poor service. If minimum wage legislation is in force, the contractor should be required to conform to it.

Staff qualifications: Where appropriate, staff qualifications and in-service training requirements should be specified.

Property rights over equipment: In cases in which the contractor takes over the service from the government, existing buildings, equipment, or vehicles may be used by the contractor. The contract should clearly define the ownership and disposal procedures for these assets. A detailed inventory should be attached to the contract describing the assets and their age, condition, and value at transfer. If the property is to be sold to the contractor, terms of reimbursement must be negotiated.

Payment terms: This section should define how payments are to be calculated and when they are to be made. If payments are linked to the exchange rate (or another index), the calculation method should be clearly defined. Generally, payment is made after a unit of service has been completed. This practice provides an incentive for the contractor and protects the government against the contractor's failure to perform. Payment in advance (for

example, monthly or quarterly), based on estimated costs, is sometimes acceptable, however, especially when the contractor is a nonprofit organization. Four main payment mechanisms are used for nonsupply contracts—

1. *Cost reimbursement contracts* provide for payment of incurred costs, to the extent described in the contract, in addition to a set fee for the service.
2. *Fixed-price contracts* establish a fixed price for the entire contract. Such an approach may work for the service component of a central medical stores management contract, where medicines and supplies are paid for separately, but not for more variable services such as transport.
3. *Percentage-of-turnover contracts* pay on the basis of a fixed percentage of turnover (for example, a percentage of the value of medicines managed or transported).
4. *Cost per quantity contracts* pay on the basis of some measure of the quantity of medicines handled (for example, pharmaceutical transport may be charged per metric ton per kilometer or per cubic meter per kilometer).

Accounts and reports: The contract should define the reports necessary for effective management of the contract. These might include monthly accounting reports and reports of monthly deliveries.

Budget: The budget submitted by the contractor should be attached to the contract. It will help in the monitoring and auditing of the contract account and in budget planning.

Contract duration: The contract start and completion dates should be specified.

Contract review procedures: Contracts may specify a formal mid-contract period review, to allow problems to be overcome and procedures to be changed by mutual agreement. The health system should in any case review contract performance regularly.

Grounds for contract termination: The grounds and procedures for contract termination by either party must be clearly specified. These grounds should be fair to both parties and defensible in court in the event of a dispute.

Penalties for noncompliance with the contract: These penalties should be clearly defined. For example, the contractor could be penalized for late delivery or loss of pharmaceuticals in transit. The government could be made liable for interest charges in the event of late payments.

Health system indemnity: The contract should indemnify the health system against any claims arising from delayed deliveries, injury to patients or staff of the system or the contractor, drug reactions, product defects, and similar problems caused by the contractor's negligence or inefficiency.

Insurance: The buyer's and the contractor's respective insurance obligations under the contract should be clearly defined. Items to be considered include fire and theft insurance and employer and public liability insurance.

Notices and communication: Procedures for communicating under the terms of the contract should be defined. Generally, all communication should be in writing.

Conducting and adjudicating the tender

The steps for conducting a tender for services are similar to those in [Chapter 21](#) (for pharmaceuticals and supplies) and [Chapter 42](#) (for construction). The procedure for evaluating tenders should be outlined, made known to prospective service providers in advance, and then used to assess the prequalification requirements of providers. The key is to have a transparent process that is free from influence by special interests and to use written criteria to evaluate bids and select the contractor.

Monitoring the contract

After the contract has been awarded, it must be monitored to ensure that both parties comply with its terms and conditions. A contract monitoring office should be designated or set up to perform this task. The cost of running this office should be taken into account as part of the financial evaluation. The duties of the contract monitoring office include—

- Monitoring health system compliance with the contract conditions and correcting any health system performance defects that prevent the contractor from fulfilling the specified duties
- Monitoring the contractor's services to ensure that the standards specified in the contract are maintained and invoking penalty clauses if the contractor fails to achieve the required standards of performance
- Monitoring clients' satisfaction—for example, receiving stores should submit regular reports indicating whether the contractor delivers on time, listing any missing or damaged goods, and documenting other quality-control and service problems (the contractor should be informed whenever problems occur)
- Responding to all complaints and initiating any required investigations or interventions
- Monitoring the contractor's activity reports
- Checking the contractor's invoices and certifying payments due under the contract
- Preparing an assessment of the contractor's overall performance before the contract is reviewed or renewed
- Communicating appropriately—internally and publicly—during the execution of the contract ■

ASSESSMENT GUIDE

Criteria for evaluating the success of a contract—

- What is the purpose of this contract? Are any documents attached that justify the decision to contract? Was an assessment made of in-house costs for the contracted service?
- What types of services or goods are being contracted? Are they nonclinical (storage, transport, food, linen, laundry, or catering services) or clinical (medicines, immunization patrols, anesthetic services)?
- Who prepared the terms of the contract?
- Does the contract comply with applicable legislation?
- Who signed the contract? At what level was it tendered and signed (national, provincial, district, or local)?
- How were tenderers selected? How was the contract tendered? How many bids were submitted?
- How did bids compare with pre-tender estimates? How did the lowest bid compare with the assessment of in-house costs?
- Are required performance and quality standards and indicators defined? Are they sufficiently precise?
- Are payment terms clearly defined? Are they sufficiently precise?
- Is the contractor paid on time?
- What is the length of the contract period? Is it too short, too long, or indefinite?
- Is the contractor meeting contract standards? What are the penalties for performance failure? Have they been invoked? If yes, why?
- Has this contract been renewed? If yes, by whom and why?
- Has the contract been terminated? If yes, by whom and why?
- What is the cost of the contract? Are there any budget implications? What contract terms ensure accountability for the funds paid to the provider?
- Who monitors the contract? Is the provider required to submit any reports (accounting, productivity, and so forth)? Is the monitor required to prepare reports? Could any of these reports be located?

Annex 39-1 Sample conditions of bid document from Papua New Guinea

1 INTERPRETATION

1.1 Definitions

In these Conditions of Bid, unless a contrary intention appears:

“Acceptable [Country] Bank” means any of [Country] bank, which the Purchaser, at the request of the Bidder, has, prior to the Closing Date, advised the Bidder in writing is acceptable to the Purchaser.

“Acceptance Date” means approximately three weeks after the Closing Date or such earlier date not prior to the Closing Date as the Purchaser may in its sole discretion determine.

“Accounts” means profit and loss accounts and balance sheets together with statements, reports and notes, including a director’s report or an auditor’s report, attached to or intended to be read with any of those profit and loss accounts or balance sheets.

“Anticipated Delivery Dates” means the dates completed by the Bidder for each of the shipments specified in the Form of Bid.

“Currency nominated” means the lawful currency of [the Country].

“Bid” means the offer to sell made by each Bidder in accordance with the provisions of these Bidding Documents.

“Bid Bond” means a banker’s undertaking or bank guarantee which is:

- a. issued in favor of the Purchaser by an Acceptable [Country] Bank;
- b. for an amount denominated in [country currency] equal to 2.5 percent of the Bid Price;
- c. not expressed to expire on a date earlier than 55 days after the Closing Date; and
- d. in the form of the Bid Bond Proforma or in such other form as the Bidder has submitted to the Purchaser and the Purchaser has approved before the Bidder has submitted the completed Bid Documents to the Purchaser.

“Bid Bond Proforma” means the document contained in relevant schedule.

“Bidder” means the company submitting the bid as noted in the Form of Bid.

“Bidding Documents” means all of the documents of which these Conditions forms part inclusive of the Invitation to Bid at the commencement of these documents, these Conditions and all Schedules.

“Bid Documents” means the Form of Bid as completed by a Bidder, together with all attachments as required by the terms of the Form of Bid, including the Bid Bond and the Bid Price Schedule.

“Bid Price” means the amount tendered a Bidder as per the bid terms specified (i.e., FOB, CIF, etc.)

“Bid Price Schedule” means the document contained in Schedule 2 in which the Bidder has completed in respect of each Pharmaceutical, with details of the country of origin and the Delivery Price.

“Box” means a container containing multiple Packages, which must comply with the Box Specification.

“Box Specification” means a Box that complies with the following:

- a. the Box must
 - i. be of appropriate strength and porosity and packed in such a way as to protect the Pharmaceuticals that a Box contains from damage or deterioration from rough handling in transit to or storage in the Warehouse (where humidity may be between 75 percent and 100 percent and temperatures may be between 25°C and 35°C), and distribution from the Warehouse by sea, air, or land to remote destinations within the country of purchase;
 - ii. have sides of at least 275 gsm and top/bottom of at least 150 gsm (or as appropriate and to be completed by the buyer);
 - iii. be of a thickness of at least 7 mm (or as appropriate and to be completed by the buyer).
- b. each Box is sealed in such a way that any tampering with the Box prior to it being opened will be easily detectable;
- c. each Box must not exceed 25 kg in weight (or as appropriate and to be completed by the buyer);
- d. each Box is clearly labeled or marked in a prominent place:
 - i. with the words “Department of Health of [Country]”;
 - ii. with the earliest expiry date of any Pharmaceutical that the Box contains.

“Business Day” means any day that is not a Saturday, Sunday, public or bank holiday in the [country of purchase].

“Closing Date” means (buyer to indicate date).

“Competent Authority” of a country means the national authority as identified in the formal letter of acceptance in which that country informs WHO of its intention to participate in the Scheme.

“Conditions” or “Conditions of Bid” means the terms and conditions on which the Invitation to Bid is made comprising these conditions and all of the Schedules.

“Contract Date” means the date of the Notification of Acceptance.

“Contract Price” means the Bid Price set out in the Form of Bid submitted by the successful Bidder to whom the Purchaser gives Notification of Acceptance.

"Delivery Price" means in respect of each Pharmaceutical the amount completed in (relevant column) in the Bid Price Schedule by the Bidder as being the total price required by the Bidder to be paid by the Purchaser for the supply and delivery of the particular Pharmaceutical to the Warehouse.

"Dispensing Unit" means the smallest package or container in which a Pharmaceutical will be supplied by a Bidder (for example, this might consist of a bottle, a plastic container, a grouping of tablets or capsules in a press-out card, a bag, or some other distinct container).

"Form of Bid" means the document set out in appropriate schedule.

"Invitation to Bid" means the page that is headed "Invitation to Bid" located at the commencement of the Bidding Documents.

"Item" means an item of particulars in the Appendix to the Form of Bid.

"Notification of Acceptance" means notice of acceptance of the Bid substantially completed by the Purchaser in accordance with the relevant clause of the Conditions.

"Package" means any parceling together of Dispensing Units of a particular Pharmaceutical.

"Packaging" means the material in which Pharmaceuticals are packed for delivery to the Warehouse, including any material that protects against rough handling, humidity or temperature, the Packages or the Boxes (other than the actual Pharmaceuticals they contain), any tape or other substance used to seal the Boxes, and any other fastenings used to secure each Box.

"Performance Bond" means a banker's undertaking or bank guarantee that is:

- a. issued in favor of the Purchaser by an Acceptable [Country] Bank;
- b. for an amount denominated in (currency specified) equal to 10 percent of the Contract Price;
- c. not expressed to expire on a date earlier than 33 weeks (or as specified) after the Contract Date; and
- d. in the form of the Performance Bond Proforma or in such other form as the Purchaser may in its sole discretion approve.

"Performance Bond Proforma" means the document contained in the Bid Document.

"Pharmaceutical" means any one of the items described in the relevant column in the Bid Price Schedule.

"Product Certificate" means in respect of a Pharmaceutical the "Certificate of a Pharmaceutical Product," conforming to the format required by WHO, that is validated and issued for that Pharmaceutical by the Competent Authority of the country in which the Pharmaceutical is manufactured.

"Product Information" means in respect of a Pharmaceutical the product information submitted to a Competent Authority in support of an application for a Product Certificate and that normally consists of information for health professionals and the public (patient information leaflets) as approved in the exporting country and, when available, a data sheet or summary of product characteristics approved by the Competent Authority.

"Product License" means in respect of a Pharmaceutical an official document issued by a competent drug regulatory authority of a country for the marketing or free distribution of that Pharmaceutical and that contains the following:

- a. the name of the product (i.e., pharmaceutical);
- b. the pharmaceutical dosage form;
- c. the quantitative formula (including excipients) per unit dose (using international non-proprietary names where they exist);
- d. the shelf life;
- e. storage conditions;
- f. packaging characteristics;
- g. all information approved for health professionals and the public (except promotional information);
- h. the sales category;
- i. the name and address of the license holder; and
- j. the period of validity of the license.

"Purchaser" (indicate purchasing agency).

"Representative" of a person means an officer, employee, contractor, or agent of that person.

"Scheme" means the WHO Certification Scheme on the Quality of Pharmaceutical Products moving in International Commerce as recommended initially at the Twenty-Second World Health Assembly, in resolution WHA 22.56.

"Statement of Licensing Status" means in respect of a Pharmaceutical a statement in the format recommended by WHO issued by the Competent Authority of the country from which the Pharmaceutical is exported that the Pharmaceutical is licensed for use in the exporting country, which statement must include (where issued) the number and the date of issue of the Product License of the Pharmaceutical.

"Supply Contract" means the contract format contained in bid document.

"Warehouse" means the warehouse located at (indicate location).

"WHO" means the World Health Organization.

Annex 39-2 Sample pharmaceutical supply contract

Period of contract. One year.

Trade terms. Prices are CIF or CPT "Warehouse Port, Seatown" unless otherwise specified; however, the invitation to tender requires that cost, insurance, and freight charges be listed separately, along with the total CIF price. The contractor is the sole source of supply for the duration of the contract.

Purchase order. This is issued if there is an uncommitted balance in the country's pharmaceutical account.

Assignment. The contractor shall not bargain, sell, sublet, or dispose of the contract without previous consent of the buyer.

Prices. The contract price is the maximum price of the item packaged and delivered for the duration of this contract and payable in U.S. dollars.

Payment. Payment will be made by irrevocable confirmed letter of credit payable after forty-two days. All shipments will be inspected by an international inspection agency, and letter of credit is payable subject to submission of a clean report of findings.

Quality. All the products on this contract must: (1) meet the requirement of manufacturing legislation in the country of origin and be approved for use in that country; (2) be of USP or BP standard; (3) contain a lot or batch number and expiry date on the label of every dispensing unit; (4) be certified in accordance with the WHO Certification Scheme for Pharmaceuticals Moving in International Commerce (WHO Resolution 28.65B). This certificate should be issued by the health authorities of the country of original manufacture. Certificates of analysis shall be provided within one month of request for microbiological and pharmacological tests. Tests for each batch actually shipped should be sent as well and should reach this office before final arrival of the goods. Samples must be submitted in the case of a new supplier or new tendered item, product with changed presentation or formulation, or upon request by the buyer.

Labeling. Labels should be in English. All internal and external containers should be labeled with the INN for the active ingredient and should contain at least the following additional information: quantity of active ingredient, dosage form, number of units per pack, batch number, date of manufacture, expiry date, pharmacopoeial standard, instructions for storage, name and address of manufacturer, directions for use.

Specifications. Supplies should conform to the specifications indicated in the tender document. No alterations, unless confirmed in writing, are acceptable.

Cold storage. Items requiring cool storage and transport (for example, vaccines) should be shipped by air with proper insulating packing, ensuring product remains below 8°C for at least forty-eight hours. A written pre-advice with exact shipment details should be sent at least five days before the actual arrival of the consignment.

Performance bond. The successful tenderer may be called upon, within one week after acceptance of the tender, to deposit

with the buyer an amount equal to 2.5 percent of the total value of the contract. This amount will be forfeited if the contract is not completed within the time limit and to the satisfaction of this office.

Default. Should the supplier fail to—

- deliver the supplies by the specified date or to the specified port; or
- replace, within one month, any rejected supplies; or
- comply with each and every other condition of this contract;

the government may do any or all of the following—

- after notice to the supplier, nullify this contract without compensation and obtain needed supplies from other suitable sources;
- recover from the supplier any losses sustained by this office resulting from supplier's failures;
- delist the supplier from the "preferred list of suppliers."

Delivery. Shipment shall be made as specified in the invitation to tender, unless an alternative delivery date has been agreed upon in writing. For each consignment the supplier shall send a shipment advice, clearly indicating date of shipment, name of the vessel, and estimated time of arrival in "Port Seatown." No purchase order shall be completed by more than two (2) partial shipments. Payments for goods requested shall be made when total order is received in the purchasing country.

Indemnity. The supplier shall indemnify this government against all claims and shall bear the costs of defending such claims that are related to patent rights, trademarks, designs, and royalties.

Packaging. Supplies must be packed in immediate and external export containers, suitable to withstand rough handling in transit and storage under tropical conditions where humidity may be between 75 and 100 percent and temperatures between 25 and 30°C. On arrival at their ultimate destination, supplies should be free from damage. Containers should be sealed in a manner that makes tampering with the pack during transit easily detectable. The supplier shall be liable for all losses, damage, or expense due to insufficient or unsuitable packing. A clear packing list should be sent for all consignments, showing the individual content and including expiry dates of each carton.

Expiry date. Unless otherwise specified, all items should have at least two years and/or 75 percent of their shelf life remaining from the date supplies are received by this office. Expiry dates should be clearly stated on all internal and external containers.

Unique identifiers. All immediate and external containers should bear the words Ministry of Health together with the WHO logo. Application for exemption from this requirement should be made at the time offers are submitted.

Import documents. The supplier is responsible for providing this office with all documents necessary for taking possession of supplies and clearing them. The supplier shall be held responsible for any expenses or losses incurred by incorrect, incomplete, or late provision of documents.

SUMMARY

This chapter focuses on identifying and controlling excess costs in the selection, procurement, distribution, and use of medicines. Several analytical tools are presented that help managers quantify costs and identify areas where costs can be reduced; the information provided is also essential in designing and monitoring interventions to control costs.

Total cost analysis compiles information on variable costs associated with purchasing and inventory management to help managers consider options for change in terms of their impact on total costs. It is a key tool for pharmaceutical system assessments. The other analytical tools discussed in this chapter may be used as part of a total cost analysis, or they may be used individually for special purposes.

The VEN system categorizes pharmaceuticals by their relative public health value. It is useful in setting purchasing priorities, determining safety stock levels and pharmaceutical sales prices, and directing staff activities. The categories in the original system are vital (V), essential (E), and nonessential (N) (sometimes called VED—vital, essential, and desirable). Some health systems find a two-category system more useful than the three-tiered VEN; for example, the categories might be V and N, differentiating between those medicines that must always be in stock and other medicines.

ABC analysis examines the annual consumption of medicines and expenditures for procurement by dividing the medicines consumed into three categories. Class A includes 10 to 20 percent of items, which account for 75 to 80 percent of expenditures. Class B items represent 10 to 20 percent of items and 15 to 20 percent of expenditures. Class C items are 60 to 80 percent of items but only about 5 to 10 percent of expenditures. ABC analysis can be used to—

- Measure the degree to which actual consumption reflects public health needs and morbidity
- Reduce inventory levels and costs by arranging for

more frequent purchase or delivery of smaller quantities of class A items

- Seek major cost reductions by finding lower prices on class A items, where savings will be more noticeable
- Assign import and inventory control staff to ensure that large orders of class A items are handled expeditiously

Therapeutic category analysis considers the use and financial impact of various therapeutic categories of medicines and then compares cost and therapeutic benefit to select the most cost-effective medicines in each major therapeutic category. This analysis can be done to select medicines for a formulary or procurement list.

Price comparison analysis compares pharmaceutical prices paid by different supply systems as one measure of procurement efficiency. The analysis can also compare supply system acquisition and selling prices with local private-sector prices to gauge the cost-effectiveness of in-house pharmaceutical services and to assess price elasticity for cost recovery.

Lead-time analysis is a systematic approach to tracking procurement lead times, determining the points at which lead time can be reduced, and adjusting safety stock appropriately. Payment time should also be analyzed (when delayed payment to suppliers is feasible).

Expiry-date analysis examines levels of stock on hand and their expiry dates and compares this information with average rates of consumption to assess the likelihood of wastage (and to develop appropriate countermeasures).

Hidden-cost analysis examines supplier performance to identify any hidden costs incurred because of problems such as late deliveries and short shipments. Hidden costs may make one supplier considerably more expensive than a competitor that offers a higher unit price but better performance.

40.1 Tools for analyzing costs

The two largest centers of recurrent costs in most public pharmaceutical systems are personnel expenses and pharmaceutical purchases. Controlling personnel costs usually means reducing staff, which may be politically difficult. However, policies may be reformed so that the pharmaceutical supply system does not employ extra staff members

who contribute to lowered productivity and increased losses from wastage and theft.

This chapter concentrates on techniques for analyzing costs in the pharmaceutical supply system so that managers can identify major costs, losses, and opportunities for savings. All these techniques have been cited in earlier chapters. Here, the focus is on how to perform each analysis and how to use the results. The techniques considered are—

- Total cost analysis
- VEN system
- ABC analysis
- Therapeutic category analysis
- Price comparison analysis
- Lead-time and payment-time analysis
- Expiry-date analysis
- Hidden-cost analysis

Although these analyses can be carried out manually, the process is very time consuming, except in small supply systems that use relatively few pharmaceutical products. Using a computer to perform these analyses is much easier. Expensive computers and customized software are not required—all the analyses in this chapter can be done with commercial spreadsheet software.

40.2 Total cost analysis

In pharmaceutical supply systems, the total cost of operating the supply system is the sum of pharmaceutical purchase cost, inventory-holding cost, ordering cost, and shortage cost. Total cost analysis compiles the values of these various costs on one data sheet. The manager's objective is to identify strategies that will minimize the total cost. If an intervention will reduce ordering costs but drive up inventory-holding costs by an amount that produces a net increase in the total cost, it is not worthwhile. Alternatively, a strategy to increase ordering frequency might drive up the costs associated with purchasing, but the net savings in inventory-holding costs might be far greater than the incremental purchasing cost.

Analyzing and controlling costs

Total cost analysis has two basic applications: (1) analyzing current costs to find opportunities for cost reduction and (2) modeling the cost impact of potential changes in the supply system.

Table 40-1 shows a summary sheet for a total cost analysis. In the table, costs and inventory are shown for an illustrative warehouse and purchasing office in a Latin American country. Inventory and costs are found at all levels of the system; in a supply system with several regional warehouses, the inventory (and associated costs) may be considerably higher in the aggregate at the regional level than at the central warehouse. This result is also true for supply systems in which health facilities hold significant quantities of stock. For the most complete picture, total costs should be calculated for each significant level of the supply system; however, for simplicity's sake, this example focuses on one central warehouse.

The manager's objective is to identify apparently excessive costs in one or more cost categories and then to devise strat-

egies to minimize the total cost. A review of the compiled data in Table 40-1 might yield several ideas for reducing costs—

- Reduce the average inventory from the current five months of stock (which would reduce holding costs) by more frequent ordering.
- Reduce the cost of pharmaceutical purchases through more efficient tendering, potentially adding therapeutic subcategory tendering.
- Cut down on losses.
- Consider whether the number of employees (and salary costs) can be reduced without harming efficiency.
- Cut down on emergency purchases through better stock management.

Meeting any of these objectives would require trade-offs—when one cost component is reduced, another is likely to increase. For example, suppose that a country has the total cost profile in Table 40-1 and uses annual purchasing almost exclusively. Changing the purchasing system from an annual system to a combination of annual and biannual tenders (see Figure 23-4, in Chapter 23) might possibly reduce the average inventory value by half, but result in two annual tenders, thereby increasing the costs related to purchasing.

Holding costs and purchasing costs basically oppose each other. Frequent ordering in small quantities drives up the average cost of placing an order (or managing a tender), because the procurement and accounting offices must go through all the steps on multiple occasions. However, more frequent orders should reduce average stock levels and thus reduce holding costs. Annual ordering in large quantities tends to increase the average inventory level and holding costs but decreases the average annual ordering costs.

Usually an inverse relationship exists between shortage costs and holding costs. The shortage costs in a supply system are likely to be low when stock levels (and holding costs) are high, and vice versa.

Using the data from Table 40-1, one can model the effects of switching from an annual to a biannual tender. For example, pharmaceutical acquisition costs are projected to be the same as they were in Table 40-1. Average inventory value decreases by half to 2.9 million U.S. dollars (USD), with an associated decrease in some incremental holding costs: opportunity cost down to USD 290,000; losses down to USD 370,000. This decrease suggests a net savings of USD 660,000 in holding costs, but what are the likely increased costs? Assuming that the additional tender can be managed by existing staff, the additional purchasing costs should be limited to increases in supplies, communications, and other tendering costs. Assuming that these costs double (in the worst case), the extra incremental purchasing costs would be USD 117,000, resulting in a net savings of USD 443,000.

40.4 PLANNING AND ADMINISTRATION

Table 40-1 Total cost analysis summary

Cost category	Total (USD)	Incremental (USD)	Predictable (USD)
Pharmaceutical acquisition costs			
(Includes supplier shipping charges and duty)	14,000,000	14,000,000	
Inventory-holding costs			
Average inventory, central warehouse (beginning value plus year-end value, divided by two)	5,800,000	5,800,000	
Financial opportunity cost (10% average interest rate)	580,000	580,000	
<i>Losses from inventory</i>			
Expiry	69,000	69,000	
Spoilage/wastage	18,000	18,000	
Loss during repacking	200	200	
Short shipments from suppliers	500	500	
Obsolete medicines—no longer used	12,000	12,000	
Unexplained losses	640,000	640,000	
Subtotal	739,700	739,700	
<i>Operating costs—storage and stock management</i>			
Salaries	665,000		665,000
Space and utilities	117,000		117,000
Communications	4,000		4,000
Supplies	650,000	650,000	
Other direct costs	3,700		3,700
Depreciation	46,900		46,900
Administrative overhead	NA	NA	NA
Subtotal	1,486,600	650,000	836,600
<i>Transport costs—to operating units</i>			
Salaries	115,000		115,000
Supplies (gas, etc.)	112,000	112,000	
Other direct costs	700	700	
Depreciation	8,100		8,100
Administrative overhead	NA	NA	NA
Subtotal	235,800	112,700	123,100
Total holding cost	3,042,100	2,082,400	959,700
Holding cost as percentage of average inventory	52%		
Percentage incremental and predictable		68%	32%
Purchasing costs			
Salaries	72,000		72,000
Space and utilities	11,000		11,000
Communications	2,000		2,000
Supplies	70,000		70,000
Other direct costs	400		400
Depreciation	5,000		5,000
Administrative overhead	NA	NA	NA
Subtotal	160,400		160,400
Total additional costs of annual tender	45,000		45,000
Total purchasing cost	205,400		205,400
Shortage costs			
(Estimate 20% emergency purchases at 20% premium)	560,000	560,000	
Total cost	17,807,500	16,642,400	1,165,100
Percentage incremental and predictable		93%	7%

Note: Data are based on a composite from Latin America and do not represent any specific country. NA = not applicable; USD = U.S. dollars.

Of course, the increases would largely be in visible expenditures, and the decreases would be in hidden costs, but a real net savings to the system would occur.

Modeling the effect of alternatives for changing the supply system

Suppose that the supply system is considering three options for warehousing and distribution in the future: (1) keeping all services in-house (the current system); (2) keeping warehousing in-house but contracting out transport; and (3) contracting out both warehousing and distribution. Each of the possible new models implies significant changes in personnel needs and operating costs at the various levels of the supply system. Total cost analysis provides a convenient format to project how the supply system's operating costs would change with each option.

The basic steps in total cost modeling are the same, whatever the options being considered. The total cost is compiled for the most recent year for which data are available (as illustrated in Table 40-1), for one or several levels of the supply system, and adjusted for inflation and expected changes in use, to estimate the total cost with the current system in the year or years in which change would be implemented. Then, for each of the alternate supply system models, the percentage increase or decrease for each major total cost component is estimated and applied to the baseline cost, again adjusting for inflation and changes in use in subsequent years.

The resulting models are not exact but do predict the relative cost effect of the alternatives being considered. Sometimes the exercise identifies viable interventions that had not been previously considered. For example, in one Latin American country a total cost-modeling exercise showed that total costs could be reduced by consolidating storage at the regional level and privatizing transport and that still greater savings could be gained by contracting out for all warehousing and transport (assuming that the system could be managed). However, the models also showed that a far greater savings in total cost could result from improved medicine selection—if it produced only a 10 percent reduction in pharmaceutical acquisition costs—than could be achieved even by closing all warehouses and contracting out all storage and distribution functions.

The typical annual inventory-holding cost for a commercial firm is no more than 25 to 35 percent of the average inventory value, but the percentage could be much higher for a public pharmaceutical supply program. For example, during a multicountry assessment of inventory management practices in the Caribbean region, one country was found to have an *average* inventory of twelve months' consumption. The manager of this supply system was very proud of his stock levels, saying that he had no problem with stockouts. Of course, he had not given adequate consideration to the costs of holding inventory, which in this

case equaled half the entire annual pharmaceutical purchasing budget.

Costs may be either predictable or incremental. If the cost remains the same no matter how many transactions or how much inventory is involved, it is a predictable cost (sometimes called a fixed cost—see Chapter 41). If the cost increases directly with the number of purchases or volume of inventory, it is an incremental cost. In most accounting systems, incremental costs are termed variable costs, but for this analysis, all the costs are variable. By their nature, pharmaceutical acquisition costs, many inventory-holding costs, and shortage costs are incremental; most purchasing costs tend to be predictable, but they are likely to have incremental components. Although the difference between predictable and incremental costs can be important, most data from developing countries are insufficient to differentiate between the two. In these cases, the focus should be on identifying and addressing the major overall contributors to excessive costs, whether they are predictable or incremental.

Compiling the total cost

Many of the costs discussed in this section are visible, in that they are actual budget expenditures; others are hidden, in that the costs are not expenditures but represent reductions in available resources. Managers should understand that both visible and hidden costs are real.

In most supply systems, data gaps make assembling all this information difficult, but the effort should yield a real understanding of where expenses are concentrated and what sorts of interventions may yield substantial cost savings.

The total cost is made up of four components, which are compiled in one table—

- Pharmaceutical acquisition costs (totally incremental)
- Inventory-holding costs (predictable and incremental)
- Purchasing costs (predictable and incremental)
- Shortage costs (primarily incremental)

Pharmaceutical acquisition costs. These costs are the net cost of all pharmaceutical purchases, including shipping and insurance charges from the manufacturer and any duty or customs fees. They are an incremental cost. Data can be obtained from purchasing records, stock records, or supplier invoices.

Inventory-holding costs. The inventory-holding cost has several subcomponents, some of which are incremental and some of which are predictable.

The first entry under “inventory-holding costs” in Table 40-1 is the average inventory value (which is used to calculate the percentage of holding costs). The standard basis for valuing inventory is the original net purchase cost rather than the selling price. Four standard methods can be used for determining the original purchase cost for all items in

inventory: actual value, first-in/first-out (FIFO), last-in/first-out (LIFO), and average value. As discussed in [Chapter 41](#), most pharmaceutical supply systems are unable to accurately track actual value and should use either the average value or the FIFO method.

The key is that the method, once chosen, needs to be applied consistently from one financial year to the next; otherwise, year-to-year comparisons of holding costs and financial performance may be invalid.

The standard components of the inventory-holding cost are the following—

Financial opportunity cost is incremental and varies with the average inventory value; it is obtained by multiplying the average inventory value by the average interest rate paid on money-market accounts in local banks (or sometimes by the average interest rate charged for short-term loans).

Loss from inventory is often an incremental cost, in that losses rise as inventory values increase. The amounts may be broken down as shown in [Table 40-1](#), to the extent that data are available from inventory records. If data are not available, estimate losses as a percentage of the average inventory value, based on local expert opinion.

Deterioration and spoilage costs for medicines are more likely to occur with poor storekeeping practices, but some risk exists in all warehouses. In general, these costs are incremental—the higher the stock levels, the higher the costs of spoilage.

Expiry costs are often 3 to 5 percent of pharmaceutical inventory each year. If this ratio holds, the costs are incremental as inventory value increases. High expiry costs are a reflection of poor inventory control and storekeeping.

Obsolescence costs apply principally to equipment and spare parts, but changes in formulary lists and prescribing practices may make certain medicines obsolete. These may be viewed as predictable costs; they do not necessarily vary with the inventory size or value.

Wastage costs caused by theft, pilferage, and other unexplained losses add considerably to the cost of carrying inventories. As noted in [Chapter 23](#), losses of 10 percent are not unusual in public pharmaceutical supply systems. These are likely to be incremental costs—the total loss increases as the average inventory rises.

Operating costs for storage and stock management are a mixture of predictable and incremental costs. Salaries (which should include benefits), space costs (rent or building depreciation), utilities, communications, other direct costs, and depreciation of equipment are predictable costs unless additional staff, space, or equipment is added to manage a growing inventory. In such a situation, the added costs are incremental. Supplies are primarily incremental, in that more supplies are used as more stock

is stored and distributed. In some settings, a predictable component of the supplies cost may possibly be determined. Data should be obtained from financial records or budget books or (if necessary) by estimates from local experts. If administrative overhead is charged as a cost by the supply system, it should be added in the appropriate percentage to operating costs here.

Transport costs to operating units include predictable costs (salaries and benefits for transport personnel, depreciation of vehicles) and incremental costs (gasoline, repairs, and travel expenses for transport personnel). Again, if more drivers or vehicles were added to cope with an increased workload, these costs would be incremental.

The total of all these costs is the total inventory-holding cost, showing predictable and incremental components.

Purchasing costs. Purchasing costs (sometimes called reordering costs) are the costs associated with managing tenders, placing purchase orders, and receiving goods. Like inventory-holding costs, purchasing costs have several components. Salaries (including benefits) should include wages for all staff who are involved in managing tenders, ordering medicines, and receiving them. Note that some staff may be attached to the warehouse rather than the purchasing office, but for this purpose, their costs should be attributed to purchasing. If warehouse staff members have multiple responsibilities, including some that are related to purchasing, attribute a portion of their cost to inventory-holding and a portion to purchasing. Utilities and space costs include rent, basic communications, and all utilities for the purchasing office. Supplies include all forms used in tenders and purchase orders (this might be broken down into predictable and incremental components in a perpetual or scheduled purchasing system). Other direct costs include travel costs and maintenance of building and equipment. Depreciation may be calculated on all valuable equipment and on the building if it is owned by the system. Again, if administrative overhead is charged, it should be added using the current percentage. Additional tender costs include costs that are not included in standard purchasing costs but that are associated with the quantification, tendering, and adjudication processes, including travel, per diem, and other costs associated with committee meetings.

In a public pharmaceutical supply system that uses annual or biannual purchasing, most of these purchasing costs can be considered predictable, assuming the existence of a procurement office with permanent staff and office space. In a perpetual system, or a scheduled system with periodic orders, the costs of communications and supplies such as forms are incremental with each order placed.

Data on the individual component costs may be available from financial records or budget books; once the individual component costs (actual or estimated) are obtained and

Box 40-1 Calculations to fill the pharmaceutical inventory pipeline

The length of the pharmaceutical inventory pipeline is measured in numbers of months. It is determined by the number of levels in the distribution system, the safety stock at each level, and the average working stock (which depends on the delivery interval—see Chapter 23). The diameter of the pipeline is determined by the final outflow—the total value of medicines dispensed per month.

The following example illustrates a pipeline calculation to serve a network of 210 community pharmacies. It includes a central supply agency, district stores, and the community pharmacies.

The pipeline for the proposed pharmaceutical sales program begins with the disbursement of funds for procurement and ends at the point where funds are collected and made available for purchasing replenishment supplies. The pipeline can be broken down into a number of segments, described below and illustrated in the accompanying diagram—

Average monthly sales. The number of low-, medium-, and high-volume community pharmacies and the average monthly sale per pharmacy are estimated in the second table.

Funding requirements. With an average pipeline length of sixteen months and an average consumption for all 210 pharmacies of USD 65,000 per month, total funding requirements would be—

$$16 \times \text{USD } 65,000 = \text{USD } 1,040,000$$

Sources of funding and possible cost savings. Funding can be supplied from various sources: donations could finance the purchase pipeline and safety stock, government allocations could finance the working stock for central and district levels, and community fund-raising efforts could finance the community pharmacy funds. Improved procurement payment terms, more rapid flow of pharmaceuticals through the system (faster turnover), and more efficient bank transfers could shorten the pipeline and reduce funding costs.

Cash and medicines in the pipeline	Months
Purchase pipeline. In this example, about 50 percent of medicines are assumed to be purchased from international sources and 50 percent from local sources. For international purchases, an average of six months will elapse between the provision of a letter of credit and the receipt of the pharmaceuticals at the central supply agency. For domestic purchases, payment will be made upon receipt. Therefore, the average purchase pipeline will be three months.	3
Central supply agency safety stock. A three-month safety stock will be maintained at the central supply agency.	3
Central supply agency working stock. The supply agency will tender once a year but will receive deliveries every four months. This strategy implies a maximum working stock of four months and an average working stock of two months.	2
District safety stock. The district medical stores of the supply agency will maintain a two-month safety stock.	2
District working stock. The district medical stores will receive shipments from the central supply agency every two months, implying a maximum working stock of two months and an average working stock of one month.	1
Community pharmacy safety stock. The community pharmacies will maintain a one-month safety stock.	1
Community pharmacy working stock. The community pharmacies will be resupplied once a month, implying a maximum working stock of one month and an average working stock of half a month.	0.5
Community pharmacy cash on hand. The community pharmacies will use their revenues once a month when they purchase their resupplies from the district medical stores. On average, these funds will have been held half a month by the community pharmacies.	0.5
District to center cash transfer. Money received by the district medical stores will be deposited within the week at the local branch of the national bank. On average, this money will take one month to be credited to the account of the supply agency.	1
Cash on hand. In general, purchases made by the supply agency will represent one-third of its annual turnover. As a result, money will sit in the agency's central account up to four months, or an average of two months, before being used to effect a purchase.	2
Total pipeline	16

	Low volume	Medium volume	High volume	Total
Number of community pharmacies	150	50	10	210
Average number of patients per month per pharmacy	500	1,250	2,500	NA
Average cost per pharmaceutical item (USD)	0.20	0.20	0.20	NA
Average items per patient	2	2	2	NA
Average monthly sales per pharmacy (USD)	200	500	1,000	NA
Total monthly sales (pharmaceutical cost; USD)	30,000	25,000	10,000	65,000

Note: NA = not applicable.

recorded, they are summed to produce the total purchasing cost.

Shortage costs. Four potential kinds of shortage or stock-out costs exist: excess cost of emergency purchases, loss of revenue when clients purchase outside the system, increased morbidity and mortality caused by stockouts, and loss of goodwill caused by erosion of confidence in the system. Only the first two can be realistically quantified for a public pharmaceutical supply system.

If good procurement records for both regular and emergency purchases are available, the actual cost of emergency purchases can be calculated by recording the difference between the emergency cost and the regular cost per unit or package and multiplying by the quantity purchased for each emergency purchase. If data are not available for all emergency purchases, a sample may be used to estimate the average percentage price difference and the percentage of purchases attributable to emergency purchases (as was done in [Table 40-1](#)).

If the supply system sells medicines from one level to another, itemized data on actual purchases outside the system may be obtained for items that would normally be purchased inside. An estimate can be made for the value of such purchases based on the breakdown between purchases inside and outside the supply system.

Calculating the total cost. The total cost is calculated as the sum of the subtotals for each component. In [Table 40-1](#), the costs total USD 17.8 million. The major component is pharmaceutical acquisition, but holding costs and shortage costs are significant factors; purchasing costs are the lowest component. As discussed earlier, the inventory-holding costs are mostly incremental, and the purchasing costs are mostly predictable.

Structure of the inventory pipeline. To compile a total cost analysis, one must consider the structure of the supply system to determine where costs are incurred. As discussed in [Chapter 22](#), the inventory management system is similar to a pipeline, with warehouses and health facilities that function as reservoirs where stock is held. To ensure a continuous supply of medicines to patients, the pipeline must be filled; once filled, consumption must be matched by purchases. [Box 40-1](#) illustrates the calculations used to determine pipeline funding and expenditures.

One of the single-most important decisions in terms of cost and efficiency of the distribution system is the number of storage levels in the system. [Chapter 22](#) discusses options for selecting the best structure and considering setup, operating, and inventory-holding costs.

Generally, more levels in the supply system create higher inventory levels and inventory costs, but the increase is not

Country Study 40-1

Analyzing pharmaceutical supply system total costs and options in Costa Rica

In Costa Rica, the health care services of almost 90 percent of the population are covered under the government's social insurance scheme, the Costa Rica Social Security Fund (CCSS). As part of a health-sector reform project, the CCSS board of directors expressed an interest in addressing issues related to medicine stockouts and a large increase in warehouse costs. Management Sciences for Health (MSH) conducted an assessment of the CCSS distribution system to analyze pharmaceutical supply system costs and identify intervention options to reduce costs through improved efficiency.

The analysis showed the following annual costs in the CCSS system—

- Warehouse operations (USD 2.1 million)
- Lease for one regional warehouse (USD 3.6 million)
- Inventory losses (USD 779,000)
- Financial opportunity cost (USD 7.3 million)

By sector within the distribution system, 58 percent of the costs were associated with the main CCSS warehouse, 41 percent of the costs with system pharmacies, and 1 percent of the costs with the regional warehouses.

MSH analyzed four options to address the issues related to warehouse and distribution costs: (1) strengthening the current system; (2) implementing a direct delivery system, where the pharmaceutical supplier would be responsible for storage and distribution; (3) implementing a primary distributor system, which would outsource supply logistics; or (4) implementing a mixed system that combines elements of basic models.

As a result of the analysis and recommendations, the government instituted—

- Renewable contracts to reduce the number of pharmaceutical tenders
- An open contract with preselected suppliers to procure emergency supplies
- Direct delivery of large-volume parenterals
- Procurement of slow-moving items (orthopedic supplies) on a consignment basis

The CCSS is also using the postal service to deliver some medicines to patients more efficiently.

always directly proportional. Ordering frequency, average supplier lead time, and policies for safety stock have a major effect on inventory levels. As shown in Figure 22-4, in Chapter 22, a supply system with three levels (regional stores, district stores, and health facilities) might have three times the inventory of a two-level system (district stores and health facilities). However, depending on the inventory management system's operating efficiency, the differences in inventory levels and costs between the two types of systems might be much lower or even greater than that shown in Figure 22-4.

Overstocking at health facilities and lower-level stores can disproportionately affect overall inventory costs. The large number of these units multiplies the impact of overstocking. When conducting an analysis of inventory costs or developing an inventory control policy, the analysis needs to consider costs at each level of the system and identify options for rationalizing order frequency and safety stock levels to achieve desired services with the lowest possible total inventory in the supply system.

Country Study 40-1 describes a total cost and options analysis in Costa Rica.

Standard performance indicators and ratios

When the total cost has been compiled, several ratios calculated from total cost components can serve as basic indicators for comparing operating efficiency among different parts of the current supply system (or with alternative models). Standard ratios include—

- Holding cost as a percentage of average inventory, calculated by dividing the total holding cost by the average inventory value and expressing the result as a percentage. In commercial firms, the inventory-holding cost is usually between 25 and 35 percent of average inventory value; in a public pharmaceutical supply system, the percentage may be considerably higher, although it need not be with good inventory management.
- Purchasing costs as a percentage of pharmaceutical acquisition costs, to compare how efficiently the purchasing function is managed.
- Average inventory turnover (the total value of medicines purchased or distributed, divided by the average inventory value), discussed in Chapter 23.
- Personnel costs, space costs, transport costs, other direct operating costs, each as a percentage of total holding costs, showing the relative proportion of total costs attributable to each category.
- Total holding cost as a percentage of the value of medicines distributed or the value of receipts, giving an indication of the cost-effectiveness of maintaining in-house services rather than contracting out some or

a. Stock-turnover ratio

Note: The ratio represents the total value of medicines purchased or distributed, divided by the average inventory value.

b. Inventory-holding costs

Note: The percentage represents holding cost as a percentage of average inventory, calculated by dividing the total holding cost by the average inventory value.

all aspects of storage and distribution. A variation of this ratio is total cost to value of medicines distributed or received.

Figure 40-1 illustrates two efficiency indicators in four Latin American countries.

40.3 VEN system

The VEN system sets priorities for selection, procurement, and use according to the potential health impact of individual medicines. VEN assigns each pharmaceutical product on the formulary or essential medicines list to one of the following three categories—

V: vital medicines are potentially lifesaving, have significant withdrawal side effects (making regular supply mandatory), or are crucial to providing basic health services.

Table 40-2 Sample guidelines for VEN categories

Characteristic of medicine or target condition	Vital	Essential	Nonessential
Occurrence of target condition			
Persons affected (percent of population)	Over 5	1–5	Less than 1
Persons treated (number per day at average health center)	Over 5	1–5	Less than 1
Severity of target condition			
Life-threatening	Yes	Occasionally	Rarely
Disabling	Yes	Occasionally	Rarely
Therapeutic effect of medicine			
Prevents serious disease	Yes	No	No
Cures serious disease	Yes	Yes	No
Treats minor, self-limited symptoms and conditions	No	Possibly	Yes
Has proven efficacy	Always	Usually	May or may not
Has unproven efficacy	Never	Rarely	May or may not

E: essential medicines are effective against less severe but nevertheless significant forms of illness but are not absolutely vital to providing basic health care.

N: nonessential medicines are used for minor or self-limited illnesses, are of questionable efficacy, or have a comparatively high cost for a marginal therapeutic advantage.

Assignment to the nonessential category does not mean the medicine is no longer on the system's formulary or essential medicines list; in many cases, medicines for minor illnesses are included on the essential medicines list but may be considered a lower priority for procurement than other medicines.

The classification of medicines should not be a one-time exercise. As the national formulary or essential medicines list is updated, and as public health priorities change, the VEN or VN categories should be reviewed and updated. Any new medicines added to the list should be categorized appropriately, and category assignments for older medicines should be reviewed and changed if needed.

The VEN system was developed in Sri Lanka, where it was first applied to importations by the State Pharmaceuticals Corporation. All pharmaceuticals procured by the corporation were reviewed by a clinical pharmacologist and assigned to one of the three categories. Since the first edition of this book in 1981, the VEN approach has been adapted and used in other countries around the world.

Some supply systems may find maintaining and updating the three-tiered VEN system difficult; they may find deciding how to classify certain medicines hard. An alternative is a two-tiered VN system, in which vital medicines are those that should be available at all times, and nonessential medicines, although still on the formulary, are of lower priority and should be purchased only after the need for all vital medicines is satisfied.

Either system—two or three categories—will work if the system is maintained; the main objective is an ongoing system to give priority to essential, lifesaving medicines as opposed to expensive nonessential items.

Performing VEN analysis

Because of its broad implications for procurement and use, classification of medicines into VEN or VN categories is probably best done by a designated expert committee, such as a national formulary committee. The classification should be determined primarily on the basis of the public health impact of individual medicines. Unit prices should be a secondary consideration, and popularity of medications should have minimal influence on the process. [Table 40-2](#) provides sample guidelines for establishing VEN categories. Examples of medicines classified under this method are given in [Table 40-3](#).

Applications of VEN analysis

The major uses of VEN analysis are assigning priorities for medicine selection, procurement, and use in a supply system; guiding inventory management activities; and determining appropriate medicine prices.

Selection: Vital and essential medicines should be given priority in selection, especially when funds are short.

Procurement: A medicine's VEN classification may affect the following—

- **Order monitoring:** Orders for vital and essential medicines should be monitored closely, as shortages in these items require expensive air shipment of supplies.
- **Safety stock:** Safety stocks should be higher for vital and essential items. Inventory savings can be realized by

Table 40-3 Examples of medicines classified by the VEN system

	Vital	Essential	Nonessential
Criteria	<ul style="list-style-type: none"> • Potentially lifesaving • Significant withdrawal side effects • Major public health importance 	<ul style="list-style-type: none"> • Effective against less severe but nevertheless significant forms of illness 	<ul style="list-style-type: none"> • Used for minor or self-limited illnesses • Questionable efficacy • High cost for marginal therapeutic advantage
Health center	<ul style="list-style-type: none"> • Phenobarbitone sodium tablet, 30 g • Phenoxymethylpenicillin tablet, 250 mg • Co-trimoxazole tablet, 480 mg • Nystatin pessaries, 100,000 units • Artemether-lumefantrine tablet, 20 mg + 120 mg • Ferrous sulfate/folic acid tablet, 200 mg/0.5 mg • Adrenaline injectable, 1/1,000, 1 mL ampoule • Oral rehydration salts (ORS) powder, 1 liter (WHO) • Gentamicin injectable, 40 mg/mL, 2 mL vial • Condoms with spermicide • Measles vaccine, live injectable, 10-dose (5 mL) vial • Ergometrine maleate injectable, 500 mcg/mL, 1 mL ampoule • Salbutamol sulfate tablet, 4 mg • Vitamin A capsule, 200,000 IU 	<ul style="list-style-type: none"> • Lignocaine HCl injectable 1%, 25 mL vial • Praziquantel tablet, 600 mg • Gentian violet paint, aqueous 0.5%, 500 mL • Benzyl benzoate application, 25%, 100 mL • Magnesium trisilicate complex tablet, chewable • Chlorpromazine HCl tablet, 25 mg • Aminophylline tablet, 100 mg • Vitamin B complex tablet • Aluminum acetate eardrops, 13% • Zinc oxide ointment, 15% • Mebendazole tablet, 200 mg • Ferrous sulfate mixture, pediatric, 60 mg/5 mL • Chlorpheniramine maleate tablet, 4 mg • Lidocaine + adrenaline dental cartridge 2% + 1/80,000 	<ul style="list-style-type: none"> • Lignocaine + adrenaline injectable, 1% + 1/200,000 • Aspirin tablet, pediatric, 75 mg • Suramin sodium injectable, 1 g vial, powder for reconstitution • Nystatin tablet, 500,000 units • Amodiaquine tablet, 200 mg base • Migril tablet • Ferrous sulfate tablet, 200 mg • Propranolol HCl tablet, 10 mg • Magenta paint, 20 mL • Anti-snakebite serum injectable, 10 mL amp • Ergometrine maleate tablet, 500 mcg • Vitamins, multiple pediatric drops • Thymol mouthwash solution tablet
District hospital	<ul style="list-style-type: none"> • Diazepam injectable, 5 mg/mL, 2 mL ampoule • Atropine sulfate injectable, 600 mcg/mL, 1 mL ampoule • Nalidixic acid tablet, 500 mg • Isoniazid + thiacetazone tablet, (HT3) 300 mg/150 mg • Digoxin tablet, 250 mcg 	<ul style="list-style-type: none"> • Diazepam tablet, 5 mg • Paracetamol tablet, 500 mg • Codeine phosphate tablet, 15 mg • Amoxicilline elixir, 125 mg/5 mL • Erythromycin suspension, 125 mg/5 mL 	

reducing safety stocks of nonessential items.

- *Order quantities:* If funds are short, the VEN system should be used to ensure that enough quantities of vital and essential medicines are bought first.
- *Supplier selection:* Only reliable suppliers should be used for vital and essential medicines. Quality and service for new and unknown suppliers can be tested by awarding them contracts for nonessential medicines.

Use: Review of usage by VEN categories may suggest underuse of vital or essential items or overuse of non-essential items. VEN or VN categories can be compared with ABC analysis and therapeutic category analysis (see following sections) to monitor how well actual use compares with priorities.

Pricing in pharmaceutical sales programs: Higher prices on popular but marginally useful items, such as cough and cold remedies, can be used to subsidize immunizations and antibiotics.

Stock control: Special attention should be paid to stock levels of vital and essential items to avoid stockouts.

Assignment of staff: Stock clerks and other inventory control staff who are more experienced or more skilled should be assigned to keep track of vital and essential items.

Country Study 40-2 describes the application of the VEN system.

Using the VEN system to guide purchases

The VEN (or VN) system helps minimize distortions in the pharmaceutical procurement process and thus maximizes the health effect of available funds. When procurement quantities must be reduced, these steps can be taken—

Step 1. Classify all medicines on the national essential medicines list as V, E, or N (or V or N): If the funding shortage is temporary, consider options for limiting individual

order quantities (and increasing order frequency) for high-turnover V and E medicines, as determined by ABC analysis (see Section 40.4).

Step 2. Reconsider the proposed purchase quantities to make sure they are justified: Check assumptions, order formulas, and the accuracy of calculations. Particular attention should be paid to V and E medicines, because they will be the last eliminated from the list.

Step 3. Try to find additional funds: A clear and well-documented presentation of a system's requirements may result in increased pharmaceutical budget allocations or additional funds from donors. Introduction of a cost-recovery or a cost-sharing system may be an alternative source of additional funds in the long term (see Chapter 13).

Step 4. Remove from the procurement list any N medicines for which no clear therapeutic need exists: Then reassess funds in relation to revised estimates. If a funding gap still exists, proceed to Step 5.

Step 5. Reduce quantities of or eliminate other N items, and reassess the estimated procurement cost for remaining

items: If requirements still exceed the available budget after all N items are eliminated, proceed to Step 6.

Step 6. Limit therapeutic duplications: If the list of V and E items (or V items in a VN system) contains more than one medicine with a similar therapeutic effect, some tendering by therapeutic subcategory may be possible (see Chapters 18 and 21). If certain medicines are usually purchased in more than one strength, it may be possible to limit such duplication and reduce total quantities for the medicines in question. If these sorts of adjustments are not feasible, or if they do not produce the necessary cost reductions, proceed to Step 7. Therapeutic category analysis (Section 40.5) may be useful to identify opportunities for limiting duplication.

Step 7. Reduce the quantities of medicines that must be purchased using the "preferential weighting" or "equal misery" approach: With a VN system, this step applies to all remaining medicines on the list. With a VEN system, one option is to purchase the entire quantity of V medicines and allocate remaining funds among E medicines. The alternative is to reduce quantities of both V and E medicines.

Country Study 40-2 An example of the VEN analysis process

A country's ministry of health (MOH) felt the need to further prioritize the medicines on its essential medicines list (EML) for procurement for the public sector because its limited resources prevented the central medical stores (CMS) from ensuring the continuous availability of all products on the EML.

The national medicines committee (NMC), the committee responsible for selecting medicines and updating the EML, started planning its review of the list as part of an ongoing review process to prioritize items on the list using VEN principles. In preparation for a two-day national meeting, all members of the NMC received information on amendments to the EML proposed by various health workers (along with scientific evidence backing up the proposals). Members also received a draft protocol for the VEN allocation exercise, clarifying both the rationale for the exercise (continuous availability of the most important medicines) and the proposed therapeutic criteria for allocation to V, E, or N categories. In addition, they received a list of all medicines on the EML by level of use and therapeutic group, with a suggested VEN allocation prepared by the NMC secretariat, with assistance from selected clinicians.

At the start of the meeting, participants agreed that in view of the economic circumstances, all items of limited therapeutic benefit (N medicines) should be removed

from the list. They then used the VEN system to allocate medicines to V or E according to therapeutic relevance.

Early on during the meeting, it became clear that the NMC had to reinterpret the VEN criteria to reach consensus. For example, according to the original criteria, paracetamol did not qualify as a vital medicine. However, the majority of the committee members believed that because of the public health implications (that is, paracetamol is an antipyretic and also used for non-specific complaints), it should be a V item.

In addition to allocation by therapeutic relevance, the NMC allocated all items by level of use (H, health center; D, district hospital; and C, central hospital) and by expected consumption (A for high- and B for low-consumption medicines).

The NMC agreed with the CMS that the CMS's first responsibility should be to ensure the continuous availability of vital high-consumption items (especially HVA items). Procurement of all other medicines would depend on the availability of additional funds. In addition, the CMS would not routinely stock low-consumption (especially DEB and CEB) items. Finally, clients (hospitals and districts) would be responsible for ordering all B items well in advance (for example, once a year at the beginning of the financial year).

The preferential weighting strategy protects one or more classes of medicines or one or more classes of facilities.

In one variation, the highest-priority classes are exempted from the cuts, and quantities of remaining medicines (or facility estimates) are reduced until the procurement budget balances with estimated purchases. Another option is to reduce quantities for the highest-priority classes less than for the lower-priority classes.

The equal misery strategy for reducing quantities is sometimes applied to pharmaceuticals or facilities. If it is applied to a single list of medicines, all medicine quantities are reduced by an equal percentage until the necessary cost reductions are achieved. If equal misery is applied to individual health facility estimates, all health facility estimates are reduced by the same percentage. Equal misery is not recommended for general use in the public pharmaceutical supply system—in most situations, preference should be given to certain medicines (and sometimes to certain types of health facilities).

40.4 ABC analysis

A well-known fact in supply chain management is that a relatively small number of items account for most of the value of annual consumption. The analysis of this phenomenon is known as Pareto analysis or, more commonly, ABC analysis.

In any supply system, analyzing consumption patterns and the value of total consumption for all items is useful; in all but the smallest systems, inventory items can be classified into three categories (A, B, and C) based on the value of their annual usage. Related tools such as therapeutic category analysis and price comparison analysis build on the basic ABC analysis, and the data for these analyses can be compiled as the ABC analysis is constructed by adding data columns to the spreadsheet.

A, B, and C categories are not assigned categories like VEN categories; each line item is categorized based on the result of a particular ABC analysis. If use patterns change, the item may fall into a different category the next time ABC analysis is performed.

Applications of ABC analysis

ABC analysis is an extremely powerful tool, with uses in selection, procurement, management of distribution, and promotion of rational medicine use.

Selection. Review of class A medicines may uncover high-use items for which lower-cost alternatives are available on the formulary or in the marketplace. The ABC analysis also helps managers identify purchases made for items that are not on the formulary or essential medicines list or not approved for use in the supply system.

In a West African country, analyses of consumption in a sample of twenty health facilities showed that three of the facilities (15 percent) continued to use and stock ampicillin suspension regularly, although it had been deleted from the national formulary five years earlier in favor of amoxicilline.

Procurement. ABC analysis can be useful to facilitate procurement-related activities, such as determining sources for lower-priced products, assuring procurement is in line with public health priorities, and assessing how order frequency affects overall supply—

Determining order frequency: Ordering class A items more often and in smaller quantities should lead to a reduction in inventory-holding costs. Note that order frequency and quantity influence supply activities in at least six ways: (1) they determine average inventory (higher order quantity means higher inventory levels); (2) they determine procurement workload (higher order quantity means a lower number of orders, and vice versa); (3) they determine safety stock (more frequent ordering means less inventory and less safety stock); (4) they influence bulk prices (larger orders mean more special bulk rates); (5) they determine storage space requirements for medicines; and (6) they influence the likelihood of losses to expiry (less frequent bulk purchasing may lead to more expired medicines).

Seeking lower-cost sources for class A items: The procurement office should concentrate on getting lower prices for class A items by looking for cheaper dosage forms or cheaper suppliers. Price reductions for items classified as A products in the analysis can lead to significant savings.

Monitoring order status: Emphasis should be placed on monitoring the order status of class A items, because an unexpected shortage may lead to expensive emergency purchases.

Monitoring procurement priorities: As mentioned in the VEN system discussion, ABC analysis can help monitor procurement patterns in comparison with health system priorities. For example, an ABC analysis of Kenya's consumption of antiretrovirals showed the high proportion of the budget dedicated to nevirapine. After switching to procurement of generic nevirapine, its value shifted significantly—from representing 40 percent of the antiretroviral budget in 2005 to about 9 percent in 2007.

Comparing actual and planned purchases: ABC analysis can be used to compare actual and planned purchases in a public-sector supply system. For example, in one Latin American ministry of health supply system, the original procurement budget for the year specified that 97 items would be purchased through tender at an estimated cost of USD 2.5 million. ABC analysis of the year's two tenders showed that 124 items were actually purchased, at a total cost of USD 3.36 million. Of the

HIGH MANAGEMENT INPUT REQUIRED FOR PRACTICALLY NO COST REDUCTION

124 items purchased, 61 (nearly half) did not appear on the original procurement plan, and 34 of the medicines that had been on the plan were not purchased. The cost of the unplanned medicines was USD 1.17 million. Senior health system managers were unpleasantly surprised to learn of these discrepancies, and reforms in quantification and procurement procedure were devised for the procurement office.

Distribution and inventory management. In addition to selection and procurement, ABC analysis can also help with distribution and inventory management activities such as the following—

Monitoring shelf life: Emphasis should be given to class A items to minimize waste caused by medicines exceeding their shelf lives.

Delivery schedules: Even when all medicines are ordered only once a year, divided deliveries of class A items can lead to increased shelf lives.

Stock count: As discussed in Chapter 23, cyclic stock counts should be guided by ABC analysis, with more frequent counts for class A items.

Storage: Improving control for the issuance and storage of class A medicines at user points, such as hospitals and health centers, can minimize waste, pilferage, and organized theft of medicines.

Use. Review of high-use items by health officials, practicing physicians, and other health workers may suggest areas of overuse and underuse as exemplified in a Kenya hospital (Country Study 40-3).

Performing ABC analysis

ABC analysis can be applied to total annual consumption, to consumption during a short period, or to a particular tender or set of tenders; the basic methodology is the same no matter which data are used. The basic steps are also the same whether the ABC analysis is done manually or by computer, although the process is much easier with a computer.

The process is described in eight steps and illustrated in Tables 40-4 and 40-5 and Figure 40-2; the example used in the illustrations comes from an essential medicines program in Central Asia in 2010. The values shown are for part of one tender and do not represent annual pharmaceutical consumption in the country.

Step 1. List all items purchased or consumed and enter the unit cost: The cost is for one basic unit of an item (column 3 of Table 40-4). The basic unit should be the same as the issue unit tracked on stock records, except when a smaller basic unit such as a milliliter or a gram is needed to incorporate several different bottle, tube, or vial sizes

Country Study 40-3 Using ABC analysis to control antimicrobial resistance in Kenya

The Drug and Therapeutics Committee (DTC) at Aga Khan University Hospital in Nairobi established a multi-disciplinary antimicrobial subcommittee to focus on interventions to contain antimicrobial resistance. The DTC did an ABC analysis of 793 medicines for 2005 and found that the top four products were antimicrobials, accounting for almost 10 percent of the medicine budget. Meropenem, an expensive, broad-spectrum carbapenem, had the highest consumption by value.

Top five medicines by value in ABC analysis for 2005

Medicine	Quantity	Cumulative percentage of budget
Meropenem, injectable, 1 g	3,346	3.44
Tazocin, injectable, 4.5 g	3,056	5.62
Augmentin, injectable, 1.2 g	15,212	7.70
Zinnat, tablets, 500 mg	48,422	9.60

The results of a retrospective drug use evaluation on Meropenem from 100 inpatient records reinforced the

need for its rational use: only 40 patients received the standard treatment regimen (5–7 days); 35 received it despite inappropriate indications; 27 patients got a sub-therapeutic dose; and 27 patients were given a 7–14-day regimen without valid justification.

In response, the DTC endorsed the development of an order sheet that restricted the use of Meropenem and six other antimicrobials. The antimicrobial order sheet was piloted in the intensive care unit and in surgical and medical wards. It was subsequently refined and launched hospitalwide. The DTC also endorsed the subcommittee recommendation that the microbiologist be involved in intensive care unit rounds, where the threat of antimicrobial resistance is high. Health care providers received information on the correct use of Meropenem and other antibiotics. The ABC analysis was repeated for 2006, and the results showed a 62 percent decrease in Meropenem consumption compared with 2005.

Source: Shah, Konduri, and Gunturu 2007.

40.16 PLANNING AND ADMINISTRATION

Table 40-4 How to perform an ABC value analysis, using 2010 data from a Central Asian country (steps 1–4)

1	2	3	4	5	6

IU = international units.

for the same item. See Chapter 50 for a discussion of issue units, basic units, and pack sizes.

Ideally, the actual CIF (cost, insurance, and freight) acquisition unit cost for all items should be used, but this cost is difficult to track when multiple purchases of an item have been made at different prices. The most accurate alternatives are a weighted average or a FIFO average, as discussed in Chapter 41. In Table 40-4, the unit cost of one basic unit (tablet) of acyclovir was 5 units of the local currency, which is the equivalent of USD 0.012.

Step 2. Enter consumption quantities: Enter the number of basic units consumed or purchased during the period under review. Make sure that the same review period is used for all items to avoid invalid comparisons. Table 40-4 shows that for acyclovir, 3,700 tablets were purchased over the twelve months under review.

Step 3. Calculate the value of consumption: Multiply the unit cost by the number of units consumed or purchased to obtain the total value for each item. In Table 40-4, column 5 shows that for acyclovir, the total value of purchases was 18,500 local currency, or USD 430. After this amount is calculated for each item, add up the total value of all items at the bottom of column 5.

Step 4. Calculate the percentage of total value represented by each item: Divide the value of each item by the total value of all items. Enter the results for each item under the heading “Percentage of Total Value,” as shown in column 6 of Table 40-4. At this point, any ABC list will look something like Table 40-4; in the example, amikacin (the second item) represented 0.87 percent of total value. (Carrying the percentage to two decimal places is useful because several items may be close together in value and many may represent less than 1 percent of total value. The data are easier to understand when these items are clearly differentiated with two decimal places.)

Step 5. Rearrange the list: Rank the items in descending order by total value (column 5), starting at the top with the highest value. For example, in Table 40-4, the highest-value item was ketamine, which now becomes item 1; ampicillin 500 mg moves to second place, and so forth. This rearrangement yields a list that is also ordered by percentage of total value, as in Table 40-5.

Step 6. Calculate the cumulative percentage of total value for each item: Beginning with the first item at the top of Table 40-5, add the percentage in column 6 to that of the item below it in the list (creating column 7). For example, ketamine represented 13.28 percent of total procurement value. Ampicillin 500 mg represented 11.04 percent; the cumulative percentage of the two items was 24.32 percent (rounded) of total procurement value.

Step 7. Choose cutoff points or boundaries for class A, B, and C medicines: In general, the following boundaries are

Figure 40-2 How to perform an ABC value analysis (step 8)

used: A items have the highest annual usage, with 10 to 20 percent of the items usually accounting for 75 to 80 percent of the funds spent. B items represent another 10 to 20 percent of the items and use 15 to 20 percent of the funds, and C items account for 60 to 80 percent of the items but only 5 to 10 percent of the value of annual consumption.

These boundaries are somewhat flexible; for example, class A status might be given to items that cumulatively account for 70 percent of the funds. The decision depends on how volume and value are dispersed among items on the list and how the results of the ABC analysis are going to be used. If class A items are going to be managed more intensively than class B and C items, allocation of items to class A must be based on management capacity. Using the suggested boundaries with the Central Asian example would result in only two products in the A category; therefore, cumulative value might be the more appropriate way to categorize in this instance.

Step 8. Present the results graphically: Plot the percentage of the total cumulative value (column 7) on the vertical or y axis against the item number on the horizontal or x axis. Figure 40-2 shows a graph of the sample ABC analysis. The number of items in the medicine list influences the slope of the ABC curve. Figure 40-3 shows the results of ABC analysis for a full year’s medicine consumption in two large supply systems; note the difference in the shape of the curves in comparison to Figure 40-2. In Country I, 25 class A items of a total 344 accounted for about 75 percent of the total value. In Country II, which shows a less steep ABC curve, 34 items of 220 total items (15.5 percent) represent nearly 70 percent of the total value. To limit the number of items in class A, a cutoff point was selected that represents a lower proportion of the total value. In general, the steeper the curve, the higher the proportion of the total value that would be included in class A.

40.5 Therapeutic category analysis

Therapeutic category analysis reviews the volume of use and the value of various therapeutic categories and subcategories of medicines. This technique builds on ABC analysis, sorting the ABC list into therapeutic categories (based on the cumulative volume and value of the individual medicines in those categories). Table 40-6 shows a summary therapeutic category analysis, using data from a Caribbean country. Table 40-7 provides details on the top three therapeutic categories in Table 40-6.

Applications of therapeutic category analysis

The applications of therapeutic category analysis are similar to those of ABC analysis. Managers should focus cost-control efforts on the therapeutic categories that show the highest consumption and greatest expenditures.

Selection. Therapeutic category analysis can be used to choose the most cost-effective products for essential medicines lists and formularies and find opportunities for therapeutic substitution. For example, in Table 40-7, look at the comparison between methyldopa and atenolol. If all hypertensive patients in the sample were converted from methyldopa to atenolol, the health system would save about USD 33,440—over 20 percent of the

total expenditures for pharmaceutical purchases in this country.

In addition, therapeutic category analysis can help provide information for pharmacoeconomic analysis. Pharmacoeconomic analysis is the process of comparing cost, therapeutic efficacy, and safety. Two techniques are most commonly used in comparing treatment regimens: cost-minimization and cost-effectiveness analysis. Other pharmacoeconomic techniques such as cost-utility and cost-benefit analysis are less appropriate for comparing treatment regimens (see Chapter 10). Cost minimization is the simpler of the two techniques—it is used when two therapeutic options are the same in terms of therapeutic benefit and safety but one is less expensive. As discussed in Chapter 10, cost-effectiveness is used to compare the costs and benefits of therapeutic alternatives when cost minimization alone is not appropriate. (For more information on pharmacoeconomic analysis, see Bootman, Townsend, and McGhan 2005.)

Procurement. As discussed in Chapters 18 and 21, some supply systems tender for certain therapeutic subcategories (for example, first-generation cephalosporins) rather than for individual medicines. A therapeutic category analysis would show managers how many different products in a subcategory are being purchased. If duplications exist—for example, two oral products are being purchased—tenders

40.20 PLANNING AND ADMINISTRATION

Table 40-6 Therapeutic category analysis summary

	Formulary code	Formulary category	Number of products	Category total cost (USD)	Percentage of total cost	Cumulative percentage of total cost

could specify only “oral first-generation cephalosporins.” Review of [Table 40-7](#) does not yield obvious candidates for subcategory tendering.

Use. Therapeutic category analysis can help promote rational medicine use by identifying potential problems of irrational use: for example, managers can compare information from the summary ([Table 40-6](#)) and the detailed analysis ([Table 40-7](#)) with known patterns of morbidity to see how well use matches the patterns. For example, in [Table 40-7](#), note that 7,467 courses of therapy (COTs) of chlorpropamide were used; the manager might ask how that corresponds with the incidence of diabetes that would justify the use of chlorpropamide. Note that the use of chlorpropamide was almost three times greater than the use of glibenclamide (and chlorpropamide’s unit cost was seven times higher). Are these patterns rational for the situation? [Table 40-7](#) does not have enough information to make that determination, but a small, well-targeted study of prescribing might be used to find out (as described in [Chapter 28](#)).

In addition, this type of analysis can identify overprescribing and leakage by comparing the number of COTs that theoretically should have been provided against patient contact data—for example, are the numbers of diabetic patients treated consistent with the number of COTs?

Performing therapeutic category analysis

Therapeutic category analysis is divided into two phases: the summary analysis and the detailed analysis. The sum-

mary analysis starts with the same steps taken as part of an ABC analysis, then includes a classification by therapeutic category. The detailed analysis is a more in-depth look at the high-cost categories identified in the summary phase.

Summary therapeutic category analysis. The summary analysis consists of five steps—

Steps 1–3: Follow the first three steps in ABC analysis (see [Section 40.4](#)) to produce a list of medicines, with the volume and value of use calculated for each medicine.

Step 4: Add a column and assign each of the medicines to a therapeutic category, as discussed in [Chapter 16](#). The key requirement is a standard formulary coding system. The system can be simple (with relatively broad categories) or complex (with many subcategories). Commonly used coding systems include the World Health Organization (WHO) Model List of Essential Medicines and the American Hospital Formulary Service (AHFS) Pharmacologic-Therapeutic Classification. More detailed, multilayered schemes are the Anatomical, Therapeutic, Chemical Classification System with Defined Daily Doses of the WHO Collaborating Centre for Drug Statistics Methodology and the U.S. Department of Veterans Affairs Drug Classification System.

Step 5: Rearrange the list into therapeutic categories by sorting according to the formulary codes. The values and percentages for the various therapeutic categories are then summed from the results for the individual items in

the category and cumulative percentages are calculated, producing a summary therapeutic category analysis (see Steps 4–6 under ABC analysis).

In the summary therapeutic category analysis in [Table 40-6](#), fifty-eight different therapeutic categories are represented; this country uses the Organisation of Eastern Caribbean States' Pharmaceutical Procurement Service formulary coding system (OECS/PPS 2006), which has seventy-four possible therapeutic categories. The system is based on the AHFS system, with minor modifications.

Note that seven of the categories were responsible for nearly 70 percent of total expenditures. This grouping resembles class A in ABC analysis, and the principle is the same—a relatively small number of therapeutic categories often consume most of the funds in a supply system. To reduce costs, managers should look first at these high-cost therapeutic categories.

Detailed therapeutic category analysis. The second phase of the analysis focuses on the high-cost categories identified in the summary phase. The goal is to identify possible changes in therapeutic strategy that might prove to be cost-effective. This analysis compares the cost for a defined daily dose (DDD) of the medicines (the average daily dose for all patients) and the cost of a defined COT.

This stage of the analysis starts with the detailed list of medicines for important therapeutic categories assembled in phase 1. The list of medicines within the categories can be sorted either alphabetically (which is probably easiest for additional data entry) or by value. Data fields (columns) are added to the list to enter the number of basic units per DDD, the annual use in DDDs, the cost per DDD, the standard COT in days, the annual number of COTs, and the average cost per COT (see [Box 40-2](#)).

After the standard COT is determined, the final step in constructing the detailed therapeutic category analysis is multiplying the DDD cost by the COT and dividing the annual number of DDDs by the COT (see [Table 40-7](#) for examples).

40.6 Price comparison analysis

Procurement prices can be compared with prices from other systems, and sales prices can be compared with local private-sector prices. These comparisons can help managers set prices for cost-sharing programs and understand whether continuing with current in-house pharmaceutical services is cost-effective.

Acquisition price comparison

Acquisition price comparison analysis tells the manager whether the system is getting the maximum benefit from

Box 40-2 Determining DDDs and COTs

The DDD can be obtained from at least two sources; the official list is published periodically by the WHO Collaborating Centre in Oslo, Norway (WHOCC 2011), and the Management Sciences for Health *International Drug Price Indicator Guide* (MSH 2010) includes the DDD for selected essential medicines. Note that the DDD in [Table 40-7](#) is listed in terms of comparison units; in the references cited here, the DDD is specified in grams and International Units, so they must be converted to comparison units. For example, the DDD for ampicillin is 2 grams, which converts to eight capsules of 250 mg, four capsules of 500 mg, and four ampoules of 500 mg for the injection. The official DDD for ampicillin suspension would be 80 mL (0.8 bottles of 100 mL), but the official DDD does not differentiate between adult and pediatric dosages. For the various pediatric suspensions in [Table 40-7](#), the DDD was assumed to be 40 mL. The annual number of DDDs is obtained by dividing total annual consumption by the DDD; the cost per DDD is calculated by multiplying the comparison unit price by the DDD.

The average COT will differ according to local policy and custom; for example, some health systems might specify a standard course of ten days for outpatient antibiotic therapy, and other systems might say five or seven days. The COT for chronic medications can be set at thirty days (for ease of comparison). The COT for inpatient medicines might be set at five days (again, for ease of comparison).

available procurement funds, and if not, how much might be saved with alternative procurement practices.

Applications. The obvious application of price comparison analysis is to measure procurement performance and to focus efforts on obtaining better prices. The comparison of average tender prices with international prices can be used as a routine indicator of procurement system performance.

The analysis can also identify certain medicines that should be considered for alternative methods of procurement. For example, if a supply system is currently purchasing all medicines from local suppliers, the price comparison analysis may indicate some medicines that could be obtained for a significantly lower price through international tender or even through direct procurement from one of the international nonprofit agencies.

[Country Study 40-4](#) shows the results of a 2009 price comparison analysis from a Latin American country.

Country Study 40-4 Price comparison analysis

In this analysis, 2009 prices from local suppliers in a Latin American country were compared with the Organisation of Eastern Caribbean States' Pharmaceutical Procurement Service (OECS/PPS) prices, based on information from the MSH *International Drug Price Indicator Guide*.

The Latin American country received a better or the same price locally as the OECS/PPS did internationally for twelve of thirty products—in some cases, particularly for solutions, the local price was better than the international price (largely because shipping costs are

a major component of the international price). OECS/PPS international prices were better on eighteen of thirty products. Certain items, in particular, made a difference; for example, items that had higher local prices combined with large order quantities, such as chloramphenicol suspension, halothane liquid, lidocaine solution, and rifampicin tablets. The country could have saved over USD 143,000 by purchasing only those four items internationally. The accompanying table shows the format for the price comparison analysis.

Description	Strength	Form	Comparison unit	Total units purchased, two tenders	Total USD at country tender price	Total USD at OECS/PPS tender price	Country price as percentage of OECS/PPS price
Acetazolamide	250 mg	Tablet	Tablet	3,000	200.40	60.00	334.0
Allopurinol	100 mg	Tablet	Tablet	15,000	171.00	300.00	57.0
Benzathine penicillin	2.4 million IU	Solution	Ampoule	60,000	30,840.00	36,000.00	85.7
Bisacodyl	5 mg	Tablet	Tablet	30,000	3,486.00	2,700.00	129.1
Cephalexin	500 mg	Capsule	Tablet	500,000	32,250.00	32,050.00	100.6
Chloramphenicol	1 g	Solution	Ampoule	25,000	12,857.50	25,000.00	51.4
Chloramphenicol	125 mg/5 mL	Suspension	100 mL bottle	125,000	110,000.00	58,750.00	187.2
Co-trimoxazole	80 mg+40	Tablet	Tablet	2,000,000	28,800.00	28,800.00	100.0
Co-trimoxazole	240 mg/5 mL	Suspension	100 mL bottle	110,000	56,100.00	50,600.00	110.9
Dextrose in NaCl, 1 L	5%/0.9% mg	Solution	Ampoule	110,000	80,300.00	99,000.00	81.1
Diazepam	5 mg	Tablet	Tablet	200,000	2,420.00	1,700.00	142.4
Erythromycin	250 mg	Tablet	Tablet	500,000	29,800.00	19,550.00	152.4
Furosemide	40 mg	Tablet	Tablet	50,000	500.00	290.00	172.4
Gentamicin	80 mg/2 mL	Solution	Ampoule	200,000	18,000.00	12,760.00	141.1
Halothane	250 mL	Liquid	Bottle	2,000	92,620.00	60,000.00	154.4
Hydralazine	50 mg	Tablet	Tablet	10,000	373.00	250.00	149.2
Insulin NPH, 10 mL	40 units/mL	Solution	Ampoule	8,000	40,448.00	43,840.00	92.3
Ketamine (10 mL)	50 mg/mL	Solution	Ampoule	4,000	9,220.00	9,600.00	96.0
Lidocaine (50 mL)	2% sin epi	Solution	Ampoule	8,000	35,120.00	4,240.00	828.3
Methyldopa	500 mg	Tablet	Tablet	100,000	9,380.00	4,400.00	213.2
Metronidazole	250 mg	Tablet	Tablet	3,000,000	44,400.00	15,300.00	290.2
Oral rehydration salts	—	Powder	Packet	200,000	31,040.00	46,400.00	66.9
Oxytocin	10 U/mL	Solution	Ampoule	25,000	1,365.00	8,250.00	16.5
Phenytoin	100 mg	Capsule	Capsule	270,000	10,989.00	5,832.00	188.4
Propranolol	40 mg	Tablet	Tablet	150,000	1,740.00	1,275.00	136.5
Propranolol	80 mg	Tablet	Tablet	50,000	1,305.00	1,000.00	130.5
Quinidine sulfate	200 mg	Tablet	Tablet	60,000	7,800.00	8,082.00	96.5
Rifampicin	300 mg	Capsule	Tablet	1,600,000	221,600.00	126,720.00	174.9
Sodium chloride, 1 L	0.9%	Solution	Ampoule	70,000	39,200.00	62,300.00	62.9
Vitamin B complex	120 mL	Solution	Bottle	100,000	49,000.00	21,000.00	233.3
Average tender price as percentage of international price							175.2%
Standard deviation—average tender price/international price							144.81%
Weighted average percentage—tender price/international price							127%

Note: — Not applicable; IU = international units.

Pharmaceutical price comparison analysis. One potential source for comparative procurement information is a list of prices from a neighboring supply system. Another is the MSH *International Drug Price Indicator Guide* (available online or in a CD-ROM version that allows the user to enter local prices and compare them with the international prices that are already in the system). In addition, Health Action International and WHO have developed a methodology to assess medicine prices; the website (<http://www.haiweb.org/medicineprices>) includes survey data from many countries as well as resources for many other sources of medicine prices.

When the comparison prices have been entered for each medicine, divide the local price by the comparison price, which calculates the local price as a percentage of the comparison price. After doing this, all these percentages are totaled and divided by the number of medicines to get the average percentage.

A manager can also determine how much overall difference exists for a certain volume of purchases (the weighted average percentage) in a manner similar to the ABC analysis. Total annual values are calculated for each item for both local prices and comparison prices, based on annual consumption. The values at local prices and the values at comparison prices are totaled at the bottom of the respective columns. Then the weighted average percentage is calculated by dividing the total value for all items at local prices by the total value at comparison prices. The weighted average is useful because large differences may exist for individual medicines that skew the simple average comparison.

When using the MSH indicator prices for comparison, it is important to understand that the international reference prices reflect a combination of actual tender prices paid by selected countries' procurement programs and prices from international nonprofit suppliers such as Supply Chain Management System and the IDA Foundation; the reference prices are not actual prices. When a wide range of prices makes up the average, the average may be much higher or lower than actual prices from any of the individual suppliers or tendering programs listed. Therefore, the guide shows the median prices, which controls for skewing that may occur with price averaging.

The prices being compared must refer to the same year; the pharmaceutical products being compared must be the same generic products in the same or comparable dosage forms, and the comparison units must be the same. If all these points are not addressed correctly, the price comparison analysis will be invalid.

Comparison of supply system prices and private-sector prices

This analysis compares acquisition and selling prices against local private-sector wholesale and retail prices.

Applications. The analysis provides useful information for cost-recovery programs. Note in [Table 40-8](#) that CMS sales prices at a 30 percent markup were, on average, 84 percent of the private-sector wholesale prices for the same medicines (47 percent of the average retail sales price) and 92 percent of the sales prices from the local nongovernmental organization (NGO) warehouse. This finding might seem to indicate that the CMS could increase prices somewhat. However, this simple comparison is not enough to make a determination, because the key issue is how much services are valued by patients. If public pharmaceutical services are not valued as highly as private-sector medicines and services, there may be no room at all for price increases.

The most useful application of this type of analysis is to indicate the cost-effectiveness of in-house pharmaceutical services. If supply system procurement acquisition prices are higher than or nearly as high as the private-sector sales prices, and procurement system improvements are unlikely to be able to significantly reduce acquisition prices, further investigation is warranted—for example, serving public-sector patients through contracts with private pharmacies may be more cost-effective.

Doing the analysis. This analysis demands some extra effort to get comparative information. Information on average wholesale or retail prices may be available from the local pharmacy association, but if it is not or if it is not reliable, prices in local wholesale and retail outlets can be obtained through a simple survey, focusing on a limited list of essential medicines (see MSH/RPM 1995). If a wide range of prices is obtained in the survey, using the simple median retail price rather than an average of the prices may be best.

This analysis is set up in the same way as the preceding price comparison analysis, building on the list used for ABC analysis and adding columns of comparative prices from the private sector. If the public supply system is selling medicines from one level to the next or to the public, columns should be provided for both acquisition and selling prices. Again, a percentage comparison is made for both individual medicines and an overall average. To show the private-sector price as a percentage of the supply system prices, the retail price is divided by the supply system price. To show the supply system prices as a percentage of the private-sector prices, supply system prices are divided by private-sector prices.

[Table 40-8](#) illustrates a comparison between CMS prices and local wholesale prices.

40.7 Lead-time and payment-time analysis

Lead time is defined as the interval between submitting an order and receiving the goods. In many countries, most pharmaceuticals purchased by the public sector are imported, and lead times are frequently long and variable.

Table 40-8 Price comparison: CMS 30 percent markup compared with private-sector wholesale and retail prices and NGO prices

Description	Strength	Issue unit	Projected CMS 30 percent markup on 2009 cost	CMS prices as percentage of average			CMS price as percentage of average retail price	CMS price as percentage of average NGO May 2009 unit price	CMS price as percentage of average NGO price

Table 40-9 Lead-time analysis

Purchase order	Contract lead time	Actual lead time	Shipment days overdue	Contract payment time	Actual payment time	Payment days overdue
KIT-8001	45	57	12	45	43	0
LUC-8001	45	27	0	45	112	67
LUC-8001	45	119	74	45	20	0
MON-801	45	30	0	45	63	18
VIN-8000	45	21	0	45	96	51
Average lead time		50.8 days		Average pay time		66.8 days
Percentage of orders overdue		50%		Percentage of late payments		75%
Average delay when overdue		43 days		Average delay when payment overdue		45 days

Source: Data come from the Caribbean pooled procurement program.

Note: LUC-8001 was shipped in two partial shipments, one on time, the other not.

Payment time is defined as the interval between receipt of goods at the warehouse and payment to the supplier. This interval is of concern in supply systems that have delayed payment terms with suppliers; in such systems, monitoring and controlling payment time is of paramount importance if the system wishes to continue to pay on delayed terms.

An analysis of lead times and payment times for purchases by an international pooled procurement program is presented in [Table 40-9](#). It shows the variability that occurs in practice and illustrates how to construct a lead-time and payment-time analysis table. Note that the supplier was late in delivering half of this small sample of orders. The average lead time for all shipments was more than fifty days, compared with the contractual forty-five days, but the average delay nearly doubled the contract lead time, adding forty-three days on average. In the same table, the procurement agency paid within the contracted forty-five days for only two of the five shipments. The average payment time was sixty-seven days (rounded up), and for those payments that were overdue, the average was double the contract requirement.

These results have two major implications. First, this supplier has a highly variable lead time, and the procurement office needs to either adjust safety stock to cope with the worst case or switch suppliers. Second, the purchaser may have little choice if payment time is not improved—the supplier may refuse to ship without prior payment. The payment delays may also be affecting the supplier's interest in delivering on time.

When evaluating supplier offers and planning orders and deliveries, managers need to use the expected delivery date based on past performance rather than the promised delivery date. Many supply systems take the simple average actual lead time from past deliveries and assume that it is the expected lead time. Thus, for the supplier in [Table 40-9](#), the expected lead time would be fifty-one days (rounded up) instead of the promised forty-five days. A variation of

six days would probably be acceptable in most situations, but two of five shipments were delayed longer than fifty-one days (much longer in one case). [Chapter 23](#) discusses options for adjusting the simple average lead time to cover substantial variation; one of these methods should be used for this supplier.

40.8 Analysis of expiry dates

Analysis of expiry dates compared to inventory levels is useful for determining how much stock is at risk of wastage. [Table 40-10](#) shows the results of an expiry-date analysis in an illustrative country.

The analysis is done for each medicine by determining the average monthly consumption during the past year (adjusted for periods out of stock), and dividing the quantity in stock by the average monthly consumption to determine the stock position in months. Then the number of months remaining until expiry is calculated.

If the months until expiry are greater than the stock position in months, the risk of wastage should be limited. If the stock position is higher than the months until expiry, some risk exists. Multiply the months until expiration by the average monthly use to get the projected use before expiry; subtract this total from the stock on hand to obtain the quantity of stock at risk. The unit acquisition price, multiplied by the quantity at risk, yields the value of stock at risk.

Options to solve the problems identified in this analysis include increasing the use of some of the items at risk by substituting them for other commonly used items (with the consent of prescribers and dispensers). It may be possible to return some of the items to the supplier for credit, or perhaps a barter arrangement can be negotiated with another warehouse or supply system.

In the example from [Table 40-10](#), substantial quantities of stock would clearly have been lost to expiry unless

Table 40-10 Illustrative expiry-date analysis (January 2010)

Name, strength, and form	Issue unit	Issue unit cost (USD)	Average monthly use	Current stock position (units)	Current stock position (months)	Expiry date	Months until expiry	Projected use	Quantity of stock at risk	Value of stock at risk (USD)

Water for injection, 10 mL	Vial	0.06	117	400	3.4	April 2010	3	350	50	3.00
Total value at risk										2,615.52

IU = international units.

action was taken. Note that for cephalexin tablets and injections, action was needed quickly because of the rapidly approaching expiration date. It was already too late to use up dexamethasone or water for injection. The chlorhexidine gluconate presented the highest financial risk (almost one-third of the total value at risk).

For some of the items at risk, increasing use through substitution might be feasible. For example, cephalexin tablets could be substituted for erythromycin. Penicillin injection might replace cephalosporins (if they are commonly used). Substitution would be a less appropriate solution for medicines such as codeine, diazepam, or phytomenadione; probably the best solution for these items (and for most overstocks) would be a barter arrangement with a neighboring supply system.

The real value of expiry-date analysis is that, if used regularly, it can help avoid a situation like the one illustrated by detecting potential wastage problems before they are insoluble.

40.9 Hidden-cost analysis

The concept of hidden costs was introduced in Chapter 18. Hidden costs are those costs that occur because of poor supplier performance; they are not obvious in the invoice price.

The total cost of purchasing an item from a specific supplier is the sum of the quoted price, any shipping and handling costs, and any hidden costs. In comparing quotations from different suppliers, procurement officers should consider the expected hidden costs for each supplier, based on past performance. One way to do this is to calculate the hidden cost ratio (hidden costs divided by visible costs). Visible costs are the sum of cost, insurance, and freight (CIF) for all past orders. Hidden costs are the sum of the following—

- Commissions for local agents
- Cost of late deliveries (including air freight for emergency needs, use of more expensive alternatives, higher cost for emergency replacements, and so forth)
- Cost of delivery errors (sum of costs incurred because of short shipments, incorrect medicines shipped, shipments delivered to wrong port, additional port costs because of lack of proper documents, and so forth)
- Value of losses caused by poor packaging
- Replacement cost of unusable medicines (short shelf lives, disintegrated medicines, and so forth)

The value of cost-saving contributions (deferred payment terms, suggestions for less expensive dosage forms, and so forth) is subtracted from this total.

In the example illustrated in Figure 40-4, assume that Supplier A has provided pharmaceuticals to a supply system at a net CIF cost of USD 100,000 (the visible cost). A review

Figure 40-4 Impact of hidden cost on total cost

of the procurement office's records might show that for these purchases, the following hidden costs were incurred—

- Unusable medicines (replacement cost for tablets that disintegrated in transit; expired products not replaced by supplier) = USD 6,000
- Commission for local agents (3 percent) = USD 3,000
- Late deliveries (air freight and higher price for temporary emergency stocks) = USD 9,000
- Delivery errors (2 percent average short packing) = USD 2,000
- Losses from poor packaging (not covered by insurance) = USD 3,000

Based on this experience with Supplier A, the procurement office calculates a hidden cost ratio of 23 percent, derived from $(\text{USD } 6,000 + \text{USD } 3,000 + \text{USD } 9,000 + \text{USD } 2,000 + \text{USD } 3,000) / \text{USD } 100,000$. This information can then be used to project total costs of later orders for comparison with competing suppliers. A hidden cost ratio of 23 percent for Supplier A means that the total cost for the pharmaceutical supply system will be about USD 1.23 for every USD 1.00 quoted by Supplier A for a product. If Supplier A quotes a CIF price of USD 100 for an item, the total expected cost would be USD 123. If Supplier B quotes a CIF price of USD 110, but Supplier B has an estimated hidden cost ratio of only 5 percent, the expected total cost (USD 115) would make Supplier B the most cost-effective choice.

Precision in calculating hidden cost estimates is rarely possible, but criteria for reviewing supplier performance might include hidden costs as one aspect of comparison. If

large differences in hidden cost ratios exist between two suppliers, based on past performance, this might be a deciding factor in the choice. As discussed in Chapter 18, if hidden costs are to be considered in evaluating supplier offers, this fact should be clearly specified in procurement evaluation criteria and in tender documents. ■

Glossary

ABC analysis: Classification of inventory items into three categories (A, B, and C) according to the value of their annual use, which is useful for analyzing medicine consumption and use, comparing actual versus planned purchases, justifying procurement budgets, guiding procurement patterns, and setting priorities for stock management.

Analysis of expiry dates: The analysis of stock position compared to expiry dates in the supply system inventory to avoid or minimize losses caused by wastage.

Lead-time analysis: The analysis of supplier lead time (interval between decision to order and receipt of stock), to help in selecting the best suppliers for future procurements, and payment lead time (interval between receipt of goods and payment to supplier), to monitor procurement office compliance with contracts.

Pipeline analysis: Analysis of the logistics system to identify the optimal location and quantities of stock in the distribution network, which serves as the basis for devising more efficient ordering and stock-keeping policies and procedures.

Price comparison analysis: The comparison of a supply system’s costs and prices to those of other programs or systems; for example, comparison of procurement prices to those paid by neighboring supply systems or obtainable internationally, or of sales prices to prices in the local private and NGO sectors.

Technical efficiency: Using inputs to achieve the greatest output for a given cost or to achieve a given output at the lowest cost. For pharmaceutical management, this includes therapeutic efficiency (selection and use) and operational efficiency (management of procurement and distribution):

Therapeutic category analysis: The analysis of expenditures by therapeutic category, for comparison with morbidity patterns and public health priorities, as a means of focusing cost control efforts:

VEN system: A system of categorizing medicines by their public health value (vital, essential, and nonessential), which can be useful in setting purchasing priorities, determining safety stock levels, and directing staff activities.

ASSESSMENT GUIDE

Indicators related to analytical techniques

- Numbers of medicines and value of average consumption for medicines in classes A, B, and C from ABC analysis
- Value of unplanned purchases (items not on original quantification list) as a percentage of value of total purchases
- Average supply system acquisition price as a percentage of average international price for indicator medicines
- Average medical stores sales price as a percentage of local wholesale sales price for indicator medicines—private and NGO sectors
- Average public-sector pharmacy sales price as a percentage of local retail pharmacy sales price for indicator medicines
- Ratio of net sales (or value of distributed medicines) to inventory—also called “inventory turnover”
- Operating margin on total sales—the value of total sales, minus the cost of goods sold, divided by the total sales
- Inventory-holding costs as percentage of average inventory value
- Purchasing costs as a percentage of average inventory value
- Average lead time and payment time for each major supplier
- Value of medicines at risk of expiry as a percentage of inventory value

Total cost analysis

Data elements that contribute to a total cost analysis include—

- Availability of expenditure reports or budget estimates of operating costs in warehouses and purchasing offices
- Value of accounts receivable from patients and from other facilities
- Value of bad-debt write-offs
- Value of total purchases and total sales (or value of medicines distributed)
- Value of cost of goods sold (or distributed)
- Beginning and ending inventory value for the fiscal year for major warehouses and health facilities, and average inventory value
- Inventory shrinkage: the sum of beginning inventory value plus purchases, minus the sum of cost of goods sold plus ending inventory value

- Value of any donations received or stock returns from clients
- Value of operating costs—predictable and incremental—for stock management functions (ideally at each major level of the system)
- Value of expired or wasted stock removed during the year and any such stock remaining
- Value of operating costs associated with pharmaceutical transport
- Value of operating costs—predictable and incremental—for purchasing functions
- Value of incremental costs associated with managing tenders
- Value of incremental costs of emergency purchases to cover shortages
- Value of lower-level purchases outside supply system (for centralized procurement systems)

Analytical capacity in supply system

- Which departments or offices in the supply system are responsible for analyzing recurrent costs and developing cost-control strategies?
- What kinds of analyses and reports are produced (and how frequently are they produced)?
- Are computers and spreadsheet software available for analyzing costs in the pharmaceutical supply system?
- What kinds of software with analytical and reporting capacity, in addition to spreadsheets, are available?

VEN analysis

- Does a two- or three-tier system exist for prioritizing procurement according to public health value (similar to VEN or VN)?
- If no formal system exists, how are priorities determined when funds are insufficient to purchase all medicines requested?

ABC analysis

- Has an ABC analysis been done recently of medicine consumption or purchases (and if not, does the system have the data and the capacity needed to do this analysis)?
- How do use and expenditures compare with health priorities?
- How is information from ABC analysis used to improve purchasing and inventory management?

Therapeutic category analysis

- Have recent efforts been made to analyze consumption and expenditures by therapeutic category (and if so, how is the information used)?
- How are the merits of one pharmaceutical product compared with those of other products in medicine selection and procurement?
- Does the purchasing office sometimes tender by therapeutic category or subcategory rather than for specific medicines?

Price comparison analysis

- What sources of data are available for price comparison analysis? (See also price comparison indicators above.)

Lead-time and payment-time analysis

- How are lead times and payment times tracked and used by the purchasing office?

Expiry-date analysis

- How does the supply system track expiration dates? Are reports prepared on the expiry status of medicines in stock?
- What is done about stock that will likely expire before it can be used?

Hidden-cost analysis

- Are hidden costs calculated for regular suppliers to the supply system, and if not, are records adequate to compile the information?

SUMMARY

Effective financial planning and management are vital for the successful generation, safekeeping, and use of funds to achieve program objectives.

Many government budgeting and accounting systems operate on a cash basis, recording a transaction only when cash is involved. Private-sector or semi-autonomous government programs, including many revolving drug funds (RDFs), use an accrual system, which also records non-cash transactions such as medicines issued. Public-sector managers can complement government accounting systems with elements of an accrual system to support more effective and efficient program management.

Long-range financial plans include projections of funding and expenditures over several years and thus facilitate long-range planning for health services. For an RDF, a long-range plan can project the point in the future when revenues from medicine sales will be sufficient to cover medicine program expenses. The realization of projected revenues depends on the development and implementation of detailed pricing strategies for medicines.

The first-year figures from a “rolling” long-range plan provide the basis for an annual budget, which is used

to plan and control spending for the current year. Whereas government budgets may be based on fixed funding, an RDF budget is flexible, with the level of expenditure dependent on sales revenue. A cash flow forecast helps ensure the availability of sufficient cash to cover anticipated obligations each month. Cost analysis is used to measure program efficiency and to help set prices.

Principles for effective financial control include—

- Dividing duties among different individuals
- Regulating transactions through the use of written procedures, budgets, and purchase-request systems
- Recording and monitoring all transactions
- Instituting both random and scheduled third-party auditing

The accounting system should produce the following standard reports on a monthly and annual basis—

- Budget performance report
- Income and expense statement
- Cost-center expense reports
- Balance sheet
- Summary of accounts payable and receivable

41.1 Introduction

Government allocations continue to be a major source of financing for pharmaceutical supply in many countries. Although ministries of finance and of planning (see [Chapter 11](#)) traditionally have made public-expenditure decisions, program managers can often lobby for more funding for their programs and activities. They are better able to do so if they understand the issues involved in public-sector resource allocation, can argue effectively for greater investments in health, and can demonstrate responsible and efficient use of existing resources. However, the trend in many resource-limited countries has been to decentralize health services, including pharmaceutical management. In a decentralized environment, local governments and health facilities become more responsible for managing services and mobilizing resources, with the role of the central government focusing more on regulation.

With public financing of pharmaceutical supply, managers of pharmaceutical programs are responsible for ensuring that resources are used in the best way possible, with the goal of achieving program objectives. Financial management is vital to this role. Managers need to plan, control, and monitor the generation, safekeeping, and use of funds, and they

must be able to provide appropriate financial reports to government authorities and donors. This chapter is designed to provide managers with a working knowledge of key financial management concepts and skills.

Pharmaceutical programs generally define their objectives in terms of services provided. However, financial objectives are becoming increasingly important as programs try to maintain or expand services, often in the face of reduced funding. Programs need to seek increased government and donor funding, generate additional revenues from cost sharing, and be efficient and cost-effective in providing services. To achieve these objectives, program managers must be able to—

- Prepare long-range plans to project the need for services, devise the most cost-effective way of providing them, outline the resources needed, and help secure government and donor funding
- Prepare and communicate program policies and procedures
- Set sales prices that are affordable, competitive, and meet program cost-sharing goals (discussed in [Chapter 9](#))
- Prepare and use budgets to plan and contain expenses

- Prepare cash flow forecasts to ensure the availability of cash to cover anticipated financial obligations
- Analyze costs to assess cost-effectiveness and monitor efficiency
- Control and manage the collection, safekeeping, and spending of funds
- Keep proper accounting records and prepare reports for management, government, and donors

Public-sector financial management systems, as traditionally designed, are often less than ideal for managing pharmaceutical programs—especially with regard to collection of sales revenue, which is often a new and unfamiliar task for government ministries. Given such limitations, managers of government programs may need to develop and use complementary systems to help them manage their resources effectively. New directions in public health-sector management also include decentralizing health care services, and adapting the traditional central medical store (CMS)—traditionally operated as part of the ministry of health—to serve as an autonomous or semi-autonomous supply organization operating on a commercial, but non-profit, basis (see [Chapter 8](#)). In addition, governments more often incorporate private-sector options in pharmaceutical supply management, such as contracting out specific services, which must be accounted for within the budgeting and financial planning system.

This chapter describes both how to get the best results with existing government financial management systems and how to develop complementary procedures to enhance

efficiency. A system that combines both approaches should provide a good basis for effective financial management. The chapter presents sample budgets and reports based on the hypothetical case of a government pharmaceutical program that is beginning to sell and account for medicines, as in an autonomous revolving drug fund (see [Chapter 13](#)). These examples are each inter-related, and the figures can therefore be followed from one to another.

41.2 Getting the best from a government finance system

In recent years, many government departments have begun to follow the private-sector principle of demonstrating “value for money” through the effective and efficient use of resources. They have often been hampered, however, by the limitations of budgeting and accounting systems designed only to control spending. In addition, a changing public-sector environment, featuring health care reforms such as decentralized responsibilities and autonomous management, greatly affects how a country carries out its health-sector financial management.

For example, vertical health programs that focus on targeted health interventions, such as HIV/AIDS or tuberculosis control, are usually financed by donors and operate in parallel to the government pharmaceutical supply system. Governments have recognized the inherent inefficiency in this parallel system and have made integrating vertical health programs into the government system a priority

Country Study 41-1

Negotiating prices for services to vertical programs in East Africa

A revolving drug fund frequently subsidizes vertical health programs when they operate in parallel. Often, storage space and other resources consumed by vertical programs are 50 percent of the total, whereas they pay only a minimal fee for those services. For example, in the recent experience of a national central medical store (CMS) revolving drug fund in East Africa, vertical programs used 60 percent of storage space but paid fees of only 6 to 10 percent of the value of their supplies to the CMS. This situation meant that on the remaining 40 percent of activities, the CMS had to charge a 50 percent markup to cover costs.

Vertical programs often deliver supplies to the CMS without giving distribution details, resulting in supplies that take up space for months or years. A monthly storage-fee invoice to the vertical programs should help alleviate this practice. Also, vertical programs should

meet the full cost of disposing of their expired stock. To avoid the inequalities between resources used by vertical programs and what they pay for those resources, the CMS needs to negotiate a realistic memorandum of understanding (MOU) with the vertical health programs, supported by reliable, up-to-date activity costs for the following—

- Procurement
- Clearing and forwarding
- Storage
- Distribution
- Disposal of expired stock

The MOU should be based on vertical program contributions to the CMS that are relative to the resources they consume, and the charges must be specified in detail.

Source: Rational Pharmaceutical Management Plus Program/Management Sciences for Health.

objective. Resource-intensive functions such as procurement, quality assurance, storage, and physical distribution may be integrated under the essential medicines program, whereas financing, quantification, and monitoring may stay under the control of the vertical program. Progress on integration has been mixed. In some cases, cost savings and efficiency gains have been higher than anticipated, but frequently, integrating health programs has been restricted by program-level resistance and perceived weaknesses in government management of the system. Integration can provide savings and benefits, but is reliant on strong government commitment to the process and the willingness of programs to give up some or all of their activities (see [Country Study 41-1](#)).

Government pharmaceutical programs generally suffer from the same problem: the accounting system keeps track of expenditures for pharmaceutical procurement, but it does not record the value of medicines distributed or lost. The main problem is usually that the government accounting system operates on a cash basis, recording a transaction only when cash is received or spent. Under such a system, medicines purchased on credit are not recorded in the accounting records until payment is made, and medicine issues are not recorded at all if cash is not received. A cash-based system does not record donated medicines or equipment, medicines issued free of charge, medicine losses, purchases and sales on credit, accounts receivable, accounts payable, or depreciation, nor does it maintain an accounting record of the stock of medicines. Without such information, managing a program properly is almost impossible.

A private-sector program, or a semi-autonomous government program such as an RDF, is more likely to use an accrual-basis accounting system. Such a system records all transactions at the time they are made. For example, a purchase of pharmaceuticals on credit is recorded when the products are received, increasing the balance in the pharmaceutical stock account and creating a liability to the supplier. When the supplier is paid, the liability is canceled and the cash balance is reduced. All noncash transactions, such as donations of medicines, depreciation, and stock write-offs, are also recorded.

[Figure 41-1](#) compares a traditional government budget (cash basis) with an RDF budget (accrual basis). The two budgets are based on the same events, except that the RDF budget includes noncash transactions. The government budget for 2005 shows pharmaceutical purchases of 230,000 U.S. dollars (USD) as an input to the system but shows no figure for services delivered as an output. The RDF budget, however, shows the projected cost of pharmaceuticals issued (USD 250,000) as a measure of program output; the USD 230,000 of pharmaceutical purchases is recorded in a separate pharmaceutical stock account.

Unlike the government budget, the RDF budget also takes into account the value of income received from vertical

programs, the cost of expired or lost medicines, and depreciation of fixed assets. In the government cash budget, for example, operating income is shown as USD 260,000 (based on a government allocation of USD 135,000 plus projected sales revenue of USD 125,000), which will be used to purchase pharmaceuticals valued at USD 230,000 and to pay expenses of USD 30,000. Total operating income in the RDF budget, however, includes income received from services provided through vertical programs (USD 185,000) and sales revenue of USD 125,000, for a total of USD 310,000; this operating income will be used to distribute USD 250,000 worth of medicines (cost of medicines issued), cover stock losses of USD 12,500 (cost of expired medicines), pay operating expenses of USD 30,000, fund depreciation of USD 10,000, and generate an operating surplus (income less expenses) of USD 7,500. The assets that represent that surplus and the reserve of USD 10,000 for depreciation appear as an increase of USD 17,500 in pharmaceutical stock from the previous year (see closing balance in the pharmaceutical stock account in [Figure 41-1](#)).

Note also that the format of the RDF budget provides more useful management information by grouping categories; for example, showing the deficit created by buying and selling the medicines in the pharmaceutical account. In both the government and the RDF formats, the actual income and expenses for the previous year are shown next to the budget figures for comparison.

When possible, an accrual basis (which recognizes receivables and payables without a cash exchange) should always be used. However, if a cash basis must be used because of government rules, elements of an accrual system should be used to complement the government accounting figures and provide more complete information. Priority should be given to those elements that, when adjusted, would have the greatest effect on the overall figures. The most important element is generally maintaining complete accounts for pharmaceutical transactions.

In order to track pharmaceutical transactions on an accrual basis, accounts should be opened for stock, accounts payable, and accounts receivable. This double-entry system reflects each transaction in two accounts. The pharmaceutical stock account starts with the stock balance and all subsequent pharmaceutical transactions are reflected in the account, so that at any given time the balance reflects the value of stock on hand. Medicines bought on credit increase the stock balance in the stock account and create a liability in accounts payable. Medicines received as donations (valued at the equivalent local cost) increase the stock balance in the stock account and are credited to a donations-in-kind account. The cost of lost, damaged, or expired medicines reduces the stock balance in the stock account and is debited to a medicine losses account. The cost of pharmaceuticals issued or sold reduces the stock balance in the stock account and is debited to

			Closing balance	<u>88,000</u>	<u>105,500</u>

* Because the budget must usually be completed before the end of the current year, a latest estimate of the current year is made for comparison purposes. The latest estimate for the current year is typically compiled from actual figures for the first nine months and a revised estimate for the last three months.

a cost-of-medicines-issued or cost-of-sales account. All transactions are valued at the purchase cost, and the balance in the stock account therefore equals the cost of stock on hand. An average cost should be used in the stock account for items purchased from multiple suppliers at different prices or from the same supplier at different times and for donated goods. Sales prices are normally based on these average costs. Also, stock in transit and in quarantine should be identified separately from stock on hand to avoid overstatement of availability.

Although the cost of expired medicines is often a small percentage of the total budget, the cost of disposing of expired and damaged pharmaceuticals can be enormous because of regulatory requirements and lack of disposal facilities. In addition, there is usually a hidden—but substantial—cost for storing expired medicines. Government regulations often fail to recognize medicine expiry as an integral part of pharmaceutical management; for example, the same regulations authorize writing off medicine expiry as writing off other losses (such as truck tires). Also, RDFs frequently do not include an allocation for the physical disposal of expired medicines. In such circumstances, disposal of expired medicines often has very low priority, and expired stock tends to accumulate in the storage area for months or even years. As a result, if storage is limited, it may become necessary to rent additional space to accommodate new supplies.

The cost of pharmaceuticals issued can be calculated by recording the cost of each medicine at the time of issue, but this procedure usually requires a computerized inventory system. The figure can be calculated manually, however, by adding the cost of pharmaceuticals purchased and donated to the cost of the opening pharmaceutical stock and deducting the cost of the closing pharmaceutical stock. Provided that the same method is used to value both opening and closing stocks, the resulting figure represents the cost of medicines used plus the cost of expired, missing, and damaged medicines.

The other adjustments that can be made to produce an accrual-based report from a government account relate to depreciation and operating expenses. However, because a government usually replaces fixed assets through capital budgets, these adjustments are probably not worth making unless the program will have to replace assets from self-generated resources in the future. Also, bringing operating expenses, such as salaries or electricity, onto an accrual basis may not be worthwhile if the amounts are relatively small and the expenses are paid on a regular basis.

The remaining sections of this chapter describe other elements of good financial management that should be in place, whether a program is governmental or autonomous. Some of these elements relate to the planning and management of sales revenues, which apply only to those programs that currently sell pharmaceuticals or plan to in the future.

41.3 Long-range financial planning

It is important to have a long-range view of both program objectives and activities and the resources needed to carry them out. A long-range plan for any program must include a realistic financial plan showing what funding is anticipated and how it will be spent. Without a financial plan, unachievable objectives may be set. A long-range plan might cover five years and should be a “rolling” plan—updated each year for a new five-year period beginning with the current year. The plan is broken down to show what activities will be carried out each year, as well as each year’s estimated funding and expenditures. Program planning and financial planning are inseparable, and both program and financial managers must be involved in developing the financial plan.

A long-range plan is just as necessary for a grant-funded pharmaceutical program as it is for an RDF. With a grant-funded program, a long-range plan attempts to forecast services based on estimated levels of fixed funding and, at the same time, to justify additional funding. With an RDF, it is a plan for both revenue generation and services, with each being completely dependent on the other. Often, a program is funded through a mixture of grant and revenue monies. For example, administration could be covered by a grant, whereas the purchase of medicines is funded from revenue. With decentralization, funding usually goes to the health facilities to buy supplies from the CMS. Often, sales prices must cover all operating expenses and capital expenditures. Donors may finance some capital expenditures.

In summary, long-range financial planning is important because it results in—

- A documented summary of results compared with the previous year’s plans and objectives
- An assessment of resources required for necessary services
- A review of the financial feasibility of plans and a determination of whether more funds will be needed or activities will have to be reduced
- A plan for long-term resource generation and investment
- Greater ability to seek funding successfully
- Prioritization of essential program activities
- A plan to obtain resources when they are needed
- A tool that can be used to set periodic programmatic and financial benchmarks

Figure 41-2 shows an example of a long-range financial plan for a grant-funded government pharmaceutical program that is to be converted to a revenue-funded RDF over a three-year period. The structure of the plan serves both types of program equally well. All long-range financial plans must build in a factor for annual inflation, as this example does. For expenditures on imported goods, changes in exchange rates

* Cost of goods sold is expected to increase with volume from additional facilities served by the CMS and with inflation—estimated at 5 percent annually.

over time must be considered as well. [Box 41-1](#) gives further details on adjusting for price levels and exchange rates.

The long-range financial plan shown in [Figure 41-2](#) projects increased year-to-year sale of medicines. The price markup is calculated to cover all costs (including cost of medicines, packing, distribution, medicine expiry, and general expenses) and leave a nominal net operating profit. To meet nonprofit criteria, the net profit would normally not exceed 1 percent of sales revenues. Although general operating expenses will increase over time, the rate of increase should be less than the growth in sales revenue because

administrative costs are composed of fixed or semivariable components. For example, whereas personnel costs increase from USD 69,700 in 2009 to USD 107,000 in 2014, the percentage of personnel costs in relation to sales falls from 7.0 percent in 2009 to 5.5 percent in 2014. By limiting the increase in general expenses to a rate below the increase in sales, the CMS can progressively reduce the gross margin charged (from 15.8 percent in 2009 to 12.7 percent in 2014) and increase the percentage of revenues spent on pharmaceutical supplies (cost of goods sold) from 83.0 percent in 2009 to 86.8 percent in 2014.

Box 41-1 Adjusting for price levels and exchange rates

Any comparison of funding amounts at different points in time requires consideration of the possible effect of inflation and changes in the exchange rate. Such situations include budgeting and forecasting future expenditure needs, pricing in revolving drug funds, and analyzing expenditure trends.

Inflation

Inflation can arise when the cost of imported goods rises because of rising world prices or exchange rate depreciation. Inflation also arises when the growth in a country's expenditure or consumption of goods and services exceeds the growth in its supply or production of goods and services.

Changes in the price level make the comparison of expenditures in different years more complicated: the purchasing power of a given budget depends on the price level during that year. Expenditures that are not adjusted to account for changes in the price level are called nominal or current-price expenditures; when they are adjusted to reflect changes in the price level, they are called real or constant-price expenditures. To compare expenditures in different years, they can be translated into the same "price units" using a gross domestic product (GDP) deflator series, which is usually available from the ministry of economic planning or another central government agency. In these series, one year is chosen as the base year, and other years are expressed as values relative to the base year.

The accompanying figure shows the evolution of health expenditures in an illustrative country, Kenya, over time, in both current prices and constant prices. Using current prices, expenditures appear to increase from 2005 to 2010. However, when expenditures are translated into constant dollars, in this case using 2007 as the base year, it becomes clear that the real value of expenditures has

actually fallen from 3,000 million of the local currency in 2005–06 to 1,800 million in 2009–10.

Exchange rates

The exchange rate is the price of foreign currency that equalizes the balance of payments. It is the price at which the inflow of foreign currency from exports and foreign aid is equal to the demand for foreign currency to purchase imports. The exchange rate may be fixed (determined by the government) or flexible (determined in foreign exchange markets).

Changes in the exchange rate over time can make expenditure projections more complicated when a significant proportion of total expenditures is on imported goods (such as medicines). That is often the case in countries undergoing structural adjustment, where the exchange rate may be experiencing large, somewhat unpredictable changes. In those circumstances, it is often useful to separate the local currency and foreign currency items in the budget, so that the foreign currency costs can be updated more easily in response to new information. The ministry of health or planning may be able to provide assistance in making projections about the exchange rate.

41.4 Costing

Cost analysis is an important management tool that allows managers to measure the efficiency of their programs and price products and services equitably to their clients. Efficiency can be understood as getting the most output for a given quantity of resources (for example, purchasing more pharmaceuticals with a constant budget) or achieving a given level of output at minimum cost (such as treating a bacterial infection at lowest cost). Efficiency concepts are discussed in more detail in Chapter 10. By determining the cost of each unit of output (which, in a pharmaceutical supply system, is the cost of medicines and services provided), managers can evaluate the efficiency of their programs over time or make comparisons with other organizations. Cost figures can also be used to estimate the financial effect of serving various patient volumes, different patient types, or different disease types, as well as to set prices. Total cost analysis is a good tool for assessing all costs in an entire pharmaceutical system (Chapter 40).

The starting place in determining medicine costs is the original purchase price of each medicine. Price varies over time, depending on the supplier, the date of purchase, the unit of purchase, and the volume of purchase. The costing method depends on the purpose of the exercise: an average cost can be used for making comparisons, and the cost of the most recent purchase should be used for setting a sales price. If significant transport costs are involved for imported medicines, they should be added to the purchase cost of the particular medicines supplied.

Other costs, including the transport charges for in-country distribution, are best allocated evenly over the total number of dispensing outlets, particularly if the cost information is used to set prices. Adding high transport costs to the cost of medicines sent to remote places is not equitable, especially because the patients in those areas are often poor.

If the total operating costs of the pharmaceutical supply system amount to 10 percent of the total cost of the medicines distributed, the total cost of each medicine is its purchase price plus its in-country transport costs (for imported medicines) plus 10 percent. A charge for depreciation, expiry, and obsolescence losses should be included in the total.

If medicines are being repackaged, the cost of such procedures may be attributed to the specific medicines as direct costs. However, if the overall costs are low (say, less than 10 percent of the total medicine costs), allocating them to individual medicine prices may not be worthwhile because such costing can be complicated and lengthy. Donated resources should be included at the equivalent local cost so that the full cost of each medicine is calculated. Finally, for costing and pricing to work properly, the accounting system should be on an accrual basis, or all bills must be paid promptly; otherwise, cost calculations will not be accurate.

Figure 41-3 Break-even analysis: 2004 prices for different volumes

Sales revenue	0	190,000	380,000	570,000	760,000
Cost of medicines issued	0	152,500	305,000	457,500	610,000
Cost of expired medicines	0	7,625	15,250	22,875	30,500
Variable expenses	0	160,125	320,250	480,375	640,500
Operating expenses (fixed expenses)	60,100	60,100	60,100	60,100	60,100
Total expenses	60,100	220,225	380,350	540,475	700,600
Number of patients	0	250,000	500,000	750,000	1,000,000

Note: Break-even point is where number of patients is approximately 500,000.

Figure 41-2 shows that certain costs are direct and others indirect. *Direct costs* are those that can be attributed directly to the items being costed (for instance, the purchase price of the medicine). *Indirect costs* are those that cannot be attributed directly, such as medicine losses and general operating expenses. The easiest way to allocate indirect costs is to treat them as percentage additions to the direct cost of each medicine.

Costs are often divided into fixed (predictable) and variable (incremental) costs (Chapter 40). Rent for a warehouse would be a fixed cost, because it would not vary with the quantity of pharmaceuticals held. Packing materials would be a variable cost, because materials needed vary directly with the quantity of medicines issued. This division between fixed and variable costs is useful when determining the break-even point (the production or service volume at which sales revenue equals expenses). Figure 41-3 shows a graph of the revenue and expenses with various patient volumes, using 2004 prices and expenses. Sales prices set must be sufficient to cover the fixed and variable costs, as well as the need for reserves, at the expected volume of sales. In the figure, this point is achieved with a volume of about 500,000 patients.

In practice, many costs are semivariable; this factor should be taken into account when using break-even analysis data. Salaries are an example of a semivariable cost. With increasing activity, additional staff will probably be needed, but unlike the proportional cost increase shown in [Figure 41-3](#), the increase in staff costs should be considerably less than the increase in patient volumes. Even warehouse rents are not always a fixed cost. Often, as product volumes increase, they can be accommodated in the existing warehouse, but when the warehouse is full, additional volume can only be accommodated by renting more warehouse space.

41.5 Setting prices for pharmaceutical sales and services provided

The development and implementation of detailed pricing strategies are key to realizing the projected revenues from pharmaceutical sales that are part of a long-range financial plan.

Building on the long-range plan shown in [Figure 41-2](#), [Figure 41-4](#) presents an example of price setting to achieve the pharmaceutical sales revenue of USD 457,531 projected for 2005. The example is simplified—including only four medicines and two geographic regions—but it shows how prices can be set based on each medicine's cost. The example is for the year in which sales revenue is projected to exceed total expenses in the five-year plan. In this analysis, net sales revenue of USD 457,531 is shown under (3) Summary Forecast. Gross sales revenue is projected at USD 481,688, with an anticipated total volume of social discounts or waivers valued at USD 24,157.

Projected purchase costs for each medicine, together with total operating costs, determine the medicines' full cost. Pharmaceutical sales prices are then established, based on these total costs, with various markups added and adjustments made as necessary to achieve a program's social as well as financial objectives. Adjustments for social discounts and regional equity should take into account willingness and ability to pay. If pharmaceutical use estimates are available by region, revenue contributions by medicine and by region can be calculated. Price adjustments are then made as needed to ensure that the sum of revenue contributions will equal the overall projected sales revenue. For example, in [Figure 41-2](#), the 2005 figures have been produced by forecasting sales, other income, cost of sales, packing expenses, distribution expenses, and general costs, which together produce a small operating surplus (net operating result) of USD 8,600. Perhaps several drafts of the financial plan were necessary to achieve an acceptable operating result within revenue and cost parameters. For pricing purposes, the focus should be on the USD 930,000 cost of goods sold. The gross-margin target is USD 169,700 plus the expired medicine cost of USD 9,800, for a total of USD 179,500. The

markup needed to earn USD 179,500 on cost of sales of USD 930,000 is 19.3 percent. So the default pricing markup for 2005 should be 19.3 percent. Pricing for RDFs is discussed in more detail in [Chapter 13](#).

41.6 Budgeting

In addition to a long-range financial plan, it is necessary to have a detailed budget to plan and control spending for the current year. An annual budget should be based on the first-year figures from the current rolling long-range financial plan and should reflect the activities programmed for the year.

The budgeting process must begin well before the start of the year, because it takes time for budgets to be approved. Approving government budgets, in particular, can be a lengthy process, where a predetermined schedule exists for submitting a draft budget to the ministry of health, which then forwards the budget to the ministry of finance. If the budgeting is decentralized, the process will take even longer and will have to start earlier.

The budget should show funding sources as well as expenses. A grant-funded government budget is a fixed budget, or a zero-balance budget, where funding is known and the objective is to make sure that expenditures do not exceed the funding level. If any income comes from sales revenue, the budget is flexible, since the level of expenditure will depend on the level of income.

Budget detail

All the resources to be obtained should be shown in the budget, including resources that are to be donated, so that the budget reflects the total resources needed to carry out planned activities. Separate budgets are prepared for operating (recurrent) funds and capital (development) funds.

The operating budget covers the cost of all items consumed during the year, including salaries, allowances, medicines, transport, travel, postage, telephone, office supplies, heat, electricity, water, and office rent. Any donated items, such as medicines or office supplies, should be shown and identified in relation to a specific funding source. When assets are to be replaced from sales revenue, depreciation should be included here as an expense.

The capital budget must show all land and buildings to be bought or built, as well as vehicles and equipment to be purchased. All assets that have a long life (more than one year) or a significant value should be included. The definitions of life and value should be in accordance with government regulations or with current accounting standards, if not covered by regulations. A donated item, such as a vehicle, should be shown in the capital budget and identified in relation to a specific funding source.

Sales revenue					481,688
Less social discounts	6.60				24,157
Net sales revenue					457,531
Cost of medicines issued					366,025
					91,506
Less: stock losses	5.00				18,301
Gross profit					73,205
Less: overhead expenses	16.42				60,100
Operating profit	3.58				13,105
Less: stock replacement reserve	2.00				7,320
Net profit					5,785

Notes: In a decentralized program, the field programs would use the sales price of the central program as the purchase price for their program. The other costs added to the transfer price would be those incurred at the field level. If reserves are managed at the central level for the whole program, they would not also be maintained at field levels.

^a Use the price of the most recent purchase.

^b Drug 2 is manufactured locally. Freight and duty costs for other medicines were estimated as a percentage.

^c All other costs and markups for reserves are allocated as a percentage of direct costs, based on the annual budget.

^d A nonprofit organization would not have a profit markup but would have markups for building necessary reserves to cover a bad year or a disaster (such as major stock damage), assuming insurance is not available.

^e This adjustment relates to a cross-subsidy from nonessential medicines (here drugs 2 and 4 are essential).

^f An average of 5 percent of services are provided free over both regions. The higher level of social discounts in Region 1 is not borne only by the full payers in that region.

^g This cross-subsidy is from the richer Region 2 to the poorer Region 1. Region 2 is assumed to have twice the volume of sales of each medicine as Region 1.

Budgeting method

In government programs, although budgets are prepared according to program needs, the amounts approved generally follow a historical basis: that is, the previous year's budget is adjusted by a percentage to reflect the expected change in overall government funding and, to some degree, shifting program priorities. Resource-allocation decisions may also be affected by political and other external forces, as discussed in [Chapter 11](#).

The main purpose of budget preparation is to determine and obtain the level of funding needed to provide services. After the amount of funding is decided, the job of the manager is to use those funds to achieve approved program objectives in the most cost-effective way. This task is not easy when the distribution of funds among line items is inefficient and cannot be changed.

In programs that have some autonomy and that have funding from donors or from sales, the budget is prepared more as a planning tool, with a relationship among program activities, expenditures, and income. For example, in the 2005 RDF budget shown in [Figure 41-1](#), the ability to purchase and distribute medicines valued at USD 250,000 depends on the ability to recover half the cost in sales revenue. After the budget is approved, the manager has some autonomy to reduce or increase expenditures, depending on funding levels, or to shift funds among line items to achieve maximum efficiency.

Whichever method of budgeting is used, the preparation involves identifying, quantifying, and costing the resources needed; determining the level of available funding; and adjusting expenditures to the expected level of funding.

Identify, quantify, and cost the resources needed. Each activity in the workplan must be examined, and the staff time, supplies, and equipment needed to carry it out must be quantified. For example, a CMS manager must decide how many staff are needed to properly handle and record the medicines, what types of equipment (such as forklifts or computers) are needed, what it takes to operate them, and what supplies are needed. (See the discussion of quantification of pharmaceutical needs in [Chapter 20](#).) After each resource needed has been quantified, the cost can be estimated. If any of the resources are to be purchased long after the budget is prepared, a percentage for inflation should be added to the current price.

Determine the level of available funding. Funding may include government allocations, donor grants, and sales revenues. It is important to show each funding source separately and to show the relationship between any dedicated funding source and the expenditures to which it relates. Not all the government funding may materialize—sometimes only salaries are maintained at the budgeted level. The budget should be prepared as if the whole government allocation will be provided, but managers should antici-

pate that some funds may not arrive and pace spending accordingly.

In the case of revenue generated from sales, managers should be conservative when preparing estimates because of the risk that such revenues might not be forthcoming (for instance, because of collection problems). Sales revenues depend on the forecasted volume of sales for each medicine and its price. From this revenue it is necessary to deduct the sales value of medicines to be provided free (either for poor clients or for exempt services) and the value of any estimated losses—such as those due to leakage, deterioration, theft, or expiration.

Adjust expenditures to the expected level of funding. This adjustment is cyclical. Activities are originally determined in accordance with needs and with an optimistic view of funding. As the actual level of funding becomes clear, if it is less than hoped, activities are reduced or made less costly. Setting priorities among activities is useful so that it is known in advance which activities will be cut if funding is lacking.

The budget must always show the basis for each line item. For example: Fuel for transporting medicines—USD 16,000 (four vehicles at 20,000 miles per year, 10 miles per gallon, USD 2 per gallon). A budget that clearly relates financial estimates to activities is easier to justify and provides a stronger basis for obtaining the required funding. The RDF budget example in [Figure 41-1](#) shows the number of patients to be served, which is useful to include. Types of patient (children), disease (malaria), and geographical areas to be covered could also be included.

41.7 Cash planning

Even though there may be sufficient funds in the budget, there may be times when not enough cash is available to pay the bills, especially if funding is irregular or large payments must be made (such as for a bulk purchase of pharmaceuticals). A cash flow forecast helps ensure sufficient cash to cover all anticipated financial obligations each month. An example of a cash flow forecast is given in [Figure 41-5](#).

The cash flow forecast should be prepared from the workplan and budget. The process is simple: start with the anticipated cash balance (cash in hand and at the bank), and add receipts and deduct payments in the months when they are expected to fall. In the example shown in [Figure 41-5](#), grants are expected to be received periodically, in January, April, July, October, and December. Sales revenue is expected to vary only slightly each month. A loan of USD 50,000 will be available in January. Capital purchases, receipts, and payments relating to accounts receivable and payable should be included in the cash flow forecast, but items that do not result in cash receipts or payments (depreciation, stock losses) can be omitted.

Figure 41-5 Cash flow forecast

	Cash Budget 2005	Monthly Allocation

41.14 PLANNING AND ADMINISTRATION

If the balance at the end of any month is negative, funds will be insufficient that month. When this happens, either activities or funding schedules will have to be changed, or credit will have to be obtained. If a significant surplus exists, putting the funds into a deposit account at the bank to earn interest may be desirable, but speculative risks should not be taken to earn higher returns.

In circumstances where an additional sales markup is made on pharmaceuticals to cover replacement cost, it may be appropriate to put the additional funds generated into a separate bank account so that they will be available when the time comes to replace the pharmaceuticals. Likewise, the depreciation fund could be put into a separate bank account as a special reserve. Payments to such special-reserve accounts should be treated as cash payments in the cash flow forecast so that these funds are not perceived as being available to cover operating costs. In the month when they will be used to replace pharmaceuticals or a fixed asset, the funds should be shown as incoming revenue. Because such procedures are not considered best practice in modern financial management, however, they should be considered only by programs with limited financial management capacity.

Failure to predict cash flow accurately can result in cash shortages, which can mean problems in paying salaries (resulting in demoralization of staff), replenishing pharmaceutical stocks, keeping vehicles operational, or replacing equipment. Any one of those problems can prevent a program from achieving its objectives.

41.8 Controlling and managing resources

Good financial controls and a sound accounting system are the basis for effective financial management. Although financial managers and accountants are responsible for establishing and maintaining the control and accounting systems, the general manager must know enough about the system to supervise staff members and to detect any problems.

The first principle of cost control is that the benefit of control efforts should exceed their costs—measured in money, time, or effort. Some government-based controls are so cumbersome and bureaucratic that they prevent the organization from meeting its objectives. For example, the use of multistage, paper-based procedures for controlling goods received has resulted in delays of weeks and months in processing supplies following delivery, preventing customers from being supplied, even though supplies were physically available. Process flows should be analyzed and modified to avoid such a scenario.

Standardized financial controls and accounting procedures help ensure that resources are generated and used properly and that a complete and accurate financial picture

of operations, assets, and liabilities can be obtained. See [Box 41-2](#) for a financial control checklist.

The three main principles of an effective financial control system are to—

1. Divide duties among individuals so that no one person can control all phases of a transaction. For example—
 - Tasks of requesting payment, authorizing payment, and issuing checks should each be carried out by a different person.
 - The person who prepares a bank reconciliation should not handle or record receipts or payments.
 - The person making purchases and the person paying for them should be different, and they should report to different supervisors.
2. Use financial control procedures to regulate transactions. For example—
 - Issue preprinted, serially numbered receipts for all inflows of cash.
 - Deposit all cash receipts in the bank and make deposits promptly.
 - Minimize the use of cash and require detailed expense reports with receipts for such transactions.
3. Use the accounting system to record and monitor all transactions and assets. For example—
 - Record all issues of medicines in the accounting records and include the value of stocks in the accounting system.
 - Produce monthly income and expenditure statements from the accounting system and review the figures for stocks, sales, and waivers.

Usually, government systems require extensive approval procedures before funds can be spent. Managers still must ensure, however, that the funds have been spent wisely and well. The first step is to have a strict approval process for expenditures. This process includes keeping good records of uncommitted fund balances for each line item (with separate amounts for each donor, if necessary) and approving expenditures only after ensuring that they are within the budget and that adequate cash is currently on hand. If the spending follows the current budget and the budget has been regularly reviewed so that it is in line with program needs, the use of the funds can be approved.

Reviewing prices paid for services or products is important to ensure that the best price and quality were obtained, and to check that the services or products were actually received. For example, before paying a bill for painting a storeroom, the manager should visit the storeroom to see whether the job was done well. Before paying for a batch of medicines, the manager should go to the store and see whether they are on the shelves and shown in the stock

Box 41-2 Manager's checklist for good financial control

Controlling receipts

- Issue prenumbered receipts for all cash received.
- Keep all original receipts and copies of canceled checks.
- Control all receipt books in use and in stock, and lock up all unused receipt books.
- Keep all cash and checks received separate from other funds. Do not use them as a source for payments, and bank them promptly.
- Reconcile the bank balance every month.
- Use a register to record all checks received.
- Do not cash personal checks from petty cash.
- Use a register to record all donations of supplies or fixed assets, showing the value.

Controlling assets

- Maintain up-to-date inventory records and reconcile balances each month with the accounting records.
- Physically check a sample of inventory balances each month.
- Maintain a fixed assets register.
- Keep up-to-date maintenance and inspection records.
- Put permanent identification tags, numbered sequentially and recorded in the asset record, on all equipment.
- Make a photographic or video record of all equipment and assets.
- Protect against loss or theft of assets with appropriate security and insurance.
- Keep usage records for equipment and vehicles (for example, log books).
- Monitor advances and accounts receivable and make sure that they are cleared within a prescribed period.
- Make arrangements for recovering overdue staff advances from salaries.
- Place cash reserves in low-risk, interest-earning investments (such as bank savings accounts).

Controlling expenditures

- Establish detailed procurement procedures.
- Obtain written bids or quotes for all purchases above a specified limit and file them with the purchase order.
- Use a local purchase order for all local purchases.
- Check that goods and services purchased are received and recorded (pharmaceuticals must be entered in inventory records).
- Check that the quality, quantity, and price of goods

or services received correspond to purchase specifications.

- Make all payments for goods or services by check.
- Require supporting documentation for all purchases.
- Make sure that all expenditures are genuine, reasonable, and in line with program plans and budgets.
- Check the proposed expenditure against the budget and ensure that the budget is up-to-date regarding donor contributions and sales revenue.
- Check that funds are available.
- Check that the petty cash balance is maintained at the agreed level of imprest.
- Control liabilities
- Manage supplier accounts so that balances are paid promptly when they are due for payment.
- Maintain control over suppliers' invoices, know what supplies have been paid for and when they will be delivered, and monitor date of receipt.

Many programs use computerized management information systems that carry out or support these controls. Such computerized systems can greatly improve the level of financial control by providing regular, up-to-date information, data analysis, and report generation with levels of detail that are not possible using manual systems. These systems, however, bring their own control challenges, which are best addressed before and during the implementation phase. They include—

- Conducting a thorough review when planning a computerized system. The system should be designed to make the most of the computer's functionality and should not just mimic the previous manual system.
- Completing a review of system rights and privileges and incorporating those attributes as well as any changes in the new system. System rights and privileges specify who can change the system, change data, edit master files, enter and confirm different transactions, and has read-only access. The review team needs to include senior management and the internal auditor (if there is one); the review should not be left solely to information technology staff.
- Reviewing software license agreements to ensure all aspects of the program are included and sufficient flexibility exists to support potential evolution of the program.
- Establishing a system security policy.
- Establishing a data backup policy.
- Ensuring that internal and external audit staff members are qualified to audit computerized systems.

records. Checking a few of the items purchased should be sufficient.

To avoid spending the entire available budget during the first few months, program managers may establish a monthly spending limit, requiring special approval of any expenditure in excess of that limit. However, to avoid lengthy approval delays, financial managers may want to establish special procedures to accommodate known fluctuations caused by planned outlays for annual rents or capital improvements. Because the expenditure budget is based on a particular level of funding, updating the budget is vital if any significant variation in funding is expected (anything over 5 percent would be significant). For example, if a donor that was going to provide 10 percent of the pharmaceutical supply can now provide only 5 percent, the budget must be revised. If additional funding is generated, the expenditure budget can be increased accordingly or the surplus reserved for unidentified future requirements.

The accounting and reporting system must provide fast, accurate information in terms of funds received and expenditures made so that budget adjustments can be made promptly. With increased use of computers in program management, budgeting tasks can be handled more quickly and more accurately, but manual record keeping is still the norm in many places. If computer-based systems are used, making regular backup files or printing hard-copy reports periodically is a good practice. In either case, a budget report must be produced every month. This report shows the budgeted and actual figures for each revenue and expense category for the month and for the year to date and also shows the variance between the year-to-date budget and the year-to-date actual figures. All significant variances must be investigated and appropriate action taken. A sample budget report is shown in Figure 41-6.

Cash and bank movements and balances should be reviewed daily to make sure that receipts and payments are as expected and that funds are sufficient to meet obli-

gations. A statement should be obtained from the cashier each morning showing the opening balance, cash received by source, payments made, closing balance for the previous day, and payments due that day.

Usually, imported supplies will be paid for in foreign currency (often U.S. dollars). To protect against currency fluctuations, maintaining a U.S.-dollar bank account to hold funds for future procurement is sensible, when this is possible. The U.S. dollar is also the currency frequently used for donated funds. When such funds are provided for procurement purposes, donors should be persuaded to pay in U.S. dollars deposited to the CMS dollar account. This procedure not only preserves procurement capacity of the funds against exchange-rate movements, but also avoids commissions charged by banks to exchange dollars into local currency and then back into U.S. dollars.

It is also important to have an annual external audit, which helps ensure that controls are operating properly and that transactions are being properly recorded. This institutional audit should cover both donor funds and the organization's own funds. Separate audits of individual donor funding should be discouraged because they do not provide a complete picture and consume excessive amounts of management time. Instead, managers should attempt to persuade donors to share in the cost of the institutional audit.

41.9 Accounting and reporting

An autonomous pharmaceutical program can normally establish its own accounting and reporting procedures, provided they are in accordance with generally accepted accounting principles. However, a government program usually must follow uniform accounting procedures. As described in Section 41.2, standard government accounting systems may not provide adequate information on transactions or assets and may not allow performance to be measured accurately. In order to satisfy management needs, supplementary records must be kept and additional reports produced. The following books, or subsidiary ledgers, are usually required for a complete accounting and reporting system—

- Cash-received book showing the date and source of receipts (such as donor, government, or sales point) and when and where the cash was deposited
- Cash-paid book showing payee, purpose, funding source, and bank account
- Petty cash book for small cash payments
- Accounts receivable ledger with accounts for people who owe money to the organization
- Accounts payable ledger with accounts for people who are owed money by the organization
- Journals showing purchases and sales made on credit,

transfers between accounts, and donations in kind

- General ledger with income, expense, asset, and liability accounts
- Salary book showing details of staff salaries and allowances
- Inventory records showing the quantity and cost of all medicines received, issued, and on hand by type of medicine
- Fixed assets register showing the quantity and cost of all fixed assets bought, sold, and on hand

Some of these ledgers may be consolidated in an integrated, computerized accounting package.

The chart of accounts, which sets out the accounts structure, lists all accounts—with a unique code for each. The code is used primarily to identify the type of asset, liability, revenue, or expense (for example, bank account, medicine sales, or salaries), but it can also be used to identify a responsibility center (such as a regional distribution center) or donor fund (such as a tuberculosis program). For the accounting system to provide the control and information required, the accounts must be structured appropriately. For example, in order to readily produce a report showing expenses for each regional center, each expense item must be coded by regional center and posted to a separate account. The coding structure should be detailed enough to provide needed managerial information but not so complex that excessive effort or skill is required to code and process transactions accurately.

Transactions must be recorded and processed promptly and accurately. For example, if all pharmaceutical issue records are not up-to-date in the accounting books, it will be impossible to reconcile the inventory balances in the accounting department with those shown on the warehouse stock cards.

The accounting system should produce a number of basic reports that provide all the information needed to review financial progress and status. In particular, the reports should indicate clearly if the program is—

- Meeting its financial objectives—for example, covering costs or generating a surplus
- Operating efficiently and effectively
- Looking after its assets
- Generating and using resources properly
- Meeting donor requirements

Reports should be produced both monthly and annually. The most common standard reports are as follows—

Budget performance report: This monthly report compares budgeted and actual revenue/expenses (see [Figure 41-6](#)).

Income and expense report: This report, produced monthly and annually, shows all income and expenses to date

and the cumulative surplus or deficit (Figure 41-7). For comparative purposes, actual figures for the previous year and budget figures for the current year are shown. A key figure is the deficit or surplus in medicines funding as a percentage of the cost of medicines issued or the cost of sales. This figure shows the extent to which medicine costs are being recovered. For the 2005 figures shown in Figure 41-7, the deficit of USD 138,000 represents 57 percent of the cost of medicines issued (USD 242,000). This deficit means that 43 percent of the cost of medicines is being recovered, taking into account stock losses. In Figure 41-2, the projected surplus (contribution line) of USD 170,300 for 2007 represents 14 percent of the USD 1,211,800 cost for medicines sold. These percentages are a measure of effective pricing, revenue collection efficiency, and control over stock losses.

Balance sheet: This report, produced monthly and annually, shows the soundness of the program at one point in time. It shows the balances at the end of the period for all assets, liabilities, reserves, and fund balances (Figure 41-8). Certain key ratios help managers to evaluate the program's financial health. The ability of the program to meet its current liabilities in the short term is measured by comparing the cash balance with the accounts payable (in 2003, this would be USD 4,520 compared with USD 4,230). The same measure in the medium term compares the total current assets with the total current liabilities (USD 62,650 compared with USD 7,246 in the same example). When assessing the ability of a program to meet its liabilities, it is vital to be sure that the amounts for pharmaceutical stock and accounts receivable are realistic—that is, that they will result in cash income that can be used to meet those liabilities. Note that a strong balance sheet can be a misleading indicator of an organization's financial health. For example, abundant long-term assets cannot satisfy immediate short-term liabilities. Provisions should be made to account for obsolete and slow-moving medicine stocks and for old accounts receivable in the balance sheet.

Pharmaceutical stock account: It is important to prepare a summary of the pharmaceutical stock account as an attachment to the income and expense report (see Figure 41-7). This summary shows the total figures for pharmaceuticals received and issued, as well as opening and closing balances, and it provides a picture of the movements in that account. If a computerized accounting program is used, the program should be able to produce a similar report for each pharmaceutical, a feature that is useful for measuring sales frequency and months of stock on hand. Chapter 40 discusses a number of analyses that can help managers understand and control inventory costs.

Accounts payable and receivable: These additional reports support the figures shown in the balance sheet and show the balance for each debtor and creditor, with a

Total long-term loans and equity	<u>70,455</u>	<u>87,404</u>

require separate reports, the reports can be prepared by funding source, provided that this capability is built into the account structure. Producing reports by responsibility center or funding source is easy if the accounting system is computerized. However, with a manual accounting system, the accounts can be set up in only one way—by responsibility center or by funding source. The decision should be based on the relative importance of each kind of analysis and the ease of extracting information from the accounting system. For example, if regional sales are of interest, these data can be extracted from the monthly regional reports.

Where a pharmaceutical sales program is in place, it is important to record and report revenue lost because of

free distribution of medicines. Waivers for sales to the poor and exemptions applicable to special age groups or other categories should be recorded using special receipts. Such transactions should be authorized by the manager. They should be put into the books as sales and debited to a special account for free issues. They will then appear as an expense in the income and expense report.

In order to measure a program's output in terms of pharmaceuticals issued or the surplus or deficit from pharmaceutical sales, it is necessary to record the cost of pharmaceuticals issued. This process is an accounting transfer from the pharmaceutical stock account to a cost-of-issues account. The pharmaceuticals issued are valued at the cost of purchase—that is, at the same value at which they entered into the pharmaceutical stock account.

When quantities of a pharmaceutical in stock have been bought at different prices, there are different ways to value the quantity issued and, at the same time, the value of stock on hand. See [Box 41-3](#) for a comparison of the three common methods. It is important to remember that the accounting method used determines how much surplus or deficit is shown in the income and expense report and how much stock value is shown in the balance sheet. Consistency is most important—the same method should be used each year. If a change is made in the methodology used, it must be disclosed in the organization's financial statements.

The average method is recommended because it is the easiest to understand. Calculating the average cost is simple: the financial balance in the stock account is simply divided by the number of units on hand. The average cost is updated every time a new purchase is made. Issues are then charged out at the average cost of the items in stock.

In the case of high inflation or large exchange fluctuations, where a computerized accounting program is used, keeping stock records in a stable foreign currency may be useful. Local currency records must still be kept, however.

In an autonomous RDF, generating sufficient revenue to replace stocks is extremely important. This is best done by creating a reserve for the purchase of replacement stocks. For example, if the replacement cost is expected to be 20 percent above the current cost, an extra 20 percent markup should be added to pharmaceutical sales prices, and an amount equivalent to that 20 percent for all sales for the month should be added to the reserve set aside to replace the stocks (see Section 41.5 and [Chapter 13](#)). ■

Box 41-3 Three methods of accounting for medicines issued

FIFO (first in/first out). Issues are charged out at the purchase cost of the earliest batch in stock. This method charges less to cost of sales and values stock higher.

LIFO (last in/first out). Issues are charged out at the purchase price of the latest batch in stock. This method charges more to cost of sales and values stock lower.

AVG (average). Issues are charged at the average price of the items in stock; the average is updated every time a new purchase is made. This puts the same value on issues and stocks.

LIFO is the most conservative method because it puts the lowest value on stocks and the highest value on issues. The average method is somewhat conservative, and the FIFO method is the least conservative. With both FIFO and LIFO, record keeping is more complicated, because it is necessary to keep track of how much balance remains from each purchase, and issues may have to be charged out at two or more prices.

Example of the effect of the three methods of accounting for medicines issued

	# Units	Unit price (USD)	FIFO (USD)	LIFO (USD)	AVG (USD)	Avg. unit cost (USD) ^a
Bought January 1	100	1	100	100	100	
Bought February 1	100	2	200	200	200	
Balance February 1	200		300	300	300	1.50
Issued February 22 ^b	120		140	220	180	
Balance February 28	80		160	80	120	
Bought March 1	100	3	300	300	300	
Balance March 1	180		460	380	420	2.33
Issued March 26	80		160	240	186	
Balance March 31	100		300	140	234	

^a Average unit cost changes with new purchase.

^b The figures for the February 22 issues are calculated as follows:

 %o FIFO—100 units at 1 USD and 20 units at USD 2;

 %o LIFO—100 units at 2 USD and 20 units at USD 1;

 %o AVG—120 units at the average unit cost of USD 1.50 (total cost of USD 300 divided by total quantity purchased of 200).

ASSESSMENT GUIDE

Current pharmaceutical budget and expenditures

- What is the ministry of health's (MOH) per capita budget or total expenditure on pharmaceuticals, in U.S. dollars?
- What was the value of the public pharmaceutical budget spent per capita in the last year, out of the average value of the same budget during the past three years?
- How much of the public pharmaceutical budget was spent, of the public pharmaceutical budget allocated?
- During the last fiscal year, how much did the central medical store spend on fuel for transport, maintenance, administration, hired labor, warehouse space (rent, telephone, utilities), or other costs (describe)?

Accounting system

- Is the pharmaceutical program's accounting system on a cash basis or an accrual basis?
- Do accounts exist for stock? What accounting method is used to value pharmaceutical stocks and issues—first in/first out (FIFO), last in/first out (LIFO), or average costing?
- Are records kept on the value of donated medicines? The cost of expired or lost medicines? Depreciation of fixed assets?
- Are records maintained for accounts payable? Accounts receivable?
- Does a chart of accounts exist? Is it structured to provide necessary management information?

Financial planning, budgeting, and cash planning

- Is there a long-range financial plan projecting both funding and expenditures for the next five years, and maintained on a rolling basis? Is a factor for inflation built into the plan?
- If pharmaceutical sales are anticipated, have pricing strategies been determined? Does the plan project the point at which revenues will cover expenses?
- Which offices are responsible for developing and approving budgets? (List steps and persons or offices responsible.) What information is used in developing budget requests?
- What information and supporting documents are submitted with budget requests?
- How does the MOH access budgeted funds for routine procurement—by scheduled allocation or access whenever needed?
- What approvals are required for expenditures?

- How does the MOH access funds for emergency procurement?
- What is the average lead time for MOH approval of procurement allocation (for both routine and emergency procurements) and for approval of foreign exchange allocation?
- How does the MOH access foreign exchange for procurement?
- Is the annual budget based on the first-year figures from the long-range financial plan? Are there separate operating and capital budgets?
- Does the budget relate financial estimates to activities in terms of the number of patients to be served, types of patients, diseases, and/or geographical areas to be covered?
- Has a cash flow forecast been developed to support the budget?

Costing

- Are the costs of in-country transportation, repackaging, medicine losses, and other operating expenses included in total pharmaceutical costs?
- Are analyses performed with regard to the cost of serving different patient volumes, different patient types, or different disease types?
- For an RDE, has a break-even point been projected?
- What method is used to value inventory?

Financial control and reporting

- Are duties divided among individuals so that no one person can control all phases of a transaction?
- Are preprinted, serially numbered receipts issued for all inflows of cash? Are cash receipts deposited promptly?
- Is there a budget approval process by which expenditures are approved only after ensuring that funds are available?
- Is the budget revised when funding is greater or less than anticipated?
- Is a budget report produced every month, showing budgeted and actual figures and variances for each revenue and expense category? Are causes of variances analyzed and addressed?
- Are income and expense reports, balance sheets, summaries of the pharmaceutical stock account, and reports on accounts payable and receivable prepared monthly and annually?
- Is an annual institutional audit performed by external auditors?

SUMMARY

This chapter describes methods for developing effective storage facilities, a process in which supply system managers play a key role.

Storage facilities are of three basic types—

- Mechanized warehouses rely on the use of mechanical handling equipment. They are appropriate where most goods are stored in bulk on pallets.
- Manual warehouses are appropriate where goods are stored in smaller quantities, mostly on shelves.
- Storerooms are fitted with shelves, refrigerators, and a secure cupboard or safe. Every facility needs a location where medicines and medical supplies can be stored safely.

Satisfactory storage accommodation may be obtained by reorganization or renovation of an existing facility, lease or purchase of a commercial warehouse, or putting in a new building. A new building may involve ground-up construction or the erection of a prefabricated building that is purchased and assembled on the preferred site. Most of the chapter focuses on managing traditional construction.

There are six stages in the procurement and construction process—

1. *Inception*: conducting a needs assessment; setting up a project team; appointing consultants
2. *Feasibility*: carrying out a feasibility study; obtaining a budget allocation
3. *Site selection and acquisition*: selecting a site or building; obtaining the site or building
4. *Design*: preparing a detailed design brief; selecting storage methods and choosing materials-handling equipment; planning space; designing the building
5. *Tender and project planning*: selecting a procurement method; drawing up a contract; conducting the tender process; planning the project
6. *Construction and commissioning*: managing the construction contract; commissioning the facility

Following procurement and construction, building and equipment maintenance adds an ongoing stage to the process.

42.1 Types of storage facilities

Well-located, well-built, well-organized, and secure storage facilities are an essential component of a pharmaceutical supply system. An effective building provides the correct environment for the storage of medicines and commodities and assists the efficient flow of supplies. Storage facilities designed with these factors in mind will help maintain pharmaceutical quality and reduce operational costs. Storage facilities fall into three categories: mechanized warehouses, manual warehouses, and storerooms.

Mechanized warehouses are designed around modern methods of storage and materials handling. A mechanized warehouse typically has tiers of pallet racks. Mechanical handling equipment is used to unload and store goods received and often to load outgoing goods onto delivery vehicles. Mechanized warehouses can range from very simple buildings using manually operated handling equipment and manually operated stock control systems to highly complex operations that are entirely automatic and computer controlled. Mechanized medical warehouses are most likely to be primary stores at the national or regional level. Typically, they are located close to major transport routes.

Manual warehouses may also hold some stock on floor pallets, but most items are stored on shelves and are moved without mechanical assistance. Medical supply warehouses at the regional or district level are usually manual ware-

houses. They are often attached to a hospital, which they also serve.

Storerooms are needed in every health facility to store medicines and medical supplies safely. The smallest facilities may need only a medicine cupboard, but most facilities require a room fitted with shelves and refrigerators, along with a secure cupboard or safe for controlled drugs.

This chapter provides guidelines to help managers make rational choices about designing and constructing warehouses. This material focuses on management of construction from the ground up. There are six stages in the process: inception, feasibility, site selection and acquisition, design, tender and project planning, and construction and commissioning (see [Table 42-1](#)). Following the planning and construction process is the continuing activity of building and equipment maintenance, which lasts throughout the life of the building.

In recent years, options have emerged for purchasing prefabricated warehouses and placing them at prepared sites rather than going through a new construction process (see [Box 42-1](#)).

This chapter is not a comprehensive technical manual and is not intended to be a substitute for the advice of a specialist. In most cases, specialist staff or outside consultants will be needed to deal with design and construction management issues. The day-to-day management of medical stores is covered in [Chapter 44](#).

Table 42-1 Steps to plan and build a storage facility

Stages and tasks	Principal responsibility of—
Inception stage	
State the aim of the project (needs assessment)	Supply system
Establish the project team and appoint consultants	Supply system
Feasibility stage	
Identify quantity and type of storage space needed	Project team
Review options for reorganizing existing warehouse space	Project team
Consider leasing or purchasing an existing building	Project team
Determine whether a building is needed. If so—	Project team
• Establish operational requirements and prepare outline brief	Project team
• Assess financial, material, and personnel resources required	Project team
• Contact relevant authorities	Project team
• Survey regulatory requirements	Project team
• Assess availability of incentives	Project team
• Establish outline budget and obtain budget allocation	Project team
• Establish a program for the design and construction stages	Project team
Selection/acquisition of site stage	
Short-list and evaluate potential sites and buildings	Project team
Select and acquire site or building	Supply system
ESTABLISH FEASIBILITY AND PROCEED WITH DESIGN	
Design stage	
<i>Outline proposals</i>	
Develop design brief	Project team
Survey site or building	Project team
Prepare outline proposals showing main dimensions, allocation of space, and construction methods	Project team
Prepare cost estimates	Project team
Select suitable design	Project team
Obtain development consent	Project team
<i>Scheme design and detail design</i>	
Design each room and fix sizes	Project team
Determine needs for storage and handling equipment	Project team
Decide on construction method and all materials	Project team
Make new cost estimate	Project team
Prepare and agree on final design drawings	Project team
DESIGN SHOULD NOT BE CHANGED AFTER THIS POINT	
Production information	
Prepare production drawings, specifications, and bills of quantities, giving all information needed to construct the works	Project team
Select all fittings, fixtures, and equipment	Project team
Obtain approval from building regulations authority	Project team
Make final cost estimate	Project team
Tendering and project-planning stage	
Select method of building procurement	Project team/supply system
Prepare short list of contractors, or prequalification tender	Project team/supply system
Assemble tender documents and invite tenders	Project team/supply system
Analyze bids and select the best	Project team/third-party observer
Make any changes required for cost reasons	Project team/supply system
Agree on contractor's program and procedures	Contractor/project team
Finalize insurances and sign the contract	Contractor/supply system
Tender for and obtain mechanical handling equipment	Project team/supply system
CHANGES BEYOND THIS STAGE WILL COST EXTRA TIME AND MONEY	
Construction and commissioning stage	
<i>Site work</i>	
Supervise work on-site	Project team
Hold regular progress meetings with contractor	Contractor/project team
Prepare valuations and make interim payments	Contractor/project team/supply system
<i>Handover</i>	
Witness tests, inspect the works, and list defects	Contractor/project team
Hold handover meeting and accept keys and building manual	Contractor/project team/supply system
<i>Commissioning and defects period</i>	
Commission building	Supply system
Check that the defects have been rectified	Project team
Settle final account by releasing the retention sum	Contractor/project team/supply system

42.2 Inception stage

From a consultant's standpoint, a good client (the supply system) should be knowledgeable and discerning. Most of the key decisions in a building project are made during the inception and feasibility stages, when client input is critical. These decisions fundamentally affect the cost and ultimate effectiveness of the project and should not be made casually. Particularly when resources are limited, careful feasibility planning is necessary to design and build effective warehouses at the lowest cost, while taking future needs into account.

The logistics team should assume responsibility for identifying the most suitable locations for medical stores throughout the country, based on an overall analysis of the distribution system (see [Chapter 22](#)). After an individual store location has been selected and outline zoning approval has been obtained from the relevant authorities, the detailed building procurement process can start. This process begins with a broad needs assessment, which guides the decision about whether to procure a prefabricated building or construct a new building and defines the critical operational parameters for the proposed building (see [Box 42-2](#)). This needs assessment will form the basis for developing the

detailed design brief in conjunction with the project team and technical consultants.

The project team

A project team should be formed as soon as the decision to obtain storage space has been made. A senior pharmaceutical program manager or health official should direct the team. Its composition varies, depending on the size of the project and the project stage. The full team for the implementation stages of a large project such as a new central medical store (CMS) normally includes the lead consultant (usually an architect or engineer), a client representative, the supply system representative, a cost consultant, a structural engineer, a mechanical services engineer, an electrical engineer, an information technology specialist, a quality assurance/regulatory consultant, and a logistics and materials-handling consultant.

A wide range of other people and organizations should be consulted. Broadly based consultation is essential to the development of an appropriate building design. Too often, a project design takes shape without adequate consultation between the people who are to work in the building and the specialists who are designing it.

Box 42-1 Installing a prefabricated warehouse

Prefabricated warehouses offer an alternative to conventional warehouse construction methods. Such warehouses are built using technologically advanced materials, which simplify structure assembly. The kit consists of pre-engineered and prefabricated warehouse modules (framework, panels, doors, and other requested sections) produced to technical specifications in a controlled environment. While the warehouse is being manufactured to the client's design, the concrete slab foundation is poured at the selected site according to predetermined specifications; the slab is the only element that is "constructed." Once the slab is completed and quality tested, the necessary building components are shipped to the site. The manufacturer's staff supervise and certify warehouse assembly. This approach can be used to install any size warehouse facility (central, provincial, district, or health center). The process generally takes three to six months whereas a conventional construction project can take up to thirty-six months.

Advantages of opting for a prefabricated warehouse include—

- There is no need for engineers or architects on site (lower costs).

- Materials are produced by the supplier according to technical specifications.
- The structure can be installed in any location regardless of availability of local construction expertise.
- There is no need for an extensive design process (faster timeline and lower costs).
- Modular design allows for easy extension.
- Having few conventional construction steps results in less material loss, lower risk of accidents, and fewer delays.
- Composite materials used for the walls and roof require less repainting and fewer roof repairs, dramatically reducing maintenance and operational costs.
- Materials provide high thermal insulation and class 1 fire resistance.
- The possibility of prequalified suppliers simplifies complex procurement procedures (construction tender process), thus shortening the procurement phase.
- The cost of installation can be 65 percent of conventional construction, and operations and maintenance costs may be halved.

Box 42-2 Conducting a needs assessment for site planning

The needs assessment should consider the following factors—

- Who will own the store—public or private sector?
- Who will operate the store—public or private sector?
- What is to be stored—types of medicines and supplies and approximate annual volumes?
- Who are the major suppliers?
- Who are the major customers?
- In what formats will goods be stored (pallets, cartons, or individual packs)?
- Will bulk packages be “broken” to fulfill individual customer orders?
- What type of materials-handling equipment is likely to be appropriate?
- What are the likely restock and distribution frequencies?
- What temperature and humidity controls will be needed within the store?
- How will goods be protected against fire and theft?
- Will stock control be manual or electronic?
- What are the intended operating hours for the store?
- How many administrators and manual workers will be needed on the staff?
- What facilities should be provided on-site to ensure staff welfare?
- How will staff members reach the site?
- Who will monitor the performance of the store and how will this be done?

Appointment of consultants

If the project is complex, suitably qualified consultants should be appointed at the earliest possible stage for estimating building design costs, cost control, construction site management, and logistics and materials handling. The roles and responsibilities of the consultants are very much dependent upon the chosen procurement route to be followed (see Section 42.6). If the project is small and simple, professional consultants may be appointed after the feasibility stage, when alternative sites or buildings are being considered.

Building design. Professional design assistance is essential to ensure that a building satisfies the design brief and is constructed in accordance with building codes. There are various ways of procuring a design service.

In the *conventional* model, a lead consultant directs the project team; typically this person is an architect, but he or she could be an engineer. The lead consultant is appointed by the client to prepare the design, specifications, and bills of quantities, in liaison with the engineering and cost consultants. In some countries, all other consultants work directly for the lead consultant, and the cost of their services is included in the lead consultant’s fee. In other countries, each consultant is appointed separately by the client.

After the contractor is hired, the lead consultant monitors the building work and certifies the payments to be made to the contractor. Finally, the lead consultant certifies when the building is complete and agrees on a final account with the contractor. The principal advantage of this model is that the lead consultant acts as the client’s agent throughout, which helps ensure that the finished building is completed to an acceptable standard.

In the *design-and-build* model, the client appoints an architect to prepare a design with an agreed-upon level of detail. The contracting company quotes a fixed price for building this design but is allowed to modify construction details to suit its own working methods. The architect has no executive authority on-site but may continue to act as an observer for the client.

In the *turnkey* model, the client hires a contracting company to provide a complete building product for a fixed price. The contracting company is responsible for appointing the design team, which prepares a scheme in accordance with a design brief that has been agreed upon with the client. A variation on this model is where the contractor supplies a prefabricated building to erect at a client’s preferred site. The building may include warehouse equipment and even information systems.

In the *public-private partnership* model, the client contracts out the entire building construction, building operation, and building maintenance process to a private consortium for an extensive time period; in essence, the client pays an annual fee and gets a building and complete pharmaceutical storage service in return. At the end of the contract period, ownership of the building reverts to the client. Preparation of a clear and legally binding contractual agreement is essential.

The principal advantage of the last three models is cost. The principal disadvantage is that quality control is largely in the hands of the contracting company, which has a vested interest in saving money and increasing its profit margin.

Cost control. The cost consultant prepares a preliminary cost estimate for the project. This estimate is updated as the design evolves. This consultant may also contribute to the assessment of contractors’ tenders, assist the architect in

negotiating any variations in the contract with the contractor, and audit the final account.

Logistics and materials handling. If the project is large and complex and involves extensive mechanical handling equipment, the advice of a specialist is needed at an early stage. Without this advice, an accurate design brief cannot be prepared, and expensive mistakes may be made. Some architects have the appropriate expertise. Alternatively, advice can be obtained from a materials-handling consultant or a supplier of materials-handling equipment.

The appointed consultants should have relevant experience, the resources to manage the project, and a proven ability to complete satisfactory buildings on time and within budget. The selection process should not allow corruption or favoritism; a formal tender helps minimize such problems. The client and project team should prepare a list of qualified firms and invite each to submit a formal proposal for consideration by the team. The proposal should set out the consultant's approach to the project and specify the fee to be charged. Before making a final decision, the project team should visit the offices of the short-listed consultants, view some of their completed projects, and talk to other clients.

42.3 Feasibility stage

The first task of the project team is to establish whether more space is really required. It may be more cost-effective to achieve the desired results by reducing the order interval, by reorganizing stock within existing buildings, or by contracting out for supply chain services. If the team decides that new construction is the preferred option, the feasibility study should establish the following—

- Type of store required
- Approximate size of the store and site
- Options for obtaining space
- Assessment of prefabrication versus new construction
- Regulatory requirements
- Potential development incentives
- Short list of possible sites or buildings for the store
- Staff recruitment and training implications
- Outline budget or cost plan, including an assessment of operational and maintenance costs
- Workplan for project completion
- Site selection and acquisition for new construction

Rebuilding from scratch or buying a prefabricated building may be more cost-effective than renovation. Although it may appear at first that renovating an existing building would save money, such “savings” are often offset by lost opportunities for improving efficiency. Chances are that if the current structure is not adequate, a renovation alone would not be the best solution.

Identify type of store required

A mechanized warehouse is required if a large percentage of products will be received and stored on pallets. This type of warehouse requires powered forklift trucks and other equipment capable of moving pallets within the store. Pallets may be stored on the floor (pallet standing/block stacking) or on pallet racks. Pallet standing—especially block stacking—can be very space efficient, but limits the ability to handle goods on a FIFO (first-in, first-out) or FEFO (first-expiry, first-out) basis. Pallet racking generally makes the most efficient use of space consistent with FIFO or FEFO handling. If pallet racking is chosen, the number of tiers determines the internal height of the store. This critical decision of how to design the pallet storage needs to be made at an early stage; it is dictated largely by the type of handling equipment used. A mechanized warehouse should not be considered unless an effective supply and service network exists for mechanical handling equipment. Preferably, several sources of such equipment should be available. If battery-powered mechanical handling equipment will be used, building space estimates will need to include a battery-recharging area.

A manual warehouse is appropriate if the majority of products will be received and stored in packages that can be moved around by hand or with the assistance of trolleys. A manual store may also require some floor pallets. If pallets are to be handled, manual pallet trucks will be needed to off-load them from the delivery vehicles and move them around the store. Most items in a manual warehouse are likely to be stored on shelving units with a top shelf not more than 1.7 meters high and with no package weighing more than 25 kilograms, which means that the internal height of the store is not a critical factor.

Establish approximate size of store and site

The final size of the warehouse and the detailed site layout are established during the design stage. It is essential, however, for the project team to establish approximate sizes during the feasibility stage for three reasons—

- To short-list suitable sites or buildings
- To establish a realistic design brief
- To prepare a budget estimate

Determining store size is complex, because the size of the store is affected by many factors. The most important factors are—

- The volume of individual items
- The maximum stock level for each item
- The way in which goods are stored (floor pallets, pallet racking, or shelves)

DE-JUNK OR EXPAND

- The efficiency of the inventory control and store-keeping systems
- The type of storage required (for example, climate control, refrigeration)
- Quarantine or isolation requirements
- Environmental regulatory and emergency response requirements
- Subdivision of the administrative facilities, if there are multiple users of the store

Stock volume can be estimated from calculations based on volume of past shipments, by analysis of shipping volumes for specific items, or by using item-by-item analysis.

Calculations based on the overall order value and volume of past shipments. If the total value and volume of a shipment are known, it is possible to calculate the value per cubic meter of mixed medicines and other medical supplies and to use this figure as a basis for store sizing. Adjustments may have to be made for inflation if the data are drawn from different periods. This method is most appropriate for calculating volumes at the CMS and other primary stores when a strict annual or periodic ordering system is used and the stock is “topped up” at known intervals.

Analysis of shipping volumes for specific items. For instance, 1 million aspirin, 300 mg, in tins of 1,000, in cartons, from a current supplier might occupy about 1.6 m³. A computer program (spreadsheet or database) can use this type of information for store sizing. This method is retrospective. It does not take account of differences in bulk for similar items from other sources.

Item-by-item analysis using average volumes taken from a range of suppliers. The WHO publication *How to*

Estimate Warehouse Space for Drugs (Battersby and Garnett 1993) provides a method for making an item-by-item analysis. This type of approach applies mainly to specialist areas, such as vaccine stores, where storage equipment costs (for example, cold rooms and freezer rooms) are high, and the risk of underestimating the specialized storage space has severe programmatic implications.

Whichever method of estimating stock volume is used, the store size and type are determined by—

- Maximum net volume of goods to be stored
- How goods are to be stored and handled (floor pallets, pallet racking, or shelving)
- Type of stock location system used (see [Chapter 44](#))
- Climatic conditions
- Area of ancillary spaces, including loading bays; cold rooms; packing areas; locations for storing hazardous materials, climate and air management, and materials-handling equipment maintenance; offices; sanitary facilities; and staff lounges

Finally, the required site size is determined by—

- Size and type of store—a tall, mechanized warehouse has a smaller “footprint” than a manual warehouse that would handle the same volume of inventory
- Space and clearance needed for ancillary buildings, including those for the storage of fuels and hazardous chemicals—safety considerations determine how far away from other buildings hazardous substances should be stored
- Access and parking for delivery and staff vehicles

- Access for fire engines and other emergency services
- Office space
- Water runoff management
- Site security
- Site area needed for future expansion

Select method of obtaining space

There are seven ways of obtaining necessary storage space—

1. *Erect a temporary building.* These buildings are most suitable for use in emergencies, but erecting a temporary building is a rapid and effective solution to a short-term storage problem. A number of excellent temporary warehouse buildings are now available. Their main problem is that because they are fabric-clad, they are inherently less secure than a permanent building.
2. *Reorganize, renovate, or extend an existing health system warehouse.* This approach can be the quickest and cheapest, but only if suitable buildings are available.
3. *Lease a suitable commercial building.* This approach has the advantage of speed and avoids a large capital investment, but nevertheless there will be costs to outfit the space to suit the specific needs of a medical warehouse.
4. *Buy a suitable commercial building.* Again, this approach has the advantage of speed, assuming funds are available, but there will be fitting-out costs.
5. *Build a standard building.* Many countries have standard designs for health service buildings. Advantages of this approach are that design lead time is reduced, cost is more certain, and the design should be proven. The disadvantage is that the performance of standard designs has often not been evaluated effectively. Poor designs may be perpetuated.
6. *Build a purpose-designed building on an existing site, or obtain and develop a new site.* This approach is likely to have the longest lead time and may be the most expensive, but this may not necessarily be so, especially if the government already owns the land. It should ensure the closest fit to the specified requirements.
7. *Purchase a prefabricated building to install at the preferred site.* Assuming a vendor is able to accommodate design requirements, this may be more cost-effective than new construction.

Regulatory requirements

Before searching for potential sites, a review of the federal, regional, and local regulatory requirements that apply to stores facilities is essential. Zoning restrictions, water management laws, and permit or license requirements may all affect the viability of a particular site. In some cases, air or noise emissions or the impact of increased traffic within

the area need to be considered. These issues may require an environmental impact assessment; overlooking the implications to the project of such issues could have devastating consequences.

Potential incentives

Often, development incentives exist within territorial areas. Such incentives may include funding of employee training, project financing, land donation, tax reductions and deferrals, and assumption of some operational costs. Incentives can often be more important than logistics benefits when siting the store, particularly if the project has an element of private-sector ownership or operations. A ministry of health may even be able to defer operational or construction costs to other funding sources in the government.

Identify possible sites or buildings

When the sizes of the store and the site have been established, a short list of suitable sites or buildings should be prepared.

Identify staff recruitment and training implications

An assessment of personnel needs should be made at an early stage so that salaries and wages can be budgeted for and a recruitment and training program planned.

Establish an outline budget and obtain a budget allocation

Funding may be obtained from government sources, donor agencies, or commercial sources. The cost consultant should prepare a budget for submission to the funding authority (see Figures 42-1 and 42-2). The budget should include estimated costs for site acquisition, consultants' fees, and construction or installation costs. It should also include an assessment of annual operational and maintenance costs; if these items are not considered and budgeted for, the facility may not be sustainable. After funding is approved, site selection can begin.

The feasibility stage ends with the preparation of a detailed workplan for the design phase, setting out the tasks and timelines for the participants. An outline workplan for the construction phase should also be prepared.

42.4 Site selection and acquisition for new construction

When a budget allocation has been obtained, the project team should recommend the most suitable site or building from the short list.

Figure 42-1 Budget outline for constructing a medical stores from the ground up

Name of project:	
Date of budget:	Anticipated construction start:
Net area:	Gross area:
<p>Capital costs</p> <ol style="list-style-type: none"> 1. Site acquisition: total cost + commission and fees 2. Construction <ol style="list-style-type: none"> a. Off-site infrastructure (access roads, utilities, etc.) b. On-site infrastructure (roads, utilities, walks, paving, landscaping, security fencing, water management, etc.) c. Building (structure and works to 1.5 meters outside exterior walls) d. Fixed equipment (shelving, pallet racking, climate control and air management, refrigeration, water treatment, water storage for firefighting, etc.) e. Materials-handling equipment (forklifts, pallet trolleys, etc.) f. Information technology equipment (computers, bar-code readers, etc.) g. Furniture and other loose items 3. Professional services (surveys, soil analysis, water analysis, planning, architecture, regulatory licenses/permits and engineering) 4. Miscellaneous costs (utility connection fees, plan approval fees, legal fees) 5. Inspection and testing (job inspection, material testing) 6. Contingencies (cost escalation contingency, construction contingency) 7. Financing (loan fee, interim and permanent financing costs, bond legal fees) <p>Recurrent costs</p> <ol style="list-style-type: none"> 8. Annual operational costs (staff salaries and overheads, insurance, equipment maintenance, security, communications, utilities) 9. Average annual maintenance costs (repairs and renewals)

<ul style="list-style-type: none"> • Steel frame • Gable and cladding • Chromadek sheeting • Personnel doors x 2 • Roller shutter doors x 8 • Plans and engineer's certificate • Estimated concrete floor cost • Erecting the building • Storerooms for flammables and corrosives • Office block • Dock levelers • Cold room • Fitting out and contingency

Selection

In some countries, zoning laws completely prohibit development in certain areas and allow only buildings of a particular type in other areas. Other regulations may limit the size and position of buildings on a chosen site. A suitable site must satisfy all the regulatory requirements, be economical to build on, have convenient and unrestricted access for vehicles and staff, be adequately served by utilities and communications, be secure, and have potential for future expansion.

The Assessment Guide at the end of this chapter lists some criteria for site selection.

Acquisition

A site and the buildings on it, or both, may be purchased outright or leased on a long-term or short-term basis. Use of government land or outright purchase is the conventional route for government projects. Leasing may be a suitable method for an agency such as a nongovernmental organization (NGO) whose needs are limited in time. Whichever method is chosen, it is essential that the transfer of ownership or leasehold title be legally correct to avoid later disputes.

42.5 Design stage

There are four stages in the design for new construction. At the end of each stage, the project should be reviewed and a formal decision made to proceed to the next stage. The stages are—

1. *Preliminary proposals*: Preliminary design proposals are prepared and costed. An acceptable scheme is selected. If the building is to be procured on a turnkey or public-private partnership basis, the contractor may be chosen at this stage.
2. *Schematic design*: The design is developed in sufficient detail to enable the client to approve basic spatial

arrangements, materials, and appearance. A more detailed cost estimate is prepared. Mechanical handling equipment suppliers should be consulted where appropriate. At this stage, it may be necessary to obtain formal permission to build from the relevant government authority and seek agreement on the scheme with the fire department. The layout of the building and basic method of construction should not be altered after this stage.

3. *Detailed design:* The construction details are worked out. The cost estimate is refined. Specialist subcontractors and suppliers (such as cold-room manufacturers) are consulted, and quotations are obtained. Formal application is made for approval under local building regulations. If a design-and-build contract is to be used, the contractor is typically selected at this point. Major construction details should not be altered after this stage.
4. *Production information:* Final construction drawings are prepared, together with specifications and bills of quantities. These should be sufficiently detailed to enable contractors to tender for the project.

Client's role

Although executive responsibility for building design and monitoring of the construction contract rests with the project team, the client is responsible for establishing the initial project brief and for raising the necessary funds to cover design and construction costs. In addition, the client's representative on the project team has a project management role to play in the following areas—

- Attending meetings of the project team and monitoring progress
- Developing the brief
- Formally reviewing and approving the scheme as each design stage is completed (altering major decisions made at a previous stage is extremely disruptive and may cause delays and increase costs)
- Ensuring that communications within the team are timely, clear, and accurate
- Scheduling periodic and ad hoc reviews with the client as required
- Arranging payment of fees for planning and building control applications
- Arranging payment of consultants' fees
- Attending meetings with prospective contractors

If the project is large, the client may choose to employ a professional project manager to undertake some or all of these tasks.

All members of the project team, in turn, should ensure that the client is kept fully informed of progress and is pro-

vided with copies of drawings, correspondence, and other documentation.

Some of the general design features that should be considered during the design stages are outlined below. Note that most of these points apply to both ground-up construction and prefabricated building installation.

Detailed project brief

The detailed project brief is the key design document. It should be developed in discussion with the people who will operate, use, and regulate the building. The brief is not a fixed document. It will change and expand as the design develops in response to input from the client and from the project team. Typical elements of a brief are outlined in [Table 42-2](#).

Store and site planning

Storage buildings and site layouts should be planned to allow for future expansion with minimal disturbance to existing building elements, roads, and other physical infrastructure. Air-conditioning, other climate-control elements, and fire management systems are often significant expenditures and dictate building design.

Storage buildings should be planned for maximum flexibility of use. The layout of shelving, racking, and ancillary spaces is certain to change during the life of the building, and the building's future uses will be either enhanced or limited based on the initial investment and design. Buildings with widely spaced columns (wide-span structures) are generally easier to reorganize than those with closely spaced columns. Wide-span structures are more expensive to build, but their long-term advantages are likely to justify the extra expense in all but the simplest manual stores. An alternative approach in "high-bay" warehouses is to use the racking system as part of the building structure. In such cases, the storage system is effectively fixed for the life of the building.

Stores that have a relatively square plan are generally cheaper to build and more efficient to operate than stores that are long and narrow. In a large store, cross aisles should be provided at reasonable intervals to reduce travel time from aisle to aisle. The most appropriate spacing depends on picking frequency. A rule of thumb is a cross aisle every 10 to 20 meters. When assigning storage locations, it is good practice to place slow-moving product lines in long aisles and fast-moving product lines in short aisles (see [Figure 42-3](#)).

Storage methods

Goods can be stored in four basic ways: shelves, floor pallets (pallet standing), pallet block stacking, and pallet racks. The choice of storage method depends on the form in which goods arrive: in bulk on prepacked or store-packed

Table 42-2 Typical elements of a project brief (“functional program”)

Brief	Elements
Operational brief	<ul style="list-style-type: none"> • Inventory management and stock control systems and stores management procedures • Description of major activities, including flow of goods and paperwork • Type of stock to be accommodated • Environmental and security (zoning) requirements for different types of stock (see Chapter 43) • Quality control and regulatory requirements • Approximate volumes of stock to be accommodated in each zone • Approximate throughput of store (maximum cubic meters per day received and dispatched) • Operational requirements for shipping goods to other countries (if relevant) • Type of store required (mechanized, manual, or manual to be upgraded) • Schedule of staff • Types and number of delivery vehicles • Number of staff and visitor vehicles to be accommodated • Phasing and program expansion
Site development brief	<ul style="list-style-type: none"> • Site development restrictions • Access and parking for vehicles and access for pedestrians • Access for emergency services • Water supply and water storage, including water storage for firefighting • Site security and lighting, including gatekeeper’s accommodation and barriers • Landscaping • Schedule of individual buildings (main store, flammables store, fuel store)
Building accommodation brief	<ul style="list-style-type: none"> • Storage <ul style="list-style-type: none"> – Loading bay – Incoming goods area (for checking, inspecting, sorting, unpacking, and palleting, including power outlets for refrigerated vehicles) – General storage areas (ambient, controlled temperature, controlled security) – Isolation and quarantining of goods – Order assembly and dispatch area, including secure storage for assembled orders – Handling equipment storage, including charging points for electric vehicles – Ancillary storage (office consumables, packing materials, waste) – Battery charging area (if required) – Generator room (if required) • Administration <ul style="list-style-type: none"> – Detailed schedule of accommodation and facilities required for record keeping (including computers, bar-code readers, RFID readers, and other IT equipment as appropriate), communications, pharmaceutical information, product testing, training • Staff welfare <ul style="list-style-type: none"> – Sanitary facilities and changing rooms – First-aid room – Lounges and cafeteria or lunchroom

pallets, or as smaller packages. The four storage methods are discussed more fully in Chapter 44. Figure 42-4 illustrates the major dimensional constraints of pallet racking. Figure 42-5 illustrates the major dimensional constraints of shelf storage.

Environmental control and energy conservation

Opportunities for energy conservation exist in all aspects of warehouse design, construction, and operation, from site selection to equipment selection. A well-designed store can significantly moderate internal temperatures in a passive way. Passive design works with the site’s microclimate by using trees for shade and shelter, orienting the building correctly for natural lighting and ventilation, and selecting appropriate building materials and methods to control internal temperatures.

In hot, dry climates, good construction and nighttime ventilation can maintain daytime temperatures sev-

eral degrees below ambient temperatures. In hot, humid climates, effective cross-ventilation is required. In cold climates, storage buildings should be well insulated. Mechanical systems such as air-conditioning need to be chosen with a view to future maintenance. Sophisticated systems may not be sustainable.

Adequate electrical lighting is required throughout the store. Bright sunlight and fluorescent lighting affect some pharmaceuticals, and stores should be designed to prevent such damage.

A building design should always consider water management. Rainwater runoff from the site may require special permits or isolation and treatment. Sprinkler systems or fire water may need to be contained, sampled, or treated prior to release to a public system. Regulations should be reviewed carefully and requirements included in the site design.

In tropical climates especially, close attention should be paid to design measures that reduce or eliminate damage by pests, such as termites, reptiles, and rodents.

Figure 42-3 Options for layout of store aisles

Telecommunications and information technology

Good telecommunications and access to information technology (IT) are increasingly vital components of a pharmaceutical store. Modern IT equipment is already being used for stock control in remote areas, and reliable Internet connections will soon be an essential requirement for effective supply chain management. The pharmaceutical industry has used bar coding for many years. Radio frequency identification devices (RFID) are likely to supplant bar coding on products within the next decade, and their use should greatly improve the accuracy and speed of stock control operations (see [Chapter 49](#) on pharmaceutical management information systems). Buildings should be enabled and ready to exploit this technology when it becomes available locally.

Special storage conditions

The building must provide specific storage conditions for different types of pharmaceuticals. Quarantine and isolation requirements must be incorporated into the design. The quality assurance consultant should provide detailed requirements. See [Chapters 19](#) and [44](#) for more details.

Ancillary accommodations and loading bays

The design and sizing of ancillary accommodations should be carefully considered. These spaces include offices; staff rooms for rest, recreation, and eating as well as sanitary facilities and changing rooms; receiving and packing areas; and storage space for pallets and other packing materials. [Chapter 44](#) details these requirements.

The vehicle loading bay area is particularly important. It must be protected from the weather and large enough to receive the maximum number of vehicles expected at any one time. In larger stores, the loading bay should be raised so that the floor of the vehicle is level with the floor of the warehouse. Dock-leveling devices are available to suit vehicles of different heights, but vehicles often do not have appropriate structures to be secured to the dock leveler.

Guidelines for security

Pharmaceuticals are small, valuable, and therefore prone to theft (see [Chapter 43](#)). The warehouse complex should be designed with security in mind.

- Unsupervised access from the loading bay to the store itself should not be possible. The main storage area where order picking takes place needs to be especially secure. The drivers' waiting area should be isolated from any area containing products and also from administrative offices.

- Ideally, the office area should have windows overlooking the loading bays and the warehouse access.
- The staff rest area, sanitary facilities, and changing rooms should not have direct access to the warehouse or from the outside.
- Visitors and drivers should have separate sanitary facilities.
- Staff parking should be well separated from the loading area.
- Adequate perimeter fencing and external lighting should be provided.
- Emergency evacuation doors should be alarmed to the main office.

Mechanical equipment specifications

The storage systems and mechanical equipment needed to operate the store effectively, including shelving, should be specified in the design. Some of this equipment will be supplied and installed as part of the building contract, but some may be supplied under a separate “fitting-out” contract.

Fire protection and emergency response

All sections of the warehouse should have adequate fire-detection equipment and be well supplied with firefighting appliances. Smoke alarms are inexpensive to install and provide warning in case of fire. The design should satisfy local building codes and the requirements of insurers in the following respects.

Site and building layout and construction. Key aspects of design planning for fire safety include—

- Accessibility by the fire department
- Adequate escape routes and emergency doors with locks that do not prevent staff from leaving the building in an emergency (such as push bars with doors opening outward)
- Compartmentalized buildings to reduce the risk of a fire’s spreading
- Isolation doors with appropriate fire ratings between bays
- Electrical connections, wiring, and devices meeting fire safety codes
- Noncombustible building construction materials

Fire-detection and firefighting equipment. Essential components of a fire safety system include—

- Adequate provision of smoke alarms, heat detectors, and fire alarm sounders to ensure that fires are detected as soon as possible
- Correctly positioned fire hydrants and hose pipes with an adequate and reliable supply of water

Figure 42-4 Pallet racking: Dimensional constraints

Clearance for lights, sprinklers, etc.

- Correctly designed sprinkler systems (because if a poorly designed system is set off by accident, water may ruin some stock; or if there is a fire, the system may soak stock that is well away from the core of the fire); choice of a dry or wet system must be made with the building managers and the insurers of both the building and its contents
- Adequate numbers and types of fire extinguishers suitable for chemical fires (so staff can extinguish small fires before they spread)
- An automatic or manual telephone link to the fire service

Construction standards

The method and standard of construction required should be agreed on as part of the project brief—development process or spelled out in prefabricated warehouse tender documents. These decisions are important because they affect the initial cost of the building and largely determine how long it will last and how much it will cost to maintain. The government may have standard equipment and construction requirements for all buildings of a particular type.

Figure 42-5 Shelving: Optimal layout with ergonomic considerations

Standardized requirements help simplify maintenance and reduce costs.

Before finalizing the design, it is essential to check that it complies with all relevant engineering and health and safety standards. Failure to do so could create many operational problems after the storage facility is completed.

42.6 Tender and project-planning stage

The tender stage marks the transition point between the design and construction phases. The five procurement routes described below illustrate a range of tendering possibilities. Variations exist, and the project team should recommend the most appropriate method.

Conventional procurement

In conventional procurement, tenderers submit bids based on a set of tender documents complete enough to enable the building to be constructed. There are variations on this method. In a “fast-track” contract, the contractor is appointed as early as possible in the design process and starts work on-site before the design work has been completed. The aim of this approach is to build more quickly by overlapping the design and construction stages.

Fast-track procurement should be considered only if all parties to the contract are experienced and extremely well organized.

Design-and-build procurement

In a typical design-and-build procurement, tenderers are provided with design drawings and specifications. The tender submission is a fixed-price offer to build the tendered design. The successful tenderer is free to change construction details within the limits set in the tender documentation. The client may appoint a professional representative in a monitoring role to report on the activities of the contractor and to ensure that the client’s requirements continue to be met as the scheme develops. Alternatively, or in addition, the successful design-and-build contractor may “take over” the client’s design team, which will then develop the design for construction.

Turnkey procurement and procurement of prefabricated buildings

In turnkey procurement and procurement of prefabricated buildings, the tender documents consist of a performance specification or schedule of requirements. Tenderers are required to submit preliminary design proposals as part of

their bid submissions. The successful tenderer then prepares a fully worked-out design for approval by the client before construction begins. Again, the client may appoint a professional representative to monitor the contractor's activities.

Public-private partnership procurement

A relatively new approach to building procurement is the public-private partnership model, which is essentially a long-term agreement that uses private financing for public services. Under this arrangement, tenderers are invited to bid not just for construction and outfitting of the building, but also for its day-to-day maintenance and operation for a defined period—typically thirty years. In the case of a medical store, the service agreement could include all aspects of inventory management, up to and including ordering and distributing medicines and commodities. The successful contractor charges an annual fee that covers the amortized cost of the building, its operation costs, and the contractor's profit. The contractor's performance is monitored against a set of predefined indicators, with financial penalties in the event of service failure. At the end of the contract period, the building and its equipment are handed back to the client organization in satisfactory condition, as defined in the original contract.

The contract

There should be a formal building contract for all building projects, however small. Informal arrangements lead to disaster. Various forms of contracts are in use, ranging in complexity from a simple letter of agreement to a complex document. Contracts are often country or organization specific. A few are widely used internationally.

The contract is the legal agreement that commits the contractor to carry out work for the building owner according to the drawings, bills of quantity, and materials specifications within a specified time. A financial penalty may be imposed if the building is not completed on time. The contracting agency (client) agrees to pay the contractor a specified sum of money at agreed-upon stages during the course of the work or upon satisfactory completion. Following completion, the contractor has an obligation to rectify any defects that arise within an agreed period after the handover date, which is typically six months or one year. The total contract sum may be varied if the nature or extent of the work changes. Under conventional procurement, the architect is a third party to the contract and can both represent the owner and act as arbiter in case of contractual disputes.

Tendering

A competitive tender is usually the best method of selecting a building contractor or source of a prefabricated building.

Negotiation with one contractor may be applicable when only one company is suitable for the job or when a government building agency (for instance, the ministry of works) is to undertake the project. In all other cases, the tender short list should be drawn up after careful screening. A list of each contractor's projects should be requested and verified. Commercial and bank references should be obtained. Previously completed projects should be visited, and it is helpful to talk with the architects and owners of these buildings about how the contractor performed.

Government clients generally have strict tendering procedures designed to prevent corruption and ensure accountability. There are three basic systems—

1. *Open tendering*: Under this arrangement, any suitably qualified contractor can submit a bid. The tender board then considers bids.
2. *Prequalification tendering*: The contract is advertised, and interested contractors make formal prequalification submissions. The tender board meets and agrees on a short list of contractors. They are invited to submit bids, which are considered by the tender board.
3. *Short-list tendering*: A short list of tenderers is drawn up by the project team or the client. Bids from this list are then considered by the tender board. This method is adopted by most private-sector and NGO clients. A minimum of three contractors should be invited, but the rules may require a larger number.

The tender instructions specify the date for the return of the bid, how it should be presented, and when bids will be opened. It is helpful to ask a trusted third-party observer, such as a bank official or lawyer, to observe the bid-opening process. The witness's testimony will be valuable in any future disputes from unsuccessful bidders. After the bid opening, the bids are analyzed by the project team, and the most economically advantageous one is selected. An economically advantageous bid is not necessarily the cheapest; all aspects of the bid require consideration, including time to completion and contractor reputation and reliability. A comprehensive and carefully constructed bid analysis template is absolutely essential in the case of the unconventional procurement routes described at the beginning of this section. If cost reductions need to be made, they should be negotiated before the contract is signed.

Project planning

Discussions are held with the successful contractor, and a construction or installation program is worked out, including site-access management and construction site security. All contractual matters, including the property and liability insurance obligations of the client and the contractor, are finalized and checked by both parties. If a performance

bond is required, it is finalized (see [Chapter 39](#)). Facilities for construction workers should meet appropriate standards, with special attention given to site safety and to providing welfare facilities. Injury and other health-related work stoppages or interruptions can significantly delay a project.

The client finalizes funding arrangements so that payments can be made to the contractor on time and at the agreed-upon stages. The contract is then signed.

42.7 Construction and commissioning

The contractual role of the client during the construction phase is largely confined to making payments to the contractor, approving any changes in the cost of the project, and attending formal site meetings. The contract supervising officer (usually the architect) is responsible for the day-to-day administration of the contract. The client should never issue direct instructions to the contractor; instructions should always be channeled through the supervising officer. The supervising officer should regularly provide the client with the following—

- Minutes of the site meetings
- Reports on the contractor's progress and changes in the program
- Reports on significant contractual or construction problems
- Reports on labor issues, including health-related or injury incidents
- A photographic record of the site preparation and construction, which may be carried out by the contractor's staff
- Payment valuations
- Details of changes to the design or specifications (variation orders)
- Details of changes in the cost of the project (cost reports)

In addition, the client must prepare to take over and commission the building. Staff must be allocated, recruited, and trained; equipment, furnishings, and stationery must be purchased; contract arrangements must be made with utility companies; and management systems for the new facility must be drawn up. Transport arrangements need to be established. These tasks are demanding and time-consuming, and adequate resources should be allocated to them.

Supervision

The supervising officer should carry out regular site inspections, preferably once a week, to ensure that the contractor is following the drawings and specifications. If the project is

large, a full-time site architect or a site monitor or clerk of works may be appointed by the client. The site monitor has no executive authority. His or her role is to act as the project team's "eyes" on-site and to report to the project team and the supervising officer.

Valuations and payments

The contractor's work should not be paid for until it has been approved by the supervising officer. Any unsatisfactory work must be corrected before it is included in a valuation. Typically, valuations and payments are periodic (often monthly), based on a measurement of work actually completed. Alternatively, for simple projects, they may be made in defined amounts at defined construction stages (for example, 10 percent of the total contract sum when the floor slab has been laid). Payment is made against a certificate issued by the architect. A percentage (usually 5 to 10 percent) of the value of the certificate is retained by the client until the contractor has rectified all defects after the end of the specified defects-liability period. The defects-liability period usually extends for six or twelve months after handover.

Handover

The building is handed over to the client after the design team has fully inspected the completed building and witnessed satisfactory tests of the water supply, drainage, fire protection, and mechanical and electrical services, and after the contractor has corrected any problems. A few outstanding items may remain to be finished, but the list should be short and completion should not interfere with the client's use of the building. The client should attend the pre-handover inspection and should not accept the building unless satisfied. The supervising officer then certifies that the contractor has achieved practical completion.

The contractor hands over all keys to the building and provides the client with instructions on the use of mechanical and electrical equipment. The design team provides a building manual containing a complete set of "as-built" record drawings (drawings revised to show changes made during construction) and general guidance on maintenance. The client's building maintenance officer should be briefed at this stage so that he or she gets to know the building during the defects-liability period.

Commissioning

The client or operator moves into the building and commissions it. At this stage, various "growing pains" can be expected. Some of these will be operational, and some will be caused by building defects. Building problems should be resolved by the contractor and the project team.

Defects liability

During the defects-liability period, the project team, the client, and the contractor agree on the final account. At the end of the defects-liability period, the supervising officer inspects the building again and instructs the contractor to rectify any defects that have arisen. The contractor should be given reasonable access to the building to do so. When all defects have been corrected, a final certificate is issued, and final payment is released to the contractor. If a major contractual dispute has arisen, the issuance of the final certificate (and payment) must be delayed until this dispute is resolved according to the terms of the contract.

Building or renovating a new medical stores facility is a major expense. The temptation to profit personally from the project by bribery or kickbacks is a reality that must be tackled head-on by the project team. Strict controls should be in place to prevent this problem. Advance payments should never be made to the contractor. The client should pay only for work that has been correctly completed and certified.

If the construction process runs into serious problems, a dispute may arise that the parties are unable to resolve. Arbitration is a method of settling such disputes without the need for legal proceedings. Informal hearings are held under the control of an arbitrator, whose judgment is final and binding on the parties to the dispute. This procedure is quicker and less expensive than judicial proceedings. However, arbitration may not be adequate if significant differences of opinion exist as to the quantity or quality of work performed. The type of arbitration procedure and scope of its application should be clarified in the initial contract.

42.8 Building and equipment maintenance

A building and its equipment will not continue performing satisfactorily unless both are regularly maintained. Buildings need both emergency and routine maintenance, but buildings and equipment rarely fail if they are looked after and serviced in a systematic way. A planned cycle of routine maintenance should include general cleaning, replacing lightbulbs, drain clearing, and maintaining fire extinguishers, mechanical equipment, and similar items. Similarly, there should be a planned cycle for periodic maintenance, including painting and replacing life-expired elements such as mechanical equipment and roof finishes. The client should have adequate recurrent and capital budgets and the human resources necessary to carry out these tasks over the life of the building. ■

Glossary

Commissioning: The process of preparing a building for operation. It includes adjusting the heating, ventilating, and air-conditioning systems; establishing security procedures; and training occupants.

Contract sum: The total amount payable by the owner to the contractor for performing the contracted work. Depending on the contract terms, this amount may be adjusted at the end of the contract, to take account of variations approved during construction.

ASSESSMENT GUIDE

Is additional space really required, or can existing space be maximized by—

- Changing delivery intervals?
- Disposing of damaged and expired drugs?
- Reorganizing space within an existing warehouse?
- Contracting out for supply chain services?

If additional space is required, establish availability of funds and consider building procurement. What type of warehouse operation is required?

- Mechanical? If yes, are the necessary equipment and servicing infrastructure available?
- Manual? If yes, will this decision unduly limit future program development?
- Manual, upgradable to mechanical? If yes, are funds available to ensure that the building is designed and built to be suitable for upgrading?

What is the most practical and cost-effective way to obtain additional storage space?

- Erect a temporary building?
- Renovate an existing warehouse?
- Lease a commercial warehouse?
- Buy a commercial warehouse?
- Build a standard warehouse?
- Build a purpose-designed warehouse?
- Purchase a prefabricated warehouse?

What is the most cost-effective method of building procurement?

- Conventional design service?
- Design and build?
- Turnkey or prefabricated package?
- Public-private partnership?

Compare short-listed sites or buildings against the following criteria—

Site development potential

- Will the relevant authorities allow the site to be developed as intended?
- Is the site large enough to satisfy current and expected future needs?
- Is the existing building on the site suitable, or will it have to be demolished?
- Does a risk of contamination or interference exist from neighboring operations?
- Do rights-of-way, liens, and underground rights affect the development potential of the site?
- Is the site well drained? Is there any risk of flooding or other weather-related risk?

- Is the site protected from landslides, earthquakes, avalanches, and other natural hazards?
- Are ground conditions suitable for building economically?
- Will regulatory requirements (for example, environmental, labor, licenses, taxation) affect the development potential of the site?
- Can the site be developed at an acceptable cost?
- Are any fiscal or other incentives available to help fund the project?
- Are there any community issues that could affect the development potential of the site?

Access

- Is the site close to the relevant transport links?
- Do local access routes suffer from vehicle congestion?
- Is the site well served by public transport? (Public transport is needed by staff.)
- Are routes to the site accessible year-round by all types of vehicles?
- Is there adequate access for vehicles and space for parking?

Utilities and communications

- Does the site have a reliable main electricity supply?
- Does the site have a main water supply, borehole, or other reliable source of clean water?
- Is the water supply sufficient for firefighting?
- Does the site have main drainage? If not, are ground conditions suitable for a septic tank or other autonomous system?
- Is there an existing standby generator? If so, is it powerful enough to supply the cold rooms and refrigerators in the new store?
- Does the site have access to reliable telephone, Internet, and postal services?

Security

- Is the site likely to invite intrusion or vandalism?
- Can the site be properly monitored and supervised outside normal working hours?
- Is the site easily accessible by the fire department, police, and ambulance services?

Future conditions

- Will access to the site and the security of the electricity, water drainage, and communications systems be adversely affected by future development in the area?
- Will adequate resources be available to maintain the building and equipment over the life of the building?

Design-and-build procurement: In this method, the contractor takes responsibility for the detailed design and construction of a building based on an agreed-upon preliminary design.

Final account: A financial reconciliation prepared at the end of a building contract, in which the contract sum is adjusted to take account of all variations that have occurred during the construction process. (These variations include design changes by the client, design changes as a result of site conditions, claims for extra payment by the contractor for delays that are not its responsibility, and counterclaims by the owner for damages caused by the contractor's failure to keep to the program.)

Final certificate: A document issued by the architect or contract supervisor that states the amount of money owed by the client to the contractor (or vice versa) at the end of the contract.

Program or brief: A written statement of the owner's conditions and requirements for the project.

Public-private partnership procurement: A method in which the client pays an annual fee for complete building construction, maintenance, and drug storage service over an extended time period.

Record drawings: Drawings revised to show changes made during construction.

Retention: A sum (typically 5 percent) withheld from each payment made to the contractor during the course of construction. This money is usually released to the contractor after all defects have been rectified and the final certificate is issued.

Subcontractor: One who has a contract with the primary contractor to perform a portion of the work.

Turnkey procurement: A method in which the client hires a contracting company to provide a complete building product for a fixed price.

SUMMARY

Security breaches include theft, bribery, and fraud. They can have a substantial, and sometimes disastrous, economic and health effects. A comprehensive security system includes—

- Analysis of the sources of security breaches
- Determination of methods to improve security
- Consideration of costs and savings
- Implementation of security measures

Security breaches can be found through a mix of informal and formal investigations, independent inventory counts, consumption comparisons, and surveys of medicine outlets. The conditions that lead to theft often include—

- Shortage of the products in the market or at service-provision points
- High product demand
- High product value and hence a good open market for the product
- Economic conditions that lead people to market stolen products
- Weak security measures that make theft easy

Theft prevention may require—

- Providing unique identifiers for all pharmaceutical supplies
- Dealing with the sources of theft
- Closing the outlets for stolen medicines
- Improving record keeping and instituting a perpetual inventory control system
- Improving salaries for staff members who handle medicines
- Controlling access to the storage facility

Controlling bribery requires mechanisms to prevent suppliers from influencing the choice of medicines, purchase quantities, and selection of suppliers.

Fraud control requires close attention to quality assurance procedures and routine stock control procedures. Security measures may be expensive, but they are often very cost-effective.

43.1 Introduction

Theft, bribery, and fraud can interfere with the effective functioning of national pharmaceutical supply systems. In some countries, security breaches can be the single most devastating problem for pharmaceutical programs. A strong security system can—

- Minimize shortages
- Minimize abuse or misuse
- Contribute to accurate record keeping on medicine consumption and disease prevalence

In one Central African country, a hospital pharmacist routinely allowed for losses of 80 to 90 percent on certain medicines when she placed her orders to ensure that she received enough supplies to treat hospital patients. In an extremely poor Southeast Asian country, losses caused by theft are estimated to be more than 30 percent of the total pharmaceutical supply, despite theoretically strict accounting requirements for medicines. The government medical store in an East African country is reported to have placed an order for more than 100,000 U.S. dollars' (USD) worth of pharmaceutical cocaine, which vanished from the wharf when it arrived.

Pharmaceutical pilferage was a problem in a facility in one West African country. Managers took measures to make

pilferage difficult, including reinforcing doors and windows, clearly and systematically shelving medicines, putting into place a perpetual inventory system for fast-moving and high-demand pharmaceutical products, and limiting unauthorized access to the store. Despite those measures, medicines still disappeared. Suspecting that the facility's storekeeper might be involved, the managers announced a plan that denied their own free access to the store and gave the storekeeper the authority to search the managers when they exited the store. In addition, the managers made the storekeeper financially responsible for any future losses, which prompted him to voluntarily quit his job, indicating that the storekeeper was comfortable working there only as long as he was able to pocket some of the medicines. Most losses or thefts are caused by employees working alone or in collusion with others.

Other examples can be cited. In a Central American country, inventory records showed that stock levels of oral ampicillin, antibiotic eye ointment, and dozens of other products were intentionally overstocked—enough for three, five, ten, and up to thirty years—because government buyers received special “commissions” for their purchase. Theft of antibiotics for black market sale and treatment of sexually transmitted infections is common in many countries. Hospitals in the United States have a difficult time controlling staff pilferage, and several incidents in recent years have involved theft and resale of significant quantities of public-

sector medicines. In a scandal involving pharmaceutical suppliers and airport personnel, a consignment of antiretroviral medicines (ARVs) headed to an African country from a European country was flown back to Europe before it even reached the store.

Security breaches can and should be confronted. Theft and wastage are caused by a mixture of cultural, political, and economic factors. Nevertheless, even when bribery and theft are coordinated or condoned at high levels, countries have been able to reduce these activities when supply system managers have made a strong commitment to do so.

Improving security involves analyzing the sources and nature of security breaches, developing methods for improving security, and comparing the costs of security measures with the financial and public health costs of inadequate security. [Country Study 43-1](#) shows how Ethiopia assessed and addressed security concerns before introducing a new antiretroviral therapy (ART) program.

In 2004, the World Health Organization (WHO) launched a Good Governance for Medicines program to—

- Raise awareness of the impact of corruption in the pharmaceutical sector
- Increase transparency and accountability in medicine regulatory and supply management systems
- Promote individual and institutional integrity in the pharmaceutical sector
- Institutionalize good governance in pharmaceutical systems by building national capacity and leadership

The program website (<http://www.who.int/medicines/ggm>) offers many resources that relate to the issues covered in this chapter.

43.2 Analysis of security breaches

Security breaches include theft, bribery, and fraud, and they can occur at all levels of the pharmaceutical supply cycle, including procurement, storage, and distribution. Shortages caused by these activities can lead to suffering and death.

Country Study 43-1 Securing antiretrovirals from theft: Ethiopia's experience

In 2005, Ethiopia started its first large-scale public program to distribute ARVs free to patients with HIV/AIDS through selected public hospitals. Previously, ARVs were only available from private pharmacies to patients who could afford their cost. Because the initial phase of the treatment program was limited, the government gave first priority to clinically eligible patients with low or no income and to special groups, such as children and pregnant women. When the availability of ARVs increased, a policy of universal access replaced screening patients based on income. Because the demand for ARVs outweighed the supply, and because ARVs are high-value and high-demand products, preserving the limited supply of ARVs through secure storage was of paramount importance.

Following an assessment conducted by Management Sciences for Health's Rational Pharmaceutical Management Plus (RPM Plus) Program, a parastatal pharmaceutical procurement and distribution organization called PHARMID was given responsibility for clearing, storing, and distributing ARVs at the central level. RPM Plus evaluated and recommended PHARMID based on the availability of separate storage space; security of the premises (strong walls, secure ceiling, metal doors, barred windows, armed guards); limited access to storage spaces; adequate record keeping and inventory control; history of security breaches; measures against culprits; availability

of insurance on products and safe transport; and presence of a dedicated store manager for ARVs.

RPM Plus also assessed the public hospitals that were to distribute ARVs to patients and found that all aspects of the storage capacity, security, and record keeping were weak. Because putting ARVs into such a vulnerable environment would be risky, RPM Plus helped the facilities address security concerns through a number of interventions, including renovating the physical infrastructure (improve storage space; reinforce walls, ceilings, doors, and windows); providing lockable storage cabinets and dispensing booths; developing information system tools for inventory control, reporting, and auditing; and developing standard operating procedures and training staff members in how to use them.

Now, the public hospitals store ARVs in separate bins and monitor their movement weekly. Specific staff members are assigned to manage ARVs, and access to the medicines is limited to these people. The treatment register that is maintained for all patients in the program gives a running total of patients and the medicines they have taken. The register makes it easy to calculate the number of medicines dispensed, which ensures that the inventory status is reliable. The register is an important monitoring tool that helps minimize the vulnerability of ARVs from theft and pilferage.

Figure 43-1 shows the main types of security breaches and the levels at which they occur.

Some factors that promote theft are—

- Shortages of essential medicines
- High demand for medicines in the private sector
- Poor physical security in stores
- Weak inventory records
- Unlimited access to stores by unauthorized people
- Paying staff members salaries that are significantly lower than necessary for self-support
- Access by underpaid staff members to high-value products
- Inadequate legal systems for dealing with thieves

Politically motivated thefts can be a form of sabotage that creates generalized shortages and discredits the government, or they can be a means of financing political operations through the sale of stolen pharmaceuticals.

Stolen medicines find their way to four major types of outlets. They may be exported to adjacent countries through legitimate or illegitimate trade routes; sold to local private warehouses, pharmacists, or physicians for subsequent retail sale; sold directly to the public through street vendors; or distributed to family and friends.

43.3 Searching for security breaches

Identifying major security breaches and the places where they usually occur is the first step in controlling them. Several methods exist for uncovering theft, bribery, and fraud—

- Taking unannounced physical inventory counts
- Checking consumption using inventory records
- Monitoring and reviewing patient records
- Surveying suspected sales outlets
- Gathering anonymous, informal information

Informal channels (such as informants, spot checks, and ad hoc staff meetings) may be one way of determining whether a problem exists. Pharmacists, physicians, politicians, and other officials often know of, or at least suspect, diversion. Large stocks of unissued and unusable medicines at medical stores, the overnight disappearance of large quantities of medicines, systematic failure of deliveries to reach their final destinations, and frequent shortages at well-supplied facilities indicate a security problem. Responding vigorously to informal reports of diversion can be quite effective.

Unannounced physical inventory counts can uncover security breaches at all levels. The results of a surprise stock count should be compared with medicine receipts and

issues. Sampling only a selection of facilities at various levels may be sufficient to determine the extent of the problem; certainly, any facilities where problems are suspected should be included in the sample.

Consumption comparisons using inventory records can sometimes be revealing. For example, in one Central American country, theft of significant quantities of medical supplies, equipment, and food was uncovered by comparing the stock issued to each facility with the past consumption patterns at that facility. This comparison suggested that certain hospitals were ordering suspiciously large quantities of supplies. The hospitals and departments involved were then carefully examined, and security breaches were identified. A similar approach has been helpful in other countries. This system depends on the presence of an up-to-date record-keeping system. An organized group involved in stealing will intentionally make the record-keeping system non-functional, so that the control system will not be effective.

Surveys of suspected private outlets for black market sales are often effective. When government-purchased pharmaceuticals can be distinguished by capsule type, batch number, packaging, or some other identifier, a survey of street vendors, pharmacies, and physicians' supplies can identify pharmaceuticals from government sources. Tanzania is one country that has labeled packaging for artemisinin-based combination therapy differently for the public and private sectors, to track leakage.

43.4 Controlling theft

Three common forms of theft are—

1. Slow, sustained, small-scale leakage that may go unnoticed for a long time. Staff members with access to the medicines storage area are usually responsible for such losses.
2. Large-scale robbery that may involve people both inside and outside the pharmaceutical supply system. For example, groups that conduct clandestine actions, such as political groups involved in guerilla warfare, may raid warehouses to meet their pharmaceutical supply needs.
3. Diverting a shipment before it reaches its destination, which may involve people in responsible positions with access to information on the movement of goods.

When the major sources of losses have been identified, methods to control theft, bribery, and fraud should be implemented. Theft can be tackled by prevention and control measures that include installing physical barriers (closing outlets for stolen goods; reinforcing doors and windows); using human and electronic security guard systems; providing adequate storage and shelving; enforcing

Figure 43-1 Summary of common security breaches

**Suppliers** (manufacturers, foreign suppliers, importers)

- Intentional short packing
- Intentional omission of expensive active ingredients
- Shipping of products near their expiration date
- Dilution and repacking of liquid medications
- Delivery of incomplete orders and billing for full amounts

**Wharf/Airport**

- Off-loading of government shipments directly onto vessels bound for nearby countries
- Petty theft by port workers
- Major theft from wharves, customs warehouses, airport fields, and elsewhere

**Purchasing Office**

- Acceptance of bribes in return for purchase of unnecessary types of medicines, purchase of excessively large quantities of medicines, or purchase from specific suppliers
- Intentional overpurchasing to obtain quantities sufficient for systematic diversion into the black market while maintaining legitimate government distribution

**Medical Stores** (central, regional, and hospital)

- Major theft through breaking and entering
- Major systematic theft by employees
- Acceptance of bribes from suppliers for intentional overordering of specific items
- Intentional underordering by government pharmacists or storekeepers, so that shortages will arise, followed by compensatory purchasing from local pharmacists who offer illegal "commissions"

**Transportation**

- Selling of medicines by drivers and at markets along the delivery route
- Consumption of preparations containing alcohol by delivery staff, who then refill bottles with water
- Systematic diversion of large quantities for black-market sale
- Theft of large quantities by nursing staff for use in their own unofficial private practices

**In Hospitals**

- Petty theft by delivery staff, nurses, and doctors for personal and family use
- Drinking of spirited preparations by hospital staff, who refill bottles with water
- Systematic diversion of large quantities for black-market sale
- Theft of large quantities by nursing staff for use in their own unofficial private practices

**Outpatient Departments**

- Patients faking illness to obtain medicines for resale
- Visits by patients to several clinics to obtain multiple prescriptions for antibiotics, analgesics, and other popular resale items
- Writing of multiple prescriptions by physicians—to the same person or to false names—in return for a share of resulting black-market sales

**Health Centers/Village Health Workers**

- Pilfering of health center supplies by government physicians and health workers for use in their private practices
- Popular black-market items overordered from medical stores and diverted by physicians, nurses, dispensers, or laborers

Figure 43-2 Unique identifiers

correct and regular record keeping and inventory audits, and maintaining an active procurement and shipment tracking system; improving working conditions of personnel, including salary increases; educating staff and increasing their moral awareness and responsibility; involving other stakeholders and the community as watchdogs; and taking disciplinary or legal measures against the thieves and their collaborators.

A hotel in Harare, Zimbabwe, had problems with guests' missing property and came up with the idea of writing "thou shalt not tempt" on visible places, such as ashtrays, toilets, mirrors, and doors. The message to the guest is to keep valuables in a safe place and not to leave them in the open. Keeping high-value and high-demand products out of public view and limiting access to authorized personnel will minimize theft.

The private sector can be more successful at preventing theft and pilferage because it uses the enumerated measures systematically and consistently.

Inventory control

Good inventory management and stock control systems are essential for detecting and controlling theft (see [Chapter 23](#)). At each level in the supply system, records should indicate how much of each type of medicine was received and issued, who received or issued the medicines and verified the amounts, the source of medicines received, and the destination of every issue. Such information provides an audit trail for the purchase, distribution, and consumption of medicines. The records also provide a basis for comparing medicine consumption with use of services and a starting

point for tracing security breaches. Such recorded transactions will have great value if they are documented and reported monthly and if feedback is provided to the reporting facility.

A good information system alone is often not enough, and additional deterrent measures are needed.

Unique identifiers

An individual or group caught with medicines believed to be stolen may claim that the medicines were purchased. Theft is difficult to prove unless medicines have unique identifiers, as shown in [Figure 43-2](#). A country can require suppliers to identify medicines in one or more of the following ways—

- Imprint all containers (bottles, boxes, foil packages) and external packing (cartons, crates) with a unique client seal or monogram.
- Register batch numbers on all immediate containers and external packing and (if purchase quantities are large) agree not to sell products from the same batch to any other buyer in the country or in adjacent countries.
- Emboss tablets and print capsules with a unique client monogram.
- Color code tablets and capsules.
- Use electronic tagging devices. The latest technologies involve electronic identifiers detectable through GPS (global positioning systems), which can trace the location of a tagged product. This option, however, is expensive and may not be feasible in resource-limited environments.

Unique identifiers have been introduced in many pharmaceutical programs. They can, however, increase medicine prices significantly, and this economic disincentive has led to the discontinuation of the program in some countries. Whether identifiers should be used depends on the following factors: the types and quantities of medicines purchased, the capacity and willingness of suppliers to provide identifiers, the incremental expense of doing so, the speed with which deliveries are needed, and the source and extent of pharmaceutical theft.

Imprinting containers and packaging. Container imprinting is the most common type of identifier. The immediate container and the external packing are imprinted with the name or initials of the government program, the seal of the government, or some other symbol. In one South American country, individual foil packets as well as external boxes contain the program title “Medicamentos Básicos,” and all are printed with the same color code. In Sri Lanka, all container labels are required to bear the national seal. In Malaysia, containers are labeled as ministry of health property.

Imprinted containers can be used to identify stolen pharmaceutical products only when thieves keep the products in their original containers. If large numbers of pills are packaged in plastic-lined containers, culprits can easily remove the inner lining and destroy the identifying imprint. They will have to take much more time and effort to remove pills from individual foil packets or blister packages. In some countries, the business is so lucrative that thieves produce their own packing materials or containers to elude such preventive measures.

Container imprinting adds extra time and cost to the packing process. A requirement to imprint all immediate and external containers may delay shipments, increase the price, or dissuade some suppliers from bidding. One solu-

tion is to require imprinting only for orders that exceed a set minimum quantity or order value.

Batch number registration. The use of batch numbers as unique identifiers is less obvious to thieves than imprinted containers. By forbidding contract suppliers to sell products with the same batch numbers anywhere else in West Africa, one country was able to identify stolen goods and close several major black market wholesale and retail outlets, recovering thousands of dollars’ worth of stolen government medicines.

Because the unique batch number requirement does not add time to the manufacturing process, it is less likely to add to the cost or delivery time. However, suppliers may not be willing to restrict sales of a batch unless the requesting supply system purchases all or most of the batch. Thieves who are aware of the system can still remove the label or discard the container. Furthermore, the use of batch numbers as unique identifiers is effective only if the contractual requirement is monitored and enforced.

Tablet embossing and capsule imprinting. Imprinting individual tablets and capsules with the pharmaceutical program’s initials or seal provides the most effective protection against diversion for resale in the private sector. However, it is also the option most likely to increase medicine prices. [Country Study 43-2](#) gives an example of this practice in Southeast Asia. The embossing and imprinting process is easiest to implement in state-owned factories. With commercial suppliers, lead times may increase and prices may greatly increase because of the embossing requirement. The pricing gap may decrease if imprinting is required only for large-quantity orders.

See [Chapter 19](#) for additional information on using product identification technology to ensure the integrity of the pharmaceutical product and to deter theft and counterfeiting.

Country Study 43-2 Tablet and capsule embossing in Southeast Asia

In one successful government pharmaceutical supply program, contracts with suppliers specified that tablets and capsules in quantities greater than 500,000 units had to be embossed with the Ministry of Health initials. All tablets produced by the government pharmaceutical plant also had to be embossed.

Theft of attractive items such as diazepam, paracetamol, antibiotics (used extensively for sexually transmitted infections), and other medicines was a steady, if small-scale, drain on supplies in major hospitals. Individual ampicillin and tetracycline tablets, which cost the government less than USD 0.04, were sold for USD 0.50 to USD 1.00 each on the black market.

The embossing of tablets did not stop these thefts, but it substantially reduced large-volume theft and subsequent sale to commercial pharmacies and physicians. In one year, losses caused by theft during the wharf-clearing and delivery process amounted to 5 to 10 percent. A thorough investigation of pharmacies and doctors’ offices in the capital city uncovered several places that dealt in stolen pharmaceuticals. This investigation led to a rapid reduction in thefts. Without the embossing on the tablets and capsules, proving that the medicines had come from government stores would have been difficult, if not impossible.

Good management

One principle of theft control is to provide secure storage places with limited access at all points in the distribution system. A weak physical infrastructure predisposes itself to easy break-ins. Cheap locks, glass windows without metal bars, poor lighting inside and outside the stores, weak walls and doors, and congested and disorganized storage that makes taking inventory difficult all provide a weak link in the security system. If security guards exist, they are often not supervised well, nor are they well trained or equipped to protect the property. In urban locations where private security companies have strong monitoring and support systems, outsourcing external security is cost-effective. [Country Study 43-3](#) describes a pilot project for improving inventory control in Sierra Leone.

A second principle is active use of the information system to detect theft and trace the point where it occurred. The best inventory system is useless unless periodic physical stock counts are compared with recorded stock levels, and unfortunately, many record-keeping systems are not well monitored,

and information is not updated regularly. The transaction between stores and dispensaries in many places is recorded only in bulk quantities and not by individual pharmaceutical products. Claiming a product as issued when, in fact, most of it is diverted, is very easy. Detailed record keeping and a patient treatment register with specifics on prescribed quantities can ensure that every product is accounted for. Record tampering and excuses of lack of staff for handling record keeping can be cover-ups for potential corruption.

Although designing a system that prevents theft at every point in the flow of medicines from port to patient is probably not possible, measures can be implemented to attack the problem at its major sources—

- Strengthen physical storage facilities with solid doors and windows, and reinforce with bars.
- Introduce systematic and orderly shelving.
- Use unique product and container identifiers.
- Strengthen inventory-control systems at all levels.
- Maintain a perpetual inventory system with regular physical counts.

Country Study 43-3

Experience in improved inventory control in Sierra Leone

The Sierra Leone Ministry of Health introduced improved security measures as a pilot project. At the time, the supply system lacked proper storage and inventory control, and essential medicines were in short supply. More than USD 1 million in medicines had been stolen the previous year. The project's main aims were to enforce accountability, strengthen security, and provide training in store and pharmaceutical management at central medical stores and selected district, hospital, and peripheral health unit levels.

Improvements were made at the hospital level. First, the hospital store was renovated. Wooden doors were replaced with reinforced double-lock steel doors, windows were fitted with steel bars, and the ceiling was reinforced to prevent access from adjacent rooms. A large lockable shelf was provided for expensive, fast-moving items. All other items were kept in sealed boxes on pallets. A storekeeper was appointed. The hospital pharmacy was cleaned, obsolete items were removed, and shelves and medicine cabinets were constructed. The pharmacy was divided into two parts: a mini-store and a dispensing room equipped with a small lockable cabinet. The mini-store supplied the dispensing room. Replenishment was made with a special requisition form only after previous receipts had been accounted for. The dispenser or pharmacist issued

medicines by official prescription to patients through a dispensing window. Access to the store was limited to the storekeeper in charge. At the end of the day, the storekeeper, the dispenser, and the cashier audited the day's transactions and tallied the money received against the supplies issued. The money was then deposited in a special revolving drug fund that was used to replenish medicines. The strict physical and inventory record control and the weekly perpetual inventory of selected fast-moving medicines improved security.

Worries existed, however, about the system's integrity. Several creative methods of pilfering were discovered. In one of the stores, the containers all appeared to be in place when viewed from floor level; when viewed from a height (the supervisor climbed a ladder), empty spaces could be seen where medicines had been removed. It was also discovered that medicines had been removed from their containers and the empty containers replaced on the shelves. After these thefts were discovered, the storekeepers were held responsible. Subsequently, such pilfering techniques were abandoned.

The security system was effective for a few years, but ultimately, the system broke down as major economic and social problems engulfed the country.

Source: G. Daniel, unpublished data, Africare, 1994.

- Insist on perpetual record checking with discrepancy reporting.
- Concentrate security measures on fast-moving, popular, and expensive items.
- Assign responsibility for security to one person.
- Limit store access to accountable staff members only.
- Disallow individual prescription filling from the store.
- Improve staff salaries and working conditions.

When corruption and theft are prevalent in a supply system, extremely low staff salaries are often a contributing factor. Increasing salaries to a level comparable to local private-sector salaries for similar positions is expensive but may be cost-effective if losses can be controlled.

Many of those responsible for handling valuable and expensive ARVs are government employees. Constraints relating to the civil service that might hinder good security management include—

- Compulsory rotation (may apply to trained staff)
- Exposure to recruitment embargoes/vagaries
- No hiring/firing responsibility
- No control over remuneration
- Lack of resources
- Government security personnel (only) on duty at key sites; they may be military staff, for example, untrained for the job required

Some physical security measures that can be used at all levels in the supply chain include—

- Improved external and internal lighting
- Alarm systems
- Watchdogs
- Private security agents
- Secure fencing
- Double locks
- Strong, lockable delivery boxes and containers
- Closed delivery vans

Narcotics and controlled medicines require special security management practices. Special procedures may include restricting who can access information regarding purchases and shipments and planning for increases in usual product volume that might occur when, say, a country is introducing or scaling up methadone maintenance programs as a way to decrease the spread of HIV. Methadone products are generally low cost; however, their street value may be much higher, making them valuable targets for thieves. Managers need to consider ways to mitigate risk; for example, in Vietnam, providers add a low-temperature caramelizing agent to the liquid methadone preparation, which makes it impossible to concentrate—adding heat will quickly give the product a tarry consistency that makes it impossible to inject.

The United Nations (2007) has developed guidelines on procuring controlled substances for dependency treatment.

Box 43-1 provides a sample of techniques used in various parts of the world. Unfortunately, the comparative effectiveness of the various methods has not been tested and is likely to vary from country to country, depending on the commitment of individuals and on political, cultural, and economic circumstances.

Law enforcement and closing of outlets

When the major outlet for stolen goods is black market sale within the country, the incentive to steal is reduced greatly by closing black market outlets. This step is more easily taken if the outlets can be readily identified and if pharmaceutical products carry unique identifiers.

Governments that condone the presence of open-market drug peddlers are often victims themselves, because the medicines sold in these illegal outlets are often products stolen from government programs. Eliminating unauthorized outlets is a first step in controlling theft and irrational medicine use.

Unfortunately, police may be unwilling or unable to spend time on such activities. To solve this problem, the pharmaceutical section of one Southeast Asian ministry of health managed to obtain authority from the police department for its own staff to investigate and prosecute violations, which improved enforcement efforts. Such a solution would not work, however, if theft were coordinated or condoned at the upper levels of the supply system.

When stolen pharmaceuticals are sold through a multitude of street vendors, closing the outlets may not be feasible because they are difficult to identify and locate. In those instances, control can be exerted more effectively at the sources of theft rather than at the outlets.

43.5 Bribery

Illegal payments from suppliers to purchasing officials can occur at all levels and in any country. The supplier may try to use bribery to influence which medicines are bought, how much is purchased, or which suppliers are selected. A determined supplier can influence decisions in most supply systems. Bribery is made more difficult if separate mechanisms are established for making each of those three decisions and if all decisions are made by a committee rather than by an individual.

Measures that can discourage bribery include making sure the system is transparent; identifying the parties involved; bringing the culprits to justice through an anticorruption or similar mechanism; and instituting court action. If bribery is considered a major issue in an organization, using covert techniques can help identify the individuals or the network.

Box 43-1 Techniques for theft control

Monitor selected items

Monitoring should be targeted at those products that are most likely to disappear—those that are fast moving, chronically in short supply, in high demand by consumers, expensive, lifesaving, and easy to hide or disguise.

A simple way to monitor targeted medicines is to—

1. Select a drug product that is particularly likely to be pilfered or that may be misused (prescribed inappropriately), for example, tetracycline tablets.
2. Check pharmacy or storeroom inventory records to determine consumption during a specified period (example: 8,000 tablets were issued during a three-month period).
3. Check medical charts or prescription ledgers and count the number of treatment courses over the same period (example: 101 adults were dispensed fifty-six tetracycline tablets each).
4. Convert treatment courses to dose units (example: 5,656 tablets).
5. Compare this figure with the stock issued from the storage area. If the difference is significant, further investigation and possibly punitive action are warranted.

A system of supervision that incorporates scheduled and unscheduled visits to facilities will deter theft and fraud. A monthly audit system and report on stock status coupled with on-the-spot physical counts of selected items will indicate foul play. Such preventive measures will help minimize losses and ensure that the problem is identified and addressed before large losses occur.

At the port

Containerization. If the port is equipped to handle containers, containerization reduces both major and petty theft because containers are physically secure (although entire containers can be stolen).

Rapid port clearance. Inadequate and inefficient port-clearing procedures can lead to long delays, providing opportunities for theft if security is weak. Increased efficiency in port clearing reduces theft. Ensure that all necessary documents for clearance (airway bill, invoice, certificate of analysis, certificate of free sales) are ready.

At the medical stores

Limited access. Access to medicine storage areas should be limited to the store's staff members only. Hospital pharmacies should not be accessible on evenings or

weekends or when the pharmacist or dispenser is not present. Limited extra supplies for emergency rooms and wards should be entrusted to medical officers or nurses when the pharmacy is closed. Their distribution should be accounted for and monitored by pharmacy staff.

Secure locks and doors. These physical barriers are essential to good security. [Country Study 43-3](#) describes improvements that can be made.

Unannounced searches of medical stores and hospital staff and security staff. In some countries, the pharmacist or medical director personally supervises periodic, unannounced searches.

Independent stock count. Staff members from the central pharmaceutical supply office should visit all major medical stores periodically to perform either a complete or a sampling stock count and an audit of receipt and issue records.

During transport

Document verification. A selected staff member should be responsible for checking receipts against the packing slip. A separate invoice should be sent from the issuing store, and the receiving form should be verified against this invoice. This control measure shows where shipments have partially or completely disappeared in transit. A waybill used during any delivery (that records the date of travel, destinations, driver, particulars of the vehicle, products transported, date of arrival, and signature by the dispatcher and the person in-charge at the destination) is an important tracking measure.

Packing seals. Shrink-wrapped pallets and tape, wax seals, and wire seals used to close cardboard boxes or other transport containers make tampering obvious to see.

Strongboxes. When large shipments are made to small numbers of facilities, portable strongboxes or built-in compartments with padlocks or tamper-proof strings should be used. One key should remain at the issuing store and the other at the receiving store.

In hospitals

Pharmaceutical accounting. Ward and outpatient staff should record all pharmaceuticals received and dispensed. These records should be checked periodically (monthly or bimonthly) against pharmacy issue records. A daily treatment register that keeps a record of all patients treated, by age, gender, diagnosis, and prescribed

quantities, can give a running total of medicines that can be linked with stock status.

Issue-consumption verification. For dangerous and controlled medicines, and for medicines that are frequently stolen, a consumption report showing the time, date, patient, patient's number, dose, and remaining stock levels should be submitted to the pharmacist with each order for additional stocks.

Presentation of prescriptions for ward issue. For selected expensive or frequently abused medicines, the hospital pharmacy should be provided with a copy of the signed prescription to be filed with the pharmacy before medicines are issued to the ward.

Rotating stock containers. Wards can keep a limited number of labeled containers for each medicine they stock. When the containers are empty, they must be returned to the pharmacy for replenishment, along with the dispensary record for the medicine. The containers allocated for each medicine should hold enough stock for several days. Excessive replenishment of stock is cause for suspicion.

Locked transport boxes. The pharmacy can issue medicines in wooden or metal boxes with padlocks. Each ward should have its own box. The pharmacist should have a key for all ward boxes, and the head nurse should have the second key for that ward's box.

Upgrading of transport staff. In several countries, security has improved when nursing students, dispensers, or nurses, rather than laborers, collect medicines from the pharmacy. When the pharmacy establishes and adheres to an appropriate issuing schedule for wards, nursing staff are able to allocate time to collect medicines.

Upgrading of pharmacy staff. Gradual replacement of untrained dispensary staff with trained pharmacists and dispensers has been credited with reducing theft in some countries. A combination of more careful screening of individuals, professional socialization, and higher pay may explain this observation.

In outpatient departments and health centers

Maximum dispensing quantities. Setting a maximum quantity prevents patients from altering prescriptions to obtain large amounts of medicines and prevents collaborating physicians from writing excessively large prescriptions.

Recording of individual prescriptions. This measure is recommended to increase the dispenser's accountability. A patient treatment register serves as a prescription record of all medicines issued, corresponding to the disease. The register makes any discrepancy in prescription amount, overprescription, incompatibilities, or evidence of irrational medicine use easy to see.

Influencing choice of medicines

In [Chapter 16](#), it was noted that the participation of a panel of respected physicians, pharmacists, and public officials often improves the appropriateness of medicine selection and makes the process more credible and therefore more acceptable. Another advantage of involving multiple participants is that it lends greater visibility to the selection process. A supplier will find it more difficult to persuade a whole group to buy an unnecessary type or brand of medicine than to influence one or two individuals.

Influencing order quantities

When inventory control is poor, purchasing officers usually have to estimate rather than calculate the amounts to purchase. If no consumption data are available to compare with these estimates, order quantities can be inflated by bribe-seeking purchasing officers without great risk of detection. In contrast, when inventory control and forecasting are effective, when a systematic method of calculation is used to determine order quantities, or both (see [Chapters 20 and 23](#)), the supplier or a purchasing officer will have much more difficulty influencing the amounts ordered.

Influencing supplier selection

Suppliers in many countries attempt to influence the selection of the supplier for a particular order. As discussed in [Chapter 21](#), a transparent tender process and tender awards made by a broad-based committee are the best ways of combating this problem.

43.6 Fraud

Manufacturers and importers may dilute liquid preparations, omit or reduce the quantity of expensive active ingredients, or short-pack their shipments. Some suppliers may even provide counterfeit or spurious products. This type of fraud can be uncovered by proper quality assurance practices ([Chapter 19](#)) and thorough checking of receipts by the receiving clerk at the medical store or pharmacy ([Chapters 44 and 46](#)).

Specialists from the Ethiopian Ministry of Health paid visits to selected winners of tenders and found that although many suppliers claimed to meet the criteria for bidding on tenders, they failed to meet even the basic requirements. Their visit to India showed that over 80 percent of forty-

Country Study 43-4 Cost-benefit scenario from Ethiopia

Investing in strengthening security in the pharmaceutical sector can result in major cost savings and overall health benefits to the population. Theft of medicines and other medical products directly disrupts health system services by denying health providers and patients the means of addressing illnesses. Effective medical practice demands that pharmaceuticals are available in the quantity prescribed and when needed, and averted thefts mean more medicines are reliably available for initiating or continuing treatment. Strengthening security will ensure that not only high-value products such as ARVs are protected from theft, but also all other essential medicines in the facility.

The following table demonstrates the cost-benefit scenario from Ethiopia's HIV/AIDS treatment program in 2004. The scenario is based on—

- Strengthening physical security measures at the health facility level (drug store and dispensing pharmacy)
- Using local materials and labor
- Employing two security guards for one year
- Treating patients with first-line combination ARVs for one year

Expense	Cost
Cost of one-time physical security reinforcement:	USD 1,800
• Metal doors and locks (3)	
• Metal windows (5)	
• Steel bars for windows (5)	
• Flood lighting	
• Lockable storage cabinets (6)	
Cost of security guards for one year (2)	USD 1,440
Total estimated cost of security	USD 3,240
Estimated Cost of ARVs	
Cost of first-line ARVs for five patients for one year	USD 3,000

The table illustrates that a small one-time capital investment for physical reinforcement of USD 1,800 and a recurrent annual cost of security guards for one year of USD 1,440 are equivalent to the cost of treating five patients with ARVs for one year. If the facility has a patient load of 500, the theft of one year's worth of ARVs will cost the system USD 300,000. This figure does not take into account the inestimable loss of life or interruption of treatment.

Physical security measures need to be complemented by other management and inventory control actions, but this case in Ethiopia illustrates that a small investment in security can have high returns.

five pharmaceutical suppliers to the Ethiopian government medical store failed to meet several basic quality assurance standards.

Falsifying transaction records, such as invoices and receipt and issue vouchers, is a major type of fraud that does not involve the physical product. Many phony suppliers forge official documents—such as WHO or national government certifications, quality control data, or free trade papers—and pass off the counterfeit or stolen pharmaceutical products as genuine to countries with weak regulatory systems. These transnational and international practices can be curbed with close collaboration between countries, WHO, the World Trade Organization, and consumer interest groups.

The supplier should be held accountable both for intentional errors, such as fraud, and for mistakes in formulation or packing. Fraudulent product ingredients have caused deaths, and suppliers have been prosecuted accordingly. Precise specification of product requirements and rigid enforcement of contracts are essential, as described in [Chapter 39](#).

Temptations and pressures always exist that may lead personnel in responsible positions to commit fraud, so constant monitoring is required.

43.7 The cost of security

In some cases, no additional costs are specifically attributable to security control. Several methods for preventing security breaches serve a dual purpose, because they are also necessary for the effective procurement and distribution of pharmaceuticals: establishment of a pharmaceutical selection committee, quality assurance, inventory control and forecasting, and checking of receipts.

Other security measures may be quite costly but are worth the investment. Imprinting containers, embossing tablets and capsules, hiring special security staff, constructing secure warehouses and storerooms, and regularly monitoring and auditing stock records all can be expensive. Those expenses must be weighed against the potential savings in resources and in health from reduced theft, bribery, and fraud (see [Country Study 43-4](#)).

Breaches in security can have substantial medical as well as financial costs. Fraud may have serious and even life-threatening medical consequences if the supplier uses insufficient amounts of active ingredients. Theft raises costs by increasing the volume of pharmaceuticals that have to be purchased; it also has medical costs resulting from shortages

ASSESSMENT GUIDE

Prevalence of leaks

- Is pharmaceutical leakage a problem?
- What are the annual losses as (1) absolute value and (2) percentage of total annual pharmaceutical purchases?
- Where do leaks occur: at ports, at primary and intermediate stores, at health facilities, during transport?
- What types of leaks are experienced in each setting: petty pilferage, major thefts, diversion of shipments, bribery and corruption, supplier fraud? Which are the most significant?
- What are the products targeted?
- Are high-value and disposable items, such as ARVs, always receiving priority attention?

Security systems

- Does an effective inventory control system exist?
- Are special procedures in place for narcotics and other controlled medicines?
- What systems are used to control theft? Have thefts been detected in the past year? What measures were taken after detection?
- What systems are used to control bribery and corruption? Is a committee system used? Has bribery or corruption been detected in the past year? What measures were taken after detection?
- Are physical security systems in buildings and vehicles adequate or inadequate?
- Are doors and windows secure?

- Are stock/bin cards used and completed regularly? Is there regular internal auditing?

Theft detection

- How is theft detected: informers, physical inventory count, consumption comparisons, surveys of selected outlets?
- Are the police cooperative?
- Are junior staff members cooperative?
- Are senior managers cooperative?

Fraud detection

- What systems are used to control supplier fraud? Has fraud been identified in the past year? What measures were taken after detection?
- Are product and packaging specifications adequate?
- Do supplier contracts specify penalties in the event of fraud?
- How is fraud detected: visits to suppliers, receiving inspections, or assays?
- Are any laws or regulations in place for controlling fraud?

Bribery

- Where and at what level and in what form is bribery taking place?
- Is the procurement system transparent enough to prevent bribery in all its forms?
- Has the organization experienced bribery in the past? What measures have been taken?

and the use of inappropriate medicines. Bribery and corrupt procurement can be particularly costly. Traditionally, in one South American country, 7 to 10 percent of the procurement value is paid to procurement officials. This corruption “tax” adds up to several hundred thousand U.S. dollars each year because these bribes are added to the medicine’s price. ■

SUMMARY

This chapter discusses medical stores management at central-level stores and at regional or district-level stores that are independent from health facilities. This supply model represents the traditional top-down system that is operated by a governmental or parastatal entity or a nongovernmental organization; however, a number of countries have now decentralized many of their pharmaceutical sector operations, including stores management. [Chapter 8](#) discusses supply chain options, including the trend toward decentralization. In addition, many supply systems contract out certain operations to private-sector companies. Managing contracts requires skills such as defining and monitoring performance indicators and negotiating payment and service terms. See [Chapter 39](#) for more information on contracting. The tenets of this chapter, therefore, apply to stores operating in either the public (often called central medical stores) or nonpublic sectors.

Medical stores management should assist both the flow and reliability of supplies from source to user as economically and reliably as possible, and without significant wastage, loss of quality, or theft. The primary purpose of a store is to receive, hold, and dispatch stock. This materials management process is implemented through inventory control and warehouse management systems, which may be manual or computer based. The primary purpose of inventory control is to manage stock and ensure the smooth flow of goods by determining what, how much, and when to order stock. Consequently, it provides essential information for procurement management. Warehouse management comprises the physical movement of stock into, through, and out of a medical store warehouse. The systems should also be designed to provide information for performance monitoring.

The following are characteristics of a well-managed stores operation—

- The store should be divided into zones that provide a range of environmental conditions and degrees of security.
- There should be an appropriate zone to suit every item to be stored.
- Stock should be arranged within each zone according to some orderly system.
- Stock should be stored off the floor on pallets, on pallet racks, or on shelves. Each of these systems requires specific types of handling equipment.
- Good housekeeping—cleaning and inspection, the disposal of expired and damaged stock, recording of stock movements, and the management of security—should be maintained.
- The management structure should be clearly defined.
- Staff should be appropriately qualified, trained, disciplined, and rewarded.
- Clearly written procedures and handbooks should be available.
- To promote efficiency, staff should have good working conditions and facilities.
- Stock should be verified regularly and periodic audits should be conducted.

Although the essential characteristics of materials management are the same for all systems, the level of sophistication of medical stores varies widely, and each store approaches its system and documentation differently. Therefore, the basic features presented in this chapter are adaptable, depending on the complexity of the medical stores management operation.

44.1 Information for materials management

The goals of medical stores management are to protect stored items from loss, damage, theft, or wastage and to manage the reliable movement of supplies from source to user in the most economical and expeditious way. Effective management of information is the key to achieving these goals. The integrated process is known as materials management. A fully developed system has three key components—

1. An *inventory control system* ensures that the right goods are acquired, in the correct quantities, monitors their quality, and minimizes the total variable cost of operations (see [Chapter 23](#)).

2. A *warehouse management system* monitors the physical flow of goods within the system, such as receipts, storage, and issues.
3. A *performance monitoring system* checks that the systems are operating effectively.

Information is essential to management (see [Chapter 49](#)). Collecting, processing, and disseminating information may seem costly, but the cost of developing and maintaining an information system should be balanced against the costs of ineffective inventory control (see [Chapter 23](#)). The design of the information system is important, but its success depends primarily on well-trained, organized, and supervised staff. [Country Study 44-1](#) describes some of the

inventory control system challenges to the central medical stores in Namibia.

Manual versus computerized systems

The information system must include data on products entering and leaving the warehouse, products in stock, products on order, and ways to monitor the progress of orders in the supply pipeline. Key elements of the system are well-designed forms, computerized information systems, and clearly defined procedures.

Two decades ago, most public supply systems relied completely on manual stock records, but now, many programs have changed to computerized systems. Even with computerization, however, many countries still maintain a manual system, such as bin cards, as a backup, especially during the transition to computerization. There is a widely held belief that computerization solves the problem of inventory control. This belief is misguided. A computer is not a substitute for trained staff; it is simply an additional tool for staff to use (see [Chapter 50](#)). Both manual and computerized systems perform the same fundamental information-processing tasks: data input, data storage, data processing, data retrieval, and data dissemination. The difference is that a computerized system enables some tasks

to be accomplished more rapidly, accurately, economically, and flexibly. Even with a computerized system, data must be entered, manipulated, and interpreted by skilled and knowledgeable staff.

Procurement information

The procurement process (Chapters 18–21) involves medical stores input at all levels of the distribution system. These inputs are described below.

Procurement can be handled from a department within the medical stores or from an external unit. The medical stores unit provides the (internal or external) procurement unit with a list of the types and quantities of medicines needed for its operation. After a supplier is selected and a purchase order is placed, the procurement unit informs the medical stores unit about suppliers, unit prices, the quantities on order, the expected arrival dates of shipments, and other vital information.

The procurement unit tracks information on inventory status, new shipments received and taken into stock, issues made to health facilities, expired medicines, damaged medicines, and audit data from physical stock checks.

The medical stores unit also tracks issues to individual health facilities, noting methods of transport, delivery

Country Study 44-1

Central medical stores inventory control system operations in Namibia

Namibia operates a classic central medical stores (CMS) distribution system with a CMS and two regional medical stores. Administratively, the regional stores do not have any links with the CMS—the relationship between them is one of customer and client. The CMS distributes medicines and supplies to the two regional medical stores, all district hospitals, and local hospitals and clinics in the surrounding regions, while the regional stores and district hospitals are responsible for distributing to other facilities within their geographic jurisdictions.

Facilities are expected to order products from CMS every six weeks, and it usually takes CMS about four weeks to process and deliver the order. An assessment of the CMS distribution showed, however, that stock records were not adequately maintained and physical inventory counts did not correspond with either stock records or computerized records. Because the regional stores and health facilities had no effective systems for deciding when, what, or how much to order, most facilities ended up placing many emergency orders within the six-week order period, which stretched the capabilities of the already overburdened CMS.

A computerized inventory control system had been installed at the CMS several years earlier, but most of the staff members who were initially trained to use it had left the public service; remaining staff members, therefore, were not using the system to its full advantage. Many functions that could have been handled by the system were done manually or with spreadsheets. Moreover, management personnel reported that they did not have enough time to acquire the additional skills that would help them use the system.

As a result of the CMS assessment, a number of recommendations to improve the inventory control system were made: conduct complete physical inventory counts at all levels and use the results to update or introduce stock records; develop standard operating procedures for store management; and train staff on how to maintain stock records and use the computerized inventory control system to their best advantage.

Source: Management Sciences for Health/Rational Pharmaceutical Management Plus Program.

times, and confirmation of receipts from user units. This tracking should generate information on the monthly and annual value of total issues, issue quantities, details of specific products, and how budget allocations are used.

After an order has been placed, its progress should be monitored until it is received at the central medical stores (CMS). A good monitoring system makes it possible to estimate realistic delivery times and to decide whether any supplementary or emergency orders are needed, well before a stockout occurs.

Both manual and computerized systems should identify milestones during the lead-time period to facilitate communication with suppliers and to prompt corrective action if required. Important milestones of the procurement lead time are—

- Order initiating date
- Date of award to supplier (for tenders)
- Letter of credit information
- Shipment information and date
- Arrival at port
- Port-clearing date
- Date of issuing a receiving report

An effective supplier information system should include general information on suppliers and products, lead times, merit ratings, value of purchases, product quality, payment methods, and prequalification based on good manufacturing practices. Information about supplier performance should be compiled throughout the procurement cycle to assist in choosing future suppliers. [Chapter 21](#) discusses the features of a procurement information system in more detail.

Stock records

Stock records contain information about suppliers, customers, prices, stock receipts, stock issues, stock losses, and stock balances. These data are essential for planning distribution.

A stock record (manual or computerized) must be maintained for each item in the inventory. The stock record documents all transactions relating to an item. It may contain information about reorder level, reorder interval, reorder quantity, lead time, stock on order, and estimated consumption rate. Many stores also maintain bin cards for each product in each storage area to record information on issues, receipts, and stock balances. In some stores, this bin card is the most current and accurate record of inventory movement.

The design of stock cards and bin cards depends on the choice of inventory control system. For details regarding the design, selection, and use of different types of inventory control systems, see [Chapter 23](#); examples of a stock record card and a bin card are provided in [Annexes 44-1](#) and [44-2](#).

When a shipment of medicines is received at the CMS, it is inspected to ensure that it meets the specifications in the supply contract. If the shipment is satisfactory, the receiving section of the warehouse produces a receiving report (see [Annex 44-3](#)). This report brings the procurement lead-time period to an end.

Individual health facilities are the end users of medical supplies. Maintaining information from health facilities is essential in order to monitor consumption, forecast pharmaceutical requirements, and make other management decisions. Many medical stores information systems also keep general information on facility location, facility status, population served, method of distribution, delivery schedule, value of issues, and extent of current budget utilization.

Performance monitoring and reporting

A store should monitor and evaluate its operations to identify problems in the system that need to be addressed. Record-keeping and reporting systems should be designed to make the collection of data for routine monitoring as simple as possible (see [Chapter 48](#)). Stock records are a vital source of information on how effectively the distribution system is being managed; therefore, maintaining these records accurately and keeping them up-to-date is vital. They provide detailed evidence of how products flow through the system and can be used to identify where problems are occurring so that corrective action can be taken. Operational indicators can track progress at two critical levels: from the supplier to the store, or “upstream,” and from the store to clients, or “downstream.” Upstream information includes lead-time from supplier to the store, number of medicines procured, and monthly stock status reports. At the downstream level, the store should collect routine lead-time information; distribution information by facility, district, and product; client satisfaction and consumption data; and order-fill rate. [Box 44-1](#) shows a list of sample indicators. The medical stores should prepare regular reports on stock and order status, such as those described in [Chapter 23](#), and send them to relevant parties such as the ministry of health, public health programs, donors, lower-level warehouses, and health facilities.

Communications

The medical stores must maintain effective communications with suppliers, with procurement and inventory control units, with lower-level warehouses and health facilities, and with managers from the ministry of health. Periodic meetings with the staff members of client facilities can help ensure good communications and a more effective supply system.

Box 44-1 Examples of monitoring and evaluation targets and indicators

- Number of sites to which medicines are distributed
- Quarterly report delivered on time
- Payment voucher processing time
- Number of patients receiving treatment
- Percentage of medicines that are wasted (as a result of breakages, expiries, pilferage) as a proportion of overall stocks
- Time elapsed from order receipt by store until shipment receipt by client
- Order processing time within the store
- Lead time between the supplier and the store
- Lead time between the store and the client
- Forecast for store commodities completed
- Percentage of commodities out of stock in service delivery sites
- Percentage of products tested for which a quality problem was detected
- Percentage of shipments to service delivery sites that are consolidated
- Percentage of cost savings as a result of price negotiations

44.2 Flow of stock and information

Stock, and the information that accompanies it, should flow through the warehouse in an orderly manner. This process has six stages—

1. *Receiving*: Goods that arrive in the receiving room are quarantined, inspected, and if found to be acceptable, entered into the stock-recording system. Receiving reports are prepared.
2. *Storage*: Accepted goods are moved to their allocated storage positions in the warehouse, where they are stored in first-in/first-out (FIFO) or first-expiry/first-out (FEFO) order. Records for stocks on hand and on order are adjusted.
3. *Allocation of stock*: In most medical stores, the manager determines whether to allocate the complete quantities requested when a requisition is received. The decision can be made in collaboration with the requesting facility but generally depends on stock status, a review of facility consumption patterns, and, in some cases, budget status.
4. *Order picking*: An order-picking list is prepared (this may be the original requisition form rather than a separate list). Workers use this list to identify and col-

lect the allocated items from the warehouse.

5. *Order assembly*: Individual orders are assembled and checked in the packing area. They are then packed for delivery. Delivery documentation is prepared.
6. *Dispatch and delivery*: The packed goods are held in designated secure areas pending shipment, then loaded onto the transport and dispatched, accompanied by the necessary documentation, including a packing list recording all items and quantities. Ideally, an invoice showing unit costs of medicines and total value should accompany the shipment. Signed delivery notes are checked when the vehicle returns. If errors or damage have been reported, appropriate action is taken.

Formal and informal physical stock counts should be taken regularly to ensure that stock is being correctly handled and that losses and inaccuracies are properly accounted for.

Stock receipt

Importation and port clearing are described in [Chapter 24](#). The procedure outlined here assumes that those tasks are carried out by an import unit attached to the CMS. Port clearing may, however, be contracted to a clearing agent or made the responsibility of the supplier. In such cases, the goods are delivered directly to the CMS or are collected from the agent's warehouse. Final responsibility for inspection remains with the CMS.

With the exception of locally purchased items, multiple copies of the supplier's shipping documents and supplier's invoice should be received by the CMS before supplies arrive at the port of entry. This information is recorded on a manual or computerized form to track each purchase order. In addition, the import unit should record the arrival information. This advisory is clipped to the purchase order in the supplier's file to await the arrival of the shipment.

When notice is received of a shipment's arrival at the port, the necessary customs forms are completed. It is always necessary to visit the port to arrange for the release of the shipment.

Containers are inspected against the supplier's shipping document. The first part of the receiving report is completed ([Annex 44-3](#)). Any apparent damage and missing shipping cases are noted and reported to the port authorities, insurance agents, and customs officials.

When the shipment arrives at the warehouse receiving area, contents should be quarantined until they have been checked ([Figure 44-1](#)). The receiving clerks systematically check the cases and their contents against the supplier's invoice. Discrepancies, variations, and damage are noted on the invoice. A prompt and thorough inspection based on predefined criteria is essential to quality assurance and as a

Figure 44-1 Checking received goods

precursor to any insurance claim. [Table 44-1](#) is a checklist with sample inspection criteria.

The annotated invoice is signed and dated by a senior staff member. Observations are summarized on the second part of the receiving report.

One copy of the receiving report is filed according to the purchase order number to which it corresponds. The other copy and the annotated supplier's invoice are passed to the stock control section. In some warehouses, a separate copy goes to the accounting department.

The items are then entered on their respective stock record cards ([Annex 44-1](#)). The new stock on hand and on order totals are calculated, as well as the average cost per unit for each item. If a computerized system is used, receipts are entered into the system as prescribed in the software manual.

Planning for space requirements

As mentioned in other chapters, the massive increase in funding for pharmaceuticals from global health initiatives such as the Global Fund and the U.S. President's Emergency

Plan for AIDS Relief has increased the storage and distribution volume needed in some countries by two- or threefold. In addition, managing these "strategic" stocks can be challenging; for example, in the case of what to do with "dead" stock that never gets issued. Stores, therefore, need to work carefully with their clients to communicate about scale-up of initiatives such as antiretroviral therapy and distribution of bed nets to prevent malaria that will affect space and distribution planning and to develop policies on managing strategic stock.

Stock storage

After incoming stock has been checked and approved, it is formally released from the receiving area and moved to the warehouse to be stored in the appropriate zone. New stock may be stored on floor pallets, pallet racks, or shelves. If a fluid or semifluid location system is used (see Section 44.4), the exact location of each item must be recorded. If a bin card system is in use, receipts should be entered on the bin card when the items are transferred to the storage area.

Table 44-1 Inspection checklist for medicine receipts

Product	Notes	Checklist
All shipments	Compare the goods with the supplier's invoice and original purchase order or contract. Note discrepancies on the receiving report. Take a sample for testing (if preacceptance sampling is a standard procedure).	<ul style="list-style-type: none"> <input type="checkbox"/> Number of containers delivered is correct <input type="checkbox"/> Number of packages in each container is correct <input type="checkbox"/> Quantity in each package is correct <input type="checkbox"/> Drug is correct (do not confuse generic name and brand name) <input type="checkbox"/> Dosage form is correct (tablet, liquid, other) <input type="checkbox"/> Strength is correct (milligrams, percentage concentration, other measurement) <input type="checkbox"/> Unique identifiers are present, if required (article code, ministry of health stamp, other code) <input type="checkbox"/> No visible evidence of damage (describe if present)
Tablets	For each shipment, tablets of the same drug and dose should be consistent.	<ul style="list-style-type: none"> <input type="checkbox"/> Tablets are identical in size <input type="checkbox"/> Tablets are identical in shape <input type="checkbox"/> Tablets are identical in color (shade of color may vary from batch to batch) <input type="checkbox"/> Tablet markings are identical (scoring, lettering, numbering) <input type="checkbox"/> There are no defects (check for spots, pits, chips, breaks, uneven edges, cracks, embedded or adherent foreign matter, stickiness) <input type="checkbox"/> There is no odor when a sealed bottle is opened (except for flavored tablets and those with active ingredients normally having a characteristic odor) <input type="checkbox"/> There is no odor after tablets have been exposed to room air for 20 to 30 minutes
Capsules	For each shipment, capsules of the same drug and dose should be consistent.	<ul style="list-style-type: none"> <input type="checkbox"/> Capsules are identical in size <input type="checkbox"/> Capsules are identical in shape <input type="checkbox"/> Capsules are identical in color (shade of color may vary from batch to batch) <input type="checkbox"/> Capsule markings are identical <input type="checkbox"/> There are no defects (check for holes, pits, chips, breaks, uneven edges, cracks, embedded or adherent foreign matter, stickiness) <input type="checkbox"/> There are no empty capsules <input type="checkbox"/> There are no open or broken capsules
Parenterals	Parenterals are all products for injection (IV liquids, ampoules, dry solids for reconstitution, suspensions for injection).	<ul style="list-style-type: none"> <input type="checkbox"/> Solutions are clear (solutions should be free from undissolved particles, within permitted limits) <input type="checkbox"/> Dry solids for use in injections are entirely free from visible foreign particles <input type="checkbox"/> There are no leaking containers (bottles, ampoules)

Stock control using FIFO and FEFO

In order to avoid accumulation of expired and obsolete stock, items should be stored and issued on a FIFO or FEFO basis, according to the following guidelines.

The stock control system must record the expiry date and the date of receipt. Stock must be stored so that earliest-expiring or first-delivered batches can be picked and issued first. When small quantities are involved, this goal can be achieved by placing the newly received stock at the back of the shelf behind the existing stock. When larger quantities are involved—for example, several pallet loads—the newly received items can be placed on the upper levels of the pallet racking. They remain there until the older stock has been issued. The picking stock is kept in an accessible position, assuming that orders are picked by hand in relatively small quantities. In warehouses where whole pallet loads are picked for distribution to lower-level stores, accessibility is less of a concern because mechanical transporters are used.

Newly arrived stock sometimes has an earlier expiry date than a previously received batch of the same item. If a FEFO system is used, this stock should be “promoted” so that it is issued before later-expiring stock. Making this adjustment is particularly important with products that have short shelf lives, such as vaccines.

Note that the system for stock rotation may be determined by the scheme for price increases, if medicines are sold to clients. If pricing is done on a FIFO basis, this system should also be used for stock management, except when newer stock will expire before it can be used under a FIFO rotation.

Order allocation

Under a pull distribution system, lower-level stores and health facilities submit requests, or requisitions, for supplies. At most medical stores, a designated official is responsible for reviewing requisitions and allocating stock based on inventory levels at the requesting facility and in the issuing warehouse as well as on past consumption at the facility. In many countries, facilities use a set formula for quantification based on their inventory control system to prevent over- or underordering. Usually, the order quantity is rationed at the warehouse level only if there are insufficient funds or stock. The requesting facilities may have budgets that must be considered in making allocations. After the allocation has been made, the order can be picked.

Order picking

The allocated quantities form the order-picking list. This list is passed to the storekeeper. In a large store—especially one that uses a fluid location system (see Section 44.4)—the picking list often needs to specify the exact position of the items to be selected. In a small store, the storekeeper prob-

ably knows where everything is. The listed items are taken from stock in strict FIFO or FEFO order and transported to the packing area, where order assembly takes place.

In large stores, it is common to use separate zones or rooms for storing specific types of products, such as anti-retrovirals, which must be locked up. A specific storekeeper is also assigned the responsibility of managing these products. In such instances, it may be necessary to divide the picking list for a given customer into several smaller picking lists, according to the number of separate storerooms or areas in use. A similar approach would be needed when generating goods received notes and transferring fresh supplies to individual storage areas.

If bin cards are used, the stock issued should be recorded on the bin card as it is pulled from the storage area.

Order assembly

At a secured shipping location, the supplies are arranged in the order in which they appear on the picking list or requisition voucher. The order is double checked by the storekeeper or shipping clerk before the items are packed, sealed, and labeled for delivery. Some items, such as vaccines and controlled substances, require special packing and handling.

Order dispatch and delivery

In the most commonly used in-house delivery system, supplies are generally distributed according to a fixed delivery schedule. In some instances, a collection system may be used, whereby representatives from health facilities collect supplies from the store. The shipping clerk completes a delivery voucher ([Annex 44-5](#)). The voucher lists the number and type of shipped packages. Their specific content is not identified unless the items require special handling, such as vaccines, loose items (such as bulk germicides), and medical gas tanks. The voucher is signed by the driver, who takes two copies with him, together with two copies of the invoice or completed requisition form. The third copy of the delivery voucher remains bound in the delivery vouchers book, which is maintained by the shipping clerk.

When the delivery arrives at the receiving facility, the driver and the facility’s receiving officer count and inspect the containers. Any apparent loss or damage is noted on the delivery voucher. The receiving officer and the driver sign both copies; each keeps one copy. Ideally, the received parcels should be opened and verified against the requisition form in the presence of the driver. Because of time constraints, however, immediate inspection is not always possible.

The signed delivery voucher certifies that the driver has safely delivered the supplies. The receiving store retains the two copies of the completed requisition form. One is signed

and dated and returned to the delivering store. Any differences between the contents of the delivery and the requisition form are reported on the requisition form, and an investigation takes place if there are discrepancies.

The driver returns the signed copy of the delivery voucher to the inventory clerk, who signs and dates it and also signs and dates the permanent copy in the delivery vouchers book. That copy (now bearing the signatures of the driver, the receiving officer, and the inventory clerk, with the respective dates) is placed with the file copy of the completed requisition form.

Some supply systems require that the receiving facility send a written notification of receipt. In such cases, the receiving facility should return a signed copy of the completed requisition form to the CMS before the facility's next requisition date. The date of its return is entered in the register of requisitions (stores issues ledger; see [Annex 44-6](#)). If the receiving facility does not submit this "certified received" copy, the supplying store may refuse to fill the next requisition. The copy is filed in the individual requisitioner's file by date. If any discrepancies have been noted and subsequently verified, all relevant records, including the inventory card, must be adjusted. Again, all these records can be computerized, with file copies maintained.

Inventory taking

The bin card ([Annex 44-2](#)) and the stock record card ([Annex 44-1](#)), the computer file, or both provide a continuous record of each supply item in stock. The filed copies of the purchase orders and the verified copies of suppliers' invoices are used to document additions to the inventory.

The medical stores unit must regularly take physical counts of stock on hand to check that the stock balance on perpetual inventory records is correct. The government or stores audit office should also periodically certify that the recorded transactions and net totals are accurate. The audit is carried out by examining procurements and requisitions and is verified by a physical stock count. As discussed in [Chapter 23](#), the cyclic stock count is now preferred to the traditional annual count. The cyclic count is easier to manage and is more likely to allow reconciliation of discrepancies between records and physical stock.

Both active and safety stock in all locations should be counted as scheduled and compared with the numbers on the respective cards (or computerized records). Inventory verification, at every location where supplies are stocked, should be planned to—

- Enforce procedures and regulations designed to prevent loss and wastage
- Ensure that security measures are adequate
- Provide an additional form of evaluation that may reveal defects in the warehousing system

- Provide regular evaluation of storage conditions and the adequacy of storage facilities, layout, and stock arrangement
- Identify surplus, expired, and obsolete stock

44.3 Zoning stock within the store

Medicines and essential medical supplies must be located in a part of the store with the correct combination of temperature and security. This initial zoning process is the most basic way in which supplies are arranged.

A zone can be a separate building or room, a locked cupboard, a refrigerator, a freezer, or a cold room. [Table 44-2](#) indicates several possible combinations of temperature and security and illustrates how to classify items according to their storage requirements. Thus, an item classified "2B" in this scheme would be stored at +15 to +25–30°C in a secure store.

The product manufacturer's storage instructions should be followed to the extent possible. If these instructions cannot be followed, the product must be kept in the most suitable conditions available and used as quickly as possible. The product manufacturer should be consulted before violating recommended storage conditions, to determine how long the product will remain safe and effective under the actual storage conditions.

If no specific storage instructions are given, "normal storage conditions" apply. Normal storage conditions for medicines have been defined as "storage in dry, well-ventilated premises at temperatures of +15°C to +25°C, or, depending upon climatic conditions, up to +30°C" (WHO 2003). Each storage zone should have at least one thermometer, and temperatures should be recorded daily at the hottest time of day.

Table 44-2 Temperature and security zones

Category	A Normal security	B High security	C Flammable	D Corrosive
1: Uncontrolled temperature	X	X	X	X
2: +15 to +25–30°C (controlled humidity)	X	X		
3: 0 to +8°C	X			
4: –20°C	X			

Notes: The +15 to +25–30°C zone is assumed to be air-conditioned and therefore humidity controlled. In temperate climates, this temperature range can be achieved without air-conditioning, but humidity control may still be necessary. Cells marked X are commonly required temperature and security zones. Other combinations may be required for specific products. For example, zones "3B" and "4B" may be needed for vaccines if the vaccines have a black-market value—for instance, hepatitis B—or there is a particular problem with security for refrigeration equipment.

Storage at uncontrolled room temperature

Many products can be safely stored at uncontrolled room temperature. However, the temperature in the upper part of a store can exceed +40°C even in temperate climates. In cold climates, temperatures will drop below freezing in unheated stores. Such temperature extremes may damage some items. [Chapter 19](#) discusses items known to be sensitive to extreme storage conditions.

Storage at controlled temperature and humidity

In hot climates, it is necessary to store many items in air-conditioned rooms. In humid climates, dehumidifiers are useful for preventing moisture damage. In cold climates, stores may need to be heated in winter to protect products that are damaged by freezing.

Cold storage

The potency of vaccines, sera, test kits, and many other items depends on cold storage. Vaccines, in particular, are temperature-sensitive and must be kept at precisely controlled temperatures from the point of manufacture to the point of administration.

Cold-chain defects are a frequent cause of problems in immunization programs. The World Health Organization's (WHO) Department of Immunization, Vaccines and Biologicals publishes comprehensive advisory material on designing and implementing a cold chain (see the WHO Immunization, Vaccines and Biologicals website). This material should be referred to for detailed technical advice. [Table 44-3](#) summarizes the requirements for an effective cold chain.

National and regional vaccine stores should be equipped with standby generators; ideally, district vaccine stores should have them as well. Having backups ensures that vaccines and other products are protected in the event of a power failure.

Secure storage

Narcotics and other controlled substances should be kept in a secure room or in a safe. Ideally, a red warning light or warning bell that will activate when the door is unlocked should be fixed close to the store. The keys to the secure store should be kept in a safe.

Entry to the store must be controlled. No more than two assigned officers should have access. Typically, one should be the director of the store, the most senior pharmacist, or the most senior storekeeper (see also [Chapter 43](#)). Such precautions may also be needed for non-narcotic medicines that are frequently stolen. For example, many stores keep expensive products, such as antiretrovirals, in a secured space.

Flammables

Flammables, such as alcohol and ether, must be stored in special buildings or rooms. A separate building is best because it greatly reduces the risk of a fire's spreading to the main store. The flammables store must be well ventilated and fireproof. It must be fitted with an "explosion hatch," which may be part of the roof or part of a wall.

Fuel must never be stored in or near a medical store. Fuel tanks should be placed inside a locked compound to prevent theft. There should be a continuous earth bank or low wall around the tanks. The area enclosed should be sufficient to hold the total potential volume of fuel stored to ensure that fuel is contained if a major spill occurs. With these precautions, if a fire occurs, the risk of its spreading will be reduced.

44.4 Stock location within a zone

Within each zone, stock may be located in fixed, fluid, or semifluid locations. Fixed location systems are the simplest to manage, because each stock item is always stored in the same place, but they waste space. Fluid location systems make better use of available space, but require sophisticated stock management, because the location of each stock item varies over time. Semifluid systems combine features of both systems.

Fixed location

In a fixed location system, each stock item is allocated to specific shelves, pallet racking, or an area of floor. A fixed location system is like a house in which each family member has his or her own room. A room is left empty if a person is not at home.

For a fixed location system to work well, the store has to be large enough to accommodate the maximum possible level of stock for every item, including safety stock. As stock is used up, the storage location is emptied and left vacant until a new shipment of the item is received.

With a fixed location system, stock administration is relatively easy. Goods can always be found in the same place. However, this system has certain disadvantages—

- Fixed location systems are inflexible. If there is a change in the quantity ordered or a change in packaging, the assigned location may become too large or too small.
- If a new item is ordered, there may be no place to store it.
- Theft may increase because all store staff are familiar with the locations of valuable items.
- Storage space may be wasted, because at times it is largely empty.

Fluid location

In a fluid location system, the store is divided into many designated locations. Each location is assigned a code. Individual items are stored wherever space is available at the time of delivery. A fluid location system is like a hotel. Rooms are assigned only when guests arrive.

A fluid location system uses available space efficiently, but it requires sophisticated stock administration. Experience suggests that a store using a fluid location system can be 20 to 25 percent smaller than one using a fixed location system.

The administration of a fluid location system works as follows—

- The procurement unit provides information on the type, volume, and weight of goods arriving.
- The storekeeper assesses which locations will be empty when the new stock arrives and assigns an appropriate location. These data are recorded in the stock control system.
- If insufficient space is available, other goods may be moved to create more space.
- The stock control location records are updated.

Fluid location systems require a classification system that allocates a unique identifier code to each stock item and to each location. Also, the stock record for each batch of each item must always indicate the physical location of the item in the store. In a fluid location system, different batches of a particular item may be stored in several different places. For example, if item number 150-050-48 is 500 mg amoxicillin, 150-050-48: B1-B could be a batch of this product stored in aisle B, bay 1, cell B, and 150-050-48: C2-B could be another batch of the same product stored in aisle C, bay 2, cell B.

Fluid location systems benefit immensely from the use of a computerized bin location and storage system, which improves productivity and optimizes storage capacity. Such systems identify not only locations of items, but also the best location for storing an incoming consignment within storage areas.

Semifluid location

A semifluid location system is a combination of the fixed and fluid systems. It is like a hotel that has regular guests. Regular guests are always given the same room. Casual guests are given any room that is available.

In a semifluid location system, each item is assigned a fixed space for picking stock. When an order is prepared, the order-picking staff members know where to find each item. The remainder of the store is filled on the fluid location principle. When the picking stock runs low, the fixed locations are restocked using items from the fluid locations.

A semifluid location system is not as space-efficient as a fluid location system. However, picking stock is stored at a convenient height, eliminating the need for mechanical handling during order picking in stores that issue in relatively small quantities.

Another feature is that picking stock is always kept in the same place. Unlike in a fixed location system, however, less risk exists that changing requirements will disrupt the system. If demand increases for a particular item, the picking stock can be replenished more frequently. As new products are introduced, picking bays may be subdivided to provide sufficient space.

44.5 Stock classification

Items should be clearly organized within each zone of the store. Such organization makes it much easier for store personnel to control stock, take periodic stock inventory, and pick orders.

In stores that use the fixed location principle, items can be physically organized in one of several ways—

- Therapeutic or pharmacological category
- Alphabetical order
- Dosage form
- Random bin
- Commodity code

In a fluid location system, clear organization and unique product identification are absolutely essential to the success of the system. Otherwise, items get lost. Coding by any one of the first four methods is inappropriate for a fluid location system, because the position of a particular stock item will vary over time. For example, if antipyretics are randomly distributed about the store in a fluid location system, organizing the store on the basis of therapeutic class is not feasible.

However, therapeutic or pharmacological class, alphabetical order, and classifications may be used as ways of organizing the stock records, whatever stock location system is used. One of the advantages of a computerized stock control system is that records can be sorted in a variety of ways for different management purposes; for instance, according to therapeutic classes or in alphabetical order.

Therapeutic or pharmacological category

Therapeutic or pharmacological classification may be an effective way of organizing medicines in smaller stores and in the dispensaries of small clinical facilities where the storekeeper is also the dispenser. It is not an advantage in larger stores.

Alphabetical order

Alphabetical order (by generic name) is also attractive in peripheral stores that keep a small number of items. However, each change in the national (essential) medicines list or in the level-of-use list requires reorganization of the stores themselves and of the stock administration system. This method may not result in optimal use of available space.

Dosage form

A system based on dosage form is commonly used in smaller warehouses. Tablets and capsules are stored together, with separate areas for oral liquids, injections, creams and ointments, and topical liquids. Within each dosage-form area, products may be stored in a fixed, fluid, or semifluid manner and further organized by any of the other systems described in this section. The main advantages are that the forms are easy to recognize when receiving goods and this system allows optimal use of space.

Random bin

The random bin is a unique storage space identified by a code. For example, a shelving unit can be divided vertically and horizontally into cells, each with a unique location code. A unit of shelving might be labeled “B,” its bays “B1” and “B2,” and its shelves “A,” “B,” and “C.” A unique cell would be identified, for example, as B1-B (see [Figure 44-2](#)). This cell is called a bin.

The random bin storage method can combine the methods previously described. For example, items are placed alphabetically within therapeutic classifications. Generic names are used throughout. If there is more than one brand of the same generic drug preparation, all are stored in the bin for that type.

Commodity code

Commodity coding is an abstract organizational system. It offers maximum flexibility and can be used equally well in small and large stores.

This system is based on a unique article code combined with a unique location code. Examples of article codes include WHO technical specifications or UNICEF stock codes. Article codes can be designed to specify therapeutic class, clinical indication, level of use, or any other relevant data. In systems that use article coding and location coding, storekeeping staff do not need to have specific knowledge of pharmaceutical names and therapeutic uses.

Changes in the national medicines list can easily be introduced by assigning unique article codes to new products. Article coding works well in a computerized system. Tender contracts may require that only the article code be marked

on the bulk packaging as well as on the smaller units of supply. This method increases security but still allows the goods to be identified by those staff members who have access to the coding key.

The location code is totally independent of the article code and is similar to the random bin principle. Codes can be designed to incorporate any number of characteristics, including—

- Correct storage temperature for the product
- Correct security level for the product
- Whether the product is flammable
- The building where the product is located
- Pack size
- Pharmaceutical form

44.6 Stock storage and handling

Within each temperature and security zone, products must be stored so that they are easily accessible and protected against damage. There are four basic systems of storage: shelves, floor pallets, block-stacked pallets, and pallet racks. Direct storage of cartons on the warehouse floor should be avoided because their contents may be damaged by moisture. The choice of system depends on the following factors—

- Total quantity of products to be stored
- Average volume of each product
- Internal height of the storage building
- Local availability of mechanical handling equipment and the skills to use and maintain it

Pallets are generally used at the national and regional levels, where products are stored in bulk. At the district level and below, storage on shelves is most common. The fundamental rule for pallet storage is that each pallet should be used for only one product line. Pallets have the following advantages—

- They keep goods together and impose a disciplined method of storage.
- Large loads can be moved easily using mechanical handling equipment.
- Pallets are easy to transship because they do not require any unpacking and repacking.
- Pallets isolate goods from floors, which may be damp.
- If goods are supplied by the manufacturer on shrink-wrapped pallets, it is easy to see when tampering has occurred.
- Inspection for damage and for short shipments is easy to perform.
- When stock rearrangement is necessary, it is much easier to move pallets with mechanical handling

Figure 44-2 Storage and load-handling equipment

equipment than it is to move a large volume of loose stock that has been placed on shelves.

Packaging specifications

Appropriate packaging specifications reduce the risk of damage during handling. Floor pallets and pallet racks must be laid out to suit a selected pallet module. Pallets come in a range of sizes, and the size and weight of pallets affect the layout of the store and the choice of mechanical handling equipment. Although it may be difficult in practice due to the range of pallets that may be available, whenever feasible, a standard pallet size should be adopted throughout the distribution system, and all contracts with suppliers should include this specification.

Shelving

Storage on shelves does not require mechanical handling equipment and is a good choice when—

- The volume and weight of individual items are too small to justify pallets.
- The internal height of a building is not large enough for multitier pallet racking, and shelving can be used on its own or in combination with floor pallets or two-tier racking.
- Manual goods handling is locally more reliable or economical than mechanical handling.

If shelving is used in a warehouse more than 4.5 meters high, it may be possible to install an independent mezzanine flooring system supporting a second tier of shelving. This system can increase the available shelving volume by up to 100 percent, at the expense of some inconvenience in materials handling. Obviously, if a mezzanine is added, high-quality construction is critical to avoid injury to staff and damage to stored goods.

Floor pallets

Floor pallets are a good solution in warehouses with ceiling heights of less than 3 meters and in stores where the cost of pallet racking and forklift trucks cannot be justified. Many heavy or bulky items, such as rolls of cotton, medicine kits, or large hospital equipment, require floor locations. Floors should be marked to indicate pallet and aisle positions.

Block-stacked pallets

Pallets containing light goods may be stacked on top of one another in blocks. Block-stacked pallets should be used only for items without expiry dates or with very high turnover, because the first-in items are at the bottom of the stack.

Block stacking is a cheap and space-efficient method of storage, and no racking is required.

Pallet racking

Simple pallet racks generally have two or three tiers. Two tiers of racking require a clear height of about 3 meters, and three tiers require a clear height of about 4.5 meters. It is possible to have several more tiers, but sophisticated mechanical handling equipment is then required.

The benefits of shelving and pallet racking can be combined. The bottom tier of racking may be used to store the working stock. This tier is at a convenient height for manual order picking. Alternatively, a special picking shelf can be placed immediately above the bottom tier of pallets. In both cases, the upper tiers can be used to store safety stock.

Load handling

Each of the four storage systems described above requires suitable handling equipment and appropriate organization of stored goods. Appropriate handling equipment reduces the risk of injury to workers and damage to goods. Careful stock organization on shelves and pallets reduces unnecessary lifting and ensures easy access to goods during order picking.

Shelving. In order to reduce manual handling, goods should be transported to and from the shelves on trolley carts. Heavy items should be stored on the lower shelves. Whenever possible, other items should be organized so that frequently picked items are at waist height. Safety stock may be stored at a higher level.

Pallets. Loaded pallets can be moved only by using mechanical equipment. Hand-operated hydraulic pallet trucks and pallet lifts are suitable for floor pallets and for pallet racking up to three tiers high. Operations that have pallets stored at higher levels or turn over large volumes of stock must use powered forklift trucks. [Figure 44-2](#) illustrates some typical storage and handling equipment.

44.7 Housekeeping

Housekeeping tasks for a store include cleaning and pest control, a regular inspection system for issues such as temperature and roof leaks, disposal of stock, precautions against fire, and strict security measures.

Cleaning and pest control

The store should be kept tidy and should be cleaned at minimum two or three times a week; a busy store should be cleaned once a day. Most warehouses have adequate personnel available for scheduled cleanups, and adequate cleaning

Figure 44-3 Good stores management

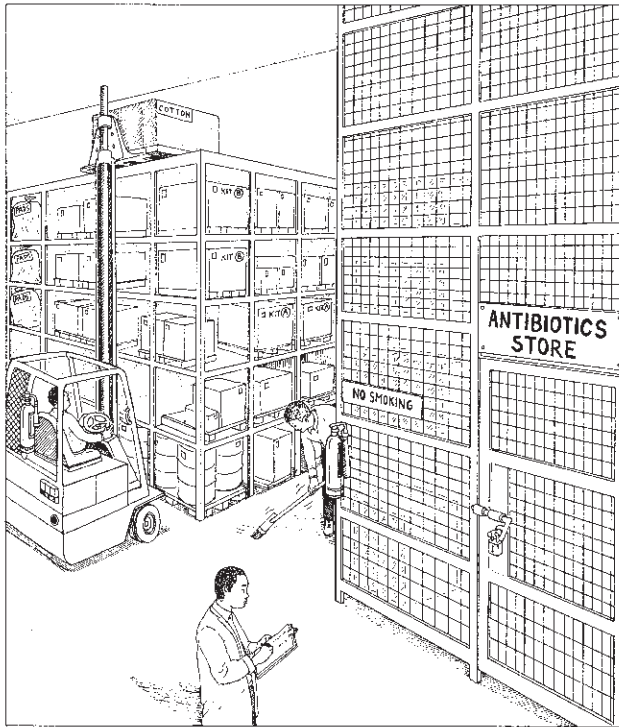

Figure 44-4 Poor stores management

equipment should be made available. Figures 44-3 and 44-4 illustrate good and bad stores management.

Pest control can be difficult, but to avoid possible contamination and physical damage to stock, insects, mice, and other pests must be kept out of the storage area. If needed, pest control measures such as poison should be implemented, with proper precautions. One of the chief reasons pests become a problem is the consumption of food in storage areas; therefore, this practice should be strictly avoided.

Inspection

Senior staff should inspect the store regularly. The chief storekeeper must make sure that storeroom employees check the shelves and pallets daily for signs of theft, pests, or water damage and for deterioration caused by climatic conditions. Storekeepers should open suspect containers and report problems to managers.

Buildings and equipment need both emergency and routine maintenance, but a regular building and equipment inspection and maintenance program prevents major failures and saves costs overall (see Chapter 42).

Disposal of expired or damaged stock

Damaged or expired stock should be placed in a designated salvage area to await authority for disposal. A written record of all stock consigned to this area should be maintained. It

is recommended that each item be valued at its acquisition cost. The responsible authority should be informed in writing that stock is to be written off. Disposal may be delayed if a committee decision is required, and substantial storage space may be needed for junk stock. When destruction is authorized, the inventory control clerk must adjust the stock records. All medicines and other potentially toxic products should be disposed of in accordance with local regulations in a manner that does not pose a risk to public health.

Fire precautions

Flammable trash, such as cartons and boxes, must not be allowed to accumulate in the stores. Smoking must be strictly forbidden, with "No Smoking" signs posted throughout the store. Senior staff must obey the rule as strictly as junior staff, and penalties should be imposed on those who ignore the rules. A smoking area outside the warehouse should be designated. Management must ensure that fire-detection and firefighting equipment are regularly inspected and that staff members receive adequate training in firefighting techniques and emergency action. Regular fire drills should be held to reinforce that training.

Staff should check frequently for fire, but management is ultimately responsible. Night watchmen can serve the dual purpose of responding to fire alarms and protecting against theft.

Security

Ideally, the chief storekeeper's office should have windows that overlook the loading bay, the compound entrance, and the store itself. A storekeeper who sits behind a closed door with the curtains drawn cannot observe what is happening at the site.

No vehicles should be allowed into the store compound unless they are authorized by the chief storekeeper or another senior staff member. A list of authorized vehicles should be prepared for the compound's gatekeeper.

Pedestrian access to the storage buildings should be strictly controlled. Visitors should report to the storekeeper's office and should not be allowed into the store area except on business. Visits by friends and family of staff should be discouraged. Business visitors should always be accompanied by a senior staff member. (See [Chapter 43](#) for further discussion of security measures.)

44.8 Human resources management in medical stores

The organization of a typical central medical store is illustrated in [Figure 44-5](#). The organizational structure at an intermediate store is generally a compressed version of this structure.

Medical stores managers are encouraged to review [Chapters 51](#) and [52](#), which discuss human resources management in more detail.

Staff training and the medical stores procedures manual

Every worker should receive appropriate job training and refresher training, as appropriate. Most warehouse jobs are nontechnical, and in-service training and supervision of staff are likely to be the most effective approach. A written manual of standard operating procedures should cover the following—

- General management policy
- Management structure
- Job descriptions
- Reporting procedures
- Stock control and other record-keeping procedures
- Operational procedures
- Health and safety procedures
- Security

The manual should include visual aids that clarify operations. These documents are normally used by the director and section chiefs to train new staff and to settle procedural questions. [Table 44-4](#) gives a sample contents list.

Each work area should have a copy of the manual. The contents of the document should be reviewed and explained in group presentations. The manual should be available to every employee, and staff members should be encouraged to use it in performing their duties. The manual should also be regularly reviewed and updated to reflect changes in operations or the introduction of new systems or procedures.

Staff supervision and discipline

The supervisory hierarchy should be clearly described to all workers. Personnel problems should be solved at the appropriate level. Section heads who do not supervise their workers regularly and effectively should be replaced.

Positive feedback and encouragement are essential. Minor lapses in performance should be kept in perspective. Major problems, such as proven cases of theft or reckless driving, should be handled through established ministry or organizational regulations. Regular staff meetings can help maintain a sense of shared purpose and ensure that all staff members understand their responsibilities.

Career development

Workers in the logistics system often have low status. They are frequently badly paid, work under poor conditions, and are not motivated. These problems result in low levels of performance.

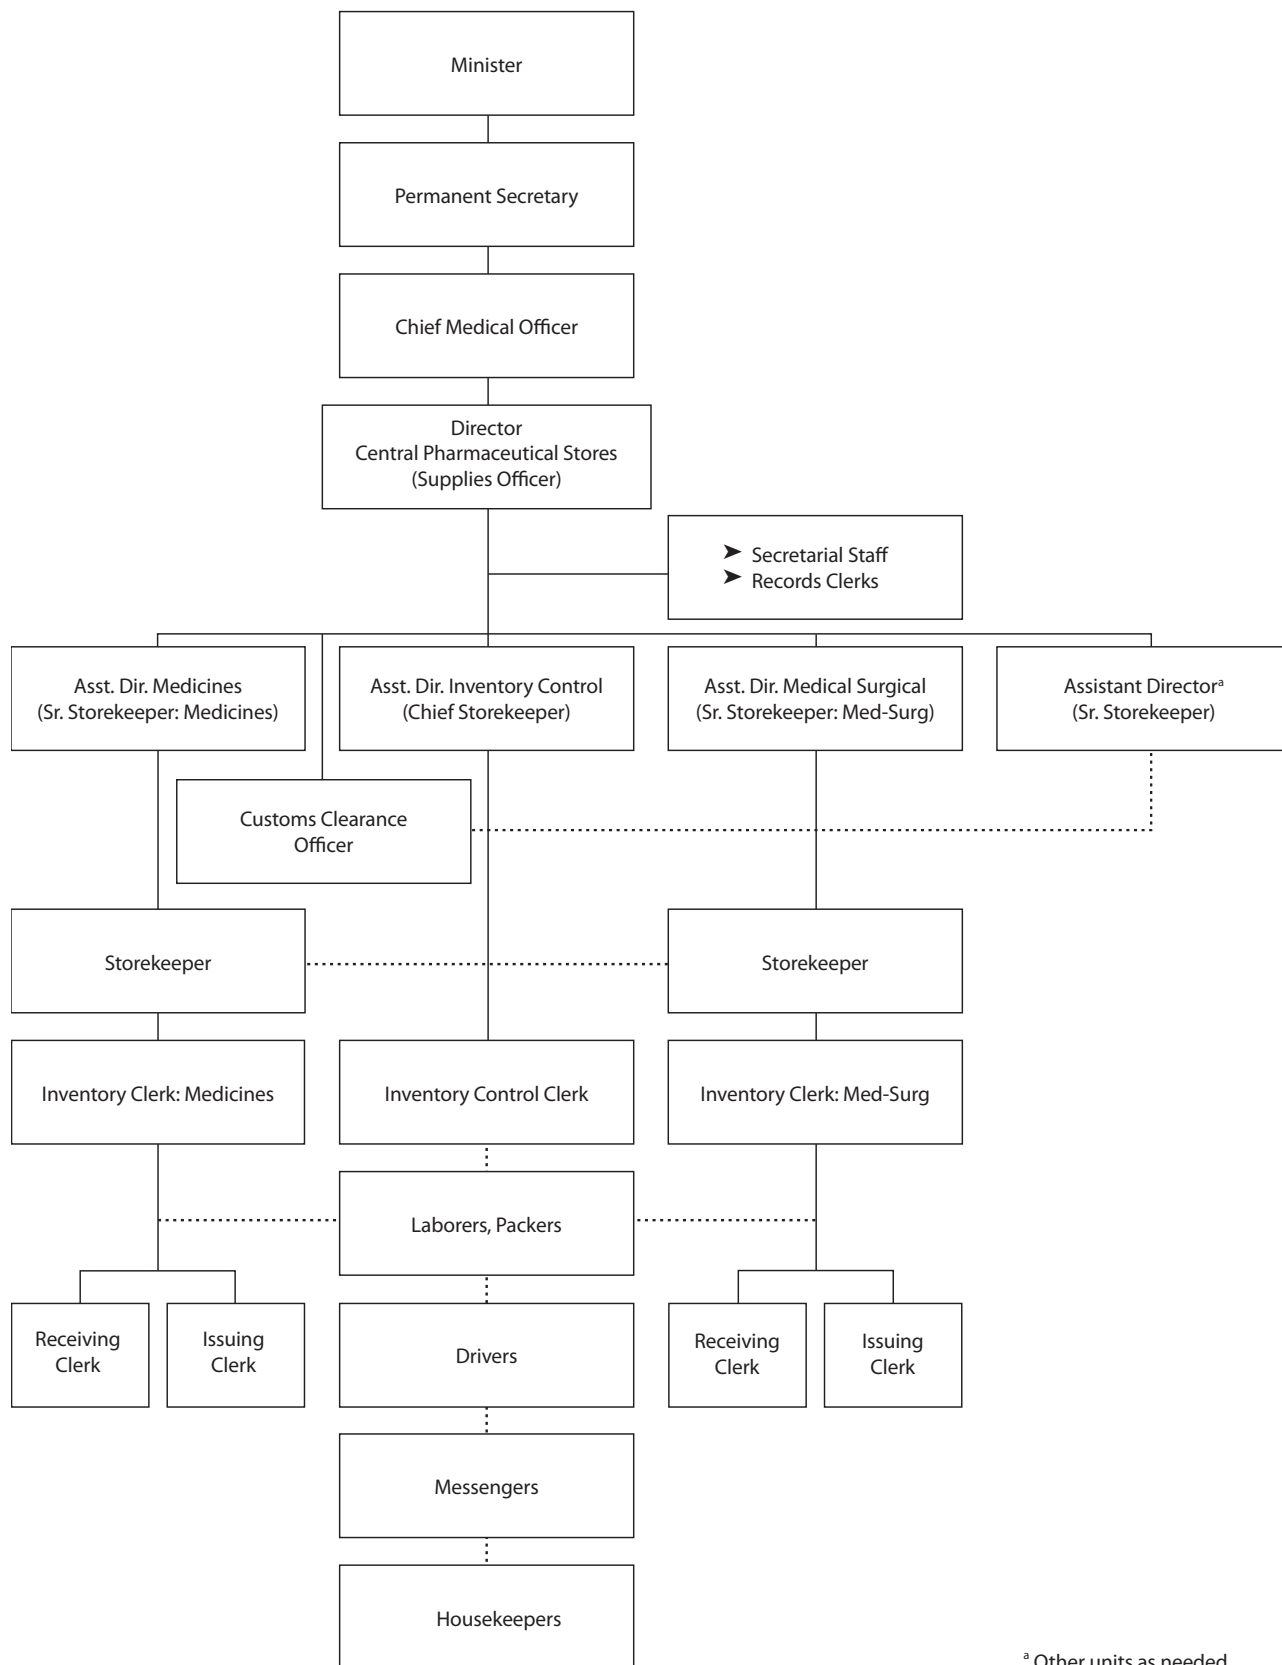

An effective store relies on staff members who want to perform their jobs correctly. When staff members perform well, they should be rewarded and praised. Although it is difficult to do in many government supply systems, improving salary grades and promoting staff who show ability and commitment will help the organization retain good staff. Staff members are also motivated by participating in training programs and other opportunities for personal development. Frequent transfers of personnel from one site to another should be avoided, if possible. [Chapter 51](#) discusses employee satisfaction and motivation.

If stores staff are treated badly by management, they will look for other jobs, and their experience will be lost. A stores operation that relies on casual labor is more likely to suffer from theft, breakages, and distribution errors.

44.9 Staff facilities

Good staff facilities encourage cleanliness, protect workers against occupational injuries, and contribute to good staff morale. Just as medicines are susceptible to damage from excessive heat or cold, staff performance and motivation suffer in these conditions.

Figure 44-5 Medical stores organizational chart

^a Other units as needed

Table 44-4 Contents of a procedures manual for a central pharmaceutical supply system

Content unit	Typical structure
Statement of operational policy	<ul style="list-style-type: none"> • Central level
Organizational staffing pattern	<ul style="list-style-type: none"> • Regional level • District level • Community level • Lines of authority
Overview of sequence of tasks and activities in supply management process (with discussion of objectives)	<ul style="list-style-type: none"> • Job descriptions (all personnel by level, each level treated separately) • Logistics information system • Flow chart of central, regional, and district information • Supply operations forms (purchase order, receiving report, inventory card, requisition/issue form, issues ledger by item and facility, delivery voucher) • Accounting system and procedures • Inventory control system and procedures • Security system and regulations • Computerized information systems • Supply system administration • Operating budget (utilities, salaries, maintenance, supplies, miscellaneous) • Maintenance procedures (for buildings and equipment) • Special operating instructions • Cold-chain storage procedures • Quality-control procedures • Shipping and packaging procedures

Sanitary facilities

Personal cleanliness is essential among workers who handle medical supplies. The store needs well-maintained sanitary facilities for staff and visitors. Sanitary accommodations should be located on the perimeter of the building to allow natural ventilation and keep the drains outside the building.

Staff rest areas

A separate rest area, with a kitchen, toilet, and pantry for preparing and storing food, improves staff morale and reduces fire hazards and the risk of vermin infestation in the warehouse. It also improves efficiency by segregating resting staff from working staff.

First aid

Adequately trained personnel with first-aid equipment and dressings should be available to treat workers who suffer injuries on the job. Emergency washing facilities should be provided in case a staff member comes into contact with a corrosive or toxic agent. Installing emergency showers may be necessary. Eye-washing sprays should also be provided. Local health and safety regulations should always be followed. ■

ASSESSMENT GUIDE

General description

- How are goods received, stored, and supplied?
- What facilities are served? How often is each supplied? What methods of transport are used? Is a delivery, collection, or mixed system in use?

Stores management and staffing

- Does an operations manual adequately describe current procedures and responsibilities?
- Are staff positions described by category, listing the positions approved to be filled and those that have been filled?

Receiving

- Are procedures for receiving and checking medicines observed? Are standard checklists used?
- What medicines were returned during the past year, and why?
- How are complaints concerning product quality handled?

Communications and reporting

- What reports are regularly issued from medical stores, for whom, and how often?

Stock control

- What stock control system is used?
- Are random and periodic stock checks carried out? Is a stock auditing system in place?
- What percentage of stock records (and bin cards) corresponds with physical counts?

Stock management

- Is stock location fixed, fluid, or semifluid?
- Are medicines issued by FIFO or FEFO?

- What was the average stockout duration over the last year?
- How many expired medicines are in stock? What is their value?
- What was the value of inventory at the beginning and end of the last fiscal year?

Storage conditions

- Are medicines zoned in correct combinations of temperature, humidity, safety, and security?
- How are medicines organized within each zone?
- Are vaccines stored and monitored in accordance with the recommendations of the WHO Expanded Programme on Immunization?
- Is the store neat, and are effective pest control procedures in place?

Buildings and equipment

- Is storage space too small, adequate, or excessive?
- Are the loading bay, receiving area, packing area, administrative area, staff rest area, and sanitary facilities adequate?
- What is the condition of roofs, walls, floors, ceilings, firefighting equipment, windows, doors, locks, burglar bars, and water supply and drainage equipment and infrastructure?
- What storage systems are used (shelving, floor pallets, pallet racking)?
- What are the conditions of mechanical handling equipment, electricity supply, and telephones?
- What computer hardware and software systems are employed and are they adequate to support inventory control needs?
- Is there direct access to international communications?

SUMMARY

Appropriate medicine use in the hospital setting is a multidisciplinary responsibility that includes—

- Selection and formulary management by a multidisciplinary committee
- Prescribing by the physician
- Procurement, storage, medication order review, and preparation and dispensing by the pharmacy department
- Medication administration by nurses or other health care professionals
- Monitoring the effect of medicines on the patient by all members of the health care team

The drug and therapeutics committee (DTC) is responsible for developing policies and procedures to promote rational medicine use. Its functions include—

- Management of the approved medicine list or hospital formulary
- Ongoing drug use review
- Adverse drug event reporting and implementation of safe medication practices

Members of the DTC should include representatives from the medical, pharmacy, and nursing staffs; hospital administrators; and the quality assurance coordinator. Subcommittees are often formed for in-depth analysis of particular issues.

The pharmacy department, under the direction of a qualified pharmacist, is responsible for the procurement, storage, and distribution of medications throughout the hospital. In larger hospitals, satellite pharmacies may bring the pharmacist closer to patient care areas, facilitating interactions between pharmacists and patients. In some settings the pharmacist is used as a resource for medicine information and specialized medication therapy management.

Medications may be distributed in bulk, in courses of therapy, or in unit doses. Unit-dose distribution is optimal for patient care but requires initial capital outlay for repackaging equipment and medication cabinets. Recent technological advances, such as computerized dispensing machines and bar coding, are now available to further promote safe medication practices.

Additional mechanisms for inpatient medicine management include—

- Patient medication profiles, maintained in the pharmacy department
- Medication administration records, maintained by nurses
- Periodic inspection of medicine storage areas
- Procedures for strict control of dangerous drugs and controlled substances
- Responsible disposal of pharmaceutical waste
- Procedures for after-hours pharmacy service

Small-scale pharmaceutical production often is not cost-effective and should be evaluated by the DTC.

The control of narcotics is of particular concern in the hospital setting and requires a systematic approach for the prevention and detection of abuse.

A hospital exists to provide diagnostic and curative services to patients. Pharmaceuticals are an integral part of patient care. Appropriate use of medicines in the hospital is a multidisciplinary responsibility shared by physicians, nurses, pharmacists, administrators, support personnel, and patients. A medical committee, sometimes called the drug and therapeutics committee, pharmacy and therapeutics committee, or the medicine and therapeutics committee, is responsible for approving policies and procedures and monitoring practices to promote safe and effective medicine use. The pharmacy department, under the direction of a qualified pharmacist, should be responsible for controlling the distribution of medicines and promoting their safe use. This task is challenging because medicines are prescribed by physicians, administered by nurses, and stored throughout the hospital.

This chapter covers hospital-specific pharmaceutical management issues, such as pharmacy department organization and alternative pharmaceutical distribution systems. Several functions of the DTC are discussed, with an emphasis on formulary management. Other important issues relevant to hospital pharmaceutical management are treated in [Chapter 17](#) on treatment guidelines and formulary manuals, and [Chapters 28](#) and [29](#) on investigating medicine use and on promoting rational prescribing, respectively. [Chapter 35](#), “Pharmacovigilance,” discusses adverse drug reaction monitoring and medication error management.

45.1 Responsibilities of hospital staff

The hospital pharmacist should be an expert on medicines who advises on prescribing, administering, and monitoring, as well as a supply manager who ensures that medicines are available through procurement, storage, distribution, inventory control, and quality assurance. The balance between these two roles varies, depending on the individual's background and the work setting. A pharmacist may assume a prominent clinical role in settings where his or her knowledge of clinical pharmacology and capacity to provide expert advice have earned the acceptance of hospital medical and nursing staff.

The responsibility for establishing policies and procedures related to medication selection, procurement, distribution, and use often lies with the DTC. Because the medicine use process is multidisciplinary, the committee should include representation from all functional areas involved: medical staff, nursing, pharmacy, quality assurance, and hospital administration.

Purchasing and stock management

In some hospitals, a separate department manages all hospital purchasing (pharmaceuticals, medical supplies, equipment, and so forth); this department may be called medical stores or materiel management. In such cases, the chief pharmacist prepares an annual budget request for pharmaceutical purchases and places orders for medicines through the medical stores.

In other settings, the pharmacy department manages pharmaceutical purchasing directly. No single individual should have total control of pharmaceutical procurement. A designated committee should review and approve all purchases; either a special purchasing committee or the DTC (see below) may manage this function.

Procedures for procurement and inventory management should be written in a manual that has been approved by hospital administration and the appropriate committees; the procedures for purchasing should follow guidelines provided in [Chapters 18](#) and [23](#). Stock management procedures are determined by the facility's size and whether a warehouse is attached to the hospital (see [Chapters 44](#) and [46](#)).

Medication use

The medication-use process can be divided into four components—

1. *Prescribing.* The physician has overall responsibility for the care of the patient, prescribing or ordering medications as part of the treatment plan. The mechanisms to ensure appropriate prescribing within the

hospital customarily fall within the purview of the medical staff committees, usually including the DTC. The DTC may establish protocols or procedures that allow pharmacists or nurses to prescribe within specific guidelines.

2. *Preparation and dispensing.* The pharmacy department, under the direction of a registered pharmacist, is responsible for preparing and dispensing medications. Policies and procedures for these functions should be approved by the DTC. The chief pharmacist reports to hospital administration.
3. *Medication administration.* Administering medications is generally the responsibility of the nursing staff. The chief nursing officer oversees all nursing functions. In some cases, physicians may administer medicines such as anesthetic agents. Other health care professionals may administer medicines within the scope of their practice (for example, midwives attending deliveries).
4. *Monitoring the effect of medications on the patient and ordering appropriate changes in therapy.* Monitoring activities are primarily the responsibility of the physician. However, observation and reporting are required from the person who administered the medication (usually the nurse) and from other members of the health care team involved in the patient's therapy. In some settings, a clinical pharmacist or pharmacologist monitors medication therapy in the hospital and consults on medication therapies that require special expertise to ensure safety and efficacy; for example, total parenteral nutrition, anticoagulation, or treatment with aminoglycoside antibiotics.

Government agencies and licensing boards regulate medications through laws and professional practice standards. The laws and regulations usually specify that the chief pharmacist be the person responsible for the control of medications within a hospital, including procurement, storage, and distribution throughout the facility.

Although the chief pharmacist is responsible for the pharmaceutical budget and the control of medications, he or she does not supervise those who prescribe or administer the medications. In addition, in some hospitals, purchasing, receiving, and storing of medications are handled by a medical stores department that is not under the supervision of the pharmacist.

These varying responsibilities illustrate the complexity of pharmaceutical procurement, storage, and use in the hospital. Efforts to improve the system should respect this complexity and include multidisciplinary representation and involvement. Coordination is required at the policy level through the DTC, at the management level (beginning with hospital administration), and through the different branches of the organizational tree.

45.2 Organization of hospital pharmacy services

In organizing hospital pharmacy services, both the way in which the staff is organized and the physical layout of the building must be considered.

Personnel

Hospital pharmacy personnel can be divided into three major categories—

1. *Management.* Management includes the chief pharmacist and sometimes deputy chief pharmacists, who are responsible for procurement, distribution, and control of all pharmaceuticals used within the institution and for management of personnel within the pharmacy department.
2. *Professional staff.* These professionals are qualified pharmacists who procure, distribute, and control medications and supervise support staff for these activities. In some facilities, pharmacists provide clinical consulting services and medicine information.
3. *Support staff.* The support staff category often includes a combination of trained pharmacy technicians, clerical personnel, and messengers.

The smallest hospitals may have only two or three pharmacy staff members, with the chief pharmacist as the only pharmacist. Larger teaching hospitals that provide extensive pharmaceutical distribution and clinical services may have more than 100 staff members.

The cornerstone for a well-functioning medication system is an up-to-date manual of policies and procedures. Staff members should be familiar with the manual and adhere to it.

Physical organization

The extent of the pharmacy's physical facility is determined by the size of the hospital and the services provided. A large pharmacy department might have the following sections within one physical space or in separate locations throughout the hospital—

- Administrative offices
- Bulk storage
- Narcotic or dangerous drug locker
- Manufacturing and repackaging
- Intravenous solution compounding
- Inpatient and outpatient dispensing
- Medicine information resource center
- After-hours pharmacy
- Emergency medicine storage

Inpatient dispensing is sometimes done from satellite pharmacies throughout the hospital. In larger hospitals, satellite pharmacies are beneficial because they enable a shorter turnaround time for individual medication orders, especially in distribution systems that dispense medications packaged for individual patients. Satellites also increase the pharmacist's presence in the patient care area, facilitating interactions with medical staff, nursing staff, and patients, and thus ultimately improving patient care.

With satellite pharmacies, there is reduced need for ward stocks. However, each satellite requires a certain minimum inventory level of pharmaceuticals. A system with multiple satellites most likely has a higher total inventory level than that of a central pharmacy system. The higher inventory and additional personnel costs needed to staff satellite pharmacies may be justified by reductions in pharmaceutical supply costs (because there is less wastage) and improvements in patient care. Whether or not multiple satellite pharmacies serve inpatients, separate pharmacies often serve inpatients and outpatients. [Figure 45-1](#) illustrates how a hospital pharmacy with separate inpatient and outpatient departments is organized in one African country.

45.3 Hospital drug and therapeutics committee

Most commonly, the committee designated to ensure the safe and effective use of medications in the hospital is the DTC. The American Society of Health-System Pharmacists' guidelines on DTCs state that "medication use is an inherently complex and dangerous process that requires constant evaluation. Organizations need to implement tools and processes necessary to meet the goals of using medications effectively and safely" (ASHP 2008).

Purpose and functions

The DTC promotes the rational use of medication through the development of relevant policies and procedures for medication selection, procurement, distribution, and use and through the education of patients and staff. [Country Study 45-1](#) lists the functions of the DTC in an Afghan hospital.

In some hospitals, the DTC becomes overwhelmed with the difficulty of obtaining an adequate supply of medications. Members are caught up in routine decisions about which medicines to buy, how much, and from whom, rather than focusing on long-term planning, policies, and programs for improving the safe and cost-effective use of medications. As discussed, in most settings, daily purchasing decisions can be handled by the chief pharmacist, with supervision by the DTC or another committee responsible for procurement.

Figure 45-1 Multiple-department pharmacy system

Source: Ministry of Health, Government of Kenya, 1994.

DDA = Dangerous Drugs Act.

Note: Forms and registers for wards, operating room, special areas, and outpatient department (OPD) injection room are the same as for the central pharmacy system.

Membership

An effective DTC requires that members participate in meetings and assist with other committee activities. Membership should include representation from—

- Medical staff (including representation from each department)
- Pharmacy (the chief pharmacist often serves as the secretary)
- Nursing
- Hospital administration
- Quality assurance staff

The committee should have broad representation but be sufficiently small and manageable to conduct business effi-

ciently: a membership of eight to fifteen members often fulfills these criteria. The committee may occasionally invite a specialist to make a presentation or provide advice on a particular issue. For example, a cardiologist may attend a committee meeting to advise members regarding a formulary decision on a new cardiac medication. DTCs often have subcommittees to address particular issues, such as antibiotic use, drug use evaluations, or medication errors. Subcommittees can manage specific tasks without consuming a large portion of the DTC's meeting time.

Hospital formulary management

The hospital formulary is the cornerstone of medication management in the hospital, and it should be the principal concern of the DTC. The issues related to medication

Country Study 45-1**Functions of a hospital drug and therapeutics committee in Afghanistan**

Facility-based DTCs will be set up by the steering bodies of the individual health facilities in association with the National Pharmaceutical and Therapeutic Committee.

The DTCs' basic functions include—

- Establishing local policies and procedures on the use of medicines
- Ensuring that the national essential medicines list and local formularies are used appropriately in the facility
- Disseminating national standard treatment guidelines (STGs) and developing local STGs for common diseases and medical conditions
- Conducting medicine use evaluations in the facility
- Conducting facility-based pharmacovigilance activities
- Monitoring medicine use at the health facility

- Providing education to local health care providers on the appropriate use of medicines

The members will be appointed according to their positions and responsibilities within the health facility. The DTC member numbers will be defined based on the health facility level. In the majority of health facilities, the DTCs will include the following members—

- One representative from each specialized medical service of health facility (senior physician)
- One representative from the nursing department
- One representative from the pharmacy department
- One representative from the administration and finance department
- Other members appointed according to their personal expertise (specialists in pharmaceutical information or quality assurance)

Source: Ministry of Public Health, Government of Afghanistan, 2009.

selection for formularies are treated in detail in [Chapter 17](#); the following list provides general guidelines for the hospital setting.

- Limit the formulary list to conserve resources—stocking all medicines on the national formulary is usually not necessary.
- Eliminate generic duplication—only one brand or label of each generic medicine should be routinely stocked.
- Minimize the number of strengths stocked for the same medication; multiples of lower strengths can be used for infrequently needed higher strengths.
- Select medications for the formulary based on diseases and conditions treated at the facility.
- Specify formulary medicines of choice for common therapeutic indications. Medicines of choice should be selected by comparing efficacy, safety, toxicity, pharmacokinetic properties, bioequivalence, and pharmaceutical and therapeutic equivalence. Cost-effectiveness and availability should be primary considerations, evaluating alternatives as described in [Chapters 10](#) and [17](#). After medicines of choice are selected, they form the basis for standard treatment guidelines and for therapeutic substitution programs (see below).
- Include second-line alternatives to medicines of choice as needed, but minimize therapeutic duplication.

- Ensure that the hospital formulary corresponds with any national or regional standard treatment guidelines that have been formally approved by the health system.

In addition to the basic formulary process, many hospitals add two more features—therapeutic substitution and use restrictions for certain medications in the formulary.

Therapeutic substitution (sometimes called therapeutic interchange) is based on the hospital formulary. The DTC provides guidelines for substituting specific formulary medicines for specific nonformulary medicines (or a specific category of medications), usually for specific disease conditions. Whenever a prescription is written for a nonformulary medicine that is covered by the therapeutic substitution policy, the designated formulary product is automatically substituted by the pharmacy department (or nurse). Note that this substitution is not generic—the two products are chemically different.

The DTC should develop formal written policies specifying which medicines (or categories of medications) are suitable for automatic therapeutic substitution. These programs usually start with relatively noncontroversial medication categories, such as antacids and vitamins, and progress over time to other therapeutic groups, such as antibiotics and certain cardiac medications, as physicians become comfortable with therapeutic exchange. Two main arguments are used to

justify therapeutic substitution programs. One is that such programs ensure that only the most cost-effective products are routinely used, a policy that has obvious benefits in terms of controlling both actual purchase costs and inventory-holding costs (see [Chapter 23](#)). In settings where funds are limited, the more limited the list of medications that are routinely stocked, the more likely that all those medications will always be available. The other justification is that the DTC has presumably spent considerable effort selecting medications that offer the best therapeutic value for the conditions covered by therapeutic substitution. An ancillary benefit is that hospital staff will be more familiar with the proper methods for handling, reconstituting, and administering the formulary products.

Therapeutic substitution is often resisted by staff physicians, but almost 90 percent of hospitals in the United States (a stronghold of physician independence) have substitution policies in place (Pederson et al. 2008). Therapeutic substitution is often practiced informally and unintentionally in hospitals where stockouts are common—if the prescribed medicine is out of stock, another must be substituted. Physicians who practice in such settings are likely accustomed to the concept.

Normally, the therapeutic substitution policy allows escape clauses for specific patients. The physician can submit a special form that justifies the use of a specific nonformulary medicine for a specific patient (as discussed below).

Use restrictions are most often applied in larger hospitals where specialist physicians are on staff. Restrictions may apply to certain individual formulary medicines or to certain categories of medicines; the principle is that restricted medicines can be prescribed only by certain specialists or can be used only on certain wards. Such restrictions are generally applied to particularly expensive medications (such as anticlotting medications) or particularly toxic medications (such as cancer chemotherapy); however, some hospitals go further, requiring specialist consultation on many different categories of medications. Restrictions should be carefully considered; they decrease the use of medicines involved (which may or may not be desirable), increase the demand on specialists (and potentially the cost of services), and increase administrative burdens for nurses and pharmacists who must manage the process.

Methods to promote formulary adherence include the following—

- Review and take action on all nonformulary medicine use.
- Prohibit use or distribution of samples of nonformulary products.

- Establish procedures and approved product lists for therapeutic substitution.
- Provide easy access to the formulary list (copies at each medication ordering location and in pocket manuals).
- Involve medical staff in all impending formulary decisions.
- Advertise and promote formulary changes.

Requests to use nonformulary medicines should be monitored by the DTC. If many nonformulary medicine requests come from a particular physician, or if requests are frequent for a particular nonformulary medicine, the committee should take action. Actions may include adding the medicine to the formulary, educating physicians on the rationale for the nonformulary status of the medicine, or banning the medicine from use in the hospital. [Country Study 45-2](#) is an example of a procedure for nonformulary medicine use in a hospital in the United States.

Drug use review

Drug use review (DUR) is a tool to identify such common problems as inappropriate product selection, incorrect dosing, avoidable adverse drug reactions, and errors in medication dispensing and administration. DUR may then be used to implement action plans for change. DUR is an ongoing, planned, systematic process for monitoring, evaluating, and improving medicine use and is an integral part of hospital efforts to ensure quality and cost-effectiveness. More appropriate and more effective use of medicines ultimately results in improved patient care and more efficient use of resources.

[Chapter 28](#) provides an overview of the concepts and approaches for investigating medication use. [Chapter 29](#) contains the specific methodologies for developing a hospital DUR program.

45.4 Inpatient medication management

In general, the issues presented in [Chapter 30](#) for good dispensing practices are relevant to the hospital setting. Patient education and medication counseling are described in [Chapter 33](#) and are also applicable in hospitals. The purchasing and inventory strategies described in [Chapter 23](#) should be applied in the hospital setting.

Medication distribution systems

Medication distribution has long been the primary function of hospital pharmacy services.

Four basic types of medication distribution systems exist—

1. Bulk ward stock replenishment
2. Individual medication order system
3. Unit-dose system
4. Automated medication dispensing

Variations of each exist, and all four systems may be in use in the same facility, depending on the strategy developed. For example, a facility may use the bulk ward stock system for high-volume, low-cost medicines (aspirin, paracetamol, and antacids) that do not require a high level of control for preventing theft or medication errors. Individual medication order systems or unit doses can be used for medicines requiring a higher level of control (see Table 45-1). In addition, automated dispensing systems are now frequently used in developed countries and will become more common in the future.

Bulk ward stock

In a ward stock system, the pharmacy functions as a warehouse and dispenses bulk containers on requisition without reviewing individual patient medication orders for appropriateness. The main advantage is shorter turnaround time between prescribing and administering the medication. The

use of ward stock medications should be minimized, but it is appropriate and desirable for certain situations—

- In emergency departments and operating rooms, medications are usually required immediately after the physician prescribes them. Unless a pharmacy satellite is located in these emergency areas, dispensing medications according to individual patient orders is not possible. Unfortunately, medicines used in these situations are often expensive, and control is always a challenge for the pharmacy department.
- In life-threatening emergency situations, medications need to be kept in patient care areas as a time-saving measure.
- High-volume, low-cost medicines can be dispensed from ward stock if the patient safety risk is low.

Individual medication order system

The individual medication order system closely resembles dispensing to outpatients: a course of therapy is dispensed according to a written prescription for an individual patient. Compared with ward stock distribution, the advantages are that the pharmacist can review the appropriateness of ther-

Country Study 45-2

Procedure for the use of nonformulary medicines in a U.S. hospital

A limited formulary of medicines may not satisfy all individual or unique patient needs. A physician may request use of a nonformulary medicine on a one-time (one course of therapy), one-patient basis.

The physician requesting the nonformulary medicine or the pharmacist receiving the medicine order must fill out the nonformulary medicine request form. The pharmacist receiving the request must inform the physician of alternative medicines that may be used. The pharmacist must also indicate how long it will take before the medicine will be available. The physician and pharmacist should avoid obtaining the medicine by special delivery or borrowing from another hospital if possible.

Nonformulary medicines will be stocked in the nonformulary section of the pharmacy only during the individual patient's course of therapy. The pharmacy will track expenses related to nonformulary medicines and report to the drug and therapeutics committee.

Nonformulary Medicine Request Form (For One-Time/One-Patient Use)

Patient: _____ Room #: _____ Date: _____

Medicine name/strength/dosage form: _____

Current formulary alternatives (suggested by pharmacist): _____

Why is this agent preferable to the formulary alternatives suggested?

Was this medicine request prompted by a manufacturer's representative? yes no

Are you requesting permanent addition of the medicine to the medication formulary? yes no

If so, will you be present at the next pharmacy and therapeutics committee meeting to discuss the advantages of this medicine? yes no

If accepted, what formulary medicines do you recommend for deletion?

Prescribing doctor: _____

Signature: _____

Table 45-1 Comparison matrix for pharmaceutical distribution system

Factor	Bulk ward stock	Individual medication order	Unit dose	Automated dispensing
Material and supply costs	Low	Medium–low	High	Very high
Pharmacy labor costs	Low	Medium	High	High
Nursing labor costs	Medium–low	Low	Low	Low
Pilferage risk	High	Medium	Low	Very low
Medication error risk	High	Medium–low	Low	Low

apy, a patient-specific medication profile can be maintained, pharmacy charges to patients are facilitated, and closer control of inventory is possible. This system can limit the time intervals for dispensing: for example, an individual supply for three days of therapy is sent initially; if therapy is continued beyond three days, the empty container is returned to the pharmacy to be refilled.

Unit-dose medicine distribution

A preferred system from a patient care perspective is the unit-dose system, which has a lower possibility for error. Medications are dispensed in unit-dose packages (each dose is separately packaged) in separate bins or drawers for each patient. Commonly, a twenty-four-hour supply is provided. Medications returned to the pharmacy can be put back in stock without concern for identity or contamination. This system is efficient but requires a large initial capital outlay for the purchase of repackaging machines and medication cabinets with individual patient drawers. The cost per delivered dose is higher than with bulk packaging, but this increased expense may be offset by reduced wastage and easier detection of leakage. Hospitals in some countries have found innovative ways of adapting local technologies to construct their own fixtures and equipment.

Automated medication dispensing

Technology-based interventions have been investigated as a mechanism to improve medication distribution and reduce medication errors that lead to adverse drug reactions. The use of automated dispensing machines has become commonplace in many hospitals, but cost remains a big deterrent for implementation in resource-limited settings. The mechanism is founded on a computer interface between the hospital pharmacy computer terminals and the dispensing machines at the clinical ward. This system electronically controls and tracks the dispensing of unit doses for each patient based on individual medication profile. The dispensing machines allow medicines to be stored on the ward and to be more conveniently accessed by the clinical staff. (See chapter 11 in AHRQ 2001 for an overview.)

Patient medication profiles

Patient medication profiles are necessary if hospital pharmacists are to monitor inpatient medication therapy. Each profile contains data on the patient's current and recent pharmaceutical therapy, allergies, diagnosis, height, weight, age, and sex. Profiles work best in conjunction with unit-dose medicine distribution or automated dispensing systems but can be used with the individual medication order system.

A pharmacy profile allows the pharmacist to review all the medications that a patient is taking before dispensing the first dose and with each new medication order. Problems with pharmaceutical therapy, such as allergies, duplicate therapy, medicine-medicine interactions, medicine-disease interactions, inappropriate length of therapy, and inappropriate dosing, can be detected and avoided or corrected.

Computerized pharmacy systems display the patient's medication profile on the screen, and the pharmacist edits the screen with each new order. Medication interactions, dosage ranges, and other monitoring functions can be programmed into the computer. In developed countries, information technology advances now provide linkages to patient-specific information from laboratory and clinical monitoring.

Medication treatment record

Also known as the medication administration record (MAR), the medication treatment record helps the nurse schedule treatments for each patient and provides a permanent record of the medications administered. It also allows nurses to review the patient's pharmaceutical regimen and provides a way to compare quantities of medications dispensed from, and returned to, the pharmacy with quantities administered to the patient. Physicians review MARs to verify current therapy and as part of their routine rounds. The trend is toward computerizing MARs; in the United States, over two-thirds of hospital pharmacies surveyed in 2005 used computer-generated or electronic records (Pedersen et al. 2006). [Country Study](#)

45-3 describes the procedure for completing a medication treatment record used in Kenya.

Ward and department inspections

The pharmacy department should undertake periodic inspections of medication storage areas throughout the hospital to ensure appropriate levels of properly stored medications, to monitor expiration dates, and to remove unnecessary stock. Figure 45-2 is a sample ward inspection record. When problems are detected in inspections, pharmacy and nursing staff must develop methods to correct the situation.

Dangerous drugs and controlled substances

Controlled substances require greater attention in the hospital setting than other medications, just as they do outside the hospital. The various definitions and categories of controlled drugs all relate to abuse and addiction potential.

Procedures specific to the procurement, reception, storage, dispensing, and administration of controlled drugs should establish a readily retrievable trail of accountability for each individual drug unit. The records should document ordering, receiving, dispensing, administration, and wastage. Perpetual inventory records should be used at all storage sites, and controlled drug stocks should be counted and reconciled against the records daily, with unexplained losses reported to the pharmacy. Controlled substances stored throughout the hospital should be securely double locked within a well-constructed storage area, with the pharmacy department in control of the distribution and duplication of keys.

Methadone maintenance therapy (MMT) programs, which some countries are endorsing as a way to prevent the spread of HIV/AIDS, can significantly impact a hospital's ability to manage controlled drugs. In general terms, hospitals are already familiar with handling largely injectable narcotics, typically in 2 to 5 mL vials, along with other

Country Study 45-3 Kenya medication treatment record

Purpose

Each inpatient has a medication treatment sheet (see opposite) on which all medications prescribed are recorded by the consultant, medical officer, or clinical officer, and on which all medications administered are recorded by the nursing staff. In addition, individual prescriptions are required for Dangerous Drugs Act (DDA) drugs and specific other medicines designated by the hospital drug and therapeutics committee.

Procedure

- At the time of admission, a medication treatment sheet is completed by the clinician with the following information—
 - Patient's complete name (all names must be included to ensure proper identification)
 - Medication allergies
 - Inpatient number
 - Ward and bed number
 - Age and sex
- For easy access during hospitalization, the treatment sheet is kept at the foot or head of the patient's bed with the observation sheet. (Because of this accessibility, the diagnosis should not be written on the treatment sheet.)
- All medication orders must be written on the medication treatment sheet by an authorized prescriber (doctor or clinical officer). The order should include the date and time the order was written; the medication name, strength, dose, route of administration, frequency, and duration; a legible official name; and the signature of the prescriber.
- In addition, for DDA medicines and specific other medicines designated by the hospital drug and therapeutics committee, individual prescriptions are required; entries for DDA medicines must be in red ink.
- When a medication is administered to a patient, the nurse or clinician administering the medicine writes the date and time of administration and signs in the appropriate place on the medication treatment sheet.
- When an ordered medicine cannot be administered for any reason, the nurse writes in the patient's nursing notes the name of the medicine, the date, and time the medicine was to be administered, and the reason that the medicine could not be administered (patient not on ward, unavailability, any other reason).
- The nursing officer should regularly review medication treatment sheets to ensure that they are being used properly on all wards and that all required information is being recorded.

small-volume preparations, but because of the dilute nature of the products used in methadone maintenance therapy for oral administration (typically 1 to 10 mg/mL) and daily treatment regimens (typically 70 mL per day), large physical volumes of products can be required. Even a small MMT program can dramatically increase the need for narcotic product secure storage space and handling of bulk products in facilities that are designed to handle much lower volumes (see [Country Study 45-4](#)). Methadone programs can also force the facilities' pharmacy service departments to take on unwanted small-scale production responsibilities.

After-hours pharmacy

Although the need for medications is continuous, many hospitals cannot justify staffing a pharmacy department twenty-four hours a day. If medications must be obtained while the pharmacy is closed, either an on-call pharmacist

can come in or a nursing supervisor can dispense medications. Medication dispensing by nonpharmacists should be limited, however, to preserve the system of checks and balances and to prevent medication errors. To minimize the risk of incorrect dispensing, the following measures can be taken—

- Establish procedures for after-hours pharmacy service.
- Require training or in-house certification of nurses before they undertake dispensing responsibility.
- Prohibit after-hours access to most of the pharmacy. A limited formulary of prepackaged and labeled medicines can be provided in a separate, locked night cabinet.
- Require completion of dispensing records by the nurse and subsequent review by the pharmacist.

45.5 Small-scale hospital pharmaceutical production

The several types of pharmaceutical production that exist have varying levels of complexity (see [Chapter 7](#)). The type of small-scale production of pharmaceuticals in a hospital pharmacy could include secondary production from existing raw materials that are usually imported and the packaging or repackaging of finished goods into smaller dispensing packs and course-of-therapy (COT) packages (tertiary production). Small-scale production can be further divided into nonsterile and sterile production or compounding. Most hospitals repackage medications in smaller unit-dose containers and may compound specialty items such as creams with special formulations; however, hospitals should evaluate the feasibility of producing any pharmaceutical products based on the availability of qualified staff, adequate facilities, sufficient equipment, and all the other necessary resources (see [Country Study 45-5](#)).

The following sections examine some of the management issues for each type of production, in order of increasing complexity.

Repackaging and course-of-therapy packaging

Repackaging and COT packaging are relatively simple forms of local pharmaceutical production. They require the ability to provide adequate packaging, labeling, and control of the final product.

Repackaging is usually considered when the product can be purchased in bulk quantities at a favorable price and then repackaged locally, where labor costs are lower, and when local-language labeling may be important. In addition to the cost savings, a more convenient package size can be made available to small health centers and individuals, as [Table 45-2](#) illustrates.

Country Study 45-4 Scaling up methadone maintenance therapy in Vietnam

In an attempt to curtail the spread of HIV among injecting drug users in Vietnam, the government piloted the country's first community-based methadone program in seven clinics in Hai Phong, Ho Chi Minh City, and Ha Noi City in 2008. HIV prevalence is higher in injecting drug users (30 percent) than any other subpopulation in Vietnam. By 2010, about 1,800 clients had received free MMT along with basic health care services and HIV care and treatment, including antiretroviral therapy.

In planning for the program, the national Pharmacy and Therapeutics Committee chose a base of 10 mg/mL of methadone solution for the therapy. This decision made it necessary to transport large volumes of narcotics around the country—typically 2.5 liters per patient year—and to squeeze large, secure storage cabinets into already overcrowded hospital pharmacies. Then the pharmacies had to dilute the solution to 1 mg/mL to dispense to patients, a procedure which, because of the regulations on handling narcotics, is fairly onerous.

This system of providing methadone therapy product can be contrasted to the United Kingdom's methadone main-

tenance program, which distributes 1 g vials of methadone powder to dispensing sites, for a total of only 2.5 1 g vials per patient year. These 1 g powder vials fit more easily into existing narcotics storage cabinets, and a single vial is simply dissolved into commercially available 1 liter bottles of simple syrup at the dispensing site to produce the appropriate 1 mg/mL dose to dispense to patients.

As a result of positive pilot program results, the Ministry of Health in Vietnam plans to expand methadone maintenance therapy to cover 80,000 clients in thirty provinces. This will require moving 204,000 liters of narcotic product per year and assuring the capacity for its secure storage.

While many factors go into choosing the most appropriate preparations to use, physical storage and distribution sizes should not be neglected. The Pharmacy and Therapeutics Committee may need to reconsider its choice of methadone formulation in order to facilitate large-scale program expansion.

Sources: *Thanh Nien News* 2010; Family Health International 2010.

Many types of glass and plastic are used, with the choice often depending on what is being packaged. For instance, acids, solvents, and corrosive materials must be packaged in glass, with lids that can be firmly closed. Fortunately, the majority of simple liquids, solids, and tablets can be packaged in rigid plastic bottles or resealable polyethylene bags of various sizes and thicknesses, usually with a write-on panel for labeling or handwritten instructions to the patient.

Nonsterile production

Nonsterile production of topical ointments and oral or topical liquids is more difficult and complex than repackaging but less demanding than sterile production. If the facility plans to carry out only nonsterile production, resource requirements can be simplified. However, standard written instructions for batch preparation and packaging must be followed, and quality control must be closely monitored for each aspect of the process.

Every product requires a well-designed production control worksheet (also called a batch documentation sheet). It clearly specifies the production formula (the detailed recipe that the pharmacist must follow precisely) and the instructions for preparation. It includes spaces to verify

packaging, labeling, and other control procedures. [Figure 45-3](#) shows a sample pharmacy production and control worksheet.

The chief pharmacist of the facility is usually responsible for developing the master production formulas and instructions, as well as for training production staff. The staff should always work from copies of the master production and control worksheet, with a unique control number pre-assigned by the pharmacist in charge. Any changes to that formula, such as scaling down quantities to make a smaller batch, should be made only by a qualified pharmacist.

A pharmacy preparation, no matter how simple, should never be made from memory. The working copy of the pharmacy production control worksheet should be readily available or posted in the production area for easy reference and initialing of each production step and control procedure.

Sterile production

Sterile production is the most demanding type, and it must be carried out in strict compliance with current good manufacturing practices (GMPs). Depending on need and capacity, sterile products that can be manufactured include eyedrops, small-volume injections, and large-volume injections (or parenteral products).

Country Study 45-5**Assessing the feasibility of small-scale pharmaceutical production in the Catholic Diocesan Hospital Pharmacies of Ghana**

The Diocesan Hospital Pharmacies (DHPs) were originally established in 1976 to provide pharmaceuticals and medical supplies to National Catholic Health Service facilities in Ghana. The DHP produced their own products such as infusions, injections, ointments, and drops to supply their clients more economically. Beginning in 1976, however, both the economy and the pharmaceutical market in Ghana expanded, and many competing pharmaceutical products became available from local and international sources. Furthermore, little additional funding was available to make capital improvements, which limited the DHPs' ability to accommodate increasing demands for improved quality assurance. In 2004, an assessment investigated the utility of the DHP to continue small-scale pharmaceutical production for thirty-three hospitals and sixty-six clinics in the context of the changing pharmaceutical market.

The assessment concluded that the DHPs—

- Should stop producing terminally sterilized products, for example, intravenous solutions, due to the high capital, personnel, and production costs, in addition to the associated risk to patients if the

requirements for sterile operations are not adequately met.

- Could continue to produce non-terminally sterile products, such as ophthalmic items, as long as they made several facility upgrades.
- Have a role in the compounding of non-sterile products, such as oral syrups, for their clients. The assessment recommended several production modifications to assure uniformity and efficiency.
- Should develop pharmacovigilance systems to identify and report adverse drug reactions and medicine product quality problems.

Overall, the assessment recommended that the DHPs focus their production on non-sterile products for which there was an increasing demand. Moreover, they should stop the production of other products that require more technical expertise and oversight due to quality and safety concerns. To ensure the supply of these sensitive products, the DHPs could consider developing a partnership with a local manufacturer or buy from international sources.

Source: RPM Plus 2004.

From a production process perspective, intravenous (IV) fluids are among the easiest products to make. The standard pharmacy production and control worksheet, including the sterility quality-control aspects, is used (see [Figure 45-3](#)). From a technical perspective, however, the production of IV fluids is very demanding on resources and personnel. Special (often quite expensive) equipment, facilities, techniques, and quality-control procedures need to be in place, along with the means to ensure continuous production with adequate reserves of ingredients and supplies, regular maintenance of equipment, and refresher training for production staff. The demands on supervisory personnel, who must ensure the high quality of the final product, are also much greater. Contaminated or incorrectly prepared IV fluids administered to very sick people can just as easily kill patients as help them.

Medications produced by the pharmacy must have adequate process and finished-product controls to ensure identity, strength, purity, and quality. A hospital pharmacy may have difficulty achieving the same cost efficiencies as a pharmaceutical manufacturer specializing in a particular product line. The DTC needs to evaluate the costs and benefits of producing such special preparations as compared to

purchasing commercial products. [Chapter 7](#) includes more details on assessing the feasibility of small-scale pharmaceutical production.

45.6 Pharmaceutical disposal

Hospitals and other health care facilities generate all sorts of hazardous waste, from sharps to materials contaminated with bodily fluids to expired or damaged pharmaceuticals. Improper disposal of pharmaceuticals can result in contaminated water supplies, the resale of poor-quality medicines, and polluted air from improper incineration.

Often, hospitals can return products to the facility from where they were obtained. However, when that option is not available, a disposal plan should be in place and should be regularly monitored. Depending on the properties of the pharmaceutical waste, incineration, land disposal, and inertization (where the product is mixed with cement) can all be appropriate methods for disposal. Special care must be taken with certain classes of pharmaceuticals, such as narcotics, or toxic drugs, like anticancer medicines. Before a disposal technique is instituted, any government laws and

Table 45-2 Pharmaceutical repackaging

Product type	Name of product	Bulk package size	Repackaged size
Liquids	Denatured alcohol	20 L	500 mL
Solids	Talcum powder	50 kg	1 kg
Tablets	Aspirin 300 mg	1,000	100
	Aspirin 300 mg	1,000	12
	Co-trimoxazole 480 mg	1,000	10 (bid for 5 days)
	Mebendazole 100 mg	1,000	6 (bid for 3 days)

regulations relevant to health care waste management and environmental protection should be reviewed.

45.7 Controlling leakage and drug abuse

Chapter 43 discusses systematic approaches for detecting, analyzing, and preventing pharmaceutical losses caused by theft, bribery, and fraud. Those approaches are applicable to hospitals and other health facilities.

The control of narcotics is of particular concern in a hospital because it may be the only type of institution regularly stocking, dispensing, and administering them. Drug addiction among physicians, pharmacists, and nurses is quite common. To avoid drug abuse and prevent leakage—

- Be alert to changes in performance, injuries, and mood swings in workers.
- Ensure double-witness and double-signature procedures for wastage of narcotics.
- Limit access to narcotic storage areas.
- Check patient charts and medication administration records for patterns of consumption; be suspicious if patients receive noticeably more narcotics during a particular shift.
- Ask patients if they received the medications.
- Use locked boxes or wire cages to ensure security for medications moved from the pharmacy to the wards.
- Issue individual narcotic boxes to each anesthesiologist daily, and make sure that the box is returned to the pharmacy at the end of the day with a written record of quantities used for each patient.
- Count narcotic stocks daily and reconcile with inventory records.

The same procedures followed for narcotics are sometimes used for antibiotics and other medicines that are easily resold and commonly lost to theft, such as antiretrovirals to treat HIV/AIDS. ■

ASSESSMENT GUIDE

Organization

- Which department and individuals are responsible for ordering medicines and managing inventory?
- What systems are used to manage inventory and procure pharmaceuticals?
- Apart from the central pharmacy, are there satellite pharmacies? If so, how many?
- How are medicines distributed to wards?
- Does a hospital formulary exist? If so, how many items are listed? When was it last updated?
- Is there an after-hours pharmacy? How is it managed?
- Does a pharmacy and therapeutics committee exist? If yes, how many meetings were held in the past year? What percentage of members attended? What issues were discussed?

Staffing

- How many pharmacy staff members—professional and support—are employed?
- What is the educational level of professional staff?
- What refresher training or continuing education have the professional pharmacy staff members received in the past two years?
- How do the professional pharmacy staff members spend their workdays—divided among clinical advice, preparation and dispensing, ward supervision, and administration?

Operation

- How many patients were admitted last year?
- What is the average number of prescriptions per day dispensed by pharmacies to inpatients? To outpatients?

- Among outpatients, what is the average dispensing communication time? What percentage of medicines dispensed are adequately labeled? What is the level of patient understanding?
- How often are ward storage areas inspected?
- Are the medication records accurately filled in?
- How many items are stocked in the central unit, satellite units, and ward stocks?
- How much does the hospital spend annually on pharmaceuticals?
- Does the hospital have procedures in place to dispose of expired or damaged pharmaceutical products?

Other pharmacy responsibilities

- Are preparations manufactured in the hospital? If so, how many? What quality-control measures exist?
- Is there a need for COT or special packaging for facility use? Are sufficient equipment, supplies, and personnel available for this type of production? Is it possible to ensure that packaging, labeling, and quality control are adequate?
- Are there any special regulations in effect that govern local manufacturing by a hospital pharmacy? Are these regulations being adequately enforced?
- Have drug use review activities occurred during the past year? If yes, who reviews the reports? What actions or improvements have occurred as a result of DUR?
- Is a system in place to track adverse drug reactions and medication errors? What actions or improvements have occurred as a result of this activity?

SUMMARY

Health facilities are the last component of the pharmaceutical supply chain. Managing pharmaceutical supply at the facility level directly affects the quality of health care. If medicines are consistently unavailable, patients suffer and staff members lose motivation. Everyone loses confidence in the health system, and patient attendance decreases. A constant pharmaceutical supply promotes effective care, inspires confidence in the health facility, and contributes to job satisfaction and self-esteem among staff.

Every health facility, however large or small, needs to store and manage its medicine stocks. Systems must be in place to ensure—

- Secure storage
- Storage in correct environmental conditions
- Accurate record keeping
- Effective reordering
- Effective stock rotation and expiry monitoring
- Effective fire and theft prevention

Health workers and managers often believe that inventory control is possible only when resources are plentiful. This is not the case. Inventory control is about managing and using the resources available. There will be “sufficient resources” only if effective inventory control is implemented.

Good inventory control makes ordering and pharmaceutical management easier. Essential medicines programs place a high priority on improving inventory control to ensure a reliable supply of essential medicines, vaccines, and other items at health facilities. To achieve this aim, staff need to be trained in inventory control, storage, and ordering procedures.

The choice of an appropriate inventory control method varies according to the type of facility, scale of operations, and staff capabilities. Despite these differences, the principles of effective inventory control remain the same.

46.1 Managing medicines at health facilities

The purpose of inventory control at the facility level is to—

- Prepare effective orders
- Maintain sufficient safety stock levels within budget limits
- Maintain records in accordance with local requirements
- Adjust inventory levels to respond to new morbidity trends and changes in standard treatment guidelines
- Provide appropriate, safe, and secure storage
- Prevent expiry of medicines

HIV/AIDS is changing the picture of pharmaceutical supply management in many facilities because of the lifelong nature of the treatment. However, the ultimate goal of inventory control is to ensure that the right medicines are kept in the right quantities and are available at the right time.

Benefits of a successful inventory control system at the facility level

Maintaining a sufficient stock of items at a health facility has many benefits. Patients receive medicines promptly, and stockouts can be prevented even when deliveries are delayed. Supplies can be replenished at scheduled intervals, saving on administrative costs and transport time. Patients

have confidence in the facility and seek help when they are ill. In addition, an effective inventory control system keeps track of and ensures accountability for supplies.

Problems arising from poor stock control

When inventory control fails, problems occur. A patient's condition may worsen or antimicrobial resistance may develop because of a delay in treatment; a patient may even die if a lifesaving medicine is out of stock. If medicines are not available in rural facilities, patients may have to make long and expensive journeys to obtain treatment. If medicine availability at the secondary level is better than at the primary level, the community will lose confidence in primary health care and seek hospital treatment instead. When a medicine is out of stock, a less suitable alternative may be prescribed. Frequent stockouts may establish or reinforce poor prescribing habits. Emergency orders, which are expensive for the purchaser and inconvenient for the supplier, may be required.

Staff commonly resist the implementation of inventory control systems. The reasons should not be ignored but rather brought out into the open for discussion. Common reasons for resistance are a perceived lack of time for record keeping or a feeling that “this is not my job.” Lack of appropriate training may also play a major role in resistance to new systems. An advocate on staff can demonstrate that the time spent on inventory management activities is time well

spent. Patients also need to understand that the time health care staff spend to maintain records ensures that their medicines will be available during their next visit.

Cost of maintaining stock

Stocking a new health facility can account for a significant amount of the facility's total annual budget. If stock is managed well, however, future expenses will be consistent with use. An efficient inventory control system saves money. Poor inventory control leads to wastage or increased costs for holding stock—

- Overstocking of certain items may tie up a substantial portion of the pharmaceutical budget, leaving insufficient funds for other important, perhaps life-saving, medicines.
- Overstocked medicines often expire; for example, some antiretrovirals (ARVs) have only a six-month shelf life.
- Poor storage conditions may result in spoiled stock (for example, dressings may be soaked by a leak in the roof, or injectable medicines may lose potency if the storeroom is too hot).
- Poor stock records and poor security make theft easier.
- A change in prescribing policy or practice may make a medicine obsolete. Without good inventory control, such changes may result in excessive wastage.

46.2 Managing the storage area

Good inventory control requires careful thought about the dimensions and design of the storage space, appropriate conditions for storage of different types of supplies, and the importance of stock rotation and systematic arrangement of stock, as well as attention to cleanliness, fire-prevention measures, and security within the store (see [Figure 46-1](#)).

Dimensions and design of the store

Storage should be located in a dry, weatherproof building. Stock should be organized and easily accessible on an adequate amount of good-quality shelving (most items in health facilities can be kept on shelves). Space and cold-chain equipment should be provided for the refrigeration of vaccines and other items. Temperature and humidity levels should be controlled within appropriate limits, and the space should be well ventilated. Pharmaceuticals and medical supplies should be segregated from linens, food, and other nonmedical items. The building should be physically secure.

Sizing. Product and packaging innovations, as well as fear of blood-borne infections, such as HIV and hepatitis B, have

increased the use of disposable medical sundries. These items require more storage space. In addition, large global funding initiatives, particularly for HIV/AIDS, tuberculosis, and malaria, have dramatically increased the volume of medicines that facilities have to handle. For example, treatment kits, such as those used for tuberculosis, and blister packs of artemisinin-based combination therapies take up much more space than bulk bottles of tablets, for example. Designers of new facilities frequently underestimate storage requirements, and older facilities are often very short of space, with supplies stored in corridors and blocking work areas. Appropriate adjustable shelving and handling equipment are often lacking. Health facilities need to be aware of possible increases in space requirements due to public health program scale-up and plan accordingly.

Hospital stores are more difficult to size because they vary with the range of services offered and the organization of services. Stock levels and lead times also need to be considered in the estimate. However, the general rule is that 1 square meter per hospital bed can be used for initial planning and costing, assuming that supplies are received every month.

Receiving bay. A weather-protected area designated for receiving supplies should be close to the storage area and preferably linked to it by a covered walkway. A pharmacy or medical stores department in a hospital may have its own delivery bay, which is often raised above ground level to facilitate unloading from large delivery vans. Smaller facilities have a single receiving bay providing access to ambulances and small delivery trucks. Designating one area of the actual storeroom as the receiving area may be necessary, if no space exists for a separate receiving bay.

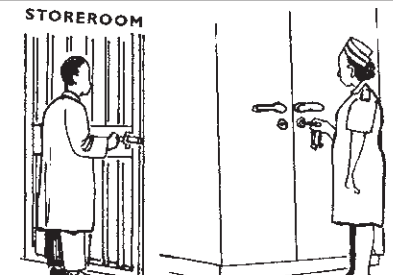

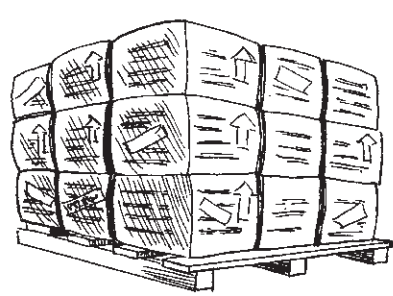

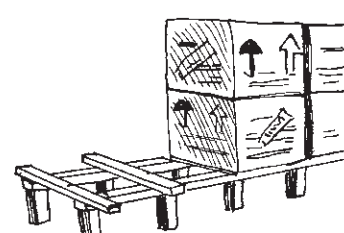

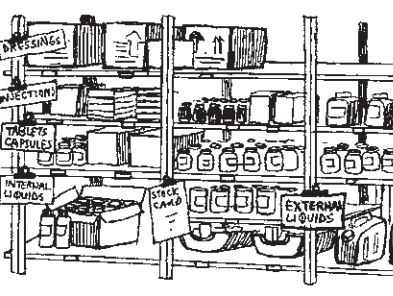

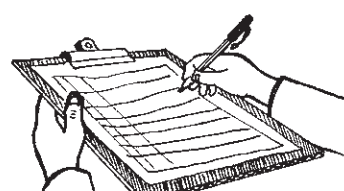

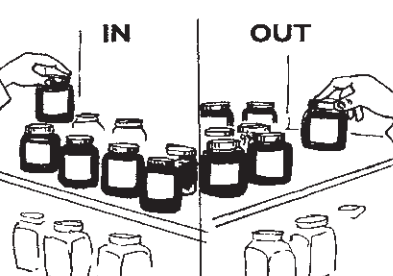

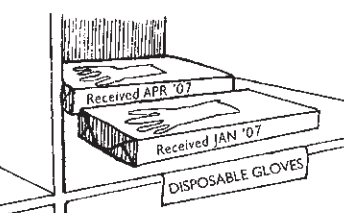

Storage of supplies

Most pharmaceuticals and medical supplies can be kept at uncontrolled room temperature. If the product has no special instructions, normal storage conditions apply. These conditions mean storage in dry, clean, well-ventilated premises at temperatures of +15 to +25°C or, depending on climatic conditions, up to +30°C.

Less stable medicines must be stored in specific conditions to maintain their effectiveness and prevent contamination. Storage instructions are product-specific. Different brands of the same generic drug may have different storage requirements because their packaging or formulation differs slightly. The manufacturer's recommendations should be followed. The expiry date provided by the manufacturer assumes that products are stored under ideal conditions. The following categories of medicines require special storage facilities—

- Products that must be kept frozen (usually vaccines and sera)

Figure 46-1 Tips for managing stock in the pharmaceutical storeroom

- Products sensitive to heat that require refrigeration
- Products that have a reduced shelf life at uncontrolled room temperature and need mechanical ventilation or air-conditioning
- Flammable products that require separate, fireproof premises
- Products prone to theft or misuse (see [Chapter 43](#))

Items needing storage in a controlled environment. The usable shelf life of the following products may be reduced if stored at uncontrolled humidity or at room temperature in hot climates—

- Some injectable products (for example, adrenaline). Most injectable preparations are less stable than solid oral forms (tablets and capsules). Injectable preparations in solution are particularly unstable, whereas freeze-dried powder preparations (for reconstitution) are less degradable. Many injectables require protection from light as well as from heat.
- Some suspensions, such as the ARV stavudine, which has a shorter shelf life than the capsule form.
- Intravenous fluids (particularly if purchased in plastic containers).
- Some suppositories, pessaries, creams, and ointments. These products may melt at temperatures greater than 30°C. If they do melt, they should not be used because the active ingredient in the formula may become unevenly distributed.
- X-ray films and chemicals. Manufacturers typically recommend storage of X-ray film at a maximum of 21°C. Opened packages are also affected by humidity. A humidity range of 30 to 50 percent is advisable. X-ray film should be handled carefully to avoid staining, creasing, buckling, and friction.
- Products containing rubber, latex, cellulose, or some plastics. Condoms, most sterile disposable medical devices, and surgical products such as syringes, needles, and catheters require protection from excessive humidity, cold, and strong light. Any of these conditions may make products brittle, stained, malodorous, and unusable. Sterility cannot be ensured if packaging is damaged.

In hot climates, these items should be stored in the coolest place possible, preferably with air-conditioning or air-circulation fans. When preparing essential medicines lists (see [Chapter 16](#)), taking account of the stability of medicines and the type of storage facilities available is important.

Items needing freezing or refrigeration. Vaccines, blood products, and some other medicines lose potency if kept, even briefly, at temperatures outside the recommended range. For those products, the cold chain must be main-

tained at every stage. (See Table 44-3 and References and Further Readings for literature on cold-chain management.)

All cold-chain equipment should meet WHO standards. Top-loading refrigerators and freezers are the most appropriate choice. Electric refrigerators of the ice-lined type have good “hold-over” characteristics in the event of a power failure. Front-loading types should be used only in places where the electricity or fuel supply is completely reliable, because they have very poor hold-over characteristics and temperature control.

Having a contingency plan in place before a refrigerator breaks down is essential. Rural health facilities are often so small and so isolated that no other source of refrigeration is available. Larger facilities frequently have more than one refrigerator and can use another refrigerator to store vaccines for short periods. Alternatively, an arrangement can be made to move the contents to a private refrigerator elsewhere in the community or to obtain a regular supply of ice packs until the defect is rectified.

Performing routine monitoring and maintenance is also important, as well as organizing an effective repair system. The temperature in each appliance must be monitored and recorded routinely at least once a day. Any breakdown must also be recorded, including the period during which the medicines were exposed to uncontrolled temperatures. Medicines are then kept or discarded, depending on the program guidelines or the manufacturer’s advice. Cold-chain monitor cards and devices in or on packages that change color or otherwise alert staff to potential damage assist in monitoring.

Freezing is as damaging as high temperatures for some items, including injectable contraceptives, ergometrine, insulin, adrenaline, and the DPT, DT, TT, and hepatitis B vaccines. Frozen toxoids can be detected by the “shake test” (if the contents clump or fail to resuspend after vigorous shaking). Evidence from Eastern Europe shows that vaccines can freeze inside a refrigerator during winter months when heat in a building is inadequate. Refrigerators incorporating a heating circuit are available to overcome this problem. Loss of potency in ergometrine injection has frequently been found in field studies, and may also be detected visually. If the solution appears colored when compared with water, the injection has less than 90 percent of stated content and should be discarded.

Short periods at room temperature (during transportation or local distribution, for instance) are acceptable for many products (such as ergometrine and insulin), even though such exposure can, to some extent, reduce shelf life. Other items, such as vaccines, should always be transported in cold boxes.

Controlled drugs. Narcotics (for example, pethidine injection, morphine preparations) and other specified medicines that may be abused are governed by special legislation and regulations that control import, export, production,

supply, possession, prescribing, record keeping, and retention of documents.

The following security measures are suggested in the pharmacy and at each user level—

- A safe or reinforced, double-locked cabinet fitted with a light (preferably with a red bulb) that comes on when the door is opened
- A special register recording details of each receipt or issue with two signatures, physical counting after each entry, and signatures at “handover-takeover”
- Independent audit (by supervisors and national pharmaceutical inspectors)

Attractive items. Some noncontrolled items are particularly prone to theft, abuse, or misuse. They include expensive medicines (cimetidine, praziquantel, ARVs); certain antibiotics; psychotropics; equipment such as scissors, safety razors, and hypodermic needles; and sundries, such as rolls of cotton. Such items should be stored in a separate, locked area or cupboard, where they can be supervised.

These items require stricter record keeping and more frequent stock taking than other items. Periodic audits should be made of consumption (issues) against actual recorded use (outpatient registers, prescription records, or ward stock records) to expose any theft or misuse. Embossing packaging or the pharmaceutical products themselves with a unique identifier can deter the diversion of pharmaceuticals into the private sector (see [Chapter 19](#)).

Flammables and corrosives. Flammable liquids commonly found in health facilities fall into three categories, according to United Nations hazard classifications—

1. Flash point of -18°C (for example, acetone, anesthetic ether)
2. Flash point of -18 to $+23^{\circ}\text{C}$ (such as alcohols before dilution)
3. Flash point of $+23$ to $+61^{\circ}\text{C}$ (for example, kerosene)

Bulk supplies of flammable substances require a separate outdoor store located away from the main buildings and pathways. Even small stocks of category-1 flammables should be kept in an outbuilding designed specifically for that purpose (AHRTAG 1994). Firefighting equipment should be readily available.

A small working stock of flammables may be kept in a steel cabinet in well-ventilated premises, away from open flames and electrical appliances. The cabinets should be marked “highly flammable liquid” and bear the international hazard symbol. The cabinet shelves should be designed to contain spillage.

Corrosive or oxidant substances (such as trichloroacetic acid, glacial acetic acid, concentrated ammonia solutions, silver nitrate, sodium nitrite, and sodium hydroxide pellets)

should be stored away from flammables, ideally in a separate steel cabinet. Appropriate industrial-type protective gloves should be used when handling these substances.

Stock rotation and expiry monitoring

The first-expiry/first-out (FEFO) rule ensures stock rotation and prevents wastage through expiry. In this system, the stock with the longest life should be placed farthest to the back (or, if shelving makes such placement impossible, farthest to the left). Stock should be issued only from the front or from the right-hand side. The expiry dates of medicines should be checked at the time of receipt and noted on the stock record. Stock nearing expiry should not be accepted unless it can be used before expiry. Facilities should regularly monitor expiry dates, and expired medicines should be removed immediately from stock. In most cases, they must be destroyed. There should be an agreed-upon procedure for disposal that protects public health. A written record is necessary, and in some countries, a committee decision is required.

Health professionals sometimes have to decide whether to use an expired medicine or withhold treatment. The medicine may still be usable and could save a life, but an expired medicine might actually kill a patient. Such decisions have ethical and legal consequences. The only legal procedure for using expired medicines is to test them, transmit the test results to the manufacturer, and have the manufacturer extend the expiry date.

No guarantee exists of a medicine’s effectiveness after the expiry date. In exceptional circumstances, when expired medicines might have to be used, a pharmacist who is experienced in quality assurance must be involved and the clinician must be informed. Medicines usually expire because they have been overordered or the FEFO rule has not been observed. In well-run stores where orders are placed regularly and stock is rotated, wastage caused by expiry should not occur. When it does, the supervisor should find out why and take corrective action.

Expired or damaged products should be disposed of following written standard procedures that conform to country laws or regulations related to hazardous waste.

Arrangement of stock

Organizing stock systematically saves time when ordering or locating items and prevents stock from being lost. [Chapter 44](#) discusses various systems for organizing stock (see Section 44.5). The systems most often used in health facilities are organization by therapeutic category, clinical indication, or dosage form, with products arranged alphabetically within those categories.

Treatment rooms and medicine trolley carts should arrange medicines by therapeutic class (for example,

antibiotics, antiasthmatics, or antihypertensives) or consistently follow another approved classification.

Liquids for internal use must be kept separate from those for external use throughout the supply chain, but particularly in treatment areas. Products for external use are often poisons. If kept with medicines for oral use, they may be accidentally swallowed, which could be fatal. To avoid risk, observe the following labeling conventions—

- External-use products should be properly labeled according to the country's pharmaceutical control legislation. Warning labels in red are recommended.
- All internal-use medicines should be labeled according to national or local requirements.

Cleaning

A clean, tidy store is easier to manage than one that is dirty, untidy, and filled with waste. A cleaning schedule with clear designation of staff responsibilities should be established.

Fire prevention

Fire-prevention measures should include a strict no-smoking rule, careful disposal of combustible waste materials, and careful handling of flammables. Firefighting equipment should be regularly checked and maintained, and staff members should be trained with regular fire drills.

Security

Access to storage areas should be restricted for security reasons. All staff members who handle supplies should be accountable for their actions. One or two responsible and trustworthy people should be accountable for the keys, and one set should be available on the premises at all times. The person in charge of the health facility is ultimately held responsible.

All storeroom windows should have burglar bars, and doors must be fitted with security locks. Work areas such as the pharmacy or dispensary should have double locks (see [Chapter 43](#)).

46.3 Inventory control within health facilities

Every facility needs an inventory management system—and written procedures—to deal with ordering supplies, receiving and storing stocks, and recording and accounting for stocks.

In larger facilities, inventory management requirements are greater. At large hospitals, pharmacists or other specialized staff members usually manage supplies. Separate facilities may exist for the various activities and types of stock. At

smaller facilities, such as health centers, activities tend to be integrated, and a single person may have multiple responsibilities. Even in a small facility, however, stocks of food and linen should be separated from medical supplies to maintain hygiene standards and to allow nonprofessional staff easy access to the food and linen.

Keeping records and ordering stock

[Chapter 23](#) outlines the principles of inventory management, which are equally relevant for small health facilities and large stores. Their application may be different, but the underlying methods are the same.

Keeping records. The most important record is the stock card or ledger. The examples in [Chapter 44](#) (see [Annexes 44-1](#) and [44-2](#)) contain most of the features that are likely to be required, but many variations are possible. At a minimum, space should exist for a description of the item and its stock number, the unit of issue (for example, 500-tablet jar, tablet, or mL), and expiry date, if applicable. Columns and rows to document receipt and issue of stock should appear below this standard information. In addition to the stock card kept next to the items on the shelf, a stock book may be used that maintains a duplicate record of each transaction. Some larger facilities may use a computerized record-keeping system for inventory management.

Ordering stock. Most health facilities use a requisitioning system to order supplies. Staff must assess the rate at which individual items are used and have a clear understanding of the safety stock concept. Various methods of calculating order quantity exist, but all are based on monthly consumption. Monthly consumption can be determined from the stock card or from the monthly stock check.

Various ways of calculating safety stocks and order quantities are described in Chapter 20. One simple system of ordering for health facility use is the imprest, or “topping up,” system to the maximum stock level. This system is particularly suitable for hospital wards and small health facilities that receive supplies frequently. In the imprest system, no running stock records are kept. The only stock control document is a preprinted sheet that describes each item and

gives its stock number, unit of issue, and imprest level—the recommended maximum stock level for that item. The amount ordered is the difference between the stock on hand and the imprest level.

Another effective system is ordering based on consumption versus maximum stock levels, typified by the approach used in the Eastern Cape Province in South Africa (see Box 46-1).

Box 46-1
Calculating how much stock to order using the maximum stock approach

The maximum stock approach consists of replenishing stock to an optimal maximum stock level every time an order comes in. Determining the maximum stock factor can simplify the calculation. The maximum stock factor varies with the frequency of orders and the lead time, according to the following table. The lead time and the order frequency are known from experience (or from an order schedule).

Maximum stock factor table

Order frequency	Lead time			
	1 Week	2 Weeks	4 Weeks	6 Weeks
Once a week	0.05	1		
Every 2 weeks	1	1	2	
Once a month	1.5	2	3	4
Every 6 weeks	2	3	4	5
Every 2 months	3	4	5	6
Every 3 months	4	5	6	7

To identify the maximum stock factor, one should draw two imaginary lines: one horizontal line on the corresponding order frequency row and one vertical line on the lead-time column. The meeting point of those two lines indicates the maximum stock factor. For example, if supplies are ordered once a month and the lead time from the source is equal to four weeks (or one month), then the maximum stock factor is equal to three.

After the maximum stock factor is identified, the next step is calculating the maximum stock using the following formula—

$$\text{Maximum stock (in issue units)} = \text{average monthly consumption} \times \text{maximum stock factor}$$

The next step is comparing this maximum stock to the current stock balance of usable stock (without any expired items)—

- If the current stock balance is greater than or equal to the maximum stock, no order needs to be placed.

- If the current stock balance is smaller than the maximum stock, then an order must be placed unless the product is discontinued or its use is influenced by some external factors, such as the end of a season, the end of a public health campaign, or modification of the essential medicines list.

After the reorder factor is identified, the next step is calculating the quantity to order using the following formula—

$$\text{Quantity to order (in issue units)} = \text{maximum stock} - \text{stock on hand}$$

Note: If the result is too small (not enough needed to place an order), an order might be placed only on the next scheduled date. In some cases, if the demand for this product is related to a particular season and the season is over, the quantity to order is decreased or nothing is ordered.

These formulas should only be used as guidelines in estimating order quantities. A modification to any one of the components of the procurement cycle (time of delivery, expiration date, disease outbreak, new physician, and so on) will influence the entire system. The requisitioning officer’s individual experience as well as the nature of each product are essential considerations in arriving at a final decision.

Example

Product A’s average monthly consumption equals 45 units. This product is ordered every two weeks, and the lead time is equal to four weeks. The current stock is 60 units. If an order has to be placed, how much has to be ordered?

1. The maximum stock factor has to be calculated. In this case, it is equal to two. Therefore, the maximum stock is equal to 90. The current stock balance is 60, so an order has to be placed.
2. The quantity to order is calculated using the recommended formula—

$$\text{Quantity to order} = 90 (\text{maximum stock}) - 60 (\text{stock on hand}) = 30$$

Source: Eastern Cape Department of Health 2000.

After the order quantity is calculated, orders are sent to the issuing store on a requisition/issue voucher (see [Annex 44.4](#)). The facility and the issuing store should always keep copies of the requisition voucher or imprest forms. Those forms should be compared to the stock cards to monitor consumption and prevent overordering.

Receiving stock

A clear procedure for receiving stock should be in place. If goods are not checked into the store on arrival, chaos occurs. The person in charge should be responsible, whether or not he or she personally undertakes the task.

All deliveries should be formally received, whether they arrive inside or outside normal working hours. The number of packages delivered should be noted in a register and signed for by both the person receiving and the person delivering the goods.

Unpacking and checking stock

Supplies should be unpacked and checked next to the storage area, which may also be used for assembling stock for distribution. Two people should perform these activities, to provide a witness in case supplies are damaged or differ in type or quantity from what was ordered (or from what is shown on the packing list). Supplies should be individually checked using a checklist like the one in [Chapter 44](#) and their receipt recorded on the supply documents (packing list or returned requisition form). The copy of the original requisition form should always be compared with documents from the issuing facility to prevent later disputes.

The issuing store should be notified of any discrepancies (using a form like the one in [Figure 46-2](#)), including—

- Missing boxes or cartons
- Open boxes or cartons
- Missing items
- Quantity different from the one shown on the packing list
- Wrong items (items not ordered)
- Damaged, broken, or poor-quality items

Staff members should see checking not simply as counting the units delivered but as part of the quality assurance system. This process includes visually inspecting the packaging, the integrity of containers, and the completeness and legibility of labels (approved medicine name, strength, any special storage instructions, expiry date). The expiry date should be checked to ensure that adequate shelf life remains (see [Chapter 19](#)).

Packaging is an important factor in maintaining the quality of medicines and other supplies when stability is a consideration. Good packaging protects the product from light

and air. Packaging should be removed only after careful consideration of the effect on pharmaceutical quality.

Finally, the delivery documents should be signed and filed for reference; they should usually be kept for a minimum of two years (or the time specified in regulations).

46.4 Distributing stock from the storeroom

Medicines and supplies need to be moved from the facility store to the places where they are used, such as treatment areas, wards, or outpatient facilities. The procedures are similar, whatever the size of the facility.

Small health facilities

Small facilities may not have a separate pharmacy, but they should have a medicine storeroom or cupboard and a dispensing and treatment area. A working stock (often a single container) of common medications should be kept in the treatment area. Oral medication should be stored in a lockable trolley cart or cupboard. A small stock of common injectable medicines should be kept on a tray in the treatment room. A separate area usually exists for cleaning and dressing wounds, where an appropriate range of items should be kept on trolley carts and in lockable cupboards. These working stocks are replenished from the storeroom daily. Working-stock containers must be kept closed except when they are actually being used, to avoid deterioration and loss of therapeutic value.

Hospital pharmacy departments

The movement and control of stocks are more complex in larger facilities where medical, surgical, and maternity care are provided. Each type of ward should have its own stock list to facilitate control and misuse, and separate storerooms may be needed. The hospital pharmacy should be responsible for restocking all medicine storage areas and may also dispense to individual inpatients and outpatients. The volume of outpatient prescriptions may justify an outpatient dispensary separate from the main pharmacy.

As HIV/AIDS programs scale up, one option for hospitals that offer antiretroviral therapy is to refer established patients to local health facilities for their medications, which reduces the time and cost of travel for patients. [Country Study 46-1](#) shows how a South African hospital has expanded its system to include other patients with chronic health conditions.

The hospital pharmacy may have working stock from which it dispenses medications to inpatients, and upon their discharge, to outpatients, and to wards, departments, and emergency trays. A “want list” should be compiled throughout the day, for daily replenishment from the storeroom.

Country Study 46-1

Improving treatment for chronic conditions with a computerized referral system in South Africa

Cecilia Makiwane Hospital is located in Mdantsane, Eastern Cape Province, one of the largest townships in South Africa. The hospital implemented the national *Comprehensive Plan for the Treatment and Care of HIV and AIDS* in October 2004, and a year later, more than 800 patients had been enrolled on antiretroviral therapy (ART). All patients collect their medication regularly at the hospital; after a patient has been stabilized and the patient demonstrates his or her ability to adhere to treatment, the doctor prescribes a repeat of the medication for five months. However, frequent trips to the hospital can be a burden. In some cases, patients may pay as much as 120 South African rands (19 U.S. dollars) for transportation to pick up their medication. This expense strains patients' already low income and can affect treatment adherence. Furthermore, these patients can overburden the hospital's pharmaceutical service, where staff also need to deal with new or complicated cases on a daily basis.

To maximize patients' access to ART, Management Sciences for Health's Rational Pharmaceutical Management Plus (RPM Plus) Program looked at innovative approaches for dispensing repeat prescriptions to established patients. The result is a fully integrated computerized program, RxSolution, designed to support pharmaceutical care activities at the facility level. RxSolution includes a referral module that optimizes dispensing of chronic medicines by shifting ART care to primary health care facilities in the local communities.

In collaboration with the provincial pharmacy team, RPM Plus staff visited all community referral clinics to ensure that the conditions and facilities required to deliver high-quality and safe medications were in place.

As one of the clinic nurses said, "We also had to ensure that not a single client misses a single dose as that would affect treatment outcomes."

After receiving training on the computer system, the pharmacy staff of the Cecilia Makiwane Hospital record patient details in the RxSolution database. As stable ART patients are recruited into the program, they are given appointment cards with the date of their next visit and told at which referral clinic to collect their medication. Using RxSolution, hospital staff members group all prescriptions by referral clinic and create a prescription pick list, a set of medication and address labels, and a patient accountability checklist. Prescriptions are checked, packaged in cartons, sealed, grouped according to the referral clinics, and dispatched by courier.

At the referral clinic, the nurse signs the distribution list, which is returned to the hospital. During scheduled patient visits, the nurse reviews progress and gives medications to the patient, with both the nurse and the patient signing that this interaction has taken place. The list is then returned to the hospital along with any uncollected medication. The hospital staff uses this information to monitor the patient adherence at each referral clinic. During the last visit at the referral clinic, the patient is reminded of his or her next clinical assessment at the hospital.

Referring patients from hospitals to primary health care facilities has always been a challenge. Although the RxSolution system was developed to support patients on ART, it has successfully been extended to other chronic conditions, thereby strengthening the delivery of quality health care to all levels.

This responsibility should rest with a limited number of individuals on a rotational basis.

Prepacking for outpatient dispensing. To save time for both staff and patients in busy facilities with high prescription volumes, prepacking commonly dispensed oral medications in appropriate quantities for standard treatment courses is useful. This packing can be done at quiet times of the day or week. Prepacking is also necessary when quantities smaller than the original pack are needed for ward stocks (see [Chapters 30](#) and [45](#)). In some countries, purchasing commonly used medicines commercially prepacked in "unit-of-use" (course-of-therapy) containers may be cost-effective. Important considerations when repacking medicines are to—

- Use containers suited for maintaining pharmaceutical quality.
- Avoid contaminating or mixing different batches of medicines.
- Label containers appropriately and assign a new "use-by" date.

Supplying inpatients. As discussed in [Chapter 45](#), three basic techniques exist for hospital pharmaceutical distribution to inpatients: bulk ward stock, individual medicine orders, and unit-dose distribution. The bulk ward stock system is still used in many countries. The imprest or topping-up system is a common method for supplying wards with bulk stock. Empty containers are returned for refilling (the

“full-for-empty” method) at weekly or twice-weekly intervals. Each ward should have a box that can be locked by both pharmacy and ward staff. Stricter security procedures should be applied for antibiotics, “attractive items,” and narcotic drugs.

In a ward stock system, the pharmacy should provide a schedule indicating on which day each ward or department is to be supplied and specifying the category of supplies. Pharmacy, stores, and ward staff must decide together about the types and quantities of medicines required, and pharmacy staff members must monitor ward stock storage and record keeping.

Emergency trays. A selection of medicines and equipment for emergencies should be placed in wards and outpatient departments. The contents should be recorded on a list and checked regularly. Whenever an item is used, it should be restocked immediately. The emergency tray should not be used for routine supplies. [Box 46-2](#) is an example of an emergency tray at a health post in Timor-Leste.

Supplying community-based health workers. Community health workers usually have a very limited selection of items. The topping-up system can be used to replenish stocks as long as requirements are small and the health center is reliably stocked. A monthly supply interval is usually adequate.

Home-based care kits. The family is usually the source of long-term care for chronic conditions such as HIV/AIDS and

tuberculosis. Home-based care kits can be supplied to community health workers to distribute to caregivers. Kits should be designed according to the individual condition, but at a minimum should contain appropriate essential medicines, such as painkillers and antidiarrheals, as well as supplies such as gloves, soap, and disinfectant. Basic care information written in local languages and using diagrams and drawings should be included. The kit contents should be restocked from the supplies at dispensaries and health centers.

46.5 Staff training

Staff members who handle supplies should be trained in the following subjects—

- Setting up a storeroom and good storage practices
- Use of stock control forms, including requisitions, stock records, and prescriptions
- Cold-chain procedures, including the use and maintenance of refrigerators
- Security and theft control

[Chapter 52](#) discusses the design and management of appropriate training programs for supply system staff and resources for available courses. ■

Box 46-2

Medicines for an emergency tray at a health post

Ampicillin powder for injection, 1 g (as sodium salt) in vial

Atropine injection, 1 mg (sulfate) in 1 mL ampoule

Calcium gluconate injection, 100 mg/mL in 10 mL ampoule

Charcoal, activated powder for oral suspension, bottle, 50 g

Chloramphenicol powder for injection, 1 g (sodium succinate) in vial

Diazepam injection, 5 mg/mL in 2 mL ampoule (intravenous or rectal)

Epinephrine/adrenaline injection, 1 mg (as hydrochloride or hydrogen tartrate) in 1 mL ampoule

Ergometrine injection, 200 µg (hydrogen maleate) in 1 mL ampoule

Gentamicin injection, 40 mg (as sulfate)/mL in 2 mL vial

Glucose injectable solution, 5% in 1 L bag

Glucose injectable solution, 50% hypertonic

Hydrocortisone powder for injection, 100 mg (as sodium succinate) in vial

Phytomenadione (vitamin K1) injection, 10 mg/mL in 1 mL ampoule (adult)

Promethazine injection, 25 mg (as hydrochloride)/mL in 2 mL ampoule

Magnesium sulfate injection, 500 mg/mL in 10 mL ampoule for use in eclampsia and severe preeclampsia and not for other convulsant disorders; available for trained midwives

Magnesium sulfate powder

Nifedipine scored tablet, 10 mg

Quinine injection, 300 mg (as dihydrochloride)/mL in 2 mL ampoule

Salbutamol injection, 50 µg (as sulfate)/mL in 5 mL ampoule

Sodium lactate, compound solution injectable solution, 1 L bag

ASSESSMENT GUIDE

See [Chapter 23](#) for indicators of stock control performance. Also, see [Annex 46-1](#) for a supervisory checklist to assess pharmaceutical management activities at the facility level.

Inventory control system

- Is there a standard inventory control system at health facilities?
- Are stock cards or stock books used for every movement of stock in or out of the facility storeroom?
- Are pharmaceuticals reordered according to a consumption-based system?
- Is the minimum or safety stock level set according to the frequency of delivery and average consumption?
- Are used stock cards, ledgers, or regulation books kept for a defined period?
- Do stock records correspond with physical stock for a sample of commonly used medicines?

Staff training in inventory management

- Have the staff responsible for ordering, storing, or distributing pharmaceuticals been formally trained in inventory management?
- Are procedures manuals for inventory management available in the health facility?

Stock storage facilities

- Have the stock storerooms been sized according to any formula?
- Will public health program expansion create a need for more storage space?
- Is there a receiving area? Is there an unpacking area?
- Is there a discrepancy report form? Over the past year, has it been used?
- Is the storeroom dry, clean, well ventilated, and between +15 and +25°C?
- Is there a refrigerator? Is its temperature regularly recorded?

Storeroom management

- When medicines or supplies are unpacked, are they stored according to FEFO or FIFO order?
- Over the past year, have expired medicines been used?
- Are there expired drugs in stock now?
- Are liquids for internal use kept separate from liquids for external use?

CLINIC: _____	DATE: _____
Infrastructure conditions: How does your store match up to the ideal store?	[✓] Check if statement is TRUE
• The store is separate from the dispensary.	<input type="checkbox"/>
• Medicines are dispensed only from the dispensing area.	<input type="checkbox"/>
• The store is large enough to keep all supplies.	<input type="checkbox"/>
• The store is kept locked at all times when not in use.	<input type="checkbox"/>
• The store has no cracks, holes, or sign of water damage.	<input type="checkbox"/>
• The store has a ceiling that is in good condition.	<input type="checkbox"/>
• Air moves freely in the store; fans and screens are in good condition.	<input type="checkbox"/>
• The windows are painted in white (or have curtains) and are secured with grilles.	<input type="checkbox"/>
• There are no signs of pest infestations in the store (e.g., cockroaches, rats).	<input type="checkbox"/>
• The store is tidy; shelves are dusted, the floor is swept, and walls are clean.	<input type="checkbox"/>
• Supplies are stored neatly on shelves or in boxes.	<input type="checkbox"/>
• Shelves and boxes are raised off the floor, on pallets or on boards and bricks.	<input type="checkbox"/>
• No supplies are in direct contact with the floor.	<input type="checkbox"/>
Storage procedures: How well is your store organized?	
• Supplies are systematically classified on the shelves (i.e., by dosage forms or therapeutic class).	<input type="checkbox"/>
• Supplies are arranged on the shelves in alphabetical order by generic name within each category.	<input type="checkbox"/>
• Tablets and other dry medicines (e.g., ORS) are stored in airtight containers.	<input type="checkbox"/>
• Liquids, ointments, and injectables are stored on the middle shelves.	<input type="checkbox"/>
• Supplies, such as surgical items, condoms, and bandages, are stored on the bottom shelves.	<input type="checkbox"/>
• Items are grouped in amounts that are easy to count.	<input type="checkbox"/>
• No expired medicines are in the store.	<input type="checkbox"/>
• Medicines with shorter expiry dates are placed in front of those with later expiry dates (FEFO).	<input type="checkbox"/>
• Supplies with no expiry or manufacture date are stored in the order received (FIFO).	<input type="checkbox"/>
• Supplies with a manufacture date only are stored in chronological order.	<input type="checkbox"/>
• No damaged containers or packages are on the shelves.	<input type="checkbox"/>
• No overstocked or obsolete items are on the shelves.	<input type="checkbox"/>
• The disposal of medicines is recorded in a separate register and includes the date, time, witness, value, quantities, and reason(s).	<input type="checkbox"/>
• Narcotics and psychotropic drugs are in a separate, double-locked storage space.	<input type="checkbox"/>
• Items are checked regularly for potential deterioration (i.e., bad odor or discolored tablets).	<input type="checkbox"/>
• Temperature-sensitive items are stored in a refrigerator.	<input type="checkbox"/>
• The refrigerator is in working condition.	<input type="checkbox"/>
• No staff food is in the refrigerator.	<input type="checkbox"/>
• A temperature record is available and up-to-date.	<input type="checkbox"/>
Stock card: How are the stock cards used in your facility?	
• Does each item in the store have a stock card?	Y N
• Is the stock card kept on the same shelf as the item?	Y N
• Is all information on the stock card up-to-date?	Y N
• Is information recorded on the stock card at the time of movement?	Y N
• Is an accurate running tally kept in the balance column?	Y N
• Does the physical count match the balance column? (Check 10 items.)	Y N
• Is a physical count made at regular intervals, such as once a month?	Y N

CLINIC: _____

DATE: _____

Ordering supplies: If delivery schedule changes

• How often do you place an order?		
• What is your average lead time?		
• What is your facility's reorder factor?		
• Do you know how to calculate the Average Monthly Consumption (AMC)? Ask/check formula.	Y	N
• Do you take into consideration stockout period when calculating the AMC?	Y	N
• Do you calculate the Maximum Stock by multiplying the AMC by the Maximum Stock Factor?	Y	N
• Has the Maximum Stock been calculated for each item in the store?	Y	N
• Is the Maximum Stock recorded on each item's stock card (in pencil)?	Y	N
• When was the last time that the Maximum Stock was reviewed?		
• When you order, do you use the Quantity to Order formula? Ask/check formula.	Y	N
• Is a standard order form used at all times?	Y	N
• Is the order costed?	Y	N
• Is the requisition book kept at the facility?	Y	N
• Is all information on the requisition form accurate and clearly written?	Y	N

Receiving supplies: How are supplies received at your store?

• Are deliveries received by a health worker in person?	Y	N
• Are deliveries inspected by a health worker before acceptance?	Y	N
• Are supplies received checked against the items listed on the packing slip/delivery form?	Y	N
• Are deliveries acknowledged and recorded on the prescribed forms?	Y	N
• Does the delivery person sign the form before he leaves the facility?	Y	N
• Have you ever sent back items to the supplier? If so, ask for the reason.		
• Are the expiry dates of all items checked before final acceptance?	Y	N
• Does the health worker check for poor-quality items, such as		
- poorly packaged refrigerated items?	Y	N
- discoloration of medicines, vaccines, and suspicious product settlement?	Y	N
- broken containers and supplies spoiled by leakage?	Y	N
- unsealed and unlabeled items?	Y	N
• As soon as the supplies are checked, are all receipts recorded on the stock cards?	Y	N
• If poor-quality products are suspected, does the health worker check for		
- unusual odors of tablets and capsules?	Y	N
- damaged containers?	Y	N
- injectables with small particles that reflect light?	Y	N
- suspension with broken glass?	Y	N
• Do you accept expired or short date or poor-quality items?	Y	N
• Are all discrepancies documented?	Y	N

SUMMARY

The management of medical and laboratory supplies and equipment shares many similarities with the management of pharmaceuticals and is just as important in providing effective health services. Although the value of supplies and equipment may equal a substantial proportion of what governments spend on pharmaceuticals, such items are rarely given enough attention. Each country's ministry of health is responsible for ensuring that commodity management standards are set and followed by instituting quality assurance mechanisms and monitoring evaluation and reporting systems.

Problems associated with supplies and equipment include lack of policies, absence of dedicated government budgets, and lack of standardization. Countries should develop a national list of medical and laboratory supplies and equipment, based on expected types of tests, treatments, and interventions to be delivered at different levels of health care. Such a national list is useful to—

- Define priority items and help ensure that the most essential items are available where needed
- Promote cost-effective use of scarce financial resources
- Reduce the number of items through standardization
- Serve as the basis for training staff and technicians

The four main criteria in selecting equipment are (1) local possibilities for servicing and spare parts; (2) local

availability of essential supplies (such as chemicals and filters); (3) a well-established brand name and a simple and sturdy design; and (4) local possibilities for training staff in equipment use and maintenance.

Finding good data on the consumption and cost of medical supplies is a challenge, especially on individual items. The number of different items and brands is much larger than the average number of essential medicines, and the specifications are much less standardized. Another problem comes from the records used to compile data: Are different sizes of X-ray films or all sizes of syringes regarded as one item? In some countries, medicines and other medical supplies and laboratory supplies come under different management structures or different budgets, which makes intercountry comparisons difficult.

Before procuring medical and laboratory supplies and equipment, specifications should be defined in close collaboration with technical staff. These specifications are needed for the procurement department and for claims in case of faulty products.

Donations of commodities and equipment to laboratories and health facilities must be handled carefully, including the assurance that donations are based on need expressed by the recipient country. When donors provide medical and laboratory supplies and equipment, problems related to the lack of standardization and to maintenance may arise.

47.1 Introduction

Clinical laboratory services are a critical, yet often neglected component of essential health systems in resource-limited countries. Laboratories play a central role in public health, in disease control and surveillance, and in individual patient diagnosis and care, yet many millions of people still do not have access to reliable, basic, diagnostic laboratory services (Petti et al. 2006).

Effective laboratory leadership and management are often lacking—many countries still do not have a national laboratory policy, a strategic plan, or a dedicated budget for laboratories. Fundamental weaknesses in the overall management of laboratory services, together with a lack of human and financial resources and poor infrastructure, prevent the efficient operation and delivery of accessible, quality-assured laboratory services to support national public health programs, including malaria and tuberculosis (TB) control and treatment and the delivery of antiretroviral therapy (ART). A greater realization of

the laboratory's role combined with advocacy from global health initiatives such as the U.S. President's Emergency Plan for AIDS Relief to build capacity for laboratory systems has resulted in encouraging signs that suggest a gradual increase in focus. [Country Study 47-1](#) describes a successful program to build leadership in laboratories in Uganda.

If laboratory services are to support health care effectively, they need to provide reliable, valid, and timely results. Functioning, good-quality equipment and uninterrupted supplies of test kits, reagents, and other consumables are mandatory. Yet many countries have given little attention to the particular needs of laboratories and what is required to create an effective commodity management system. Governments and donors responsible for procuring and managing laboratory equipment and other commodities often lack updated standard international guidance. Consequently, stockouts occur when large quantities of materials that are inadequate, inappropriate, or of poor quality are procured, and resources are wasted.

Like laboratory services and commodities, medical supplies and equipment are rarely given enough attention. Recognizing the important role of this category of products, the World Health Assembly adopted a resolution in 2007 that covers the need to establish priorities in the selection and management of health technologies, specifically medical devices. The World Health Organization (WHO) defines a *medical device* as “an article, instrument, apparatus or machine that is used in the prevention, diagnosis or treatment of illness or disease, or for detecting, measuring, restoring, correcting or modifying the structure or function of the body for some health purpose” (WHO/EHT 2011b, 4). The term *equipment* refers to a medical device that requires calibration, maintenance, repair, user training, and decommissioning. According to

WHO’s definition, medical equipment excludes implantable, disposable, or single-use medical devices (WHO/EHT 2011b). Items that have traditionally been categorized as “supplies,” including bandages and gloves, are considered devices under WHO’s taxonomy. This chapter and the rest of the book recognize the new definition of *device* but continue to refer to such nonpharmaceutical items as supplies and commodities to reflect common understanding and usage.

As a result of the 2007 World Health Assembly resolution, WHO launched the Global Initiative on Health Technologies to make core health technologies available at an affordable price, particularly to resource-limited communities. Through the initiative, WHO and its partners have developed a series of reference documents for countries,

Country Study 47-1

Strengthening laboratories to expedite the countrywide scale-up of the ART program in Uganda

With funding from the U.S. President’s Emergency Plan for AIDS Relief, Management Sciences for Health (MSH) partnered with the Joint Clinical Research Centre (JCRC) and the Ugandan Ministry of Health (MOH) to design and implement the Laboratory Performance Improvement Program for laboratory management teams from selected MOH regional referral hospitals that support the national ART rollout program. Traditionally, laboratory support has focused on providing equipment and supplies and training staff in test methods but has ignored underlying management issues. Before this program, many regional hospital laboratories in Uganda were unable to provide quality-assured basic services to manage treatment of those infected with HIV/AIDS and TB.

MSH helped bring together multidisciplinary laboratory management teams, comprising the medical superintendent, the hospital administrator, a doctor, a nurse, laboratory staff, and local staff from the JCRC-TREAT Program (Uganda’s national ART program). As part of the program process, each team took responsibility for improving laboratory performance at its own hospital by managing the resources and developing effective work processes to produce quality laboratory test results. During the program, the teams received support from a central JCRC-TREAT-MOH team of experts, including the principal technologist at the central public health laboratory.

Through a series of five workshops spread over one year, the teams learned leadership and management skills and how to work together more effectively. They learned how to apply the performance improvement process to narrow the gap between the specific results they wanted to

achieve and their actual results, created a vision of how well their laboratory could operate in the future, and then committed themselves to realizing this vision by developing and implementing an action plan. Critical to their progress were the activities that each team implemented between workshops to use existing resources to improve laboratory performance. These efforts led to the first hospital monthly budget allocation for laboratory supplies, additional space for key laboratory functions, improved laboratory staff morale, and increased productivity resulting in more essential tests being performed in a timely manner. Early in the program, MSH worked with the teams to develop a laboratory performance monitoring tool that was appropriate for their local needs. Teams used the tool at the beginning of the program and again at the end of the program to review their progress and pinpoint remaining challenges.

At the end of the program, the executive director of JCRC stressed what the Laboratory Performance Improvement Program had demonstrated—

The laboratories are critical for the quality and safety of the TREAT Program . . . There is such a huge need because the [Laboratory Performance Improvement] Program started almost from scratch as far as up-country laboratories were concerned. Only a tiny group of leaders and professionals were involved, and they almost unanimously expressed great appreciation for the importance of laboratory training, especially in management. It has exposed a big gap.

Source: MSH n.d.

covering areas such as policy, regulations, management, and innovation. The document series and other information can be found at WHO's website on medical devices: http://www.who.int/medical_devices/en.

With the increased emphasis on the importance of effective laboratory services to a country's public health, this chapter focuses particularly on issues related to laboratories. It provides guidance for procuring and managing equipment and other supplies that health facilities and laboratories use.

47.2 Using national policies to guide equipment and supply management

Sound national policies on laboratories and medical equipment with lists of related essential supplies can simplify supply issues, reduce costs, and promote efficient provision of health care and rehabilitation; however, only 33 percent of low-income countries in a 2010 survey had national policies covering health technologies (WHO/EHT 2011b). Policies should specify which medical equipment and supplies should be used in which types of medical tests, interventions, and operations. Because different medical procedures are carried out at different levels of health care, and different tests are performed at different levels of laboratory service, the policies define the sets of supplies and equipment that will be needed at each of these levels.

National laboratory policy, strategic plan, and budget

A national laboratory policy provides a framework for ensuring that health laboratory services adequately support the efficient delivery of a country's health care package. National laboratory policies usually support regional and global health goals and priorities; for example, the 2008 Maputo Declaration on Strengthening of Laboratory Systems in Africa recognizes the challenges and limitations of scaling up services for TB, malaria, and HIV/AIDS and calls on national governments, donors, and partners to integrate support to improve laboratory systems (WHO/AFRO 2008b). In addition, achieving the three millennium development goals of reducing child mortality; improving maternal health; and fighting HIV/AIDS, malaria, and other diseases requires efficient national laboratory systems.

Implementation of a national laboratory policy requires a strategic plan that provides clear guidance on the actions needed to improve laboratory systems as well as insight into implementation and budget implications for translating policy into practice. The plan and budget guide the mobilization of needed resources and help the government and stakeholders identify areas to target.

Aligning laboratory services with packages of health care

A national laboratory policy usually contains objectives to ensure the availability of appropriate functional equipment and adequate supplies of test kits, reagents, and consumables for laboratories at all levels. It may also outline strategies for ensuring an effective supply chain, national standardization of equipment and supplies, registration by the appropriate regulatory authority, equipment maintenance and servicing, management of donations, and safe disposal of obsolete equipment and expired supplies. However, neither the laboratory policy nor the strategic plan usually specifies the actual list of equipment and other laboratory commodities because these may change with technology development and innovation.

National policies and decisions on public health priorities and health care should indicate which essential laboratory tests and services each level of health care will provide and which resources the laboratory needs to deliver these services. This approach stems from the "basic package" health care concept that was developed to increase the efficient allocation and use of limited resources (World Bank 1993). A basic (or essential) package of health care includes limited and proven cost-effective interventions that focus on health conditions and service gaps that disproportionately affect the poor and address a country's major causes of morbidity and mortality. The elements of a country's basic package of care provide a foundation for determining which types of clinical and public health services, treatments, and medicines will be provided at each health care level and the rationale for referrals to the next level of care. This information is critical for compiling the essential list of laboratory tests and services required to implement the interventions, and it contributes to the management of each target disease or condition.

Developing a national list of essential laboratory supplies and equipment

Once the ministry of health has established a list of essential laboratory tests and services that each level of health care will provide, the next step is to nationally adopt the methods or technologies needed to provide each test and service, including the most appropriate types and makes of equipment. All of these steps need to be completed before compiling the lists of essential equipment and the test kits, reagents, and commodities needed to run the equipment or perform tests. Many central medical stores do not have a national laboratory supplies list, and staff members do not know which items or how much of a particular item is required to carry out essential laboratory tests. As a result, many products may not be stocked or even available in the country. Therefore, the develop-

Box 47-1**Steps for preparing a national list of essential laboratory equipment and supplies**

- Review national health plans and policies on priorities for service provision and essential health care packages to identify target diseases and conditions.
- Review standard treatment and diagnostic protocols for each disease or condition for each health care level to identify where laboratory support is required.
- For each level of health care provision, make a list of all the priority disease areas and conditions in the health care package.
- Next to each disease area, list the essential tests required at that level of health care. (Note that some tests will appear against several conditions.)
- Use this information to summarize the list of laboratory tests and services to be provided at each level.
- Obtain a consensus on the technologies and test methods to be used at each level of health care.
- Identify and come to an agreement on the capital equipment items best suited to deliver these technologies and test methods.
- Write technical specifications for each item of capital equipment.
- Identify manufacturers or vendors to supply the capital equipment.
- Prepare a capital equipment list, specifying make, model number, and so on for the national catalog.
- Identify all proprietary consumables, test kits, and reagents required to operate and perform quality control for the equipment.
- Identify all nonproprietary consumables, test kits, reagents, and minor equipment items required to deliver essential laboratory tests and services.
- Compile a capital equipment list.
- Compile a list of laboratory consumables and supplies, disaggregating proprietary and nonproprietary items.
- Come to consensus with national medical stores on VEN/ABC classification for all laboratory items in the national stores catalog.
- Prepare guidelines for administrative and laboratory staff on how to use the catalog for ordering, including explanation of VEN/ABC classification.
- Print and distribute catalogs, or where feasible, maintain an online catalog.
- Update lists annually.

ment of a standardized list is essential for laboratories to function properly.

A national committee of experts should combine the lists for each level of care into one national list of essential laboratory supplies and equipment. Similar to the list of essential medicines, this list should form the basis for standardizing procurement and distribution of supplies and equipment, as well as for training. [Box 47-1](#) summarizes the steps to prepare such a list.

The list of essential laboratory supplies and equipment should contain a complete and clear description of each item, including stock number, type, standard pack size, and the most recent unit price. With more laboratories improving availability and use of automated analyzers for hematology, clinical chemistry, and immunology, combining the complete list of all proprietary items needed to operate each analyzer is useful because the items need to be procured and supplied to each laboratory as a complete package. Nonproprietary items should be grouped either by laboratory specialty (for example, microbiology, hematology, blood transfusion, chemistry, and immunology) or by category (for example, chemicals, culture media, test kits, antibiotics, glassware, minor equipment, safety items, and disposables), and use the stock or catalog number to identify the category.

Standardization of equipment and devices

The absence of equipment policy guidelines and lack of standardization of supplies can lead to wasteful overstocking. In many supply organizations, the number of different items of equipment and other commodities can be greater than the number of essential medicines. Although equipment is not generally subject to expiration, many examples are available of accumulating stocks of outmoded analyzers, instruments, and spare parts that have been ordered but that are no longer required or are not compatible with newer types of equipment.

The world is still not harmonized in several important areas, such as electrical and measurement systems. There are at least four different types of electrical plugs; two voltage systems, with 110 or 220 volts and 50 or 60 cycles per second; three different weight and volume measurement systems; and instructions in dozens of languages. In addition, for equipment such as gauges on gas containers, different companies may use different internal standards. These variations create immense problems for countries that have not managed to standardize their equipment or that receive equipment from a number of different donors.

The obvious strategy for tackling this problem is to standardize equipment and devices as much as possible. When

the standard types and brands have been chosen, a list of standard equipment with specifications should be prepared to serve as a guideline for the procurement department and for donations.

Countries without an equipment standardization policy will often have several brands of the same piece of equipment on hand, which creates difficulties in procuring spare parts, arranging for service contracts, or providing training for staff to use the equipment. For example, a survey of laboratories in Malawi identified ninety microscopes from sixteen different manufacturers, 63 percent of which had been procured by donors (Mundy, Kahenya, and Vrakking 2006). Although 50 percent of the microscopes in use were reported to be in good condition, none had ever received professional service or repair, and in fact, were ineffectual because of mechanical faults and fungal growth on the lenses, although unskilled staff used them for malaria microscopy.

47.3 Laboratory and medical commodity management systems

Efficient laboratory and medical commodity management ensures that appropriate commodities of adequate quality are reliably available, so technicians can perform labora-

tory tests for individual patient care and health care staff can treat patients appropriately. Managing commodities in any setting (public or private sector) and at any level (local, regional, provincial, or national) requires appropriate—

- Selection
- Quantification
- Procurement
- Quality assurance
- Distribution
- Inventory management
- Disposal

The following section deals with the practical aspects of managing these components, which, although similar in many ways to how pharmaceuticals are managed, have distinct differences.

Selecting diagnostics and supplies

As indicated in Section 47.2, ensuring availability of essential commodities requires that health managers and policy makers seek input from users (health care providers and laboratory staff) and review current information on national health policies and plans and budgetary constraints. The

Box 47-2

Developing guidelines for diagnosing HIV

Standard guidelines or algorithms for HIV testing must be developed and periodically updated at the national level. HIV testing guidelines should address the range of service delivery models to be used and the settings in which they are to be deployed.

Diagnosing HIV infection involves two different types of tests—both based on detecting HIV antibodies in the blood: (a) screening or initial tests and (b) confirmatory or supplemental tests. Initial tests identify antibody-positive specimens, whereas supplemental tests confirm whether specimens found reactive with a particular screening test contain antibodies specific to HIV. A variety of simple, instrument-free initial tests are now available. The test kits contain testing devices and all other supplies needed to perform the test. Specimens and reagents are often added by means of a dropper to the test device. The results are read visually. Most of these tests can be performed in less than twenty minutes and are therefore called rapid assays. In general, these tests are most suitable for use in testing and counseling centers and laboratories that have limited facilities and process low numbers of specimens daily.

The Joint United Nations Programme on HIV/AIDS (UNAIDS) and WHO recommend three testing strategies to maximize accuracy while minimizing cost. The choice of the most effective strategy depends on the prevalence of HIV in the sample population; the sensitivity and specificity of the test; and the objectives for performing the test—surveillance, diagnosis, or blood screening purposes.

One of two testing algorithms is part of the strategy. In a *parallel* testing algorithm, blood samples are simultaneously tested using two assays. In the *serial* algorithm, all specimens are tested by a first test that is highly sensitive. If the result is negative, the specimen is considered a true negative. Positive specimens are retested with a second assay that has a high specificity. If the second assay is also positive, the sample is considered a true positive. In both algorithms, discordant samples are retested immediately using the same tests to rule out error. If they remain discordant, the client is advised to come back in two weeks for another test to rule out HIV infection.

Sources: CDC/UNAIDS/WHO 2009; Walkowiak and Gabra 2008; WHO 2010a; WHO/EHT and UNAIDS 2009.

selection process involves reviewing the health problems or conditions to be prevented, tested for, and treated at facilities in line with the country's basic health care package; developing a list of commodities by level of health care; choosing appropriate packaging or unit sizes; and basing the selection process on relevance, proven efficacy and safety, performance in a variety of settings, quality, cost-benefit ratio, previous experience, location of manufacturer, and capacity of laboratory or facility staff.

WHO is creating model lists of devices and equipment for different levels of health facilities, from health posts to specialized hospitals, (http://www.who.int/medical_devices/innovation/health_care_facility/en/index1.html).

Diagnosics. Standard guidelines for disease testing must be developed at the national level, and national and local guidelines should be developed or updated in accordance with international recommendations. The responsible coordinating body (for example, the national AIDS control committee in the case of HIV diagnosis) may need to work with the national essential medicines committee to update the existing national essential medicines list, formulary, or both to include the diagnostic needs for a public health program. [Box 47-2](#) describes different strategies for approaching HIV testing.

Selecting a limited range and type of diagnostic commodity can lead to better availability, better staff knowledge (from buying reagents that staff are familiar with), more appropriate use, and lower costs. As with pharmaceutical selection ([Chapter 16](#)), sensible commodity and equipment selection is one of the most effective ways to save costs because it has both clinical and economic implications. The WHO Prequalification of Diagnostics Programme's recommendations should be followed to ensure that laboratories purchase affordable diagnostic commodities of assured quality that are appropriate for use in resource-limited settings (WHO/DLT 2011).

Ensuring safe and effective use of diagnostic services and commodities entails a range of interventions, including incorporating laboratory testing into diagnostic and treatment guidelines, developing and implementing standard operating procedures, and using job aids and other appropriate behavior-change interventions targeted at clinicians, diagnostic service providers, and care-seekers in the community.

[Box 47-3](#) highlights the high cost of using an unapproved diagnostic test for TB.

Disposable and reusable items. The national policy on the use of disposable or reusable items may differ from one country to another. [Table 47-1](#) lists important factors to consider in making a choice. If reusable products are chosen, buying products that can be autoclaved is essential. When buying disposable components for special equipment, ensuring that what is purchased will actually fit the equipment is important. Some equipment uses standard

Box 47-3 WHO urges a ban on inaccurate blood tests for tuberculosis

In 2011, in an unprecedented move, WHO issued an explicit “negative” policy recommendation against a widely used diagnostic practice and is urging countries to ban the use of commercial blood tests to diagnose active TB. These tests, which are manufactured in North America and Europe, have not been approved by any regulatory authorities yet are widely used in developing countries. Expert analysis shows that the tests produce either false-positive or false-negative results at least half the time, which obviously puts individual patients at great risk and negatively affects public health overall.

WHO estimates that more than a million of these inaccurate blood tests are carried out every year to diagnose active TB, especially in India and China. The tests are costly for patients, who can pay up to 30 U.S. dollars for them. “Blood tests for TB are often targeted at countries with weak regulatory mechanisms for diagnostics, where questionable marketing incentives can override the welfare of patients,” said Dr. Karin Weyer, coordinator of TB diagnostics and laboratory strengthening for the WHO Stop TB Department. “It’s a multimillion-dollar business centered on selling sub-standard tests with unreliable results.”

disposables; other equipment requires product-specific supplies.

In countries with limited funds for medical supplies, challenges with using disposable syringes and needles have been expensive and have caused stockouts. As a result, facilities sometimes sterilize disposable supplies and reuse them, which creates two problems: first, disposables are not meant to be sterilized, and the practice can result in air leakage and compromised performance; second, the method of sterilization is often inadequate. It is common to see a few “disposable” needles and syringes floating in a pan of water, with or without a lid, which may or may not have been boiling for some time. Boiling only disinfects; it does *not* sterilize. The same applies for soaking disposables in a disinfectant solution. Where stockouts are a problem, every health facility should probably keep a few reusable syringes and needles in reserve. This implies that a national policy for using only disposable or only reusable materials is not always practical.

The United Nations Children's Fund (UNICEF) and WHO tackled the problem of disposable reuse by creating “auto-disable” disposable syringes, which are made so

Table 47-1 Advantages and disadvantages of disposable and reusable items

Disposables	Reusables
Advantages <ul style="list-style-type: none"> • No sterilizer or running costs • No labor cost • Safer; less risk of disease transmission (if not reused) 	Advantages <ul style="list-style-type: none"> • Cheaper to purchase • Need less storage space • Less waste
Disadvantages <ul style="list-style-type: none"> • Usually more expensive • Bulky • Waste problem • Unsafe if reused (cannot be sterilized) 	Disadvantages <ul style="list-style-type: none"> • Need sterilizing equipment, running costs, and continuous supply of bags, autoclave control tape, and glove powder • Time-consuming to sterilize • Less safe; risk of transmitting disease if not cleaned and sterilized properly

they can be used only once. Although originally more expensive than ordinary disposables, auto-disable disposable syringes are now produced in such large numbers that the price difference has disappeared. The carton in which they are supplied serves as a safe disposal box, with an inner lining that can be burned easily. The plastic melts all needles and syringes into one block, which can be safely discarded. The WHO–UNICEF–United Nations Population Fund policy on injection safety states that all countries should use only auto-disable syringes for immunization (WHO 2006a).

Kits. Pharmaceutical and supply kits contain selected medicines and medical supplies in predefined quantities (Chapter 26). The quantity, range, and purpose of kits vary according to situation. Some comprise essential medicines and supplies targeting health care delivery at various levels. Others comprise special products to meet specific program needs or emergency situations. UNICEF offers a number of different supply and equipment kits, including surgical instruments and basic sterilization and resuscitation equipment. For example, the UNICEF obstetric surgery kit for health facilities to handle 100 deliveries includes instruments and equipment for fifty deliveries with complications and surgery and a midwifery kit that contains basic medicines, renewable medical supplies, medical equipment, and basic sterilization and resuscitation equipment. UNICEF considers its basic surgery set as the minimum investment for a health facility performing basic surgical activities such as simple appendectomies. Box 47-4 contains the list of medical supply items in the basic surgery set.

Diagnostic kits are also available; for example, the Global Drug Facility (GDF) supplies diagnostic TB test kits to facilitate and promote DOTS expansion in countries with a high TB burden. In many of these countries, much of the rural population has limited access to reliable microscopy services; therefore, the kits were designed specifically to meet the needs of lower-level laboratories at the periphery of the health system. Such laboratories often do not have reliable electricity or water supplies or the expertise, equipment, and materials required to prepare good-quality stains. Receiving

Box 47-4 Contents of UNICEF's Basic Surgical Instruments Supply Kit

- 4 Clamp, towel, Backhaus, 130 mm
- 2 Forceps, tissue, Allis, 150 mm
- 6 Forceps, artery, Halst-Mosq, 125 mm, cvd
- 1 Forceps, artery, Kocher, 140 mm, str
- 1 Forceps, dressing, standard, 155 mm, str
- 1 Forceps, tissue, Collin, 160 mm
- 1 Forceps, tissue, standard, 145 mm, str
- 1 Forceps, dressing, Cheron, 250 mm
- 1 Needle holder, Mayo-Hegar, 180 mm, str
- 1 Probe, double-ended, 145 mm
- 1 Retractor, Farabeuf, d-e, 120 mm, pair
- 1 Scalpel handle, no. 4
- 1 Scissors, Metzemaum, 140 mm, cvd, b/b
- 1 Scissors, Mayo, 140 mm, cvd, b/b
- 1 Bowl, stainless steel, 180 mL

all the supplies required for performing TB microscopy in one box facilitates easier ordering and distribution and ensures the availability of a complete set of standardized, high-quality commodities. Box 47-5 has more information about the GDF TB test kit.

WHO has starter kits for laboratories that want to introduce CD4+ or viral load testing technology that include equipment, reagents, controls, installation, training, and a maintenance contract. WHO also sells reagents and control kits to laboratories with existing CD4+ or viral load equipment.

Quantification

Both stockouts and expired items occur because of poor monitoring and quantification nationally and at the facility level. Regular monitoring of the consumption of supplies and equipment is necessary to plan for future requirements, allocate supplies, identify facilities that have higher-than-expected consumption of particular items, and avoid stockouts of other items.

Effective quantification helps—

- Avoid stockouts and ensure continuous availability of essential supplies
- Avoid waste caused by overstocking
- Make the best use of scarce resources and budget within the laboratory's means
- Facilitate central bulk purchasing
- Increase the effectiveness of an existing laboratory supply program budget

- Prepare and justify a budget
- Plan for new or expanding programs and policies
- Calculate emergency needs
- Resupply an existing supply network that has become depleted of supplies
- Estimate how much space, including refrigerated space, might be needed in the future

Three primary methods exist for quantifying how much to order—consumption, adjusted consumption, and morbidity (Chapter 20). The *consumption method* employs historical data on use that should be readily available in both the central medical store and individual laboratories. This method can be applied only to products that have been used in the past or to their direct replacements (for example, one test kit being replaced by an equivalent). In the *adjusted consumption method*, data from a laboratory service with a similar workload and numbers of patients is used as the basis of the quantification. The *morbidity method* is useful when reliable

Box 47-5

Global Drug Facility TB diagnostic kits

Although medicines are essential to TB prevention and cure, their proper use depends on the availability of reliable, quality-assured laboratory diagnosis of TB. Sputum-smear microscopy for TB diagnosis, an integral component of the DOTS strategy, is a relatively simple laboratory procedure but is often hampered by the lack of appropriate diagnostic equipment and sustainable supplies of high-quality laboratory consumables. Supplying kits to low-income countries, those undergoing health-sector reforms, or those in postconflict situations could facilitate procurement and control of laboratory supplies for TB microscopy. As a result of this initiative, the kits are now regularly available through the StopTB Partnership's GDF.

The GDF designed and field-tested four kits—

Consumables kit. Each kit contains 5 × 1 liters of methylene blue plus other consumables, such as slides, filter paper, immersion oil, and lens-cleaning tissue, sufficient to process and stain 1,000 sputum specimens.

Sputum collection containers. Each pack contains 1,000 screw-capped, leak-proof, disposable sputum collection containers. The kit is distinct from the laboratory consumables to permit independent ordering and direct distribution to health facilities for collection of sputum specimens. Specimens are then forwarded to the nearest microscopy center.

Equipment starter kit. The equipment starter kit is for setting up new microscopy sites or for equipping existing sites that do not have the basic requirements. Each kit contains minor equipment items (for example, slide storage boxes, a staining rack, forceps, spirit lamp, slide drying rack) required to process and stain sputum specimens for acid-fast bacilli. This kit plus the consumables kit provides a sufficient set of materials to set up a new microscopy center.

Microscope kit. Many countries have unreliable or intermittent power supplies. Therefore, the microscope kit contains one binocular microscope suitable for use both with a country's main electricity supply and with a mirror and external light source. Accessories in the kit include a 12-volt battery, a battery charger, a mirror unit, an external lamp for use with the battery and mirror unit, a surge protector, and spare bulbs. The battery can be charged either from the main electricity supply or from a solar panel.

The consumables kit is packed in two boxes compatible with the safety regulations for the different classes of chemical reagents. The other three kits are each packed in a single box, which facilitates easy handling, storage, and transport because the total volume of each kit is less than the collective volumes if all the items were purchased individually.

Source: Mundy, Kahenya, and Vrakking 2006.

laboratory data on workload and consumption are not available. A modification of the morbidity method can be used to calculate the quantity of laboratory supplies required for TB microscopy. This method helps national TB programs accurately forecast requirements for laboratory consumables based on simple TB case data that the program already collects.

Over time, use indicators can be developed along the lines of those that exist for medicines. An example of a use indicator would be the number of milliliters of stain needed for 100 TB sputum-smear tests or the number of rolls of cotton per month per 100 medical admissions. Such an indicator becomes a useful tool for comparing consumption among laboratories or facilities and for planning future requirements.

Procurement

Procurement of laboratory and medical supplies is not substantially different from procurement of pharmaceuticals (see Chapters 18–21). Good procurement practices depend on reliable and accurate quantification of needs, transparency in selection of suppliers and in management of bids or contracting, and quality assurance of commodities. For example, bidders should have sufficient knowledge of equipment maintenance, rather than being mere equipment traders. Equipment installation and maintenance training in addition to user training should be a condition of the sales contract.

Health managers often set priorities for the selection, procurement, distribution, and use of pharmaceuticals to analyze and control costs (see Chapter 40). A limited number of items are usually responsible for a large proportion of the budget, and these can be identified by ABC analysis. These “A” items should be procured through tender, and as with medicines, the tender should be restricted to prequalified suppliers to ensure quality. The same classifications used for pharmaceuticals can be adapted and applied to laboratory and medical supplies, not only to control costs, but also as a means to ensure that all vital items are supplied in a timely manner to minimize avoidable stockouts and service disruption. VEN categories (vital, essential, nonessential) are also useful for identifying those items that should never be allowed to run out of stock. Classifying items appropriately requires a detailed analysis. Uganda, for example, is developing the country’s first lists of essential laboratory and medical supplies, which include level of health care categories and VEN classification to facilitate ordering and procurement (Table 47-2).

Table 47-3 gives examples of how cost analysis tools for pharmaceuticals can be adapted for laboratory consumables and reagents.

For several items, such as cotton and dressing materials, local procurement may be more attractive than importation.

For example, both of these items are easy to manufacture and bulky to transport. In addition, they take up enough storage space to make frequent deliveries cost-effective; local producers can provide such deliveries more easily and cheaply. However, capital equipment for laboratories is specialized and invariably has to be imported from an industrialized country—purchasing inexpensive local alternatives is *not* advisable. Service contracts should be arranged at the time of purchase and their cost included in the total procurement cost—an important point because many ministries of health do not have funds available to service equipment.

In addition to the few items that are needed in large quantities, other items are needed in small quantities only. Many of these have to be imported, but neither their cost nor their volume makes putting them through the tender process worthwhile. In those cases, buying these items through international nonprofit suppliers such as the IDA Foundation and UNICEF is usually much more cost-effective.

Requests will always come to procure items that are not on the national list of essential supplies and equipment. For these items or for new items that have not yet been included on the list, or for new items with an expected low turnover, the procurement manager should ask the following questions before placing an order—

- Is the item really necessary? Can and will it be used in the place for which it is being ordered?
- Is a feasible, local alternative available?
- Are spare parts or a way to maintain the item consistently available?

Quality assurance

The quality specifications of pharmaceuticals and laboratory reagents are usually available in pharmacopoeias or from WHO. Unfortunately, such standardization rarely exists for supplies and equipment, making the preparation of detailed specifications for each item important. Many medical supplies (for example, gloves, catheters, and sutures) come in various sizes and materials. One of the most difficult aspects of managing supplies is to ensure that the specifications for the items (size, material, pack size) are all correct.

A national quality assurance system should ensure that products meet international quality and safety standards and technical specifications. In addition to a catalog or list of essential items, a separate set of technical specifications for the items must be developed. Technically qualified personnel must prepare these specifications, which must be as accurate and precise as possible. Accurate specifications are essential for the procurement department or tender board to be able to ensure the quality of the items. Without them, issuing the tender, evaluating bids, and claiming any damages in case of faulty products are difficult. Box 47-6 gives an example of technical specifications for one item.

Table 47-2 Example from the Ugandan Ministry of Health's Essential Health Supplies List

Item code	Description	Specification	Unit	Level of care	VEN
S3	Bandages and dressings				
S3.1	Adhesive tape	2.5 cm × 5 m	1	HC2	N
S3.2	Bandage, cotton W.O.W. hydrophilic	75 mm × 4 m	1	HC3	N
S3.3	Bandage, P.O.P	100 mm × 2.75 m	1	H	E
S3.4	Bandage, P.O.P	150 mm × 2.75 m	1	H	E
S3.5	Bandage, triangular cotton	136 × 96 × 96 cm	1	HC3	N
S3.6	Bandage, crepe, stretched	100 mm × 4.5 m	1	HC2	E
S3.7	Gauze, absorbent, ribbon	25 mm × 12 m	1	HC4	E
S3.8	Gauze bandage	7.5 cm × 3.65–4 m	12	HC4	E
S3.9	Gauze bandage	10 cm × 3–4 m	12	HC4	N
S3.10	Gauze pads, nonsterile	10 × 10 cm	100	HC4	N
S3.11	Gauze pads, sterile	10 × 10 cm	45	HC4	N
S3.12	Gauze pads, sterile	10 × 10 cm	100	HC4	N
S3.13	Gauze pads, sterile	10 × 10 cm	1	HC4	N
S3.14	Gauze swabs, abdominal	30 × 50 cm, nonsterile	10	HC4	V
S3.15	Gauze, hydrophilic	90 cm × 50 m, X-ray detectable	1	HC4	E
S3.16	Gauze, paraffin	10 × 10 cm	36	HC4	E
S3.17	Gauze, paraffin, medicated	10 × 10 cm	10	HC4	E
S3.18	Gauze, W.O.W, hydrophilic	90 cm × 50 m	1	HC2	V
S3.19	Plaster, adhesive elastic	100 mm × 4.5 m	1	HC4	N
S3.20	Plaster, adhesive elastic	75 mm × 4.5 m	1	HC4	E
S3.21	Plaster, adhesive, zinc oxide	75 mm × 5 m	1	HC2	V
S3.22	Wool, cotton	500 g	1	HC2	V
S3.23	Wool, cotton	200 g	1	HC2	N

HC = health center; H = hospital; V = vital; E = essential; N = nonessential; P.O.P. = plaster of paris; W.O.W. = woven without edges.

Regulatory agencies in resource-constrained countries often lack the capacity to conduct dossier evaluation of diagnostics, and many countries recognize efficacy and safety evaluations by another drug regulatory authority as “proxy evaluations,” particularly countries participating in the International Conference on Harmonization. To help resource-limited countries make decisions related to procuring diagnostic supplies, WHO evaluates the quality and operational characteristics of diagnostics for HIV/AIDS, malaria, and hepatitis B and C (WHO/DLT 2011). Manufacturers of acceptable assays are then eligible to tender for procurement through UN programs. This scheme makes quality-assured diagnostic-related reagents, consumables, and laboratory equipment, such as microscopes, available to purchasers in member countries at reasonable prices.

Countries are also using resources from the Global Fund to Fight AIDS, Tuberculosis and Malaria to purchase diagnostic and laboratory supplies and equipment to support the control of the three diseases (GFATM 2009). In addition,

organizations can use AIDS Medicines and Diagnostics Services, which is based at WHO, as a source of information and assistance related to procurement and supply management for HIV-related medicines and diagnostics, including HIV antibody test, CD4 cell count, and HIV viral load count. WHO also maintains a list of prequalified health equipment (http://www.who.int/medical_devices/innovation/en).

Chapter 19 includes more information on quality assurance systems.

Distribution

Items are often supplied to laboratories and health facilities because they happen to be in stock rather than because they are actually needed. When stock is adequate, identical quantities of an item may be sent to all laboratories or facilities without considering their particular needs, workload, or past consumption. As a result, some laboratories experience stockouts and cannot provide testing services while others have excess stock, eventually resulting in expired

Table 47-3 Adapted codes for cost analysis of laboratory supplies

Category	Pharmaceuticals	Laboratory consumables, test kits, and reagents
Level-of-use code: Indicates the level of health institution at which the item would normally be permitted for use		
H Health center level	Items for use through the health system at health center, district hospital, and central hospital levels. For all practical purposes, hospital outpatient departments will be regarded as H level.	Items for use through the health system at health center, district hospital, and referral (regional/central hospitals) levels.
D District hospital level	Items for use at district hospital and referral hospital levels only.	Items for use at district hospital and referral (regional/central hospitals) levels only.
C Central hospital level	Items for use at referral hospital level only.	Items for use at referral (regional/central hospitals) levels only.
Therapeutic priority code/diagnostic priority code: Identifies the therapeutic or diagnostic importance of each item using the VEN system		
V Vital items	<p>The items—</p> <ul style="list-style-type: none"> • Are potentially <i>lifesaving</i>, • Have <i>significant withdrawal side effects</i>, making regular supply mandatory • Are of major public health importance (for example, needed by many patients for treatment of serious or contagious diseases, needed to control epidemics, and so on) 	<p>The items—</p> <ul style="list-style-type: none"> • Are required to perform the tests listed in the essential test list to support the implementation of the basic health care package or ART monitoring • Are required to ensure that essential tests are performed in a quality manner (according to agreed standard operating procedures), making regular supply mandatory • Are required for tests used to diagnose, treat, or control diseases of major public health importance (as defined in the basic health care package and national health plan)
E Essential items	<p>The items—</p> <ul style="list-style-type: none"> • Are effective against less severe, but nevertheless significant forms of illnesses 	<p>The items—</p> <ul style="list-style-type: none"> • Are normally used to perform essential tests in the basic health care package or ART monitoring; however, absence of the item does not necessarily prevent the test from being performed
N Nonessential items	<p>The items—</p> <ul style="list-style-type: none"> • Are used for minor or self-limiting illnesses • Are of questionable efficiency • Have a high cost for a marginal therapeutic advantage 	<p>The items—</p> <ul style="list-style-type: none"> • Are used for additional tests not classified as essential for delivering the basic health care package or ART monitoring • Have a high cost for a marginal therapeutic advantage
Procurement system code: Specifies how items will be procured by national medical stores and by the user units		
A	<p>The items—</p> <ul style="list-style-type: none"> • Are generally required for large numbers of patients • Will routinely be procured and stocked by national medical stores • Include all H-level medicines <p>Where funds for procurement are insufficient, first priority will be given to the procurement and supply of V(ital) A-list items. If funds remain after securing such VA items, procurement of E(ssential) A-list items will then be initiated. Thus, ensuring the availability of A-list items is primarily the responsibility of national medical stores.</p>	<p>The items—</p> <ul style="list-style-type: none"> • Are generally required for large numbers of tests or patients • Will routinely be procured and stocked by national medical stores • Include all H- and D-level laboratory items <p>Where funds for procurement are insufficient, first priority will be given to the procurement and supply of V(ital) A-list items. If funds remain after securing such VA items, procurement of E(ssential) A-list items will then be initiated. B	<p>The items—</p> <ul style="list-style-type: none"> • Are generally required for limited numbers of patients • Will not be routinely procured and stocked by national medical stores • Require estimates of annual needs to be made well in advance by the hospitals and submitted as appropriate to national medical stores according to a preagreed time schedule • Require that payment be made in advance before procurement by national medical stores and subsequent supply to the hospitals <p>Thus, procurement of B-list items is primarily the responsibility of the user units.</p>	<p>The items—</p> <ul style="list-style-type: none"> • Are generally required for limited numbers of tests or patients • Will not be routinely procured and stocked by national medical stores • Require estimates of annual needs to be made well in advance by the hospitals and submitted as appropriate to national medical stores, according to a preagreed time schedule • Require that payment be made in advance before procurement by national medical stores and subsequent supply to the hospitals <p>Thus, procurement of B-list items is primarily the responsibility of the user units.</p>

items and waste. Stockouts of HIV test kits or other essential equipment such as syringes and needles to draw blood may require clients to return another day or go to another clinic. However, many clients who are turned away will not come back, and an opportunity for testing is lost. *Country Study 47-2* shows how Zambia dramatically scaled up the distribution of HIV test kits in a few years.

Preprinted standard requisition lists of laboratory and medical supplies organized by service level are useful tools to simplify the distribution of supplies and promote the rational use of limited resources. Such lists indicate to the end user the range of items that are available within the system, with specifications, pack sizes, and stock numbers. The lists can also include current unit prices. In addition, such

lists facilitate checking procedures for ensuring that facilities order and supply only approved items. The lists should specify the maximum amounts of all critical items to be kept in the health facility or laboratory. The amount ordered would then be the difference between the stock on hand and this maximum quantity. For facilities with four shipments per year, the maximum amount could reflect three months' use; for hospital wards or departments, a two-week supply is probably reasonable (see *Chapter 23*).

Putting together a requisition form that is clear to everybody remains a challenge: Should it list single units or packages (for example, one syringe or a box of 100, one bandage or a pack of twelve)? How should the list be organized—strictly alphabetically or by class? Should an alphabetical list

Box 47-6 Sample product specifications

Tricot tubular bandage

- *Elasticity:* Three or four times the original width. Good resistance to lading in both directions. Keeps elasticity after washing or stretching.
- *Components:* Knitted jersey tube, without seam.
- *Material:* 100 percent cotton, unbleached.
- *Size selected:*
 - Bandage, tricot, tubular.
 - Width: approx. 5 cm.
 - Length: approx. 25 m.
 - Disposable.
 - Nonsterile.

Packaging and labeling:

- Primary packaging: Unit of use.
- One tricot bandage in a plastic bag.
- Labeling on the primary packaging:
 - Name and/or trademark of the manufacturer.
 - Manufacturer's product reference.
 - Type of product and main characteristics. If the packaging is not transparent, it must bear a diagram (preferably actual size) showing the essential parts of the product and indicating the position of the product in the packaging.
 - Lot number prefixed by the word "LOT" (or equivalent harmonized symbol) (if applicable).
 - Expiry date by year and month, prefixed by the word "EXP" (or equivalent harmonized symbol) (if applicable).
 - The words "for single use" (or equivalent harmonized symbol).
 - The words "destroy after use" (if space allows).
 - Number of units per primary packaging (if applicable).

- Information for particular storage conditions (temperature, pressure, light, humidity, etc.), as appropriate (or equivalent harmonized symbol).
- Manufacturer's instruction for use.
- Alternatively, the instruction for use can be indicated on a separate insert.

Secondary packaging: Protected unit.

- Ten tricot bandages in a plastic bag.
- Labeling on the secondary packaging:
 - Labeling to be the same as primary packaging.
 - Extra information required:
 - Number of units per secondary packaging.

Weight/volume/dimensions:

- Estimated weight: 0.500 kg
- Estimated volume: 2 cdm

Instructions for use:

- Tubular bandage applied under plaster of Paris bandage to protect the skin.
- This dressing should fit the limb snugly but not tightly and without any fold.
- If needed, it can be used as a sterile item in surgery after steam sterilization.
- This size has been chosen as being the most commonly used.
- Provision for hospitals that constantly use this item (see plaster of paris).

Conditions for stock:

- Keep under dry conditions.

Country Study 47-2 Scaling up HIV testing in Zambia

The objectives of the Zambia Voluntary Counseling and Testing Services (ZVCTS) are to coordinate the implementation of voluntary counseling and testing (VCT) services, train adequate numbers of VCT staff, review and harmonize HIV testing protocols, streamline information systems, improve tracking of specimens sent for testing, and continue research activities with the virology laboratory.

Zambia has scaled up its HIV testing and counseling services substantially since 1999; ZVCTS reports that the number of VCT sites had increased from 22 to 650 by the end of 2006. ZVCTS data show that the number of clients tested increased from 27,348 in 2002 to 337,760 in 2006—representing a twelvefold increase in the number of test kits that needed to be stored and distributed in just four years.

In 2000, six different rapid HIV test kits were used in Zambia because of the lack of harmonization across donors and facilities. Some donated test kits were either not included in the national HIV testing protocol or were inappropriate for the technical capacity and local situation. In 2001, after a literature review and consultation with kit users, stakeholders, and regional laboratory technicians, the country adopted a nationwide testing protocol. In the absence of reliable information, each newly established VCT site estimated how many new kits it needed; these numbers were consolidated and adjusted based on population, epidemiological data, and projected coverage.

ZVCTS and the Ministry of Health recognized early on that building capacity at the district level is essential to support scale-up of HIV testing and counseling services and to sustain programs in the long term. Strategies to transfer technology and skills to the district level and build local ownership began in 2002 and included estab-

lishing a pull system for ordering, developing tools as part of the commodity management information system, and training staff to quantify their commodity needs and prepare accurate reports. The information system is actually maintained at the district level; the district officer is responsible not only for aggregating data and generating and forwarding reports to ZVCTS, but also for providing feedback to facilities on a monthly basis. This monthly report compares each site's activities with other similar facilities and aims to motivate staff to maintain or improve their performance.

Facilities no longer need to collect their test kits and supplies from the Medical Stores Limited (the central medical store), because it delivers directly to the HIV counseling and testing sites. A long-established system is used for returning short-dated stock for redistribution. In 2005, mobile HIV testing and counseling units began offering services, and demand for services is reportedly high, with some sites reporting that mobile services are contributing more than 50 percent of the clients tested. Building the commodity management capacity of districts has been key to supporting the rollout of this new service delivery model, because mobile units get their commodities from and report consumption to the district level.

In 2006, stakeholders, including the National AIDS Council, the Zambia HIV/AIDS Prevention, Care and Treatment Partnership, and the Ministry of Health, developed and approved a new national HIV testing algorithm. The new standard test kit does not require refrigeration and is easier to use. The phased implementation of the new algorithm began in 2007 with support for managing the new commodities coming from new forms, standard operating procedures, and training.

Source: Walkowiak and Gabra 2008.

mention *Bandage*, *crepe*, or *Crepe bandage*? If the list is by class, should all plastics be listed together or classed as disposables, nondisposables, or something else?

The best solution for the central store and highest-level health facilities is a full list of items organized in groups and using the common pack size of items as the counting unit. For the lower levels of the health care system or for individual hospital wards, a short alphabetical list and standard order form can be used, with single items as the counting unit. Whatever the system, it needs to be logical, and the form should be tested with some end users.

Inventory management

Good management of storage and inventory involves monitoring expiration dates, inventory levels, unexplained losses (leakage), and storage conditions such as light, temperature, and sanitation, which are particularly critical for test kits and diagnostic reagents (Chapter 44). Computerized or manual records are required to control inventory effectively. These records include basic records such as stock or bin cards, monthly consumption records, inventory control forms, and a list of expired supplies (Chapter 23). The pro-

cess should be supported by an information system for performance monitoring (Chapter 49).

The following conditions need to be considered when storing supplies, especially for the laboratory—

- Restricted access to the laboratory to authorized staff
- Cleanliness of benches and shelves
- Appropriate methods for disposal of waste
- Humidity
- Temperature requirements and monitoring
- Adequate refrigerated space maintained at optimal temperatures (+2 to +6°C)
- Adequate freezer space (at -20°C and -70°C)
- Emergency power supply
- Lighting (for example, store out of direct sunlight)
- Appropriate shelving and cupboards

Safe disposal

The safe disposal of laboratory waste and other contaminated materials is of prime importance.

Although most medical and laboratory waste is similar to domestic waste, 10 to 25 percent is infectious or hazardous. These items represent dangers to both laboratory and health facility staff and the community. In addition, the uncontrolled dumping of solid, liquid, chemical, and biological medical and laboratory waste threatens the environment.

Laboratory and medical waste includes—

- Sharps
- Chemical waste—expired reagents and consumables
- Human anatomical waste
- Blood and body fluids
- Solid waste such as cotton wool, tissue paper, culture plates with used media, used blood-giving sets, empty blood packs, used test tubes, and used glass slides
- Laboratory specimens
- Equipment effluent

Incineration is the most widely used technology to dispose of medical waste, but other methods are available and may be more appropriate depending on the context. WHO has published detailed guidelines on medical waste management (Prüss, Giroult, and Rushbrook 1999) and has a website with information on disposing of hazardous medical and laboratory waste (http://www.healthcarewaste.org/en/115_overview.html).

47.4 Equipment management

Countries should develop an equipment policy that includes a maintenance plan, a budget for equipment maintenance (that is, for repairs and spare parts), and guidance on equip-

ment donations. Laboratory or health facility managers must have technical oversight of equipment management and monitor related activities. They should assign responsibilities and ensure all staff members are trained on basic equipment management requirements.

Criteria for selecting equipment

Managers must select capital laboratory and other equipment based on the proposed use of the equipment, the equipment's fit with the service provided, its performance characteristics, facility and infrastructural requirements, cost, availability of reagents and consumables, ease of operation, and input from users such as health care providers and laboratory staff. In addition to input from users, equipment should be selected in consultation with maintenance staff.

WHO's Regional Office for Africa and partners published a document that provides equipment specifications that may be useful when selecting equipment (WHO/AFRO 2008a). In addition, WHO has published a list with fact sheets of core medical equipment (WHO/EHT 2011a).

Equipment acquisition

Equipment may be acquired through direct purchase, lease, or rental. Expertise is required for the purchase and maintenance of medical equipment. Consulting experts at an early stage of the procurement process may prevent problems later.

Procuring equipment centrally is often best. If many of the same items are required, then bulk procurement may be the most cost-effective and practical approach. Regardless of how the equipment is acquired, laboratories and health facilities must consider the responsibilities of the manufacturer or distributor and the conditions of the sales contract, customer support plan, and maintenance contract.

The manufacturer or distributor must guarantee—

- Provision of all reagents, consumables, and culture materials at an affordable and sustainable price (distributors usually offer reduced prices for high-consumption items, so bulk or central ordering may be an advantage)
- A reasonable expiration date on all reagents and consumables
- Acceptable shipment conditions and assistance with customs logistics to avoid damage to equipment or deterioration of the reagents
- Installation of the equipment, staff training, and ongoing technical support
- Provision of a parts manual and an operator's manual
- A trial period for the equipment, after which it can be returned if it is not deemed suitable

- Ongoing maintenance and repairs, including emergency services

The sales contract must be reviewed carefully before completing the purchase. The contract should clearly stipulate all of the preceding manufacturer or distributor responsibilities, and a customer support plan and maintenance contract should be available for all capital equipment. Maintenance contracts are essential for all automated equipment, such as hematology and chemistry analyzers, CD4 counters, automated blood culture and liquid TB culture systems, such as the Mycobacteria growth indicator tube and Cepheid GeneXpert® TB assay, and biosafety equipment, which should also include maintenance contracts for biological safety cabinets.

Before installation, confirm who is responsible for installation and verify that physical requirements have been met, including safety checks of electrical connections, space, ventilation, water supply, and ambient temperature. Upon equipment receipt, verify package contents. The new equipment should not be used before it has been properly installed; the manufacturer should install capital equipment.

Equipment inventory management

The basis for effective inventory management is an up-to-date and complete list of all equipment in a health facility's inventory. The minimum information to be on the list includes the manufacturer, the model, the identification number, the power requirements, and the equipment's physical location in the facility. Other minimum information is listed in WHO's manual on the topic (WHO/EHT 2011c).

After the inventory list has been compiled, it needs to be updated whenever information changes, such as purchase of a new piece of equipment or movement of an existing item. In addition, the facility engineer, or whoever is responsible, should conduct an annual audit to make sure the list is accurate. The inventory list can then be used as a resource to develop budgets, identify human resource and training needs, and manage service contracts, among other activities (WHO/EHT 2011c).

Equipment maintenance and service

After installation, establish an inventory record for the equipment; define the conditions for the equipment's use; develop and implement protocols for calibration, performance verification, and operating procedures; establish a maintenance program; and provide training for all operators. New equipment must be validated and calibrated before use.

Equipment maintenance programs ensure equipment safety, fewer work interruptions, lower repair costs, longer

equipment life, and greater confidence in the reliability of test results. Maintenance involves systematic and routine cleaning and adjustment or replacement of instrument and equipment parts. Maintenance should be performed daily, weekly, or monthly, depending on the equipment. Laboratory or facility managers should schedule regular service for all key equipment by the manufacturer or representative. Having all items of the same model (for example, microscopes) serviced at the same time is efficient. Local biomedical service technicians can maintain basic equipment items such as water baths.

If a piece of equipment malfunctions, users should check the manufacturer's instructions, determine the source of the problem—which could be, for example, the sample, the reagent, the equipment, the electrical supply, or the water supply—and make one change at a time to try to diagnose the source of the problem.

Retire equipment when experts indicate the item cannot be repaired or is outmoded and should be replaced with a new model. Updating equipment prevents inaccurate test results, frees up valuable space, and reduces hazards. Any usable parts from the old equipment can be salvaged, taking into account any biohazards. Safety disposal procedures must be followed for any parts that cannot be reused.

47.5 Donations of equipment and other commodities

Donations of commodities and equipment to laboratories and health facilities must be handled carefully, ensuring that donations are based on need expressed by the recipient country. When donors are involved in providing medical supplies and equipment, problems related to the lack of standardization and to maintenance may arise. First, many donors want to buy the equipment, leaving the recipient to solve the problem of paying for installation, maintenance, and recurrent costs. Second, many donors are not sensitive to the recipient's technical requirements. Therefore, storerooms in many countries have equipment that has never been used or has broken down and cannot be repaired because of a lack of spare parts and local service facilities or a lack of instructions in the local language. Third, a donor's policy may differ from the national policy, for example, in relation to the use of disposable syringes. In general, donated equipment contributes to the lack of equipment standardization in developing countries.

All donated capital equipment and diagnostic commodities must comply with the quality standards of both the donor and the recipient country, and insisting that donated diagnostic commodities have a shelf life of at least one year is reasonable. Any instructions should be in English or in the country's national language that is easily understood by

laboratory or facility staff. Whenever possible, the donor agency pays for international and local transport, warehousing, and port clearance as well as a maintenance contract. Adequate supplies of consumables should accompany donations of capital equipment.

Most of the principles of pharmaceutical donations, as presented in Chapter 15, apply equally to supplies and equipment. Nevertheless, a few specific issues regarding equipment donations should be kept in mind (WHO/EHT 2011d). Governments should develop local policy, guidelines, and regulations to govern health care equipment donations, if they do not already exist. The most important issue is the provision for maintenance and spares. As mentioned, it should be the first criterion used in choosing equipment for procurement; it should also be the first argument for acceptance of a proposed donation.

In its guidelines on health care equipment donations, WHO (2000) outlined the four core principles of equipment donations—

- A health care equipment donation should benefit the recipient to the maximum extent possible.
- A donation should respect the wishes and authority of the recipient and conform to existing government policies and administrative arrangements.
- No double standard should exist in quality: if the quality of an item is unacceptable in the donor country, it is also unacceptable as a donation.
- The donor and the recipient should communicate effectively, with all donations resulting from a need expressed by the recipient and following a plan formulated by both parties. ■

ASSESSMENT GUIDE

Management

- Does a national laboratory policy exist?
- Have national lists of essential medical supplies and equipment been officially adopted and distributed countrywide?
- Is there an official committee whose duties include updating the lists?
- Have the lists been updated and distributed countrywide in the past five years?

Selection

- How many items does the list of essential medical and laboratory supplies and equipment contain? How are the items classified?
- Is the list divided into levels of health care? How many items exist for each level?
- What equipment, testing kits, reagents, consumables, and specimen collection supplies are needed to perform specific diagnostic tests, such as HIV diagnosis, monitoring of HIV treatment, TB diagnosis, identification of drug resistance, and so on?
- Does the laboratory equipment require unique commercial brands of testing reagents or kits?
- Does the equipment need specialized preventive maintenance and repair?
- Are the parts accessible?
- Does a service agreement exist?

Procurement and distribution

- Is procurement in the public sector limited to items on the list?
- What is the ratio of the value of items from the list procured in the public sector to the total value of laboratory supplies and equipment procured in the same sector?
- What mechanisms for procuring laboratory reagents, test kits, and consumables currently exist at the national level, the facility level, or both?

- If no system exists, can procurement be integrated into the existing medicine or laboratory supply system?
- If the procurement of laboratory supplies and diagnostics is to be decentralized to lower levels, do the staff have the skills, finances, managerial support, and information to carry out procurement functions successfully?
- Do equipment and supply donations comply with the national lists?
- Do any of the commodities have special storage requirements? Is the freezer, refrigerated, or cold storage space adequate? Is the electricity supply reliable?
- Is a procedure in place for a cold chain to maintain and monitor special storage temperatures from delivery of the commodity to storage and use? Are supplies to transport heat-sensitive commodities, including cooler boxes and icepacks, adequate? What system is in place to monitor freezer, refrigerator, and storeroom temperatures regularly?
- How much room is needed to store all the commodities between deliveries? Can more storage space be found or more frequent deliveries be scheduled? If scaling up is planned, where will additional commodities be stored?

Human capacity

- Are staff trained to handle specimens, equipment, reagents, test kits, and other consumables safely and appropriately?
- Do they need training updates for new tests or procedures? Are approved, written standard operating procedures available and followed for (1) use and maintenance of each item of equipment, (2) preparation of reagents, (3) procedures for performing each test, and (4) safety practices?
- Are supplies available to safeguard the health and safety of the staff performing HIV testing?

SUMMARY

Monitoring refers to the ongoing review of the progress toward completing program activities and achieving objectives. It allows corrective action during program implementation. Monitoring systems focus on inputs and short-term outputs and should be an integral part of day-to-day management.

Fully developed monitoring systems, which may be established in phases, typically consist of a combination of four methods—

1. Supervisory visits for continual, informal monitoring of workplan implementation and progress toward program plans
2. Routine reporting of selected data through the pharmaceutical management information system (PMIS)
3. Sentinel sites for more detailed reporting when new initiatives or rapid expansion requires more intensive monitoring
4. Special studies whenever an implementation problem or planning question requires specific additional information

Performance indicators can facilitate tracking a program's progress toward established performance targets or milestones and help compare this progress to that of other programs. Indicators should meet the criteria of

clarity, usefulness, measurability, reliability, and validity, as well as acceptance by key stakeholders.

To be effective in improving program performance, monitoring requires—

- Clear communication of plans and targets
- Regular review and sharing of monitoring results
- Follow-up to provide feedback and take corrective action

Evaluation is commonly discussed along with monitoring as part of an overall strategy. It refers to the periodic analysis of a program's progress toward meeting established objectives and goals. Evaluations fall into three categories, which differ in timing and purpose—

- Needs assessment (situation analysis, see [Chapter 36](#))
- Formative evaluation (midterm review)
- Summative evaluation (final evaluation)

Evaluations use data collected through the ongoing monitoring system, supplemented by document review, interviews, additional data collection, and field surveys using standard pharmaceutical assessment indicators. Strategies for monitoring and evaluation are normally developed in parallel to ensure a comprehensive, unified evaluation strategy.

48.1 Definitions of monitoring and evaluation

Monitoring refers to reviewing, on a continuous basis, the degree to which program activities are completed and performance targets or milestones are being met. Typically, monitoring focuses on tracking program inputs such as funding, staff, facilities, supplies, and training. As such, monitoring is part of the operational management of a program. Monitoring also tracks outputs such as availability of medicines and supplies, number or percentage of trained staff, and quality of services. Systematic monitoring of inputs and outputs can help identify potential problems and corrective actions to be taken during program implementation.

Evaluation refers to analyzing progress toward meeting established objectives, goals, or results. It provides feedback on the outcomes of activities, such as changes in prescribing behavior and health care-seeking behavior, whether plans have been met, and the reasons for success or failure. Evaluation should also provide direction for future programmatic plans. Evaluation methods may be used to carry out a situation analysis or a needs assessment as the first step in designing an appropriate intervention to improve program performance. Evaluation takes a longer-term perspec-

tive and concentrates on the strengths and weaknesses of the program strategies.

[Country Study 48-1](#) illustrates the monitoring and evaluation system put into place for pharmacy and laboratory services in a new antiretroviral therapy (ART) program in Kenya.

This chapter is concerned mostly with monitoring pharmaceutical supply systems. Monitoring is closely linked with the pharmaceutical management information system, described in [Chapter 49](#). Evaluation, which is closely linked with systematic assessment ([Chapter 36](#)), is discussed briefly at the end of this chapter.

48.2 Monitoring issues

Systematic and ongoing monitoring is essential for ensuring that program performance is on track, for improving performance, and for achieving long-term program goals and results. Unfortunately, during program implementation, attention can easily get focused on specific technical activities at the expense of monitoring activities. Too often, monitoring is done casually, without a clear plan, without a

clear link to program objectives and targets, and without any effort to use monitoring results to improve program performance.

Monitoring should be an integral part of the day-to-day management of pharmaceutical supply systems. Managers of pharmaceutical supply programs are concerned with getting the most out of scarce resources. Meeting this goal means making the program as efficient and as effective as possible. Therefore, managers need to generate current, reliable information to use in making decisions on program performance and operations.

The monitoring system should center on key program activities and objectives. To operate efficiently, it must focus on a small number of specific, clearly formulated monitoring issues that are directly related to performance and are generally taken from program plans, objectives, and targets.

Monitoring is intended to—

- Determine whether activities are being carried out as planned
- Measure achievement of targets
- Identify implementation problems to initiate corrective action
- Identify and reinforce good performance
- Identify and strengthen weak performance
- Help target supervision toward problem areas
- Assess whether activities are having their expected effect
- Assess long-term trends
- Contribute to reviewing and revising program priorities and plans

Funding agencies and donors may impose their particular reporting requirements for their own monitoring and reporting purposes. For the most part, these reporting requirements do not deviate much from standard reporting needs. The advent of international funding initiatives, such as the Global Fund to Fight AIDS, Tuberculosis and Malaria, has been accompanied by increased attention to the issue of ensuring accountability in the use of funds and achievement of program goals (see References and Further Readings). Unfortunately, specific reporting requirements, performance indicators, and targets may differ significantly between donors and funders, thereby increasing the monitoring and reporting burden of funding recipients.

Ultimately, monitoring is meant to improve the long-term performance of the program and individual staff members.

48.3 Monitoring methods

How are monitoring activities organized, and where does monitoring information come from? Information required for monitoring can be obtained through a combination

of four formal and informal methods: supervisory visits, routine reporting, sentinel reporting systems, and special studies.

Supervisory visits

Supervisory visits support the performance of individual staff or health care workers, provide some on-site, in-service training, and represent an important method for informal but direct monitoring of program implementation (see [Chapter 51](#)).

Supervisory visits should reinforce routine reporting requirements. Such visits may include checking the quality of entries on standard reporting forms, such as inventory management forms (for example, stock cards). Visits sometimes involve the collection of information, such as the availability of specific medicines, for special studies.

Routine reporting

The core of a monitoring system for pharmaceutical supply programs is the routine reporting that is accomplished through the pharmaceutical management information system. A PMIS consists of record-keeping documents; data reporting forms; feedback reports; and procedures that govern the availability, use, and flow of information up and down the system, including tracking the availability and use of medicines.

[Chapter 49](#) provides a practical overview and specific guidance on designing an effective PMIS. It emphasizes the need to build on existing recording and reporting systems, to involve users in developing the system, to use appropriate data collection methods, to integrate the PMIS with other information systems, to take advantage of practical analysis methods, and to communicate information promptly and clearly.

Depending on the program's objectives, routine reporting focuses on the availability of supplies at different levels in the system, finances, procurement and supplier performance, training, quality assurance, and medicine use. Clear presentation of reported information, feedback to those providing the information, and follow-up action contribute to the effectiveness and usefulness of the reporting system. Reports should include both quantitative information and brief descriptions of processes, key problems, and proposed follow-up actions. Some countries are now using mobile telephones to transmit routine monitoring data to a central location for timely analysis or even analyzing data at remote locations. For example, the National Malaria Control Program in Malawi is using a mobile phone-based tool to collect and analyze data on malaria commodity availability and case management indicators during supervisory visits to facilities. This method allows supervisors to identify and address problems quickly.

Country Study 48-1**Developing a monitoring and evaluation component for a new ART program in Mombasa, Kenya**

In countries that are introducing and scaling up ART programs, a challenge is improving ART access quickly while at the same time working to strengthen systems that support long-term quality care. In 2002, the government of Kenya, with technical assistance from various partners, initiated an ART program in four health facilities in Mombasa. The overall goal of the Mombasa ART program was to reduce HIV/AIDS-related morbidity and mortality and to improve the quality of life of people living with HIV/AIDS and their families in the Mombasa district. The program's specific objectives were to—

- Improve the capacity of HIV/AIDS clinics, laboratory, and pharmacy services in selected public health facilities in Mombasa to provide HIV/AIDS comprehensive care, including ART
- Provide ART to 300 patients over a period of five years in accordance with eligibility criteria
- Sensitize communities and strengthen support groups' knowledge of comprehensive HIV/AIDS care, including ART

A monitoring and evaluation system was incorporated into the program design to provide quality information to help decision makers take timely corrective actions and ensure that the program is achieving its goal and objectives.

The key features of the system were to—

- Encourage analysis and use of information by using well-defined indicators rather than *only* reporting. The system stresses the use of data at the point where data are collected.

- Monitor all aspects (input, process, output, and quality) of the program, including support systems (for example, availability of human resources and enhancement of their capacities).
- Build on the existing information system to minimize the additional burden on service providers.
- Integrate feedback mechanisms at all levels.
- Ensure system simplicity to facilitate staff training on its modification and use.
- Make sure the system is functioning manually before computerizing it.

The diagram opposite illustrates the processes and timing of the monitoring and evaluation system throughout the life of the program (five years).

Baseline status: Result of the pre-implementation assessment formed the baseline status.

Activity monitoring: Pharmacist and laboratory staff responsible for the ART program monitored the activities during the week and reported to their supervisors at the end of *each week*.

Supportive auditing: At the *end of each month*, the supervisor, together with the respective responsible staff members, performed an audit of the activities and resources and discusses problems and solutions.

Review with pharmacy/laboratory technical partner: At the end of each quarter, all staff related to ART (pharmacy and laboratory) and technical partner staff jointly reviewed the activities and progress and discussed problems and solutions. Quarterly indicators were used as a basis for discussion.

The biggest failures in routine reporting systems are overdesign and underimplementation. Collecting too much data usually results in too little analysis. Also, reporting systems that are overly complex result in poor compliance with reporting requirements. Implementing an information system takes time and money. Moreover, the more complex the system is, the greater is the need for qualified and trained staff, time, and money to make it function.

Therefore, the content of routine reporting systems should be limited to the minimum amount of information that the typical reporting unit can reasonably be expected to provide and that can routinely be analyzed for decision making and feedback purposes. Identification of key data requirements is the result of a prioritization exercise that considers the critical information needs of all components of the pharma-

ceutical supply cycle. The simple rule is: do not collect what you cannot use.

Sentinel reporting systems

When routine reporting systems are properly collecting only the minimal essential information, a great deal of potentially useful information is not included. To supplement routine reporting, sentinel reporting systems can be useful.

A sentinel reporting system consists of a carefully selected sample of health facilities or dispensaries that are given greater recording and reporting responsibilities. For example, in a country with forty districts, six districts may be selected as sentinel districts. Within each district, a sample of health facilities from each level may be selected. Sentinel

Review with all technical partners: All technical assistance partners participated in the biannual review. Quarterly indicators were used as a basis for discussion.

Midterm evaluation: The technical partner conducted a midterm review of activities related to pharmacy and laboratory and also participated in the midterm evaluation jointly conducted by all the partners with the

Kenyan Ministry of Health (MOH). Quarterly indicators were used as a basis for discussion.

Final evaluation: The pharmacy/laboratory partner conducted a program-end review of related activities and participated in the final evaluation jointly conducted by the other technical assistance partners and the MOH.

reporting differs from routine reporting in the amount of information collected, the frequency or promptness of report submission, and the level of accuracy demanded.

Sentinel reporting is common in disease control programs such as HIV/AIDS prevention, control of diarrheal disease, and treatment of sexually transmitted diseases. Sentinel sites provide a relatively economical means of collecting up-to-date, detailed information on disease incidence, antimicrobial resistance, and responses to program interventions.

Need for sentinel reporting. A sentinel reporting system is most useful when a system is undergoing rapid or substantial change, such as when a new treatment or public health intervention is being introduced. Sentinel reporting helps assess the implementation and short-term effect of changes or interventions such as—

- Introduction of a major new computerized stock management system
- Transition from a central medical stores system to a decentralized system
- Introduction or scale-up of a treatment program, such as ART or artemisinin-based combination therapy

Sentinel reporting is particularly important for new or expanded HIV/AIDS treatment programs where donors may have many new record-keeping requirements and where many unknowns may exist regarding how the patients will be integrated into the health system. Policy makers and managers can recognize and react more quickly to unex-

pected or undesirable issues related to program implementation, and information on the availability of antiretrovirals, patient adherence to medication regimens, and other key variables may be collected and rapidly reported.

Whereas the routine reporting system answers only the questions it asks, a sentinel reporting system can be useful to detect unexpected or unintended outcomes. However, recording and reporting formats developed for sentinel sites sometimes prove sufficiently useful and convenient to be incorporated into routine reporting.

Selection of sentinel sites. The level and number of health units in a sentinel system depend on the organization of the health and pharmaceutical management systems, the monitoring objectives, and the overall diversity within the country. If, for example, a country has only one central medical store and a handful of regional stores, they would all be included in sentinel reporting requirements. Generally, at least six units should be included within each level. For example, a sentinel system could include six districts, six district hospitals, and six health centers within each district (thirty-six health centers total). Larger numbers of units are needed in more populous, more organizationally complex, or more diverse countries.

Selection of specific districts, locations within districts, or health facilities is generally purposeful, not random. Selection is aimed at achieving diversity rather than statistical representativeness. The selected sites should represent the range of facilities that serve culturally, linguistically, and geographically diverse groups; the distribution of ministry and nongovernmental facilities; and accessibility.

Staffing levels at sentinel sites should be sufficient to handle additional recording and reporting requirements, which may mean hiring extra staff at some sites. Extra incentives are sometimes given for prompt, complete, accurate reporting, although this practice should be avoided. Prompt feedback of information can be sufficient to motivate staff to respond quickly and reliably. Because cost is a consideration, relatively inaccessible sites are usually chosen as sentinel sites, even at the price of omitting cultural or geographic diversity; however, if these inaccessible sites are particularly likely to suffer shortages of medicines and delayed delivery, including some of them in the sentinel system may be worth the effort, especially if there is an intent to make changes in the system to address these deficiencies.

Information required from sentinel sites. Sentinel sites may differ in the amount of information recorded, the amount of information routinely reported, or the speed at which the information is processed. Additional recording and reporting requirements should be based on the reasons that the sentinel system was established, such as monitoring a new stock management system, assessing transition to a supply agency system, or evaluating the effect of a user-fee program.

Most of the principles used in designing a PMIS apply to sentinel reporting: being selective in deciding which indicators to collect, choosing appropriate data collection methods, and building on existing recording and reporting systems whenever possible. In some instances, putting in computers at sentinel sites may be appropriate (or choosing sites that already have computer capability), even if national computerization is not currently foreseen.

Working with sentinel sites. Establishing a system of sentinel sites nearly always requires training key staff at the sites and making frequent supervisory visits, especially in the beginning. Sites may require additional forms, registers, stock records, and other materials.

Finally, a system of sentinel sites is generally maintained for a specified period of time, perhaps for the first several years of a transitional program. After that, these sites may revert to normal reporting status.

Special studies

Sometimes managers and planners need to gather information that is not available from routine or sentinel reporting. Examples of topics that may warrant a special study include—

- Names, dosage forms, and values of medicines purchased by individual health units
- Names, dosage forms, and value of recently expired medicines
- Reasons for expiration of pharmaceuticals
- Average percentage of essential medicines available

- Level of patient adherence to prescribed treatment
- Level of prescriber adherence to standard treatment protocols

Facility or population-based survey and research methods are typically used to obtain this type of information. These methods may involve expenses that are not considered in regular recurrent operating costs and may require specialists to design and carry out, but many questions can be answered with relatively simple methods and at little additional cost. For example, [Chapter 40](#) describes how ABC analysis, lead-time analysis, expiry-date analysis, and pipeline analysis can help improve performance and reduce costs.

Both managers and staff should be involved in the design and implementation of these studies, as well as in the analysis and interpretation of results. However, it is also the manager's role to identify when additional information is needed and to use experts to help design and conduct these special investigations, so that resources are not wasted on a useless effort.

In-depth interviews, structured observation, focus group discussions, or other qualitative methods (see [Chapter 28](#)) can be used to explore behavior, attitudes, practices, and causal factors.

Rapid assessments are small-scale studies that include a survey of sample facilities, use of selected core indicators, and interviews with key informants. Rapid assessments typically are designed and conducted within one month (see MSH/RPM et al. 1995).

[Country Study 48-2](#) describes how these four approaches were combined and how the system evolved for monitoring medicine and treatment fees in one East African country.

48.4 Designing the monitoring system

The principles for designing a monitoring system are to focus on key monitoring questions and indicators; keep data collection to a minimum; develop practical procedures for managing monitoring information; and consider the need to make comparisons between performance of similar programs, performance of different facilities within the program, and performance over time. Design should also consider how information will be available for timely feedback and follow-up action. The “KISS” concept should be applied: keep it simple and straightforward (or keep it short and simple).

When time pressures, financial resources, and staff members' inexperience with monitoring methods are limiting factors, phasing the design and implementation may make sense. Initial monitoring efforts can focus on issues of selection and procurement. Medical stores data, for example, are often easy to collect. As the program develops, the monitoring system and core indicators can be expanded to cover

medicine distribution and use. Regardless of the approach taken, the design of the monitoring system must be based on a sound understanding of how the system works, including the relationships between system inputs, outputs, and desired outcomes.

Managers can often benefit by designing a monitoring system that allows comparison of the performance of vari-

ous health units or facilities. When a facility is introducing or phasing in a new activity, practice, or program, it can be matched to a control site that has not yet been introduced to the new practice or program. The control site should be as similar to the program site as possible, so that any changes can be more reliably attributed to the new program. If no control site is available to use as a comparison,

Country Study 48-2

Monitoring the introduction of medicine fees in Kenya

The Kenyan Ministry of Health introduced a new user-fee program. After early implementation problems, the ministry initiated a program of management improvement and regular fee adjustments. An outpatient medicine and treatment fee was introduced in phases. To assess the effect of the program—in particular the medicine treatment fee—a comprehensive monitoring system was implemented. The system consisted of targeted field supervision, routine reporting, a sentinel system of indicator districts, and special studies.

Targeted field supervision: Supervisory staff from the MOH health financing program made regular supervisory visits to each part of the country. Information from routine reporting and other sources was used to identify problem districts and problem facilities. These were visited more often. Gradually, the role of headquarters staff evolved from primary supervision (directly visiting districts and facilities themselves) to secondary supervision: teaching supervisory skills to provincial and district staff by making visits with counterparts.

Routine reporting: Routine reporting used the financial information system (FIS) and the health information system (HIS). The FIS was developed specifically for the user-fee program and consisted of reports from districts and hospitals covering collections, expenditures, insurance claims, exemptions, and bank balances. The existing HIS was adapted to support additional information needs of the user-fee system.

Indicator districts: The routine reporting system was kept to a minimum for reasons of feasibility, cost, and staff availability. Therefore, a system of six indicator districts was developed to provide additional details on the implementation of user fees. Districts were selected to achieve rural/urban and socioeconomic diversity. Specialized information gathering in the indicator districts included (a) outpatient use data from all MOH levels as well as selected mission and private facilities; (b) rapid household surveys before and after major fee changes to assess care-seeking patterns and knowledge

of fees; (c) outpatient and inpatient surveys to assess patients' perceptions of the fee system and quality changes; and (d) a quality-of-care checklist to assess the availability of critical patient care inputs.

Special studies: During implementation, questions arose that could not be answered through either routine reporting or the indicator district system. Special studies were, therefore, conducted on the planning and expenditure process for the use of revenue; on fee preferences, to assist in expanding the fee schedule; on exemptions, to assist in adjusting exemptions to balance equity and revenue needs; and on revenue losses caused by non-collection of inpatient fees.

Uses of monitoring information: Supervision and routine reporting information were used to identify districts and facilities that were performing poorly and to strengthen their performance. Supervisory visits corrected misunderstandings of the new management systems. In some cases, staff members were intentionally flouting new rules for personal gain, and disciplinary action was taken. Districts and facilities that were performing well were identified and publicly recognized. Data from the indicator districts were used to guide decisions about the type, level, and timing of fee changes. Results from special studies were used to correct management problems and to revise management systems.

Evolution of the monitoring system: As the new user-fee system matured over a five-year period, the nature of the monitoring system evolved. Supervision was decentralized to the provincial and district levels. Routine reporting requirements were simplified to focus on the few critical FIS and HIS reports that most facilities could generate regularly. Data from indicator districts were important for monitoring major fee changes, but subsequent fee adjustments were having less and less effect, so little information was being gained from the indicator districts. Efforts were then concentrated primarily on effective local use of targeted supervision and routine reports.

Country Study 48-3 Using supervisory visits to improve medicine management in Zimbabwe

In Zimbabwe, training pharmaceutical technicians and health workers in medicine management resulted in significant improvements in inventory management and rational medicine use, but the achievements were not sustained. A monitoring program based on two supervisory visits every three months was instituted in district-level health facilities to determine whether progress in managing medicines could be maintained.

The study compared three different groups—

1. Twenty-three facilities receiving supervision on using standard treatment guidelines
2. Twenty-one facilities receiving supervision on inventory management
3. A control group of eighteen facilities receiving no supervision in either area

The evaluation measured performance using a range of indicators relating to medicine availability, use of stock cards and books, and monthly ordering, as well as adherence to the standard treatment guidelines.

The results showed that after supervision, overall inventory management and adherence to standard treatment guidelines improved significantly when compared with the control and comparison groups. In addition, supervisory visits had a positive effect on improving staff performance in other areas besides just inventory management and rational medicine use.

Source: Trap et al. 2004.

baseline data can be collected to use as a basis for assessing development after the program is started at the site. If more than one facility is initiating a program, the different facilities can serve as comparison groups to monitor how well each group is progressing. [Country Study 48-3](#) details the effects of supervisory visits using both comparison and control groups.

48.5 Using indicators for monitoring and evaluation

Indicators are variables that measure change. They may be numerical and expressed in terms of numbers, percentages, or averages. They may also be expressed as binomials such as “yes” and “no.” Indicators are useful tools for managers to track the performance of particular aspects or activities of the pharmaceutical supply system as well as the perfor-

mance of the overall system. A well-defined indicator is clearly linked to an important input, process, or outcome. A well-selected indicator will help managers quickly identify potential problems in critical areas. Indicators are extremely helpful to communicate important performance gains and losses to other stakeholders of the pharmaceutical supply system. Indicators can be developed for different levels of the supply system.

Managers should be aware that well-established indicators exist for measuring the performance of the different components of the pharmaceutical supply system (for example, WHO 2007). However, because systems can be organized in different ways, managers should adapt or modify internationally recognized indicators to reflect the realities of their own system if necessary.

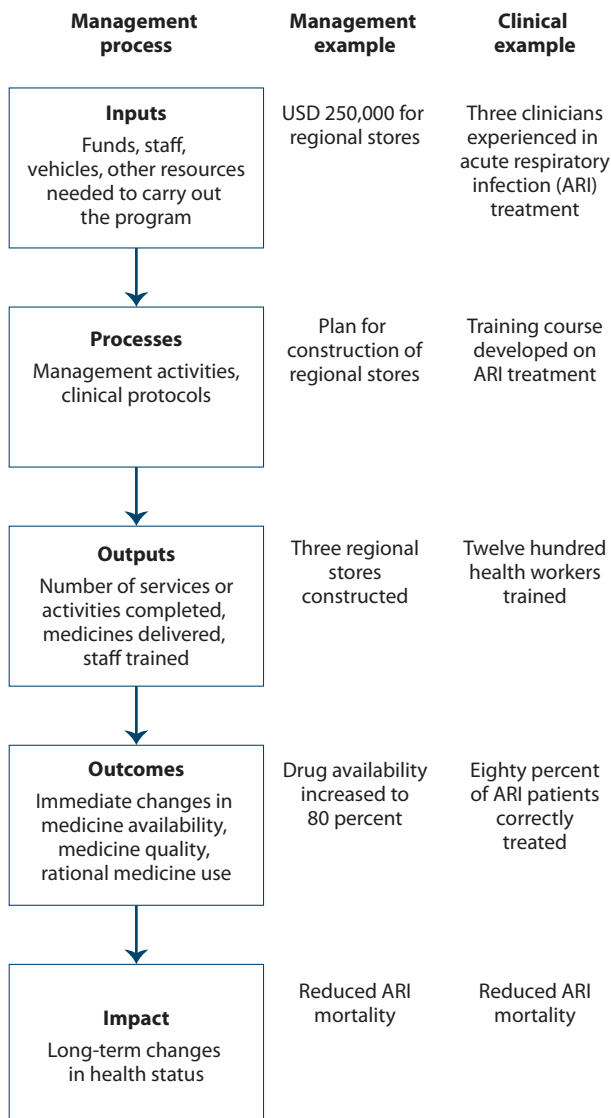

Applications of indicators

When used to make measurements at one point in time, indicators allow a manager to compare a program’s performance with a target level of performance (or with another program’s performance) and to identify areas of relative strength and weakness. Applied over time, such indicators can be used to set and monitor performance improvement targets, such as—

- Monitoring implementation of program plans and workplans
- Evaluating achievement of long-term goals
- Assessing the performance of individual units
- Identifying relative strengths and weaknesses in current policies and systems
- Measuring the effect of new policies or management systems
- Self-monitoring to improve performance
- Demonstrating needs to treasury, donors, or other funders
- Reporting on progress to senior officials, donors, or other interested parties

For program management purposes, whether at the national or facility level, performance indicators should tie directly to program plans and annual workplans and to a general performance improvement process. One way to view the management process is that it takes *inputs* (for example, human and financial resources, equipment, policies) and the implementation of certain management and clinical *processes* (meetings, trainings, development of materials) to create specific service or activity *outputs* (number of staff trained or clients served, new management system), which have immediate *outcomes* (change in practices, improved services), which lead to a desirable long-term *impact* on health status (change in disease rates, change in birth rates). This process is illustrated in [Figure 48-1](#).

Figure 48-1 The health management process and illustrative indicators

Types of indicators

Indicators can be developed for each point in the health management process to monitor specific inputs, processes, and outputs associated with both management and clinical activities. Similarly, pharmaceutical supply system managers can identify input, output, and outcome measures for each major component of the pharmaceutical supply cycle. [Table 48-1](#) lists commonly used indicators that correspond to the components of selection, procurement, distribution, use, policy, and management support.

Managers of pharmaceutical supply systems will note that many of their management activities focus on inputs such as financing, human resources, and the existence of

policies and standard operating procedures. Examples of corresponding indicators include—

- Existence of a national medicine policy updated within the last three years
- Percentage of total health program budget dedicated to procuring pharmaceuticals

Managers are also concerned with activities or processes such as procurement, stock keeping, and prescribing and their outputs. Examples of related indicators include—

- Percentage of the pharmaceutical budget spent on essential medicines
- Average supplier lead time from order to delivery (in days)
- Average inventory turnover
- Number of prescribers trained on standard treatment guidelines

Important outcome indicators for pharmaceutical management focus on aspects of availability and affordability of key medicines, quality issues, and the appropriate use of medicines. Indeed, these indicators are typically the most visible and most commonly cited in evaluating how successfully a supply system is functioning. Examples of outcome indicators include—

- Average number of days of stockouts (of key medicines and supplies)
- Average number of items out of stock at a given point in time
- Average number of medicines prescribed to a patient for a given condition

Selecting indicators

Five necessary criteria for selecting appropriate performance indicators are—

- **Clarity:** the indicator is easily understood and calculated.
- **Usefulness:** the indicator reflects an important aspect of performance.
- **Measurability:** the indicator can be defined in quantitative terms and used within existing constraints on information quality and availability.
- **Reliability:** the indicator permits consistent assessment over time and among different observers.
- **Validity:** the indicator is a true measure of what it is meant to measure (see [Chapter 36](#)). Validity must also be based on the indicator's acceptance by key stakeholders and the consistency of interpretation among different stakeholders.

Table 48-1 Examples of performance indicators and performance targets

Objective and performance indicator	Performance target
Overall performance	
Central stores: indicator pharmaceuticals available (unexpired)	90%
District stores: indicator pharmaceuticals available (unexpired)	90%
Health units: indicator pharmaceuticals available (unexpired)	90%
Health units: average stockout duration for indicator pharmaceuticals	10 days
Financing —ensure that financial resources are adequate to meet basic pharmaceutical needs	
Per capita government pharmaceutical expenditure	USD 1.20
MOH budget allocation for pharmaceuticals	15%
Actual pharmaceutical expenditures as a percentage of budgeted allocation for pharmaceuticals	85%
Medicine costs covered by user fees	60%
Procurement —obtain a regular supply of pharmaceuticals at favorable prices	
Total value of MOH medicines purchased through competitive tender	95%
Total value of MOH purchases on essential medicines list	98%
Average ratio of unit prices of indicator pharmaceuticals to international prices	0.9 to 1.1
Average lead time for external suppliers	50 days
Average lead time for local suppliers	20 days
Quality assurance —ensure that procured pharmaceuticals meet recognized standards of quality and that quality is maintained throughout the distribution chain	
Number of medicines/batches tested of number of medicines/batches procured	1 of 4
Number of medicines/batches that failed quality control testing, of number of medicines/batches tested	0
Central storage —ensure that medications are properly stored, with minimal expiration and other losses	
Medicines for which stock records and physical counts agree (all medicines)	100%
Average difference between stock records and physical count (all medicines)	Less than 5%
Drugs for which stock records, procurement records, and physical counts agree (indicator pharmaceuticals)	100%
Value of expired medicines as a percentage of total pharmaceutical purchases last year	Less than 3%
Delivery —ensure timely delivery of pharmaceuticals to health units	
Average lead time from central medical stores to health units, routine monthly orders	30 days
Average lead time from central medical stores to health units, emergency orders	5 days
Storage at health units —ensure that medicines are properly stored, with minimal expiration or other losses	
Health units using stock cards correctly	75%
Stock records correspond with physical counts	90%
Health units with expired items	25%
Health units practicing first-expiry/first-out (FEFO)	90%

In selecting indicators, considering how data will be collected is also important. Indicators may rely on generally available information from routine reporting, or they may require special surveys or other sources of information. The sources and the cost of collecting and processing these data must be carefully considered in selecting indicators.

Some indicators may be routinely available from standard recording and reporting systems (such as percentage of indicator pharmaceuticals available), whereas other indicators may require a special survey (for example, percentage of pharmaceutical costs covered by user fees or percentage

of health units using stock cards correctly). Some indicators represent annual summary measures (per capita government pharmaceutical expenditure or percentage by total value of pharmaceuticals purchased through competitive tender).

It may be useful to distinguish core performance indicators, for which data are routinely reported and monitored, from complementary performance indicators, for which data may be collected only at sentinel sites or in special studies or that may be used only for periodic evaluation purposes.

The indicator examples in this chapter draw on five useful sets of internationally recognized indicators, some of which are described in greater detail in [Chapter 36](#) (Brudon, Rainhorn, and Reich 1999; CPM 2003b; MSH/RPM et al. 1995; WHO 2007). By using internationally defined indicators for national pharmaceutical policy (Brudon, Rainhorn, and Reich 1999), pharmaceutical management (MSH/RPM et al. 1995; WHO 2007), and medicine use (Nachbar et al. 2003; WHO 2007; WHO/DAP 1993), countries can compare their performance against that of other countries.

Setting performance targets

A performance target is a desirable and—in principle—attainable standard of performance. For example, the impact indicator may be the percentage of ten indicator pharmaceutical products in stock, and the performance target may be 80 percent availability at each level for this list of indicator pharmaceuticals. Performance targets should be set for each indicator. [Table 48-1](#) presents illustrative targets for the indicators listed.

A widely used guide to developing performance targets is SMART (MSH/LMS 2008). A SMART result is—

Specific (S): The performance target is clearly written to avoid different interpretations.

Measurable (M): The target allows a team to monitor and evaluate progress toward achieving its result.

Appropriate (A): It is in line with the scope of a team's program or work activities, so that it can have influence or make changes.

Realistic (R): The target is achievable within the time allowed.

Time-bound (T): The performance target has a specific time period for completion.

Performance indicators can be compared with agreed-upon performance standards over time within the same health unit, among health units of the same level, or across countries. Initially, comparisons among health units may help set realistic performance standards, which can be adjusted upward as the system develops.

When setting targets, managers should keep in mind that costs are associated with reaching their targets, and therefore, they should consider budget and staff limitations. For example, attaining a 100 percent service level (in essence, completely filling every order for medicines in one delivery) may not be possible or practical, even though it may be theoretically desirable. Therefore, the target should be set at an appropriate level, and the manager's challenge is to have a strategy to ensure that shortfalls in the pharmaceutical service level do not jeopardize the facility's ability to provide quality care.

Formulation of indicators

If indicators are variables that measure change, they can be counted. Indicators can be in the form of counts (400 health workers trained), rates (two workshops per year), ratios (USD .90 per tin versus USD .60 per tin equals a ratio of 3:2), proportions (400 of 1,200 health workers trained equals one-third), or percentages (400/1,200 health workers trained equals 33 percent). Indicators can also require a "Yes" or "No" response ("Yes, there is a national pharmaceutical policy," or "No, standard treatment guidelines have not been updated in the last three years").

When defining a numerical indicator, considering the availability of information is important. Proportions and percentages require that the size of the whole (the denominator) be reliably known; if not, then actual counts may be more useful. For example, if the number of health workers in a district is not precisely known, specifying a count (400 health workers trained) is preferable to a percentage that cannot be verified.

Indicator pharmaceuticals and supplies

Several of the performance indicators listed in [Table 48-1](#), mentioned in [Chapter 36](#), or included in some of the chapter assessment guides are based on the availability, prices, and accuracy of stock records for a list of indicator pharmaceuticals and supplies.

Indicator pharmaceuticals and supplies are a small number of representative items, which are also known as tracer or index medicines. Economists use a market basket of common goods and services to measure inflation through the consumer price index. Similarly, the list of indicator medicines is sometimes called a basket of medicines (WHO 2006). The advantage of using a list or basket of items for indicators is that data collection and analysis are simplified.

Selecting which items to include on a tracer list is based on preestablished criteria and should include input from important stakeholders. The items should be on the national essential medicines list or national medicine formulary, therapeutically important, widely used, appropriate for the level of care where measurements will be made, and commonly available internationally (if the study includes multinational comparisons). In principle, these items should be available at all times (target 100 percent). For this reason, inclusion of medicines that are not commonly used, that are difficult to obtain, or that have other unusual characteristics influencing how they should be managed is not practical.

[Table 48-2](#) provides a list of medicines, grouped by therapeutic category, that was used to assess the pharmaceutical supply system in Tanzania. Depending on the purpose and uses of the indicators, distinguishing a list of fifteen core indicator medicines to use as indicators for all levels of the health system and a supplementary list of ten additional

Table 48-2 Example of a list of indicator pharmaceuticals and supplies

Pharmaceutical/supply	Form, dosage
Analgesics/antipyretics	
Acetylsalicylic acid (aspirin)	Tablet, 300 mg
Paracetamol	Tablet, 500 mg
Antihelmintics	
Mebendazole	Chewable tablet, 100 mg
Anesthetic	
Ketamine	Vial, 50 mg/mL
Antibacterials	
Amoxicilline	Tablet, 250 mg
Metronidazole	Tablet, 450 mg
Benzylpenicillin sodium	Vial, 5 MU
Sulfamethoxazole/trimethoprim (co-trimoxazole)	Tablet, 400 mg + 80 mg
Ciprofloxacin	Tablet, 500 mg
Doxycycline	Tablet, 100 mg
Erythromycin	Tablet, 250 mg
Gentamycin	Ampoule, 40 mg/mL
Rifampicin + isoniazid	Tablet, 150 mg/100 mg
Antimalarials	
Sulfadoxine/pyrimethamine	Tablet, 500 mg/25 mg
Quinine dihydrochloride	Ampoule, 300 mg/mL
Cardiovascular medicines	
Propranolol	Tablet, 40 mg
Hydrochlorothiazide	Tablet, 25 mg
Gastrointestinal medicines	
Oral rehydration salts	Sachet
Minerals	
Ferrous sulfate + folic acid	Tablet, 200 mg/0.25 mg
Ophthalmological preparations	
Oxytetracycline eye ointment 1%	Tube, 5 mg
Vaccines	
Polio vaccine	Vial

medicines to use at central storage facilities and hospitals may be helpful. The supplementary list of items might include other dosage forms, such as injections and topical preparations, and additional therapeutic categories, such as cardiovascular medications and contraceptives. Items to consider for the core list include oral rehydration solutions, procaine penicillin injections, paracetamol tablets, tetracycline eye ointment, iodine, gentian violet or a local alternative, benzoic acid and salicylic acid ointment, or retinol (vitamin A) (WHO 2007).

To facilitate measurement calculations and consistency, the number of items on the list should be kept small: a list

of ten or twenty medicines usually suffices. For calculating rates and percentages, using a number that divides easily into 100 (for example, 10, 20, or 25) is convenient. Larger or more diverse lists of indicator pharmaceuticals may be needed for specific purposes. When first introducing performance indicators and indicator items, however, it is probably wise to keep to a core list such as that shown in [Table 48-2](#).

48.6 Using the monitoring system to improve performance

A monitoring system gives managers a way to identify potential problems with program and staff performance and to improve performance. A formalized monitoring system facilitates the development of improvement plans and performance targets, all of which must be clearly communicated at all levels of the pharmaceutical management system. For the monitoring system to be useful, managers should review and share the results regularly and take timely action to follow up. For example, [Country Study 48-4](#) shows how a psychiatric hospital instituted a monitoring system that included regular feedback to psychiatrists to improve prescribing habits. The ongoing monitoring activities will determine if follow-up actions achieved the desired results.

Communicating plans and targets

Program plans and workplans are sometimes viewed simply as documents for fund-raising or for “the people above.” To the contrary, they should be blueprints to guide the day-to-day work of staff at all levels, who need to be aware of the plans as well as of output and performance targets. Managers should communicate plans and targets both in writing and face-to-face: memoranda or circular letters alone are usually insufficient. Often, staff members need some education or training to understand why indicators were selected, how they are measured, and how results will be used.

Reviewing progress

A schedule is needed to review program progress, with the review period depending on the nature of the plan and the specific indicators. Managers should review implementation progress for a five-year program plan, for example, at least once a year. During the review, key staff members meet to systematically assess each objective, each activity, and each output target. For an annual workplan, reviewing progress each month or at least each quarter is important. New programs should also be reviewed often as they are getting off the ground.

In a progress review, actual outputs and performance are compared against the established targets; when discrepancies exist between the expected results and actual perfor-

mance, further discussion or investigation is needed. When progress has exceeded expectations, managers should ask whether positive lessons can be learned and whether specific people should be recognized for their work. Table 48-3 provides an example of a progress review based on a work-plan to promote rational medicine use.

When progress is less than expected, it is even more important for managers to ask the reasons why. For instance—

- Were necessary funds, materials, or other inputs lacking?
- Were two units unable to communicate their expectations to each other or to coordinate their actions?
- Did key staff simply fail to take the plans and performance targets seriously?
- Is failure to achieve a specific planned output a reflection of overly ambitious plans?

A well-designed, well-implemented monitoring system can usually provide information on *what* happened or did not happen. Information about *why* things happened—or did not happen—may come from the monitoring system or may require management follow-up.

Giving feedback

No monitoring system is complete without feedback. Giving feedback to individual units or staff members tells them how well they have done the reporting and how useful the infor-

mation is. Feedback also demonstrates the value and importance of the reports. As such, it represents one of the most powerful tools for motivating staff. Feedback also improves the quality of data by breaking the “bad data cycle” (see Chapter 49).

Direct, action-oriented feedback involves presenting staff with some of the problems and successes identified in the monitoring or evaluation reports—

- Discuss the achievement of specific performance targets.
- Identify weak performers for more intensive supervision or training.
- Identify and congratulate successful districts and facilities.
- Identify policy or program weaknesses and how to strengthen them.

Always check to see whether the information has been used, how it has been used, and what action has been taken.

Taking action

Effective use of the monitoring system requires prompt follow-up action. A manager can take at least five types of action—

- Provide positive feedback to high-performing units or staff to encourage continued good performance.

Country Study 48-4

Monitoring the use of neuroleptic medicines in a psychiatric hospital in Tatarstan, Russia

Neuroleptic drugs, such as chlorpromazine, can help control symptoms related to schizophrenia, but overuse, polypharmacy, and medicine interactions can contribute to dangerous adverse effects, such as irreversible movement disorders. The Clinical Psychiatric Hospital in the Republic of Tatarstan, Russia, implemented a monitoring system to measure the use of neuroleptic drugs and related adverse effects and to institute regular feedback to hospital psychiatrists aimed at decreasing the use of neuroleptic medicines and improving overall prescribing habits.

The hospital used standardized medicine-use indicators developed by the World Health Organization (WHO) to track the outcomes related to the monitoring program. Results showed that implementing medicine-use monitoring helped psychiatrists improve their prescribing habits for schizophrenic patients, although adding an educational intervention component to regular monitoring might result in additional gains.

- Provide corrective feedback to staff or units that have not met expectations, but that should be able to take specific steps to improve their performance; many problems can be corrected through supervision and retraining.
- Reallocate resources or reassign staff to achieve a better fit between the task to be accomplished and the resources or staff available.
- Make plans and targets more realistic based on actual experience.
- Request additional information to further define a specific performance problem and the reasons for the problem.

[Country Study 48-5](#) illustrates how indicators can be used to improve performance through self-monitoring.

Whatever actions are taken after a progress review, the effects of these actions should be considered at the next progress review.

48.7 Evaluation

Whereas monitoring focuses on program activities, evaluation focuses primarily on assessing progress toward achieving goals by fulfilling program objectives—taking a step back to look at the program as a whole. An evaluation is carried out at a specific time and should have a clear purpose.

Evaluation questions

Depending on the timing and purpose, evaluations may be of three types ([Table 48-4](#))—

1. Needs assessment (situation analysis)
2. Formative evaluation (midterm review)
3. Summative evaluation (final evaluation)

A needs assessment or situation analysis is meant to appraise the pharmaceutical system or essential medicines program and to identify areas of strength and weakness (see [Chapter 36](#)). The purpose is to design a project to address major weaknesses in the system.

Formative and summative evaluations are more programmatic and concerned with answering some or all of the following questions—

- Is the program relevant? Are its goals and objectives appropriate to the present circumstances of the country and the pharmaceutical system?
- Is the program effective? Is it achieving satisfactory progress toward its stated goals and objectives? What are the reasons for success or failure?
- Are monitoring results representative? Do the results

Table 48-4 Types of evaluation

Type	Project stage	Purpose
Needs assessment (initial analysis)	Design	<ul style="list-style-type: none"> • Assess current situation • Develop program/project plan • Acquire baseline for comparison
Formative evaluation (midterm review)	Implementation	<ul style="list-style-type: none"> • Focus on implementation process • Assess progress toward goals and objectives • Improve program/project implementation
Summative evaluation (final evaluation)	Follow-up	<ul style="list-style-type: none"> • Assess program/project outputs • Measure impact of program/project • Demonstrate program/project impact to donors • Recommend future actions

Source: Adapted from García-Núñez 1992.

from the program's monitoring system reflect the actual situation?

- Is the program efficient? Are the effects of the program being achieved at an acceptable cost compared with alternative approaches to providing the same services?
- Is the program sustainable? Financially and institutionally, can the program continue with present levels of local inputs? If external financial and technical assistance is involved, can the program continue after it has stopped?
- Is the program having the intended impact? Does the program appear to be achieving or will it achieve its intended long-term health care benefits?
- What future changes should be made? What recommendations can be made for program development, new plans, or project assistance? Are new goals or objectives needed?

In practice, needs assessments, formative evaluations, and summative evaluations sometimes overlap. For example, the final evaluation for one project may also serve as the needs assessment for the next project.

Conducting an evaluation

[Chapter 36](#) describes three approaches to assessment: self-assessment, limited assessment, and structured assessment. Structured assessment is the most comprehensive but requires the most resources. The choice of assessment approach depends on available financial and human resources, timing, sponsorship, and intended uses of the results.

Health program and health project evaluations are sometimes limited assessments, consisting primarily of

Country Study 48-5
Use of indicators for self-monitoring in rural Java

The twenty-nine health centers and 109 subcenters of Gunungkidul district in Java, Indonesia, suffer from periodic shortages of medicines, as do other health facilities. These shortages are caused by limited resources; increasing patient demand; and overprescribing of injections, antibiotics, and other medicines. To address this problem, the district health team in Gunungkidul undertook a series of activities to improve and control medicine use.

The team first surveyed medicine use with three prescribing indicators. Results showed extensive polypharmacy (4.2 medicines per case), a high percentage of patients receiving antibiotics (63 percent), and a very high percentage receiving injections (76 percent). The team explored these issues in randomly selected health centers using in-depth interviews, observation, focus group discussions, and questionnaires (see Chapter 28). From this information, a self-monitoring system was developed, pilot-tested, and implemented in all health centers in the district.

Each health center completes a monitoring form each month, based on a survey of thirty cases in each health center and subcenter. Results are discussed locally and forwarded to the District Health Office for review. Data

from the four subcenters under Widoyo Health Center are compared with those from the previous month (see the accompanying figure). Using this form, health center staff can easily determine whether each indicator has increased or decreased in each facility.

The continuity of the self-monitoring process is sustained by—

- Weekly staff meetings of the district team at which results are discussed
- Monthly district-level meetings for the heads of all health centers
- Regular feedback and occasional supervisory visits to health centers by members of the district team

After two years, an evaluation showed substantial improvements in all three indicators. Despite these changes in practice, the number of attendances at health centers had remained constant. Interviews with health workers showed improved attitudes toward the use of standard treatments, willingness to improve skills, and increased communication among health workers and the district team.

interviews, secondary analysis of existing monitoring and other data, and review of available documents. Increasingly, however, evaluations are expected to contain performance data indicating what services and outcomes are resulting from the program. The starting point for an evaluation should be the data collected through the monitoring system, but field surveys using standard pharmaceutical sector assessment indicators (WHO 2007) will contribute to a much more objective, credible, and useful evaluation.

Evaluation methods and tools

An evaluation is much like a research project. The usual considerations of research design apply, including defining the scope and questions for the evaluation, choosing evaluation methods, developing and testing data collection instruments, managing data collection, collating and analyzing data, interpreting results, and presenting the findings.

Methods of obtaining information include document review, key informant interviews, data collection from existing records, and prospective surveys. These methods and the steps involved in a structured assessment are discussed in detail in [Chapter 36](#).

Knowledge, skill, and experience are required to design and execute a credible, comprehensive evaluation. See [References and Further Readings](#) for several sources that provide practical guidance on evaluation methods.

Who should evaluate?

When individuals involved in a program carry out an evaluation, they have the advantage of understanding its aims and design; however, such evaluations can be subjective and may miss important lessons. Therefore, outsiders are frequently asked to perform evaluations. Because they are disinterested, outsiders may be more objective and may bring fresh ideas. Outside evaluators might come from local universities, local nongovernmental organizations, international organizations, or organizations in other countries.

Combined insider and outsider evaluations have many advantages. The outsider, being ignorant of the local situation, can ask the difficult questions, and the insider often knows whether the true answer is being given. Having the insider view the program or project through the eyes of the outsider is also useful. The outsider benefits because the insider knows where the answers are to be found.

Resources required

Evaluation is an activity that goes beyond routine monitoring and requires staff, time, and funds to be earmarked for it. In the case of a specific program, funds for evaluation should be built into the original proposal. Careful costing should be performed, taking into account all proposed activities.

The budget should be prepared early in the planning process. A template presented in [Table 48-5](#) can be used to develop a budget. It should be updated as additional information becomes available, such as personnel daily rates and the cost of translators, if needed. Some key considerations for the budget include—

- Team member time
 - Planning time—technical lead and administrative/logistics support
 - Team member time—preparatory, fieldwork, and report preparation
- Travel costs (as needed)
 - Airfare
 - Per diem
 - Visa costs
 - Telecommunications costs (phone/Internet access)
- Contracted services (as needed)
 - Local consultant
 - Translator(s)
 - Driver(s) and car(s)
 - Conference room facilities for the stakeholder workshop (room charge, food costs, and equipment rental)
- Miscellaneous charges
- Photocopies—reference materials, reports, etc.
- Postage (mailing documents prior to visit, for example)

48.8 Some common pitfalls in monitoring and evaluation

Although monitoring and evaluation are two distinct activities, they share certain common pitfalls—

Failure to identify the basic questions: All monitoring and evaluation activities should start with a clear statement of the questions they intend to answer. Without this, the information gathering has no focus.

Overambitiousness: Collecting too much information is perhaps the most common failing. A basic rule is that more information means greater expense, less accuracy, more time spent managing the data, less time spent interpreting the data and providing feedback, and less time for using the data.

Complexity: Monitoring systems should be as practical and streamlined as possible. Cumbersome systems have often been designed from the top down, with insufficient testing and input from staff involved in generating and using monitoring information.

Lack of integration with planning and implementation: Monitoring and evaluation activities should follow directly from program plans, link closely with ongoing

implementation activities, and lead logically into the next round of planning.

Failure to build on existing systems: Existing information systems are never perfect, but considerable resources can be squandered trying to build a separate system instead of building on and strengthening existing systems.

Inadequate resources: Both monitoring and evaluation require considerable financial and human resources. It is generally better to seek additional resources or narrow the scope of assessment rather than try to gather too much information with too few resources.

Lack of objectivity: Management indicators introduce some objectivity into the assessment process; assessments based only on subjective information are less credible and less useful.

Jumping to wrong conclusions: Well-designed monitoring and evaluation systems allow some cross-checking of findings. Taken out of context, individual monitoring reports and evaluation observations can be misleading.

Lack of comparison data: Observations must be compared over time, against agreed-upon performance standards, among health units at the same level, or across countries. Good baseline data against which changes can be compared are especially useful, but to be valid, they must come from the same sources and have the same measures as the follow-up data. If the sources or measures are altered, it is difficult to say whether apparent changes (good or bad) are real or are a result of the assessment process.

Other common problems are failure to analyze data promptly, lack of feedback mechanisms to apply results, evaluations that do not gather new information, and monitoring done for the wrong reasons. Inappropriate reasons for monitoring and evaluation include doing the activity because of tradition or donor requirements and using the activity to try to resolve conflicts between donors and recipients or to get information to punish certain staff members. ■

ASSESSMENT GUIDE

Monitoring methods and systems

- Does a program or unit exist to monitor and evaluate pharmaceutical services? Who is responsible for monitoring and evaluation?
- Is monitoring based on program objectives and linked to specific activities? Are these objectives, along with output targets and performance targets, clearly communicated to concerned staff?
- Which of the following methods are used as sources of monitoring information: supervisory visits, routine reporting, sentinel reporting, special studies?
- How often are data collected? How are they used?
- Are monitoring results regularly reviewed and shared? How and with whom? Is feedback provided to concerned staff?
- What actions are taken when problems are detected through monitoring and evaluation?

Indicators

- Have performance indicators been established? If so, how were they established, and who was involved?

Do they include process, output, and impact indicators? Are they both qualitative and quantitative? Have performance targets been set?

- Have indicator pharmaceuticals been identified for indicators requiring medicine-specific information?

Evaluation

- Is progress toward achievement of program goals and objectives periodically assessed through formal evaluation?
- Does the evaluation begin with a clear statement of its basic question? Is this question used as a focus for information gathering?
- Which of the following methods are used to obtain information—review of existing monitoring reports, additional data collection, document review, interviews, field surveys using standard pharmaceutical assessment indicators?
- How is the evaluation team determined? Does it include insiders, outsiders, or both?

SUMMARY

The planning process for a new or revised pharmaceutical supply system should include a pharmaceutical management information system (PMIS). The PMIS is an organized system for collecting, processing, reporting, and using information for decision making. Information for each subsystem is collected by means of—

- Record-keeping documents, a combination of registers, ledgers, and filing systems that typically are not circulated
- Information reporting forms, such as periodic status reports, that transmit data to other departments or levels for use in making management decisions
- Feedback reports, also called analytical reports, that are usually provided to the units that collected the data

Design or revision of a PMIS should be based on the differing information needs of users at each level of the system and should build on existing forms, reports, and procedures as much as possible. Any forms should be designed through a participatory process and field-tested with staff who will use them.

Other issues to consider include—

- Selection of indicators to monitor system performance and intended results (discussed in [Chapter 48](#))
- Integration of the PMIS with other data collection systems
- Computerization at appropriate levels

A successful PMIS requires effective use of the information generated, which includes—

- Efficient data processing to reduce large amounts of data to a manageable number of key indicators, often in summary tables
- Presentation of information in graphic form to simplify interpretation
- Interpretation of information to identify trends and potential problems
- Appropriate use of technology (for example, e-mail, websites) to present and share information with a wider audience in less time
- Action in response to both positive and negative results
- Effective mechanisms to provide and receive feedback

49.1 Importance of a pharmaceutical management information system

A good PMIS provides the necessary information to make sound decisions in the pharmaceutical sector. Effective pharmaceutical management requires policy makers, program managers, and health care providers to monitor information related to patient adherence, drug resistance, availability of medicines and laboratory supplies, patient safety, postmarket intelligence, product registration, product quality, financing and program management, among other issues.

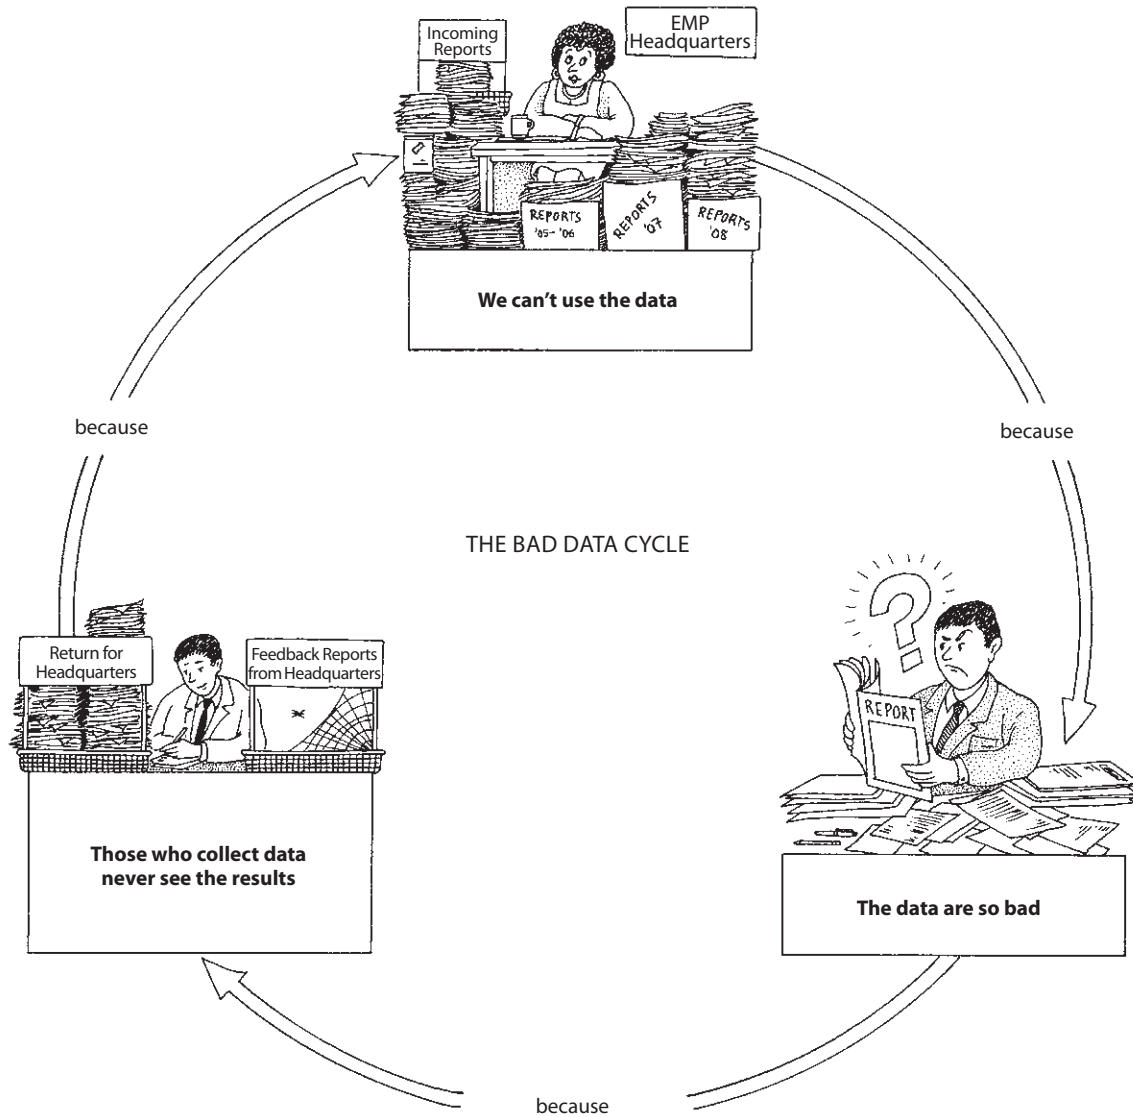

Coordinating the elements of a pharmaceutical supply system requires relevant, accurate, and timely information. Increased funding for HIV/AIDS, tuberculosis, and malaria programs has contributed to the need for accurate and timely information on a variety of parameters that affect the ability to conduct accurate quantification, procurement planning, budgeting, resource mobilization, and program management. In addition, multiple donors require different data reports, complicating program management. Because a pharmaceutical supply system uses many forms and other documents, managers often feel as if they are buried under mountains of data and that filling in the forms and producing reports ends their

responsibility. They are unable to analyze and use many of these data for improved decision making. Many factors affect the usability of these data, including data quality and quantity (for example, missing or incomplete data or too much data to analyze effectively) or a manager's lack of analytical skill. Therefore, many managers find themselves making decisions based not on information but on intuition.

This chapter focuses on the practical aspects of organizing and managing a routine pharmaceutical management information system. It should be read in conjunction with [Chapters 48](#) and [50](#). [Chapter 48](#) puts information management into the broader context of monitoring and evaluating program performance against long-term goals and objectives and against medium-term workplans and targets. [Chapter 50](#) presents a variety of tools for analyzing data produced by the PMIS.

Definition of a pharmaceutical management information system

The PMIS integrates pharmaceutical data collection and the processing and presentation of information that helps staff at all levels of a country's health system make evidence-based decisions to manage pharmaceutical services.

The features that distinguish a PMIS from a logistics management information system include—

- The incorporation of patient-specific data in addition to product-centered data
- A focus on decision making for pharmaceutical services, not just resupply
- Information on outcomes related to medicine use, such as adherence, adverse drug reactions, and pharmacovigilance, that affect pharmaceutical policy and selection decisions, including individualized treatment options
- Overarching information about the pharmaceutical sector, such as a summary of available professionals/personnel, outlets, legislation status, and distribution of personnel and facilities
- Varied data sources from the whole pharmaceutical

sector, not just activities related to procurement and inventory management

- The ability to triangulate consumption data with clinical and patient-specific data

Functions of a pharmaceutical management information system

An effective PMIS is able to synthesize the large volume of data generated by pharmaceutical management operations. It then processes the data into information for use in planning activities, estimating demand, allocating resources, and monitoring and evaluating pharmaceutical management operations. This information is often in the form of a few key indicators. Indicators should be targeted toward staff at all levels so that they can monitor both their own performance and that of the units for which they are responsible.

Another important function of a PMIS is to improve accountability. Much of the recording and reporting in a PMIS is intended to create an audit trail for products as they enter or leave a pharmaceutical supply system.

Data and information

An understanding of the distinction between data and information is necessary to appreciate how a management information system functions. *Data* represent real-world observations or measurements. Data, in and of themselves, often have little value and take on meaning only after they are processed into a more usable form. *Information* is a meaningful aggregation of data that can be interpreted for a specific use. In other words, information is processed data that contains sufficient context to make it meaningful. The tools in [Chapter 40](#) are intended primarily to aggregate data into useful information.

For example, data from a health center reveal that 3,000 co-trimoxazole tablets were distributed last month. Is this consumption level abnormal? Without analysis, this question would be difficult to answer. The data can be converted to information by comparing the 3,000 tablets distributed with the number distributed the previous month, say 1,000. This interpretation could then be expressed as a 300 percent increase in co-trimoxazole distribution. But information is indicative, not prescriptive. The manager must analyze the complete context and make decisions.

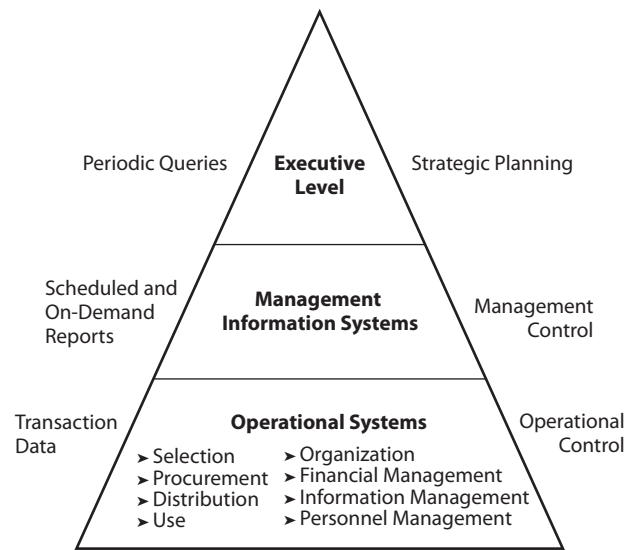

In a PMIS, data are routinely collected on a common set of indicators, usually expressed as proportions or rates. Some of these indicators measure performance toward objectives, whereas others may measure process efficiency.

The information systems pyramid

Viewing information systems as a pyramid may be helpful ([Figure 49-1](#)). At the base of the pyramid are operational systems. These include subsystems—procurement, distribution, financial management, medicine use—that handle data at the transactional level. Every item that moves in and out of inventory must be tracked, and decisions must be made about how much to supply to a health facility, when to reorder, and how much to bill. This level is characterized by a high volume of data that must be recorded and processed, usually daily and at the time of transaction. Data recording accuracy is very important at this level because every unit of medicine matters.

The next level of the pyramid is formed by management information systems (MIS). These systems typically provide summaries of operational data on a periodic basis (for example, monthly or quarterly) to help managers of specific departments monitor the performance of their units. Annual reports often summarize information on key indicators from many different operational subsystems, such as

Figure 49-1 The information systems pyramid

procurement, personnel, financial management, or stock control (see the sample report format in [Annex 49-1](#)). Information provided by the MIS helps managers answer questions such as the following—

- How do expenditures compare with the budget at a given level of operation?
- How effective is the inventory control system in eliminating stockouts and cutting stock losses?
- What is the delivery performance over the last period?
- Are the trends generally favorable, or are indicators worsening?

Information at this level may demonstrate reduced accuracy because errors might be introduced during the consolidation of data, so a certain level of variation is normal.

The highest level of the information systems pyramid is the executive level. At this level, the system further summarizes management information for use in strategic planning and policy making. The executive level of the MIS typically generates program-wide information on how effective the organization is in accomplishing its mission. Systems at this level track a limited number of indicators, less frequently. They provide users with the tools, such as total cost analysis and price comparison analysis (see [Chapter 40](#)), to perform periodic queries on data at every information-system level, either to investigate the causes of problems or to perform “what if” analyses to test the effect of changes in strategy. Some of the strategic questions that can be answered with executive-level information include the following—

- Should the transport and delivery function be contracted out?

Table 49-1 Information users and information needs

Level and function	Users	Information needs
National		
Selection	National essential medicines committee	Morbidity patterns Standard treatment strategies
Procurement	Procurement unit	Medicine-use rates Lead times Supplier performance Prices Funds available for procurement
Medicine-use education	Training unit	Number of staff trained in essential medicines use Number of public education messages developed and campaigns conducted
Financial management	Finance unit	Operating costs Revenues Value of inventory Stock turnover rates Stock fund growth or loss
Provincial/district		
Warehousing	Medical stores manager	Medicine-use rates Maximum and minimum stock levels Lead times for requisitions from the national level Shelf life Warehouse maintenance and equipment needs Stock losses
Distribution	Logistics manager	Distribution schedules Vehicle-use records Maintenance and fuel costs
Facility		
Use	Medical director, pharmacist	Prescription patterns Patient adherence Pharmaceutical availability Patient load
Inventory control	Storekeeper	Maximum and minimum stock levels Lead times for requisitions Prices Medicine-use rates Shelf life Cold-storage temperature variations

- Could savings be obtained by combining orders with those of another large buyer?
- Which districts are the best served?
- Would targeting underserved areas with more marketing and training be worthwhile?

49.2 Meeting the information needs of users with different requirements

Staff at every level and position use information to make decisions that affect the overall functioning of a pharmaceutical supply system. For example, a storekeeper can monitor the temperature chart on a vaccine refrigerator and save thousands of dollars' worth of vaccine from spoiling when the refrigerator begins to malfunction. The chief pharmacist may be unaware that large quantities of a medicine are due to expire in the warehouse. But if the pharmacist had information about expiration dates and could match that

information with data on the stock levels in health facilities, medicines could be dispatched to facilities that are running low, thereby averting waste of money and medicines.

A good PMIS alerts staff to problems and triggers critical actions at all levels. Usually, this systemwide usage means that a strict separation does not exist between data collectors and information users. Analysis and use of data are encouraged at every level of the system (see [Country Study 49-1](#)). [Table 49-1](#) summarizes key information users and some of their most important information needs at each level of the system.

49.3 Typical components of a pharmaceutical management information system

The operational systems level of a PMIS can be examined further using the analogy of the information systems pyramid. This level typically contains four subsystems: selection,

Country Study 49-1**Using the Electronic Dispensing Tool to manage pharmaceutical information at different levels of the health care system**

Although all medicines need to be carefully managed, antiretrovirals (ARVs) need special attention because they are expensive and because health care professionals in developing countries lack long-term experience with them. As part of a lifetime treatment regimen, patients must be carefully monitored for their adherence to the medicines. To maintain an uninterrupted supply of ARVs, pharmacy staff must collect timely information on medicine consumption and patient characteristics so they can accurately forecast the amount of medicines needed.

As antiretroviral therapy (ART) programs began scaling up in developing countries, assessments showed that pharmacies in ART centers did not have adequate systems in place to gather the needed data. What record keeping existed was done through manual registers that were impractical. This lack of adequate systems prevented staff from maintaining a patient's medicine consumption history and compiling the information on medicines and patients needed to support management decisions. In addition, the cost of these expensive medicines is often shared by multiple donor agencies that require different reports at different times.

The Rational Pharmaceutical Management Plus Program developed a simple, Microsoft Access-based electronic tool for pharmacy staff to use to track patients and inventory. The Electronic Dispensing Tool maintains the basic patient profile, a history of medicines dispensed, and other information that is relevant to the patient, such as adverse drug reactions. The tool also maintains consumption records that are needed to quantify pharmaceutical needs and to make other program management decisions.

Summary of data and reports*Commodity management*

- ARV and opportunistic infections medicine inventory, stock consumption, short-dated stock

Dispensing

- Medication dispensing history
- Patient characteristics (other medicines, allergies)
- Change of regimen

Patient management

- Basic patient profile with contact address
- Patient schedule of visits
- List of patients (for example, by different donor support, by age, by gender)
- Current status of patient (e.g., active, lost to follow-up, deceased)

- Number of active patients by regimen
- Number of new patients by regimen
- Age, weight, sex distribution of patients
- Patient enrollment trend

Examples

The tool is used at different levels of the health care system to manage inventory and patient information in multiple countries in Africa and the Caribbean.

Below are examples of three levels of use in Kenya—

- Many ART centers use the tool in adherence monitoring by regularly printing out the list and contact information of the patients who missed their scheduled appointments. Pharmacy staff, social workers, or nurses can then check up on the patients. Facilities also track various trends in the ART program, such as the rate of patients starting ART and the rate of patient attrition. ART sites use this information as a basis for decision making and for developing interventions; for example, Kenyatta Hospital in Nairobi changed its protocol after data identified that 63 percent of inpatients started on ARVs were dropping out of the ART program.
- The Eastern Deanery AIDS Relief Program, a faith-based organization in Nairobi, has nine satellite ART sites serving more than 5,000 patients but manages the inventory on one personal computer, using the Electronic Dispensing Tool. Each satellite site has a person responsible for record keeping; drivers pick up the previous day's data every morning, and the data are entered into the database at the central data management office. Using the tool, the data management team is able to create different reports for management and for monitoring and evaluation; in addition, the organization must submit different reports to the Ministry of Health and to donors. Once a month, the data are reconciled with the pharmacy inventory. Eventually, each site will have its own computer for individual data entry.
- The Mission for Essential Drugs and Supplies (MEDS) provides medicines and supplies to facilities serving tens of thousands of patients on ART all over Kenya. RPM Plus Kenya closely monitors MEDS ARV distribution activities by using the tool to help track pharmaceutical consumption, which is needed to quantify orders for all of its client sites. In addition, this tool has been used to create reports needed for monitoring and evaluation efforts.

procurement, distribution, and use. Information is necessary within each of these subsystems to efficiently manage finances, pharmaceutical stocks, and personnel.

The documents that form the basis of the information system can be grouped into three areas: record-keeping documents, information-reporting forms, and feedback reports.

Record-keeping documents

A combination of registers, ledgers, and filing systems (manual, computerized, or both) is used to maintain data about the activities of a specific organizational unit. Normally, records stay in one place and are not circulated to other departments or levels. An efficient record-keeping system enables its users to quickly retrieve information about activities and simplifies the job of aggregating data for reporting purposes.

Data compilation/aggregation tools

These tools are in specially designed formats (manual or computerized) that facilitate data processing. Examples include tally sheets, summary registers, and computer programs to compile data.

Data-reporting forms

Forms for reporting information differ from the data records described above because they are designed for transmission to other parts of an organization. Copies of forms filed at various points in the distribution network help establish the audit trail for tracking the flow of pharmaceuticals and funds. These forms typically include requisition/issue vouchers to document stock transfers and periodic status reports, such as monthly or annual reports (see [Annex 49-1](#)). Status reports can be descriptive and principally qualitative forms, or they can be standardized, quantitative forms designed to transmit data on specific indicators to others. In a standardized reporting chain, individual health facilities typically report to district offices. These, in turn, report to provincial offices, which report to the central office to project future pharmaceutical needs, revise budgets, and assess medicine use at the central level.

Feedback reports

Analytical reports are produced from data reported by other units. These feedback reports have two main purposes: to address issues highlighted by status reports, and to analyze how each reporting unit has performed relative to other similar units. The reports are usually fed back to the units that first collected and provided the data. Experience has shown that regular and corrective feedback is one of the best ways to improve data quality and reporting compliance.

When staff members see that their data are being used, they become much more conscientious about data collection and reporting.

A good information system also includes procedures to govern the use and flow of information up and down the pharmaceutical supply network. These procedures typically include details about how and when to collect data, the schedule for report preparation, and to whom the documents should be sent. [Figure 49-2](#) illustrates the flow of documents in a basic PMIS, and [Table 49-2](#) describes the types of documents prepared and maintained.

If parts of the information system are computerized, clear guidelines must exist for the entry, maintenance, and archiving of data, as well as for the preparation and distribution of standard feedback reports. In addition, procedures are often needed for conducting periodic analyses and sharing data among different levels of the organization.

Data collection methods can take various forms in a PMIS. Although routine collection of data from all levels and facilities for monthly, quarterly, or annual reports is most common, sample surveys, rapid assessment techniques, and sentinel reporting systems are also important (see [Chapter 48](#)). In many cases, these collection methods provide data for decision-making support that are more reliable than routine data.

49.4 Steps in designing or revising a pharmaceutical management information system

When a new pharmaceutical supply program is started or an old program is revised, the basic planning should include establishing a complete information system. All necessary forms should be available, and all staff should be trained to use these forms before pharmaceuticals start moving through the system. Without this preparation, recording of pharmaceutical consumption and forecasting of medicine needs quickly breaks down. The principal steps in designing or revising a PMIS are shown in [Box 49-1](#).

A PMIS should be based on the information needs of the users at each level. To the extent possible, it should build on existing forms, reports, and procedures. Adding as few new forms and data elements as possible and removing unnecessary forms and reports will simplify the system and increase the chances that information will be reliably recorded and reported. In some cases, worksheets may need to be developed to facilitate the collation of data from records into summary report forms.

Users need to be empowered through procedures and training to perform appropriate data analysis, understand key trends within their own units, and use information for decision making at the local level. Depending solely on feedback reports from higher levels may not be effective because

Figure 49-2 Flow of documents in a basic supply system PMIS

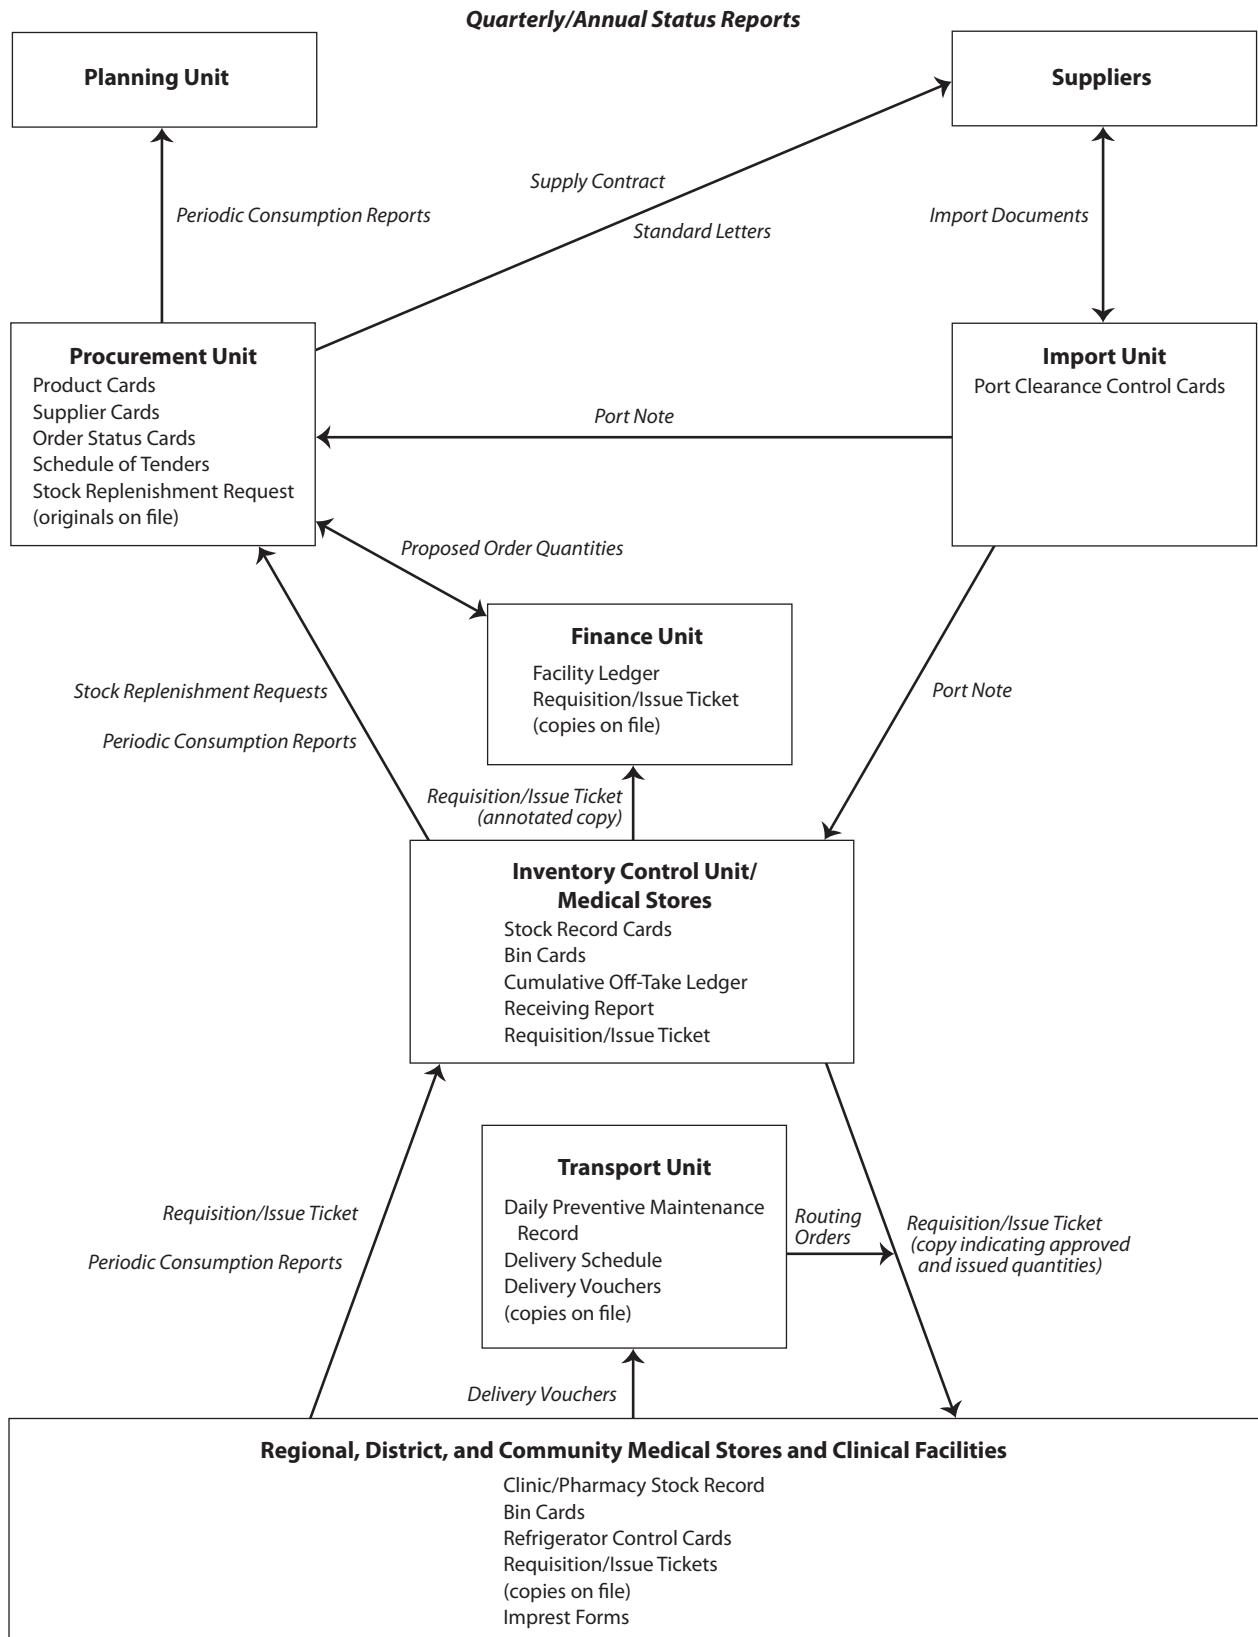

Table 49-2 Forms and records for a basic supply system PMIS

Type of document	Originated/maintained by
Forms	
<i>Supply contract</i> —statement of the terms of supply, usually publicized with the call for offers, specifying exact pharmaceutical requirements, dosage forms, quality standards, labeling and packaging, delivery date, and other supply details	Procurement unit
<i>Standard letters</i> —form letters used in correspondence with suppliers to provide and obtain information regarding outstanding orders	Procurement unit
<i>Import documents</i> —used to confirm the supply contract, guarantee payment, and certify the quantity and quality of shipment contents, and to provide other types of trade information	Procurement, supplier, shipper, banks
<i>Port note</i> —notification from import unit to procurement and medical stores that a specific shipment has arrived and has been cleared from port	Import unit
<i>Receiving report</i> —notification to inventory control that a specific shipment has been received; indicates damages, short shipments, and other problems	Medical stores
<i>Requisition/issue ticket</i> —request for specific quantities of standard items from medical stores; amended by inventory control if stocks are low; orders filled by medical stores; copies provide audit trail; return copy is packing slip	Medical stores, health facilities
<i>Stock replenishment request</i> —request to procurement to begin the procurement cycle for specific items; sent at reorder level or reorder interval	Inventory control
<i>Proposed order quantities</i> —proposed order quantities for a single procurement cycle; finance unit estimates cost and adjusts if needs exceed available funds	Procurement
<i>Routing order</i> —delivery order for drivers; provides a record of vehicle movements, indicates the order of deliveries (planned to minimize travel)	Transport unit
<i>Delivery voucher</i> —signed receipt indicating that a specific shipment of pharmaceuticals has been delivered intact	Medical stores, health facilities
<i>Imprest forms</i> —simplified supply requisitions for use by smaller clinical facilities and individual health workers	Health centers and workers
Records	
<i>Product cards</i> —product specifications and supplier history for each item; used to prepare bid specifications and select suppliers	Procurement unit
<i>Supplier cards</i> —record of experiences with individual suppliers, including delivery record, adherence to contract, pharmaceutical and packaging quality, and other performance factors; used in supplier selection	Procurement unit
<i>Order status cards</i> —used to monitor the status of outstanding orders to reduce lead times, supplier defaults, and port delays	Procurement unit
<i>Schedules of tenders</i> —summaries of offers from each supplier on each product in a tender purchase	Procurement unit
<i>Port clearance control cards</i> —used for a manual control system to monitor port-clearing activities and thereby shorten port delays	Import unit
<i>Stock record cards</i> —cards or a ledger used to record stock balances, issues, receipts, and outstanding orders; essential in inventory decisions such as when and how much to order	Medical stores, health facilities
<i>Bin cards</i> —similar to stock record cards but kept in medical stores with the physical stock to record supply movement in and out of the stores	Medical stores
<i>Facility ledger, cumulative off-take ledger</i> —records indicating the quantity and cost of pharmaceuticals issued to individual facilities; used for budgeting, billing, and/or estimating future needs	Finance unit, inventory control
<i>Daily preventive maintenance record</i> —checklist of daily vehicle maintenance activities; used to promote preventive maintenance	Transport unit
<i>Delivery schedule</i> —monthly timetable for requisitions and deliveries; prepared for maximum staff and vehicle efficiency	Transport unit
<i>Refrigerator control cards</i> —temperature and maintenance log to ensure proper cold-chain storage	Clinical facilities
Reports	
<i>Quarterly and annual status reports</i> —to national level	
<i>Feedback reports</i> —from national level to warehouse/facilities	

Box 49-1 Steps in designing or revising a PMIS

1. Identify information users.
2. Identify information needs for each user, including selected indicators (see [Chapter 48](#)).
3. Review existing record-keeping and reporting procedures.
4. Match existing information with information needs to identify overlaps, gaps, and items that can be deleted.
5. Draft record-keeping and reporting procedures to fill the gaps.
6. Develop tools and procedures to help users do simple data analysis and present key trends.
7. Prepare or modify the instruction manual.
8. Field-test any newly designed or revised records and report forms, including instruction manuals.
9. Make modifications to record-keeping forms, reporting forms, and/or the instruction manual, based on field-test results.
10. Develop procedures for preparing feedback reports.
11. Train information users at all levels in data collection, reporting procedures, and use of information.
12. If the PMIS is computerized, provide training for staff in general computer use and specific applications.
13. Monitor the system's implementation, including the quality and regularity of reporting.
14. Adapt the records, report forms, and software as information needs evolve.
15. Continuously monitor the relevancy and sufficiency of the existing PMIS and make necessary changes through a participatory process.

of delays and a lack of local context. For example, a store-keeper may wish to maintain a graph of the average number of days out of stock of selected products to see whether stock control is improving or getting worse rather than wait for someone at a higher level to send graphs drawn from local data.

It is essential to field-test any newly designed records and report forms with staff from the units that will eventually use the new system. Staff at actual work sites can almost always suggest better ways of doing things, as well as point out places where the new forms or procedures are unclear. Computerized procedures and feedback report formats should also be field-tested and revised. [Chapter 50](#) contains more information about computerization.

49.5 Key issues in designing or revising a pharmaceutical management information system

Overall, political support for making changes is crucial. Many other key issues need to be considered to ensure the success and sustainability of the PMIS.

Involve users in design and pilot testing. The usefulness and sustainability of a PMIS increase with user involvement. To embrace the system, users need to know how the PMIS can answer their questions and solve their problems. In addition, users should be trained to manage the system's evolution.

Be selective in choosing indicators. To save time and money, use proxy indicators when they make data collection

more efficient and are likely to be accurate. For example, although knowing the average number of days each medicine is out of stock would be useful, reporting the number of pharmaceuticals out of stock at a particular moment may be more practical. [Chapter 36](#) introduces the concept of performance indicators, and [Chapter 48](#) discusses their use in monitoring. In general, indicators should be designated in areas such as selection, procurement efficiency, product and service quality, distribution efficiency (stockouts, overstocks), rational use, financial management, human resources management (training activities, for example), and reporting compliance with the PMIS. [Table 49-3](#) illustrates a set of indicators for rational medicine use and the associated information for data collection for a PMIS in Namibia.

Strive for representativeness, not comprehensiveness. A comprehensive set of data appears to provide more accurate information, but, in fact, a statistically representative set of data can provide equally good information for less cost and in a shorter time. Representativeness can be achieved by using sentinel data collection systems or sampling methodologies either to select subsets of facilities to survey or to monitor lot quality to focus on the best- and worst-performing service units.

Choose appropriate data collection methods. When possible, use available data sources and rapid assessment methods to collect information on medicine use at the health service and household levels. Qualitative data collection methods include focus group discussions, in-depth interviews, structured observation, questionnaires, and simulated patient surveys (see [Chapter 28](#)). Use supervisors to gather observational data, complete checklists, and

Table 49-3 Proposed PMIS indicators for building a pharmaceutical supply system in Namibia: Rational use of medicines and quality of care

Indicator	Numerator/denominator	Data collector	Where data collected	Tool	Level	Frequency
Percentage of vital reference materials available in the pharmacy	Number present/total number	Pharmacy assistant (PA)/hospital pharmacist	Reference books	Tally sheet 1	District, regional, national	Annually
Percentage of essential reference materials available in the pharmacy	Number present/total number	PA/hospital pharmacist	Reference books	Tally sheet 1	District, regional, national	Annually
Average number of medicines per outpatient prescription	Number of medicines prescribed/number of outpatient prescriptions	PA/hospital pharmacist	30 outpatient prescriptions	Tally sheet 3	District, regional, national	6 months
Percentage of generic names per outpatient prescription	Number of medicines prescribed generically/number of medicines prescribed	PA/hospital pharmacist	30 outpatient prescriptions	Tally sheet 3	District, regional, national	6 months
Percentage of outpatient prescriptions with an antibiotic	Number of prescriptions with an antibiotic/number of prescriptions	PA/hospital pharmacist	30 outpatient prescriptions	Tally sheet 3	District, regional, national	6 months
Percentage of therapeutics committee meetings held and minuted out of number planned	Number of therapeutics committee meetings held and minuted/number of therapeutics committee meetings planned	PA/hospital pharmacist	Therapeutics committee meeting minutes		District, regional, national	Quarterly
Percentage of patients returning on time to collect refill prescriptions (ART)	Number of patients returning on time for refill/number of patients expected to collect refill	PA/hospital pharmacist	ART records		District, regional, national	Quarterly

Source: Lates 2005.

provide immediate feedback and support to staff. Finally, use sentinel systems to generate higher-quality but fewer data from a subset of health facilities (see [Chapter 48](#)).

Common errors at different points in the recording and reporting process are noted in [Table 49-4](#), which also describes common sources of problems and possible solutions.

Integrate the PMIS with other data collection systems.

System integration is particularly important in the health sector when information about service delivery is being collected. Health workers are often overburdened by multiple or vertical reporting systems for immunizations, family planning, disease control programs, and so on. In this case, try to collect data through existing reporting systems or other means, such as medical record reviews and sample surveys, rather than by introducing additional routine reports.

One important factor for computerization is the adoption of standard coding systems for medicines, health facilities, diseases, and geographic areas. A uniform coding system is essential to ensure efficient aggregation across facilities or geographical regions. In addition, standard data file structures often need to be developed to promote compatibility among different software programs in use (see [Chapter 50](#)).

Develop practical analysis methods to facilitate data interpretation and use. Users should be taught the graphics techniques described in [Section 49.7](#) for use with two to four key indicators and should use them to monitor their own performance. Worksheets can help staff aggregate data and calculate indicators manually from existing records.

Computerize at appropriate levels. Achieving the right mix of computer and manual systems is critical, as is ensuring that they are fully integrated so that units without computers can produce their reports manually. Keep in mind the adage: “If you can do it by hand, the computer might make it more efficient, but if you can’t, the computer is likely to make it worse.” Decisions about computerization should take the following factors into account—

- Availability of a dependable source of electricity, secure physical space, and adequate consumables (for example, paper, ink, CD-ROMs, backup media).
- Local human resources to support computer hardware and software installation, maintenance, and training.
- Volume of data to be processed. If the volume of data is manageable manually, computerization will only add to the cost. Computers are useful if storage

Table 49-4 Improving recording and reporting accuracy

Kinds of problems	Sources of problems	Possible solutions
Errors in recording	Too many data items are on a single page	Limit number of data items per page Use checklists wherever possible
	Data items are not clearly labeled	Label data items in large letters
	No instructions exist for data entry	Provide instructions for each data entry
	Data need to be recopied several times on different forms	Use carbons if multiple copies are necessary
Errors in deciphering	Data are not verified for accuracy	Make periodic checks on the validity and accuracy of data
	Entries are illegible	Use checklist to avoid illegible handwriting
Errors in tabulating	Data entries are abbreviated because of insufficient entry space	Leave sufficient space to avoid abbreviations
	Columns are too long	Add summary lines in long columns
	A single page has too many columns	Limit number of columns to five per page
	There is no place to tally page summaries	Add a sheet for page summaries

and retrieval or compilation of a large database is required.

- Complexity of analysis required. Computers are excellent tools that can be used to solve complex mathematical problems and produce various analytical reports, including graphical representations.

Use software appropriate for needs. The software needs of a PMIS will depend on the size of the data set and complexity of analysis. For example, a spreadsheet program may be adequate, or a database application may be the better choice, depending on the size of the data set and the types of reports needed. A spreadsheet is simpler to set up and navigate, but it is primarily designed for manipulating numbers and making calculations. Spreadsheets are very useful for doing “what if” analyses and generating graphs and are more straightforward to understand. However, a spreadsheet usually requires more redundancy in data entry, which becomes increasingly difficult to handle as the number of records increases. In addition, querying data sets is difficult in a spreadsheet. Keep in mind, however, that data can be converted from a spreadsheet to a database and vice versa.

A database program is designed for collecting, storing, and organizing data. It is more complex to set up, but data entry is generally easier and can be better controlled and validated than in a spreadsheet. A database program has more powerful querying features, which facilitate the manipulation of complex data. Modern databases, usually called relational databases, have improved techniques to efficiently store data that are complexly related. Getting the database structure right is critical to having an effective system, so expert advice may be necessary.

Any system needs to be able to create graphics, such as charts (as discussed in Section 49.7). A Web-based system, as shown in [Country Study 49-2](#), allows many different facilities at different levels of the health care system to access needed information and other resources easily. Software can be an off-the-shelf package or a package custom designed in-house or by consultants. Developing software in-house is a tempting option when an off-the-shelf package does not appear to meet all needs. However, developing software in-house or through a consultant is a difficult task that requires very careful planning. In most cases, using an off-the-shelf package and compromising on some of the desired functions may be a better solution.

Ensure that information is communicated effectively. Key decisions need to be made about what, how, and with what frequency data will be communicated to higher levels. Do all data need to be transmitted and analyzed at a higher level, or only summary data? Do raw data need to be reviewed by line managers before being submitted for analysis, or can line managers rely on analyzed feedback from a central information clearinghouse? For computerized systems, can some data be entered in decentralized computer centers and transmitted in batches, using disks, or through the Internet? Can parts of the system be designed for online use from remote locations? However data are transmitted, careful attention must be paid to setting up and monitoring reporting schedules so that timely information can be produced.

Hire or train staff with appropriate skills. Hiring and keeping knowledgeable and skilled human resources to maintain a PMIS is a challenge; skilled staff members may take positions in the private sector, where remuneration is generally better. Knowledge and understanding of the health system in general and the pharmaceutical management system in particular are important attributes

in someone who is designing or overseeing a PMIS. The level of technological expertise needed will depend on the system, but the person should have a good understanding of information system design principles. Being able to communicate with decision makers to determine the information requirements is more important than simply being a computer expert.

If the required expertise is not available in-house, contracting out the development of a PMIS and computer system may be the best option. Employees already working in pharmaceutical management should also participate in the design of the PMIS; however, some people are reluctant to learn a computerized system, which may be a constraint. [Box 49-2](#) reproduces a job description, including the qualifications and skills, for a PMIS manager in Kenya.

49.6 Implementing a pharmaceutical management information system

Implementation of PMIS changes should be more successful with proper field-testing, phased implementation, flexibility, and adequate training. Field-testing should involve not only the well-performing sites but, more important, the average or worse-performing sites.

A modular approach may be useful. Develop stand-alone modules that can be applied and tested as they are completed, rather than developing the entire system from start to finish before the users ever see it. These modules can later be integrated to form the complete system.

Flexibility is also important. Build in flexibility to add or reduce data elements, or change reporting formats, data entry screens, and feedback reports. Staff members need to

Country Study 49-2

Building a data management information system for MDR-TB surveillance in Brazil

In Brazil, the Hélio Fraga National TB Reference Center, the National TB Program, and the Rational Pharmaceutical Management Plus Program developed a new data management information system as part of a larger effort to decentralize surveillance of multi-drug-resistant tuberculosis (MDR-TB) to the states. The PMIS tracks treatment of MDR-TB patients—diagnosis, case management, and pharmaceutical provision and distribution—including second-line medicines.

The process of creating the PMIS included a stakeholder working group with representatives from decentralized sites that developed and field-tested standardized procedures, defined indicators, and implemented epidemiological and operational reporting. The information

system is Internet-based, so all tools and reports are available online, making information available to users at all levels of the system (see figure below). The MDR-TB surveillance PMIS was designed to integrate into existing governmental health surveillance systems.

The Internet-based components of the PMIS include—

- Case notification data sheet
- Quarterly follow-up data sheet
- Follow-up data sheet after treatment success
- Request for MDR-TB medicines
- Quarterly report on stock turnover for MDR-TB medicines
- Customized reports
- Data extraction tool

Box 49-2**Job description for a pharmaceutical management information officer in Kenya****Overall responsibilities**

The Pharmaceutical Management Information Officer provides assistance to selected Ministry of Health (MOH) divisions in planning and coordinating information on reproductive health and HIV/AIDS commodities for health facilities in line with the Kenya Health Sector Strategic Plan. The Pharmaceutical Management Information Officer assists in strengthening the capacity of pharmacy and laboratory staff in terms of information management for medicines and commodities at both the national and service delivery levels. The Pharmaceutical Management Information Officer also assists with the monitoring of project activities, including collecting and analyzing data related to key indicators established within the MIS, identifying and reporting problems, implementing solutions in coordination with other members of staff, and writing periodic activity reports.

Specific responsibilities

1. Act as the commodity information management liaison to MOH and Rational Pharmaceutical Management Plus (RPM Plus) staff.
2. Support RPM Plus staff to perform the commodity information management functions, which includes but is not limited to the following—
 - a. Receive and collate commodity consumption data and assist with analyzing data related to key indicators established within the MIS
 - b. Identify and report problems; implement solutions in collaboration with staff from the divisions
 - c. Support activities to ensure quality of data
 - d. Develop reports that will inform commodity resupply to sites, stock status audits, and quantification
 - e. Support the database reporting routines for reporting to stakeholders
 - f. Mentor division staff in their monitoring and evaluation (M&E) and MIS roles
3. Participate in commodity distribution planning for and in collaboration with MOH divisional counterpart staff.
4. Participate in commodity management systems strengthening and training activities that target staff in the public health sector–assisted sites. Troubleshoot problems and facilitate progress as necessary.
5. Support the MOH staff in the adaptation, updating, implementation, and dissemination of commodity management standard operating procedures and MIS and M&E tools with the goal of ensuring the effective ordering, storage, distribution, and use of pharmaceuticals and commodities in support of selected priority health care delivery programs.
6. Participate in supportive supervision, M&E, and site assessment activities as conducted by staff of the public-sector program divisions and RPM Plus staff.
7. Participate in the development and submission of appropriate monthly and other ad hoc technical and progress reports, achievements, and challenges faced in implementing the MIS to stakeholders on a timely basis.
8. Assist in the implementation and documentation of Kenya public health sector program activities with specific reference to the information management of the pharmaceutical and laboratory commodities.

Qualifications

1. Graduate degree in public health, pharmacy, or other health-related field or relevant equivalent experience.
2. Experience in pharmaceutical and commodity management systems is preferred.
3. Knowledge and skills in pharmaceutical and commodity management for ART is an added advantage.
4. Long-term working resident experience in Kenya with an understanding of the Kenya public health system.
5. Demonstrated ability to write lucid technical reports.
6. Experience in strengthening pharmaceutical management systems, including pharmaceutical policy development and implementation, supply chain management, dispensing pharmaceuticals, and counseling patients, is preferred.
7. Excellent interpersonal skills and demonstrated ability to interact professionally with a diverse staff, clients, and consultants.
8. Proficiency in English and Kiswahili, including reading, writing, and speaking skills, is preferred.
9. Computer skills, including spreadsheet, database, word processing, presentation, and electronic mail; Microsoft Office preferred. Knowledge of other graphics packages is an added advantage.
10. Ability and willingness to travel extensively in Kenya.

adapt a PMIS and perform ad hoc analyses as information needs evolve.

Many electronic tools exist that can be used in implementing a PMIS; for example, personal computers are now being used in even the most resource-limited settings, and special software packages are being developed to facilitate data analysis and reporting in pharmaceutical management (Country Study 49-1). In addition, other technologies such as personal digital assistants and geographic information systems are being used as tools in MIS (see Chapter 50).

Finally, staff at all levels need sufficient training for their roles in the information system, which may include design and development of an MIS, data collection, computerized data processing, and use of data.

49.7 From information to action

The most fundamental element of a successful PMIS is the effective use of the data generated by the system. Figure 49-3 illustrates the process of transforming data into information and interpreting them for use in decision making. The key steps are processing data, presenting information, interpreting information, and taking action.

Processing data

Data processing can take many forms, ranging from simple data aggregation by district, calculation of averages, or trend

analysis over time to the use of sophisticated statistical techniques such as analysis of variance. The objective of data processing is to reduce large amounts of data to a manageable amount, often using summary tables. It is important to remember that a computer is not necessary for data processing. Tally sheets can be developed to help users gather data from many sources and to compute totals, counts, and averages.

Presenting information

Some people have difficulty interpreting information presented in tables. Simple techniques for graphing tabular data can help simplify interpretation. However, complex tables with many elements are not good candidates to present graphically. A computer spreadsheet or graphics program can make creating these presentations easier and clearer. Some common graph types and their uses are—

- Bar graphs: comparison of values for different items or for the same item at different physical locations
- Line graphs: presentation of trends over time
- Pie charts: demonstration of the relationships among the parts of a whole
- Maps: demonstration of the geographic distribution of indicators

Figure 49-4 illustrates some common graph styles and their key uses.

Figure 49-3 PMIS information stages

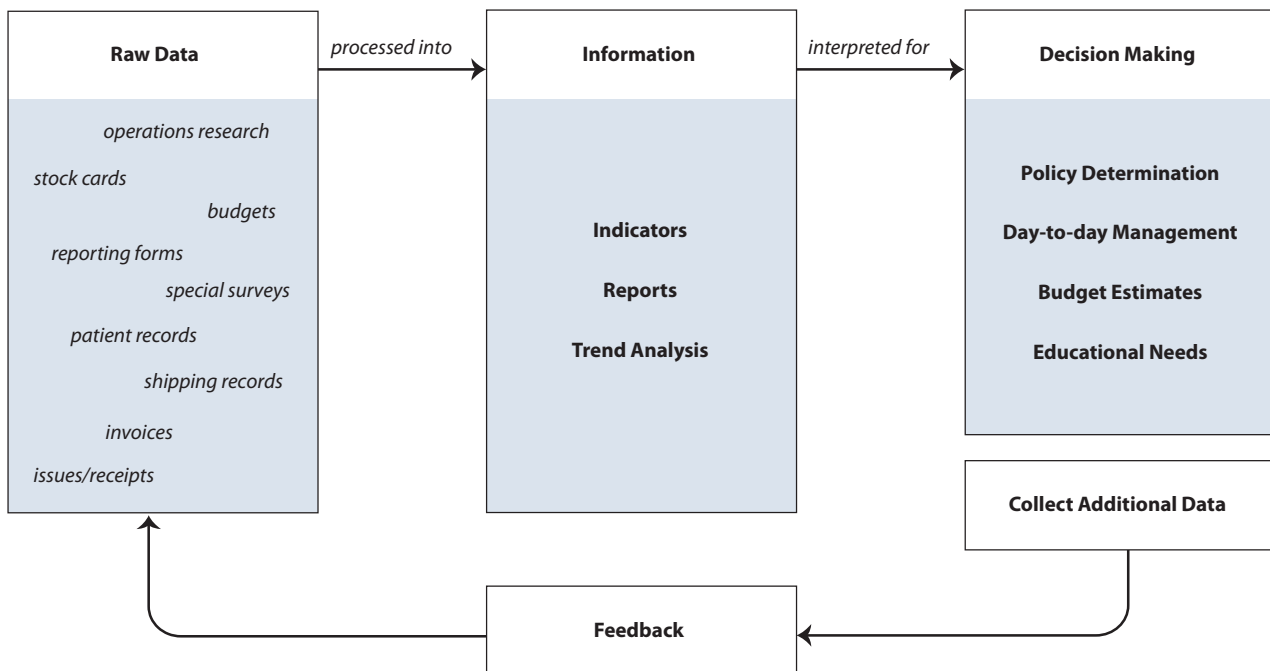

Figure 49-4 Graph styles

Bar Graph

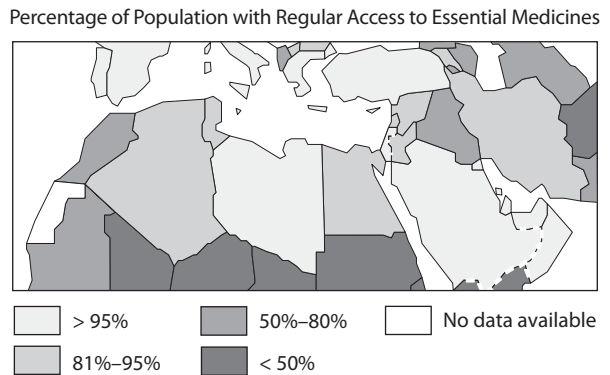

Line Graph

Pie Chart

Map

Interpreting information

Interpreting the information is often the most interesting part of using data. Interpretation is based on context, so creating detailed guidelines for interpreting data is not possible. However, listed below are some of the points to consider in this process.

Are the data correct? If the sources (registers, for example) were reviewed again, would the same figures result? Were the calculations made correctly? Procedures for validating the data should be in place to ensure their accuracy and completeness; for example, pharmaceutical inventory data should be periodically reconciled with physical stock counts. Because verifying all the data may not always be possible, periodic verification based on sampling would greatly improve data quality.

Are the data representative? Ensure that aggregation and analysis are based on a representative sample of data by ensuring that a majority of units are reporting on time. If only the best-performing units are reporting, the data interpretation may be misleading.

Do any of the figures seem improbable? In absolute terms—without making any calculations—do any num-

bers seem strange? Do expenditures seem too high or too low? Are too many essential medicines out of stock? Are too few orders from facilities being filled? Does the number of emergency purchases seem too high? (Small variations from month to month may be insignificant and should be disregarded.)

How do the figures compare with previous figures? Is a trend toward improvement evident although the figures may not seem good in absolute terms? For example, even though some revolving drug fund decapitalization may exist, is it lower than the previous year's? Using a simple graph or a wall chart can help identify such trends.

How do the figures for different geographic areas compare? Are some districts more successful than others? Do some need extra help building up their clientele or reevaluating procurement or quantification methods? Does more targeted training, education, and communication work need to be done for staff or clients?

What might be the causes of problems identified in reports? Could external factors (such as clients' economic problems or seasonal variations) be responsible for problems? What could their internal causes be (for example, poor estimation of pharmaceutical requirements or delays

Box 49-3 Example of information interpretation and use

Year	Essential medicines program price	World price	World price index
2003	3,600	3,000	120%
2004	3,300	3,100	106%
2005	3,800	3,050	125%
2006	2,800	3,000	93%

Observation: The difference between the price that the Essential Medicines Program (EMP) has been paying for its pharmaceuticals and the world price has been decreasing steadily, except in 2005.

Possible interpretations

An increasing proportion of central medical stores' pharmaceuticals are being purchased in bulk competitive tenders.

A greater share of the priority pharmaceuticals are now manufactured within the country, so the costs of transport and clearance are decreasing.

The jump in price in 2005 was caused by serious delays in the arrival of major international orders. As a result, the EMP had to replenish stocks with emergency purchases from local pharmacies.

Possible actions

The overall trend is very positive. Ensure that procurement officers are congratulated for a job well done.

Continue to focus on identifying local manufacturers to bid for large orders.

Get more information about why the large procurement was delayed. If the delay was caused by vendor performance, look for a different vendor. If caused by poor planning within the EMP, set earlier deadlines or order more stock so that the pipeline can be shortened.

in processing orders or clearing items through the ports)? Use a table similar to the one in [Box 49-3](#) to list possible interpretations of the information on key indicators.

Taking action

Interpretations of the information provide possible courses of action for each scenario.

Discuss reports with colleagues. When reports are first prepared, discuss them in a staff meeting. Other staff members may offer useful insights into why specific indicators are getting better or worse, and they may have helpful suggestions about changes that could be made.

Provide feedback. When reports are sent from other units, simple feedback can be given, such as acknowledging receipt of the report and providing a response on any issues that require action. Better yet, a routine mechanism can be developed to provide some analysis of data on key indicators in reports received from all reporting units. This analysis should help people compare their performance with that of other units. Automating the preparation of feedback reports is an important use for computers in a PMIS.

For each interpretation, identify possible actions. Note that action should not be limited to dealing with problems; focusing on positive results is also important. If one quarter had especially good results, see what can be learned from

staff about what went right and try to share it with others and replicate it (see [Box 49-3](#)).

Gather more data. If reports based on routine data indicate that a problem might exist, confirmation can be obtained through an alternative data collection method, such as a survey or a special supervisory visit.

Correct the problem. Many problems can be corrected through supervision and retraining, but situations may occur in which sanctions and disciplinary action are required. The survival of the program may depend on it. ■

ASSESSMENT GUIDE

Information system design

- Does the overall plan for the pharmaceutical supply program include an information management plan?
- Does the information management plan support strategic, program, and work-planning needs? Does it support monitoring and evaluation for assessing the implementation of these plans?
- Have key information users been identified at all levels? Have their needs for information related to management decisions been specified?
- Are data-reporting forms, such as periodic status reports, designed to be easily completed from existing registers, ledgers, and filing systems?
- Have key indicators been defined? Are their uses understood by staff at all levels?
- Is there at least one indicator for each key area of activity?
- Is the PMIS integrated with other information systems? If not, how much duplication of data exists between systems?
- If computerized systems exist, are they integrated with manual systems?
- Is the PMIS well documented? Is there an instruction manual on how to use the system? In computerized systems, are data structures and dictionaries documented?
- Are there enough trained staff? Do entry-level and in-service training schemes exist? Do staff have the capability to adapt the PMIS if necessary?

Data collection, reporting, and use

- Is an institution/unit(s) responsible for managing any health information systems? What type of information is collected and compiled by these systems?
- Are any of the systems automated? Which levels are automated and which levels are manual?
- Does the same system cover more than one vertical program (for example, tuberculosis, HIV/AIDS, immunization)?
- Are data collection methods appropriate for the types of data being collected?
- How long do staff take to fill in the reporting forms

each month, quarter, and year? Can these times be reduced?

- Are report forms standardized? Are instructions available for filling them in?
- Is the quality of data entered into forms validated?
- Do any overlaps exist in the data being reported at different intervals? Are any types of data collected that are never used?
- Do staff use any data to complete report forms before sending the forms on to higher levels?
- Where does data get aggregated and/or compiled?
- What type of reports exist?
- Are feedback reports provided routinely to the units that collected the data? Do they incorporate graphical as well as tabular information?
- Does a schedule exist for report preparation, data transmission, and feedback reporting? What percentage of facilities reports information in a timely manner?
- Is a supervisory system in place that oversees the quality of management information?
- Is the information generated by the PMIS used for management decisions? Who are the key users of data on pharmaceutical management? Have their needs for information related to management decisions been specified? What are the examples of information being used in decision making?

Computers and communication of data

- Are any pharmaceutical management data entered or compiled using a computer? At what levels of the system is a computer used (for example, hospital, clinic, warehouse)?
- What kind of software is used to enter or analyze data?
- Do any facilities lack access to reliable electricity? Telephone connections?
- Is Internet access available to facilities if desired? Are there any issues related to Internet access?
- Can computers and communication systems be locally maintained? If not, what arrangements can be made?

ANNEX

Annex 50-1 Building a product master file in a database 50.22

SUMMARY

Users should first define what functions or tasks computers will be used for, identify appropriate software for those functions, and then select hardware that is capable of using the software efficiently.

A computerization process is easier when—

- Efficient manual procedures exist
- Staff members are capable of, and interested in, learning to use computers
- Funds have been allocated for training, maintenance, and equipment upgrades
- A reliable power supply exists

Pharmaceutical management programs should usually begin with basic word processing and spreadsheet applications. Users can then gain experience and develop support systems for supplies, repairs, and security.

Specialized pharmaceutical management programs are often used for quantification of pharmaceutical requirements, procurement, inventory management, or medicine-use analysis.

Medicine information is increasingly available through electronic communications systems. Most pharmaceutical supply systems have access to Internet communications. Two main options are available: e-mail and World Wide Web browsers. Use of the Internet for international communications has become increasingly important.

Central to most pharmaceutical management applications is a product master file, including product name, strength, dosage form, therapeutic category, route of administration, and packaging. A coding system with a unique identifier for each drug product must be developed.

Personal computers, or PCs, can be used in all aspects of the pharmaceutical management cycle. Hardware refers to the computer's electronic and mechanical parts, which include—

- A microprocessor chip
- Memory chips (RAM, for random-access memory)
- Input devices (keyboard, flash drive, mouse, scanner)
- Storage devices (hard disk drive, CD-ROM, magnetic tape)

- Output and peripheral devices (monitor, printer, modem, network card, speakers)

Software refers to instructions that can be understood and executed by the computer. Categories include—

- The operating system, which coordinates and directs information for the microprocessor
- General-purpose software, such as word processing, spreadsheets, and database management software
- Special-purpose software, such as presentation graphics, project management, and accounting software
- Utility programs, such as antivirus, file backup, and data recovery programs
- Specialized pharmaceutical management software, often a custom-programmed database application

When used effectively, computer systems save money, promote efficiency, and improve the quality of services. However, poorly conceived or implemented computer systems waste money, decrease efficiency, and distract attention from other management improvements.

This chapter discusses the uses of computers in pharmaceutical management and examines special issues in computerizing pharmaceutical management information. It also includes specifications for computer applications in pharmaceutical management, considerations for hardware selection, and requirements for maintaining and supporting computers. Preparing data for computerization is discussed, along with coding systems and definitions of units. This chapter focuses on personal computers because they are the most widely used by essential medicines programs. Instructing users in particular software programs or making recommendations for the purchase of a specific piece of hardware or software is beyond the scope of this chapter.

The question today is usually not whether but rather how and how much to computerize. Even more important, however, is how to computerize efficiently. This chapter provides guidelines to help decision makers computerize their operations effectively.

50.1 Uses of computers in pharmaceutical management

Computers can be used in all aspects of the pharmaceutical management cycle, from selection to use. Using communication devices, users can exchange or share information with other computers at the same site through a local area network (LAN) or with computers anywhere in the world. The term *computers* here also encompasses devices such as personal digital assistants (PDAs) and handheld and pocket devices such as “smartphones.” Table 50-1 summarizes some of the many current computer applications for pharmaceutical management.

50.2 When and how to computerize

Computer technology changes quickly, with machines continually becoming faster, more capable, and less expensive. The benefits of computers in managing pharmaceuticals depend on the choice of tools, the commitment to using the tools, and the ability to overcome the hurdles involved in incorporating computers into the organization. No standard formula exists for successful computerization in pharmaceutical management, but rather a mix of elements applies; the right mix can yield great benefits.

Benefits and limitations of computerization

Some of the benefits of computerization are to—

- Simplify and speed up complex tasks
- Increase accuracy by checking spelling, calculations, and data integrity
- Update and access information quickly
- Automate repetitive tasks
- Provide management information for decision making
- Allow organizations to expand operations
- Streamline administrative processes
- Generate timely reports without repetition

Nevertheless, computers do have limitations. They cannot assume responsibilities, make decisions, define problems, set objectives, improve the basic data available, or make a person more organized. They cannot fulfill needs if appropriate hardware and software are not chosen, and they are not a one-time expense: funds are required for upgrades, training, and support over time for both hardware and software.

Conditions in an organization that support computerization include—

- Efficient existing manual procedures
- Other departments that have computerized successfully

Table 50-1 Computer applications for pharmaceutical management

Box 50-1 Key steps in the computerization process

1. Identify the tasks or the system to be computerized with a detailed analysis of needs compared to current systems.
2. Survey the environment and consider integrating with other systems to the extent feasible. (What software and hardware are being used by other departments? Does an institutional computer policy exist? What equipment is already available?)
3. Evaluate the staff situation (actual versus needed).
4. Select software before hardware.
5. Identify whether the software needed is available in the local language and to which original version it is equivalent (non-English-language versions are sometimes not as current as English versions).
6. Ensure the availability of supplies and maintenance.
7. Select the hardware and software suppliers that provide the most support.
8. Plan progressive implementation (one step at a time) and involve current and future users in the design and implementation process.

- Staff capable of, and interested in, operating computers
- A reliable power supply
- Adequate funds to support maintenance, training, and equipment upgrades

Conditions that can impede computerization include—

- Hardware or software not suited to the task
- Not enough trained operators
- Lack of a maintenance plan
- Lack of reliable power (voltage surges ruin computers and databases)
- Inadequate supply of storage media, paper, or printer ink and toner
- Unsuitable physical environment (exposure to dust, heat, or magnets, which can damage hardware and software)

Starting the computerization process

Begin with the basic questions: What will the computer be used for? Who will use it? Where will it be used? What is the budget for equipment, software, and maintenance? What special functions may be required? Will data need to be

Box 50-2 Illustrative phases in computerization

Phase I: Convenience computing

This phase includes tasks that could be done with a typewriter and calculator but are easier on the computer. If the computer “goes down” (temporarily stops working), the work can still be done. Examples are—

- Word processing
- Simple databases (for example, an address list)
- Simple budgets

Phase II: Periodic analyses and special activities

These tasks would be extremely difficult to do by hand but could be delayed for a few days or weeks if the computer were down. Examples are—

- Quantification exercises
- Complex project budgets
- Survey analysis

Phase III: Essential daily activities

These tasks involve large volumes of data handled daily or almost daily. If the computer went down, the work would be seriously impaired. Examples are—

- Inventory control
- Accounting
- Pharmaceutical registration

shared? Will a network be necessary? The key steps are listed in [Box 50-1](#).

In computerization, users should walk before they try to run. Trying to do everything at once increases failure rates, so organizations often computerize in phases (see [Box 50-2](#)). This strategy enables computer operators to handle increasingly demanding tasks, permits support systems for supplies and repairs to develop, and allows security systems to be put in place to protect against electrical damage, computer viruses, theft, and other hazards.

Perhaps most important, a phased approach to computerization allows users to develop a clearer concept of what computers can do, what kind of information they want from the computerized system, and which modifications they need to make in reporting and management systems to obtain that information. Computerization must be planned carefully so that implementation occurs smoothly, with a minimum of interruption and dislocation in the organization's work. [Country Study 50-1](#) provides some examples of good and bad computerization experiences.

Computer software: options and guidelines

Software is always becoming more powerful, and upgraded versions appear regularly. Upgrades may mean that the software packages require upgraded hardware resources (such as additional hard disk space, processor power, and memory) to run effectively. This factor is the main argument for choosing software before hardware and for including hardware upgrades in the budget.

Computer magazines (and their websites, which are often free) are a valuable source of comparison articles on software and hardware. "After-market" software books published by companies such as Sybex or Que are often easier to use than the manual provided by the software company.

Three broad categories of computer software are useful in pharmaceutical management: general purpose, special purpose, and utility programs.

General-purpose software

General-purpose software programs (such as word processing, desktop publishing, presentation management, spreadsheets, and commercial database programs) perform routine daily activities or periodic analyses. Software suites that combine individual programs in one software package are designed to allow easy exchange of information among the different programs, such as linking spreadsheet figures in a text document. Standard suites usually contain a word processor, spreadsheet, and presentation program, while "professional" suites also contain a database program. The most important factor in choosing general-purpose software is access to local support. Some questions to consider are: Which package is the most common locally? Is local training available? What software is used in other local offices with which our office interacts?

Country Study 50-1 Sample computerization experiences

Poor planning. The central medical store (CMS) in a sub-Saharan African country was computerized as part of a program to strengthen the computer capacity of the Ministry of Health. Unfortunately, the firm chosen to do the work did not realize that two previous attempts at computerization had failed because of internal organizational issues that had little to do with computers. The firm repeated many of the previous mistakes, because it believed that the introduction of technology could establish organizational systems and controls, and it did not examine the organization's existing structure.

An ambitious plan to computerize inventory and financial accounts within three months was devised. What resulted was hardware that could not be serviced locally and inadequate training of staff. Only a few poorly attended meetings were held with CMS management, and for many reasons, the data entered into the software were never accurate or up-to-date.

After nine months, the main CMS computer was stolen. No data backup had been made for more than three months because no diskettes were available. The last four months of data were lost, and no one thought that the system should be revived. No maintenance budget had been set aside for recurring costs, such as printer toner, diskettes, and systems maintenance, and the computers were being used only for word processing.

Computer integration issues. In a rapidly developing South Asian country, problems have occurred in the integration and transfer of data. Many departments

have computerized, and data collection and processing overlap because responsibilities have not been clearly defined. In addition, incompatible software packages have been used; coding of key data, such as locations and medicine names, has not been consistent; and data linking has been very difficult. Many of the problems could have been avoided by clear definitions of responsibilities, a software policy, and a common coding system for key data.

Well-planned computerization. A Southeast Asian country has undertaken the process of computerizing slowly. Initially, data on medicine consumption, procurement, supply, and health statistics were collected manually. Computers were first used to enter these data in a spreadsheet program. Although this system worked well initially, the amount of data to be processed eventually overloaded the system, and the decision was made to upgrade it. Appropriate software and a systems developer were carefully selected. Training of local staff by expatriate staff was very successful and is still important for maintenance of the system. Computerization has helped provide useful management data for consumption analysis, pharmaceutical procurement and supply, and reallocation of supplies among health facilities. A computerized registration system is planned. Computerization has been relatively successful in this country because a step-by-step approach was used, starting from manual systems and developing the system with end users to meet their information needs.

Word processing. Word processing programs have long replaced the typewriter. For most offices, 80 percent of computing time is spent on word processing. It is usually the easiest task to learn, because the input and output are obvious even to a novice. These programs are mainly used for correspondence and for producing documents. Features such as graphics capabilities, spelling checkers, search-and-replace functions, and generators for tables of contents make producing documents easier.

Desktop publishing. This software has word processing features but is more powerful for handling graphics, large documents, and production of files to be used by a printer for newsletters, bulletins, training materials, or books. Newsletters can also be produced using a word processing program.

Spreadsheet. A spreadsheet is a worksheet consisting of horizontal and vertical lines that define a matrix of rows and columns. It is modeled after an accountant's ledger, and data are entered in cells identified by coordinates in the matrix. Any type of data (text or numbers) can be entered in these cells, and sophisticated calculations and analyses (such as those discussed in [Chapter 40](#)) can be performed.

A major advantage of spreadsheets is their ability to revise totals, percentages, and other calculations immediately after any number or set of numbers is changed, allowing experimentation with "what if" alternatives. They can be linked to allow consolidation of accounts and can produce graphics and charts of the data entered.

In pharmaceutical management, spreadsheets are used for budgeting, financial analysis, quantification of pharmaceutical requirements, ABC analysis, price comparisons, pricing models, and creating or revising national essential medicines lists, as discussed in other chapters.

Presentation. A simple graph often has more visual impact than a complex table, so presentation graphics packages can be useful for preparing effective and attractive reports, funding proposals, overhead transparencies, and presentations.

Database. A database is like an electronic filing cabinet. Data (characters, numbers, dates, formulas, or memos) are stored in fields. The combination of fields forms a record, the records together constitute a table, and a group of tables constitutes a database. Database software can store and manipulate large amounts of data quickly. Databases are used in many business applications, allowing users to—

- Sort data in any order using multiple sorting keys
- Establish relationships between databases and generate sophisticated consolidated reports
- Improve data consistency by allowing or requiring data to be entered according to defined choices
- Quickly retrieve data according to specific criteria
- Develop complex applications using powerful programming languages
- Import and export data

In pharmaceutical management, databases are used in data-intensive tasks, such as inventory control, procurement, tender management, detailed analyses of prescriptions, accounting, and drug product registration. Databases are superior to spreadsheets for this type of application because they store more data in smaller files with less need for duplicating entries. A common field can link separate records in the database, limiting the need for duplication of data entry and facilitating data retrieval and reporting. The structure of databases permits easy data manipulation for access and reporting, and they can be designed to check the data entered for consistency with previously entered data. A relational database is particularly useful in pharmaceutical management because it allows multiple records for the same basic item (helpful for inventory management, tender analysis, or medicine-use analysis).

Special-purpose commercial software

Pharmaceutical management systems often need special-purpose commercial software packages, such as programs for presentation graphics, project management, statistics, accounting, bibliographic data, and communications.

Project management. Project management software organizes and tracks project tasks to be accomplished according to a defined schedule and shows potential conflicts in the use of resources. Budgeting information can also be included.

Statistical. Although spreadsheets and databases have standard statistical functions, using a dedicated statistical package is sometimes preferable. Epi Info, developed and distributed by the World Health Organization (WHO) and the U.S. Centers for Disease Control and Prevention (CDC), integrates basic word processing, data entry, statistical, and database functions. It is particularly useful for processing survey data and tabulating data stored in standard database programs.

Accounting. Accounting programs are available with a wide range of capabilities. Basic bookkeeping can be done with spreadsheets, but a dedicated accounting package is often more appropriate. Selection depends on local factors: What can the bookkeeper use? What does a donor use? What support is available? What bookkeeping technique is used? Is the accounting format compatible with local regulations? Increasingly, reputable local accounting firms can advise which accounting programs are most suitable for an organization.

Bibliographic. Bibliographic software greatly facilitates storing, searching for, retrieving, and manipulating bibliographic information on books, journals, training materials, and government and project documents. This kind of software requires staff to keep the database up-to-date.

Utility programs

Programs called *utilities* help manage and maintain computers and stored data. Common utilities include anti-virus, file management, file backup, file exchange, data recovery, data compression, firewall, and network software. Because operating systems now include many of the commonly needed utilities, checking the capabilities of a particular operating system is advised before buying a separate utility.

A current antivirus program is absolutely vital for computer units that handle essential day-to-day functions, such as inventory control, drug product registration, accounting, or maintenance of national health statistics. It is also essential for any system that receives data from outside sources, including branch offices within the country. A firewall program is equally necessary for any computer that connects to the Internet. The firewall protects the network from unauthorized access.

Network software

Establishing an office-based computer network may be useful. A LAN (local area network) connects the computers and printers in a single location. A wide area network (WAN) connects computers in separate locations. A LAN can be established with or without a server, although a server may be required for certain purposes, such as running centralized inventory software. If the network has a server, it must be protected in a secure, climate-controlled room and its data must be backed up regularly.

A network is helpful if a number of computers in the office need to easily share resources, such as a printer or an Internet connection. A network is essential if multiple computer users need to simultaneously access the same software program, such as an inventory program running on the server. Installing the inventory program on the server means that all of the program's data is stored in one central location (a secure server room) and that other computers on the network can access the data from various locations, such as the accounts department or the warehouse, if the appropriate permissions have been granted.

Although the cabling and configuration of the network are often done by an outside firm, someone on the office staff should know at least the basics of network troubleshooting and maintenance so that downtime is minimized if system problems occur. If physically cabling the computers together is problematic, a wireless network can also be an option.

Wireless networks can also be used to connect computers in separate locations over a WAN. Some countries have decentralized pharmaceutical operations such as distribution so that work is done at the provincial or district level rather than the central level. Using a WAN, the lower levels

of the system can connect to a server at the central level to manage inventory distribution. Maintaining the information in a central location allows users from all levels to easily share data and coordinate work. Because the data are pooled in one location, management reports are easier to produce and use in a timely fashion.

Custom software

Development of custom-built software, such as an inventory program, is a complex and time-consuming task. Although the idea of custom-built software is attractive, purchasing software that has already been written and tested by others is usually preferable, unless a suitable program cannot be found. If new software does need to be developed, approach this task in a step-by-step fashion—

- Define the system requirements.
- Choose the software and tools for developing the custom program.
- Design a system.
- Develop and program the system.
- Test and debug the system.
- Implement the system through data entry and training.
- Develop system documentation and a complete user's manual.
- Provide system support, revision, and upgrades.

Frequently, lack of time, money, or expertise results in the development of unusable software. Developing custom software always takes longer than expected and often goes over budget. Users should explore all alternatives carefully before choosing to develop software themselves. [Annex 50-1](#) contains advice on developing a product master file for pharmaceutical management database software.

Open source software

Open source software emerged when individuals inventing programming code as part of the software development process shared their inventions with other networked users. Because any user could modify any part of this code and then share it with the network, the phrase *open source software* became a natural way of describing it. Open source software differs from proprietary software because its programming code is available for inspection, modification, reuse, and distribution by others. Although open source software can be free of charge, it can also be purchased; but once attained, it is freely modified. Today, open source software is used by individuals and organizations in the public and private sectors worldwide and is gaining popularity. Linux is one of the best examples of open source software—in this case, to control the computer's operation.

Table 50-2 Computer hardware specifications

Hardware	Indicator	Significance
Hard drive	Gigabyte (GB)	The number of gigabytes describes the storage capacity of the hard drive—how much data and software it can contain.
Processor chip	Chip type, with speed in gigahertz (GHz)	The chip type and speed determine how quickly the computer can make calculations, run software, and function. Any chip sold today should be sufficient for most office uses. The type and speed are more important for computers that will be used as network servers.
RAM (random-access memory)	Megabyte (MB) or gigabyte (GB)	The amount of RAM in a system determines how many tasks the computer can run at once and how complicated a program it can handle. A gigabyte is approximately 1,000 megabytes.
Monitor	Size (inches or centimeters)	The LCD (liquid-crystal display) monitors sold today vary primarily in their physical size and can be selected on that basis and on price, unless they will be used for highly graphics-intensive work.
Printer	Characters per second (CPS), pages per minute (PPM), dots per inch (DPI)	Dot matrix printers are judged in CPS, and laser and inkjet printers in PPM. Both are important when producing large amounts of output. Printer quality is measured in DPI and is important when producing high-quality output.
Modem	Baud	The baud rate is how much information a modem can send in a second and controls how long it takes to send a file over a telephone line.
Ethernet card	Speed	The speed of the Ethernet card determines how quickly it can send and receive data on a network.
CD-ROM or DVD-ROM drive	Speed	The speed of a CD-ROM or DVD-ROM drive describes how quickly it can access and read information from a CD-ROM or DVD-ROM.
CD-RW or DVD-RW drive	Speed	The speed of a CD-RW or DVD-RW drive describes how quickly it can write information to a CD-ROM or DVD-ROM. These drives can also read information from CD-ROMs and DVD-ROMs.

Program decision makers need to evaluate a number of issues when considering the use of open source software, including—

- A definition of program needs
- The types of open source applications available for the needs
- A review of open source and proprietary software alternatives, including differences in costs
- The availability of resources to support the open source approach
- The functionality and usability of the open source application
- The availability of professional support skills

A good resource on the use of open source software in developing countries is available (Dravis 2003).

Computer hardware: options and guidelines

The size and speed of computer hardware continue to change so quickly that specific recommendations about what a user should buy are impossible to make. When purchasing computers and peripheral devices such as printers, the important issues are processing, storage, memory, and output capacities. Always buy the most powerful equipment that the budget will allow, especially if a new computer cannot be purchased for a few years. Hardware generally improves so rapidly that a computer should not be purchased until shortly before it will be used. Delaying a purchase for even

a month or two can mean a lower price or greater capabilities for the same price. [Table 50-2](#) describes different types of computer hardware. In general, larger numbers are better for the indicators listed.

The use of handheld computers called personal digital assistants (PDAs) is increasing in the health care field and in pharmaceutical management, because they are a convenient way both to access and record information while away from the office. [Country Study 50-2](#) discusses different ways that PDAs are being used by various country programs.

Geographic information systems

A geographic information system (GIS) is a computer system that captures, stores, analyzes, and displays information that is identified according to a specific location. In other words, it provides an interface between all kinds of data and a map. GIS allows data sets from different sources to be brought together in spatial context to reveal relationships and patterns that are not necessarily obvious otherwise. In public health, for example, GIS technology can combine demographic, environmental, and health data with satellite maps to determine endemic or epidemic disease patterns.

A GIS can use digitized maps or coordinates from global positioning system (GPS) receivers to determine spatial relationships. In Tanzania and Uganda, Management Sciences for Health's (MSH's) East African Drug Seller Initiative is using GPS to map the locations of public- and private-sector clinics and drug shops to determine gaps in health care coverage in remote areas.

Country Study 50-2 Using handheld computers in pharmaceutical management

The increased technological ability and convenience of handheld computers or personal digital assistants (PDAs) or smartphones have made them popular tools in the health care field, including pharmaceutical management. Many information sources have been adapted for use on PDAs, including the National Library of Medicine's MEDLINE database and pharmaceutical-specific resources, such as the *British National Formulary*. Some of these resources are free and others are subscription-based.

In addition to providing easy access to health information, PDAs and smartphones are also being used to collect, analyze, and report data more accurately and efficiently in a number of countries.

Canada. In British Columbia, PDAs are being used as part of a quality-management program in a 285-bed hospital that requires the collection and analysis of quality indicators for pharmacy services. An electronic form was custom designed based on the pharmacists' data needs for process and outcome indicators, including adverse drug reactions and medication cost savings. The resulting electronic patient care form was installed on four PDAs and each pharmacist received a two-week orientation before switching from paper-based logs. The PDA data were downloaded daily to a single PC into a common database program, where it could be easily analyzed and used for reports. Users of the PDAs found that they were able to double the number of patients they counseled, and much less time was needed to collect, analyze, and report the data.

Source: Collins 2004.

Tanzania. In an effort to improve the effectiveness of its drug product and premises inspection programs, the

Tanzania Food and Drugs Authority (TFDA) worked with Management Sciences for Health to introduce the use of PDAs in data collection and management. The TFDA inspectors collect data on a wide range of product- and site-specific information, which previously had been handwritten on paper forms, then transferred to a database. The program's PDAs include forms for port-of-entry inspections, premises inspections, and postmarket surveillance in a format that guides inspectors through the data-gathering process. Collected data are sent monthly to TFDA by public mail/transport or by hand delivery to the TFDA central office. Also, updated product references needed by the inspectors in the field are uploaded to the PDAs monthly. The new system makes analyzing data and creating reports easier, and it improves the accuracy of inspection records through design controls and by increasing inspector accountability.

Uganda. The Uganda Health Information Network is using PDAs that are connected through the local GSM cellular telephone network to help expand access to health and medical information and support data collection and analysis. Health workers in the field use PDAs to send and receive information and data via "jacks," which are relay devices that contain a GSM cellular transceiver and a data cache. The jack then communicates with a main server in Kampala. When users connect to the jack, information is both uploaded and downloaded. In the pilot of this program, the PDA system was used primarily for collecting and disseminating field data, such as weekly disease surveillance reports and broadcasting medical education material.

Source: UHIN 2004.

50.3 Specialized software for pharmaceutical management and control

Pharmaceutical systems that successfully computerize usually begin with basic word processing and spreadsheet applications and then seek specialized applications for inventory management, procurement, pharmaceutical regulation, or medicine-use analysis. This section provides an overview of types of specialized software for various tasks and guidelines to consider when evaluating alternatives. Examples of specific types of programs are given, and others are listed in the references at the end of the chapter.

Quantification of pharmaceutical requirements

Quantification of pharmaceutical requirements (see [Chapter 20](#)) is complex, and a computer can greatly speed up the process. Spreadsheets can be used if limited data are involved. Worksheets can be set up to forecast requirements using consumption data; formulas can be entered into the spreadsheet for estimates based on different scenarios. Spreadsheets can be linked, or a single spreadsheet can be divided into sections (one to record the morbidity profile, one to organize the standard treatments, and one to summarize pharmaceutical requirements within therapeutic

Figure 50-1 Summary of illustrative integrated pharmaceutical supply management software and characteristics

Management component		Uses
1.	Accounting	Accounting manages the financial aspects of pharmaceutical management activities.
1.1	Accounts Payable/Purchasing	Tracks and processes bills and payments and provides complete checking account management functions.
1.2	Accounts Receivable/Billing	Tracks all customer histories and accounts.
1.3	Job Costing and Cost Accounting	Job costing and cost accounting provide a method for collecting, analyzing, and reporting all costs associated with a particular job.
1.4	General Ledger	General ledger maintains the Chart of Accounts and provides the basis for all other financial functions.
1.5	Financial Reporting	
1.6	Accounting Standards	
2.	Distribution	Distribution addresses selling and providing pharmaceuticals to other facilities.
2.1	Client Orders/Sales Orders	Receives and processes client and sales orders.
2.2	Consumption Reporting	Reports the distribution of items in stock.
2.3	Delivery	Supports processes and methods of delivering ordered items to others.
2.4	Kit Management	Addresses putting together and breaking apart stock items for distribution.
2.5	Push System	Provides facilities with predetermined types and quantities of stock.
2.6	Repackage into Dispensable Units	Addresses breaking apart large quantities of stock into smaller packages.
2.7	Reporting	
3.	Tender Management	Tender management manages the competitive bid process.
4.	Inventory Control	Inventory control manages the stock and inventory.
4.1	Receiving	Adds stock to the inventory database.
4.2	Supplier Performance Monitoring	
4.3	Maintaining History of Transactions	Stores and archives transactions for future reference.
4.4	Selling Inventory over the Internet	E-commerce associated with selling inventory over the Internet.
4.5	Establish and Maintain Inventory Records	
4.6	Reporting	
4.7	Forecasting and Order Planning	Forecasting and order planning supports methods and processes used to estimate the quantities of pharmaceuticals needed for your organization.
5.	Procurement	Procurement manages the acquisition of pharmaceuticals.
5.1	Purchase Requisitions	Collects and disseminates information about requested items.
5.2	Purchase Orders	Creates and tracks information about a sales transaction.
5.3	Group Purchasing/Pooled Procurement	Manages the procurement for a group with similar purchasing needs.
5.4	Perpetual Purchasing	Manages the procurement of stock-based designated or calculated reorder points.
5.5	Scheduled Purchasing	Manages the procurement of stock on a predetermined purchasing cycle.
5.6	Ordering Online over the Internet	
5.7	Supplier Management	Tracks supplier information.
5.8	Reporting	
6.	Vehicle and Equipment Management	Vehicle and equipment management deals with tracking and monitoring the assets in the organization.
6.1	Vehicle Management	
6.2	Equipment Management	
6.3	Cold-Chain Equipment Management	
6.4	Load Building	
6.5	Route Planning	
6.6	Transport Personnel Management	
6.7	Transport Personnel Assignments	
6.8	Vehicle Allocation/Vehicle Tracking	
6.9	Reporting	
7.	Warehouse Management	Warehouse management deals with managing the physical stock, whether it is in-house or located in another warehouse.
7.1	Bar Coding and Related Technologies	
7.2	Managing Multiple Warehouses	Manages multiple physical or virtual warehouses.
7.3	Stock Location Tracking	Tracks the physical location of inventory items.
7.4	Reporting	
7.5	Picking	

Management component	Uses
8. Transfunctional	Transfunctional includes requirements that span the entire range of functions and includes some miscellaneous requirements.
8.1 Currency	Supports multiple currencies.
8.2 Languages	Supports multiple languages.
8.3 Interface with WHO Drug Registration Software (SIAMED)	Imports drug registration data from a SIAMED export.
8.4 Master Drug File (from WHO)	Imports the master drug file.
8.5 User Customization	
8.6 Custom Reporting	
8.7 Indicators	Addresses custom thresholds and acceptable ranges for monitoring system.
9. Technical	Technical requirements describe the architectural characteristics of the system.
9.1 Multitier Organizational Structure	Operates in a three- and four-level organizational hierarchy.
9.2 Single-User Environment	Operates in a single-user, single workstation environment.
9.3 Multiuser Environment	Operates in a multiuser, networked environment.
9.4 Software Platform: Microsoft Windows	
9.5 Security	Addresses user authentication and data security.
9.6 System Maintenance	Backs up and archives data.
9.7 Data Exchange	Supports importing and exporting data with other applications.
9.8 System Architecture	
10. User Support	User support deals with technical support facilities you may require for this type of software.
10.1 Online Help	
10.2 User's Manual	

categories). Linking spreadsheets requires an advanced level of proficiency with spreadsheets.

Quantimed is a database tool for forecasting that has been developed by MSH. Users enter consumption data (past and forecasted use) and/or morbidity data (number of expected cases for each age range and for each health problem). When standard treatments are defined, Quantimed generates a table that compares the medicines needed, using both consumption and morbidity methods (see [Chapter 20](#)). Quantimed also produces a number of other reports, including some that can help with budgeting and comparing costs among different products and treatment regimens.

Basic data analysis and production of formulary manuals

Basic commercial software can be used for many pharmaceutical management purposes, such as data analysis and publication of formulary and therapeutics manuals.

Data analysis. Spreadsheets are ideal tools for developing a medicines list, because they allow easy manipulation of both text and numbers. Creating a spreadsheet that lists medicines and data on price, consumption, lead time, and formulary category is very easy. Formulas can then be added to perform various analyses, such as ABC analysis, price comparison analysis, and therapeutic category analysis (see [Chapter 40](#)).

Formulary manuals. A word processing program can be used to develop a formulary manual with treatment guidelines (see [Chapter 17](#)). A desktop publishing program can produce documents ready for printing.

Procurement and inventory management

Spreadsheets can automate aspects of procurement and inventory management, but they are not ideal for processing large amounts of data. Database software is more appropriate for this purpose. Using the same database program for procurement, inventory management, and accounting is preferable, because these activities are interconnected.

Inventory management is often part of a commercial accounting software package, but such packages typically focus on accounting and lack features specific to pharmaceutical management, such as the ability to track multiple products for the same code number, or to track items by lot number and expiry date. The ability to track issues by lot number is important for medicine recalls.

Database programs have been developed by MSH and others specifically to manage procurement and inventory control in public pharmaceutical systems (see [References and Further Readings](#) and [Box 50-3](#)). [Figure 50-1](#) provides a summary of pharmaceutical supply management software requirements and characteristics. [Box 50-4](#) lists standard reports that should be produced by such software. [Country Study 50-3](#) illustrates how software for inventory management and procurement has been used to improve pharmaceutical management for an HIV/AIDS treatment program in Haiti.

Hospital pharmacy management software

Specialized hospital pharmacy software can support various aspects of a hospital pharmacy ([Chapter 45](#)), including—

Box 50-3 RxSolution

RxSolution is an integrated computerized pharmaceutical management system. The system is used to manage inventory; process purchase orders; handle issues to wards, out/inpatient pharmacy, and satellite clinics; dispense medication to patients; and prepare repeat prescriptions for down-referral at the facility level (down-referral occurs when a higher-level health care facility such as a hospital transfers all or part of a patient's care to a lower-level facility that is more convenient for the patient). RxSolution supports best practices for procurement, storage, distribution, and dispensing of pharmaceuticals and medical supplies, helping to ensure availability of critical products at all times. Users record information on products, suppliers, clients, prescribers, dispensers, and patients.

The program has modules for—

- Budgeting
- Procurement
- Receipts
- Requisitions
- Dispensing
- Down-referrals

Any or all of these modules may be used, depending on the needs of the site and user restrictions. The program includes a wide range of clinical and management reports, which help improve pharmaceutical use, stock availability, and financial and logistic accountability.

RxSolution is currently being used in more than 120 sites in southern Africa. Examples of how facilities are using the software include the following—

- Staff in one South African hospital can now produce the monthly tracer list report for the provincial office with one click, rather than taking a day to count stock and write up the information. They can also track expenditures to come in on budget, and easily determine the amount spent on antiretroviral medicines, which they are required to report. Store management reports now include much more financial information.
- The director of pharmacy services for a South African city reports that RxSolution allows the staff to better manage their system and cost centers, because they can more easily track budgets and monitor clinics. The main depot receives 90 to 95 facility orders each month and can complete all of the orders within two weeks.
- Installing and using RxSolution in eleven hospitals and health centers in Swaziland met the Global Fund's requirements for a reliable antiretroviral tracking system. These facilities use the system to produce regular stock, patient, and prescribing reports for national-level managers. As a result of the successful installation and use of RxSolution, the Global Fund authorized funds for Swaziland to purchase antiretrovirals.
- The chief pharmacist at a South African hospital uses RxSolution to produce ABC analysis reports for the wards and the hospital to support his pharmacy and therapeutics committee work.

See <http://www.msh.org/projects/sps/Resources/Software-Tools/RxSolution.cfm> for more information.

- Patient medication profile
- Records of intravenous therapy
- Management of total parenteral nutrition
- Unit-dose management
- Medication administration record
- Order entry and inventory management
- Medication interaction checking
- Allergy checking
- Food and medicine interactions
- Duplicate therapy checking
- Laboratory value monitoring
- Outpatient prescriptions
- Patient billing
- Patient adherence

Accounting and financial management

Most public-sector supply systems must abide by government accounting regulations, which differ from country to country. Commercial accounting software is widely available, but it may require modification to correspond with local regulations. If a specialized pharmaceutical management software program is used for inventory control, the inventory software and the accounting software should be modified to communicate with each other.

Learning how to perform basic spreadsheet analysis is now a must for the essential medicines program manager. Spreadsheets can be used for both simple and sophisticated analyses of program finances. See [Chapter 41](#) for examples.

Box 50-4 Standard reports for supply management software

Supply management software should generate standard reports to support decision making, such as the following.

Inventory reports

Stock status report: lists all products in the product master file, including product code and description, unit of measure, quantity in stock, quantity on order, quantity reserved, quantity available.

Reorder report: lists all products that are below the reorder level, with reorder quantity.

Overstock report: lists all products exceeding the maximum level.

Inventory valuation report: lists the current value of the inventory, based on the chosen valuation method (last-in, first out [LIFO], first-in, first-out [FIFO], average).

Expired or soon-to-expire stock report: lists the products that are presently expired or will expire within a defined period.

Order reports

Open order report: lists orders from customers that have been entered and not yet shipped.

Back order report: lists all unshipped back orders.

Order history report: reports on all orders (shipped and nonshipped) on file.

Product reports

Catalog report and price list: lists all products in the product master file. Can contain pricing information and be used as a price list.

Product history report: lists by stock item total quantities and sales values for each fiscal period.

Sales analysis and forecasting reports

Customer analysis report: lists sales made to each customer in a specified period.

Ranked customer analysis report: same as above, but ranked by sales volume, with cumulative percentages.

Functional lists/outputs printed by the system

List of "picking tickets"

List of delivery notes/invoices

List of stock count sheets

Multilocation reports

(If using a system that tracks stock in multiple locations)

Transfer advice report: a reorder advice report that lists products that are over the maximum or under the reorder level. This report makes it possible to determine whether a product that is unavailable or understocked in one location is available in another location.

Financial reports

(If linked to financial information)

Credit hold orders report: lists orders that are on hold because the customer is over the credit limit.

Debtors and creditors report: lists those who owe and are owed money.

Tender reports

Bid evaluation report: for each product in a tender, lists all suppliers that offered bids, with information on the supplier (country, delivery time) and on the quoted product (unit cost, quoted unit price, bid converted to base currency, manufacturer, quality of sample, and any other details).

Supplier performance report: lists, for a given supplier, details of all previous quotations, orders, and deliveries, including both a comparison between date promised and date delivered and the condition of products.

Product quotation record: for each product, lists previous bids, with details of the supplier and the quoted prices. If an order was made, this is indicated with supply timeliness and quality information.

Database listings: lists suppliers and products. The supplier listings can also be available as mailing labels and for mail-merging into a word-processed letter.

Country Study 50-3**Creating an Internet-based information system for HIV treatment in Haiti**

The daily administration of several different antiretroviral medicines as part of antiretroviral therapy (ART) requires that each patient is monitored for health status, that results of laboratory tests are tracked and communicated to doctors, and that pharmaceutical supplies are reliably available at each treatment site. Zanmi Lasante, a nongovernmental organization that operated a successful ART site in Haiti's central plateau, was funded to scale up its program to five additional sites. In rural Haiti, where doctors are few, roads are almost nonexistent, and electricity is spotty, creating and maintaining such an information system among disparate sites would be challenging.

On the basis of its experience, Zanmi Lasante decided that the cheapest and most flexible communication strategy would be to establish a small satellite connection to the Internet in each of the five new sites. Instead of placing servers in each clinic, one shared server could be guaranteed a secure environment with stable power and a reliable data backup system. Using Web-based electronic records allows data collection and review from the remote sites, and with one server, the most recent data are accessible to all. The Web-based electronic medical record system in Haiti is built with standard, open source software.

Clinic staff members enter all clinical and medication data using a standardized Web-based patient form. To facilitate data entry, the form has an electronic checklist of patient management items, including requests for laboratory tests, details of treatment regimens, and lists of standard ART medicines. Doctors can check the medicines, doses, and administration schedules. As the medicines are entered into the form, they are cross-checked to the patient record for allergies, inappropriate doses, and incompatible medicine combinations. The system displays warnings about problems—for example, if zidovudine and stavudine are prescribed together. When the form is completed, the user can print out an order for the pharmacy. As new patient information (for example, laboratory results) is added that indicates additional treatment, e-mails are automatically sent to all clinicians with links to the medical records of patients who require follow-up.

Staff members also enter warehouse stock data into Web forms, and those figures are analyzed and monitored against expected use patterns from the treatment regimens in the system.

Source: Fraser et al. 2004.

Drug use reviews

Simple analyses of medicine-use patterns can be done with spreadsheets and commercial database software. Commercial software is available for analyzing data on medicine use from large databases. These software programs are usually fairly expensive (thousands of U.S. dollars [USD] per installation).

Pharmaceutical product registration

Pharmaceutical product registration software can help the drug regulatory authority track the hundreds or thousands of registered products. Registration data can be tracked in a manual card system, sorted by product name or company, but retrieving data needed for specific purposes is very time-consuming. Database programs can automate this procedure, retrieving records meeting specific criteria almost instantaneously. SIAMED, a software program for pharmaceutical product registration, is available from WHO. Computers can greatly facilitate pharmaceutical registration by improving access to information, but they do not provide the enforcement capacity needed to give registration

meaningful impact. A legal framework for pharmaceutical registration and a flexible and efficiently functioning drug regulatory authority are prerequisites to successful computerization of drug product registration. [Table 50-3](#) presents the features needed in pharmaceutical registration software.

50.4 Electronic communications and medicine information

Communications and medicine information are discussed together because medicine information is increasingly available through electronic communication systems. An enormous amount of reference information on medicines is available on the Internet. In addition, many organizations now create their own websites to share information internally or to show their progress and activities to the outside world.

Electronic communications

Computers are powerful and relatively cheap communication tools. Computer-based communication is possible

Table 50-3 Select features of registration software

Source: WHO 2004.

through electronic mail (e-mail), the World Wide Web, computer-to-computer modem connection, or fax.

If a good telephone line is available, computers equipped with a fax-modem can send and receive fax messages or complete documents in just a few seconds. Modern word processing software can send fax messages directly from the computer. The transmission speed and quality depend on the quality of the telephone line, but error protection protocols can help ensure the integrity of the transmitted data.

The most comprehensive computer-based communications medium is the Internet. Most countries have local connections to the Internet, which can send any data (including e-mail messages or computer files) for only a fraction of the cost of a telephone connection. Once the connection is established, Internet use is relatively inexpensive, especially for universities and governments. Increasingly, Internet cafés provide access in many locations. Locations with inadequate telephone-line infrastructure are having success with wireless Internet connections, which do not rely on traditional wires and cables. Other Internet connections are made through satellite and radio transmission.

In recent years, discussion groups have formed to exchange information over the Internet. For example, E-Drug is a discussion group that uses regular e-mail to exchange information on essential medicines management

issues. PharmWeb is a website that offers information on worldwide pharmacy and pharmaceutical management issues and organizations. PharmWeb links the user to various websites maintained by organizations active in the field. See References and Further Readings for contact information for E-Drug and PharmWeb. Web-based discussion groups can be helpful sources of information on a wide range of subjects, from computer problems to pharmaceutical information.

Medicine information

Traditional sources of information on medicines are journals and textbooks, such as those listed in [Chapter 34](#). Maintaining an up-to-date library of texts and journals is costly, however, and information is not always easily accessed by users in remote areas.

Computers can greatly facilitate access to pharmaceutical information. For example, PubMed, a nonprofit service of the U.S. National Library of Medicine, provides access to millions of articles from more than 4,800 medical journals on the Web (<http://www.ncbi.nlm.nih.gov/sites/entrez>). PubMed can also be accessed with a PDA. The more commonly used and readily available computer databases for medicine information are listed and discussed in more detail in [Chapter 34](#).

CD-ROM is relatively inexpensive technology that can store about 680 megabytes of data on one compact disc. DVD-ROMs are similar to CD-ROMs, but they hold about four gigabytes of data. Many products are now available on DVD. It is important that new computers be able to read DVD products.

Through powerful indexing routines and huge storage capacity, CD-ROMs and DVDs permit very fast access to medicine information. Books such as the *British National Formulary* and *USP Drug Information* are available in CD-ROM format. CD-ROMs with medication information or advice for poisoning treatment are used in many pharmacies and medicine information centers in industrialized countries, and their use is spreading quickly around the world as computers become more widely available.

Plenty of websites offer biased information on and questionable sales of medical products, including medications, but reliable, independent information on the quality, regulation, and rational use of pharmaceutical products is lacking. Learning to evaluate website content for accuracy, bias, and timeliness is an important skill. [Chapter 34](#) has more information. See also the list of references in this chapter for some useful websites.

Developing a website

If an organization has information that it needs to communicate, it may wish to consider developing its own website. Websites can be used to disseminate information to the public or can be designed specifically for an organization's internal use (intranet). Although the design and development of the site can be contracted out if staff members do not have the necessary skills, staff should be involved in the review and approval of material for the site, because it represents the organization. Many Internet service providers (ISPs) offer hosting services for websites and can house the necessary files on their servers to make them available on the Internet.

An organization can use an intranet to share information and data if a WAN cannot be established. For example, users can access an intranet to view or submit inventory data for procurement or distribution purposes. An intranet can also be used to share files or disseminate organizational information, such as standard policies and procedures. The intranet site can be maintained at the central level of the system but accessed by other levels in the system as long as the other levels have Internet access and the proper permissions. The intranet allows pooling and sharing of information in a system without requiring a direct connection among the different levels of the system. (See [Country Study 50-3](#).)

A website developer should consider the following criteria when creating a site to ensure that it is useful and informative (WHO 2001).

General criteria to consider for every site include—

- *User-friendliness*: The first impression should include an attractive design and logical organization of information.
- *Site map*: The site map indicates logical links and organization of the site and explains how to navigate through the content.
- *Navigability*: This characteristic allows the user to find information easily.
- *Speed*: The pages should be displayed within four to five seconds.
- *Search function*: The site should have its own search engine.
- *Update*: The website should include its creation date and when the pages were updated. Information should be updated regularly.

Specific criteria to consider for an organization or program site may include—

- Mission statement
- Contact information
- Organizational structure (or management hierarchy)
- Services offered
- News, events, and meetings
- Forms to download
- Hyperlinks to other useful resources
- Publications

Answering the questions in [Box 50-5](#) can help in making a decision about whether and how to develop a new website.

50.5 Maintenance and support requirements

Using computers, like using any electronic tool, requires access to reputable repair services and supplies. Even more important, however, is a reliable, adequately trained staff.

Staff recruitment and training

Discussions about computerization often focus only on software and hardware, but computers are useless without competent staff to run them. Recruitment and training are key in maintaining good computer services, particularly when day-to-day operations such as inventory management and accounting are computerized. Investing in training staff members to use computers effectively is quite worthwhile.

Experienced typists interested in learning new skills can be recruited for word processing and data entry tasks. Computer courses are available in many countries. The

cost of courses should be built into computerization budgets, along with sufficient funds each year to train new staff and retrain existing staff in new software. Online courses are also available if one has an Internet connection. For example, Microsoft offers free, self-paced courses for most of its Office products at <http://office.microsoft.com/en-us/training/default.aspx>.

When specialized pharmaceutical management programs are installed by an outside organization, the vendor must provide adequate training that is spread out over time so that staff members can raise their own questions as they become familiar with the new system.

Provisions need to be made for staff changes. At least two people need to be familiar with each specific computer program and operation so that sickness, annual leave, or job changes will not bring the computer unit to a halt. Additional training may be necessary from the vendor if personnel leave the unit.

A highly computerized operation that uses software to support critical operations, such as procurement or inventory management, should have the support of an information technologist on-site, if at all possible. If computer hardware or software is disabled by a problem that interferes with the daily business operations of an organization, the problem needs to be resolved as soon as possible. An information technology support unit serves to ensure that the organization's hardware and software remain functional through proper maintenance and prompt attention to errors.

Protecting data

Data in a computer are stored on magnetic media, such as a hard disk, CD-ROM, DVD, or flash drive. Unfortunately, magnetic storage media can lose data, so other precautions must be taken. The computer, along with all data on the hard

Box 50-5

Developing a website or posting materials to the Web

Here are some questions that will be useful to think about to effectively plan for, develop, and maintain a website.

Vision

- What is the purpose for developing a website or for posting materials to the Web?
- What do you hope to achieve?
- What are the intermediate and long-term goals or objectives?
- Do you see this activity as part of an existing website or something new?
- Is it important for this site to have a unique URL or Web address?

Audience

- Who are your primary and secondary audiences?
- What is the anticipated size of your audiences?
- Where are your audiences located?
- What are the information and/or learning needs of your audiences?
- What is the audience's level of comfort and experience using Internet?
- What is the audience's level of Internet access?
- What is the audience's level of computer proficiency?
- Do you anticipate this site being public or private/restricted?

Content

- What type of content do you anticipate for this site?
- What content currently exists?

- What new content needs to be written?
- How often will content be updated?
- In what languages will content be presented?
- Is any of the content proprietary, or is use restricted by any parties?
- Do any donors or partners need to approve posting of content?

Functionality

- What tasks do you want users to perform when they come to the site?
- What specific functions would you like to include on the website (for example, information database, online message boards)?

Marketing

- How will you reach your audience?

Evaluation

- How will you know when you have achieved your goals?
- What evaluation methods will you use (for example, e-mail survey, phone interviews)?

Roles

- Who will develop content?
- Who will update content over time?
- Who will market the site?
- Who will provide technical support to users?

drive, might be stolen or could be harmed by dust or high-voltage electrical spikes.

Data can also be damaged by a computer virus when programs or data are exchanged between computers or when an infected e-mail attachment is opened. This risk increases when illegally copied (pirated) software is used. A virus can result in anything from harmless messages appearing unexpectedly on the computer screen to complete loss or theft of data on the hard drive. To avoid getting a computer virus, accept files only from users who take precautions against viruses, do not open unknown attachment files from e-mail senders, use virus-check software that automatically scans the computer's hard drive every day, and check any media, such as flash drives or CD-ROMs, used to share data. Regular updates of virus protection programs are needed because new viruses are created continually.

CD-ROMs and DVDs can be damaged by magnetic fields (from loudspeakers, telephones, and metal detectors), and by moisture, particles, and scratches. Thus, having only one copy of data is risky, and the importance of making backup copies cannot be overemphasized. Basic rules for maintaining backups are—

- Make at least one backup copy of all important work when it is created.
- Back up routine work daily with separate sets of CDs, DVDs, or external drives used in rotation for extra security, especially for large databases such as inventory control systems.
- Ideally, store backups off-site to guard them from fire or theft. Consider saving and archiving an entire set of data at the end of each month or quarter.

Access to computers should be restricted to authorized staff; most computer operating systems and software can be protected with passwords, which are required to enter the system (and which allow managers to track use of the computer).

Maintaining computers

Computers are adversely affected by humidity, static electricity, power surges, extreme temperatures, dust, cigarette smoke, and food or liquid spilled on the keyboards. Computers are also vulnerable to frequent switching on and off, sudden physical movements while the hard disk is running, misuse by untrained staff, and unprofessional repair attempts. To protect computers—

- Make sure that a reliable firm (or department) is under contract to support hardware and software.
- Train all operators in proper computer handling.

Box 50-6

Lessons for successful computerization

- Assess what software is needed before choosing hardware.
- Ensure software and hardware compatibility.
- Secure local support for hardware and software.
- Have a well-functioning manual system.
- Provide adequate staff training and involve staff in the computerization process.
- Computerize in phases, allowing sufficient time for each step.
- Establish and enforce strict procedures for data and equipment protection, using backups, virus checkers, restricted access, surge suppressors, and so on.
- Set aside adequate funds in each year's budget for hardware and software maintenance, supplies, and staff training.
- Plan and budget for timely hardware and software upgrades.

- Protect the computer room with air-conditioning—if possible—against excess heat, humidity, and dust.
- Do not eat or drink near the computer or smoke in the computing room.
- Protect keyboard, monitor, and computer with covers.
- Always use spike/surge protectors (for computer, printer, monitor, and fax) and an uninterruptible power supply. Car batteries with an inverter or a separate fuel generator may also provide safe electrical power.
- Move the computer only when it is switched off.
- Use reliable maintenance and repair services.

50.6 Lessons for successful computerization in pharmaceutical management

Successful computerization in pharmaceutical management can greatly increase an organization's efficiency, productivity, and capabilities, but it must be carefully planned. Expensive mistakes are easy to make through a lack of knowledge or forethought, hindering rather than helping a project. Following the list in [Box 50-6](#) and considering the issues raised earlier in this chapter will help a manager to avoid or prevent such mistakes. The information presented in this chapter should enable a manager to ask the right questions and effectively plan the computerization of an organization. ■

ASSESSMENT GUIDE

Use of computers in pharmaceutical management

- In which phases of pharmaceutical management will computerization be most useful: medicine selection and formulary development, registration, quantification of pharmaceutical requirements, procurement, inventory control, prescription analysis, other areas?
- Does a product master file exist? Has a coding system been developed to uniquely identify pharmaceutical products? Is the ICD or other coding system used to identify health problems?

Readiness for computerization or expansion

- Are computers currently used for producing correspondence, newsletters, reports? Preparation of tables, graphs, charts? Budgets and other spreadsheet applications? Electronic communications?
- Do good manual systems exist for pharmaceutical management functions?
- Are staff members capable of and interested in learning to operate computers?
- Are resources available for staff training? Supplies such as CDs and DVDs, paper, and printer ink and toner? Computer support and periodic upgrades, as needed?

Computerization planning

- Have needs been identified and the specific tasks, functions, and systems to be computerized carefully analyzed?
- Has appropriate software been identified, for example, for word processing, spreadsheets, database

management, and special functions such as presentation graphics, project management, accounting, or electronic communications?

- Is training available for each software package? Are manuals or other instruction books available?
- Have hardware specifications been defined in terms of operating system, microprocessor speed, available RAM, storage capacity, monitor, printer, modem, uninterruptible power supply? Is this hardware capable of running the software identified?
- Has the computerization process been planned in phases, so that experience with computer applications will develop in parallel with broad systems development?
- Have procedures been developed for data and equipment protection, such as restricted access, use of an uninterruptible power supply and surge suppressors, virus checking, backing up data files, and storing backups off-site?

Hardware and software support and maintenance

- Is there a firm in the country or area that sells software and provides support? Does this firm provide training in use of the software?
- Is there a firm in the country or area that sells and maintains computer hardware?
- Is there a government agency or department that can provide support services to the supply system?
- Has someone on the staff been trained, at minimum, in the basics of computer troubleshooting?

Glossary

Apple: Company that made one of the first desktop computers. It now makes the Mac line of computers and iPhones (smart-phones).

Backup: An extra copy of software or data, normally kept on file in case the original program or information is damaged or lost.

Baud: A measure of the speed at which data travels (normally between a computer and a peripheral).

Bit: A binary digit (1 or 0).

Bug: A flaw or problem in a software program.

Byte: A sequence of bits that represents a single character. In most small computers, a byte is eight bits.

CD-ROM (compact disc read-only memory): A medium for storing large amounts of data that can be accessed quickly and selectively using a CD-ROM drive. CD-ROMs are less vulnerable to damage than diskettes, which are seldom used anymore.

Chip: A generic term for an integrated circuit, a single package holding thousands of microscopic electronic components. The processor of a computer is one.

CPU (central processing unit): The "brain" of the computer, which directs and processes input and output.

Data: Numerical or verbal representations of facts that are processed to produce information.

Database: A collection of related data that can be retrieved and manipulated by a computer.

Debug: To go through a software program to remove mistakes.

Density (double, high): Describes how much information can be stored on a storage medium.

Disk: A round piece of magnetic-coated material used to store data.

Disk drive: Part of a computer that reads data from, or writes data to, a disk.

Dot matrix printer: A printer that produces lower-quality output than a laser printer. This type of printer is the best for printing on multiple kinds of paper.

Downtime: Any period when a computer is not available or not working.

DVD (digital video [or versatile] disc): A medium for storing large amounts of data that can be accessed quickly and selectively by using a DVD drive. DVDs hold more data than CD-ROMs.

Field: In a database, the basic column unit, in which the same type of information appears.

File: An organized collection of bytes stored on disk, maintained by the operating system, and referenced by name.

Hard disk: A fast-spinning, rigid piece of equipment made of stainless steel with a magnetic layer, which stores huge amounts of data inside a computer.

Hardware: The physical equipment of a computer system, such as the computer, monitor, and printer. Useless without software.

Inkjet printer: A type of printer with print quality between that of a dot matrix printer and a laser printer.

Laptop/notebook/netbook: Small computer that incorporates the CPU, monitor, and keyboard in one unit and can run on batteries. A notebook computer is smaller than a laptop, and a netbook is smaller than either.

Laser printer: A type of printer that uses laser technology to produce very high print quality.

Mainframe: Big, powerful, expensive computer, usually used by universities and the military. Usually not necessary for managing pharmaceutical supplies.

Memory: Circuitry and devices that hold the bits the computer can access. Examples are RAM (random-access memory) and ROM (read-only memory).

Minicomputer: Smaller than a mainframe but still too big or costly for an individual; may be useful for storing large amounts of data in a central medical store.

Modem: An electronic device that allows computer equipment to send and receive information through telephone lines.

Monitor: A TV-like display used with most computers to show the information being input and output.

Motherboard: The board containing the computer's circuitry, onto which all other parts of the CPU are attached.

Mouse: A small, mobile manual device that controls movement of the cursor and selection of the function on a computer display.

Network: An interconnected system of computers. The components do not have to be physically close to one another—they can be connected by telephone, data lines, or without wires.

Operating system: Software that oversees the overall operation of a computer system. It enables other software to communicate with the hardware and must be present for the computer to function. An example is Windows, used by PCs, and OS X, used by Macs.

PC (personal computer): Any general-purpose computer for individual use. Microsoft and Intel dominate the PC operating system market. Today's PCs evolved from PCs standardized by IBM

Annex 50-1 Building a product master file in a database

This section describes essential concepts for building the main reference file (that is, the product master file) in pharmaceutical management database software.

Product master file

Common to nearly all forms of database management is a master file, which includes features for pharmaceutical management, such as product name, strength, dosage form, and therapeutic category. For procurement and inventory control systems, the product master file usually has supplementary information on cost and pack size. The full description of a product can be split into database fields to sort and classify the data.

The following table briefly describes the information commonly contained in a basic product master file. The development of this file should be carefully planned around several issues, including product coding systems, definition of units, and identification of supplier-specific products.

Product master file code

A computer program must be able to identify each product quickly and without confusion. After a coding system has been chosen, it must be maintained without ambiguity, or duplication will occur. Many options exist for coding systems. The simplest system is the “dummy” code, which has no intrinsic meaning—for example, 12345 is assigned to the first item entered in the list, 12346 for the second, and so on. With this system, the only question is how many digits are needed; the key point is that the code should be unique. In most systems, a five-digit code is sufficient for many years. If a large number of different items exist, a six-digit code might be prudent.

A more complex option is an “information-bearing” code, in which each digit has significance—for example, ampicillin 500 mg capsules might be coded as AMP500C. In some countries, formal information-bearing codes have been developed at the national level for pharmaceutical products. An example is the nine-digit National Drug Code in the United States, in which the first four digits signify the manufacturer or labeler, the next three digits show the product, and the last two show the package size.

Arguments exist favoring each of these coding options, as well as others. Data entry errors are reduced with more complex coding schemes, but the time required to enter data may be greater. An information-bearing coding scheme takes more time to develop and maintain than a simple numeric code for products. Note that a separate coding scheme will be needed for therapeutic categories. Several international coding systems for medicine categories are discussed in [Chapter 16](#).

Health problem coding

Health problem information must be coded for diagnosis-specific medicine-use analysis and morbidity quantification of pharmaceutical requirements. The accepted standard is the WHO *International Classification of Diseases* (ICD-10), a hierarchical classification based on major and minor disease categories, which is available online, on CD-ROM, and for PDAs and smartphones. Most information systems are now based on the ICD system, although local adaptations often result in different groupings of individual health problems.

Definition of units

When computerizing medicines systems, considerable confusion can arise over the definition of units. For example, in the preliminary quantification exercise for a large essential medicines project, requirements for benzyl benzoate (a topical preparation for skin infestations) were calculated in milliliters, whereas the essential medicines list specified liters. This discrepancy led to a 1,000-fold error that increased estimated pharmaceutical requirements by USD 1 million.

Defining the basic unit, issue unit, defined daily dose unit, pack size, and minimum order can help avoid major mistakes.

Basic or comparison unit. The basic unit is the smallest unit in which a drug product can be conveniently dispensed or administered. It is also used to compare prices of different sized bottles or vials. The total number of basic or comparison units is equal to one issue unit. For example, 100 tablets make up one bottle, with the tablet as the basic unit and the bottle as the issue unit.

Issue unit. The issue unit is used to count and distribute the stock. It allows the comparison of items of different pack sizes

in the 1980s, except for Apple Corporation products, which are not considered to be PCs.

Peripherals: Equipment (usually hardware) that is external to the computer itself. Examples are tape drives and speakers.

Personal digital assistant (PDA): Handheld computing device that can record and store data to synchronize with a desktop computer.

Power spikes/surges: Major fluctuations in electrical current that can disrupt the computer’s internal operation and damage hardware.

Printer: A device to produce hard-copy output.

RAM (random-access memory): The main type of memory used in computers, also known as read/write memory because data in RAM can be easily changed.

Record: One entry, or row, in a database.

ROM (read-only memory): Memory where information is perma-

nently stored and cannot be altered. This form of memory is also random access.

Scanner: A piece of hardware that reads information from text or images and converts it into digital form for a computer to use.

Server: The main computer on a network; provides storage and processing capabilities for client computers.

Smartphone: A mobile phone that offers more-advanced computing ability and connectivity than a basic mobile phone. Smartphones allow the user to install and run more-advanced applications and transmit data easily.

Software: Programs or segments of programs.

Spreadsheet: A program for calculating and linking numbers.

Virus: An undesirable program that displays bizarre messages or destroys data on the computer. Transferred mainly by sharing files without testing them first with antivirus software or by opening infected attachments to e-mail messages.

but the same issue unit. The total number of issue units per pack is equal to one pack size.

Pack size. In procurement, the pack size is used to request bids. Suppliers usually give the product cost for a pack size.

See the table on the following page for more examples of units. Individual computer systems may handle these concepts

differently, but managers of pharmaceutical programs must be thoroughly familiar with the problems of defining pharmaceutical units. Unambiguous local definitions must be established, and everyone involved in recording, entering, verifying, or using the computer data must be trained to use these definitions.

Standard information in a master product data file

Description	Example	Explanation
Product code	AMP250C	Each entry in the product data file must have a unique code. (See text for discussion of coding options.)
Generic name	Ampicillin	The official International Nonproprietary Name (INN) is generally preferred. The WHO Model List of Essential Medicines, which is regularly updated, uses the INN.
Strength	250 mg	The International System of Units (SI), with related SI abbreviations, should be used. "Strength" can be split into "strength number" (250, for example) and "strength unit" (such as mg), but this method often creates unnecessary confusion and coding difficulties.
Route of administration	PO	Standard abbreviations should be used. For example, PO = per os (oral), IV = intravenous, TOP = topical.
Dosage form	CAP	Standard abbreviations should be used. For example, CAP = capsule, TAB = tablet.
Issue unit	CAP	The issue unit is the smallest unit by which a drug product can be conveniently distributed. (See text for further explanation.)
Defined daily dosage (DDD)	4	The DDD represents the usual total daily therapeutic dosage for an adult. In computer systems, it is best defined in terms of issue unit per DDD.
DDD unit	g	The unit in which the DDD is measured.
National essential medicines list (EML)/formulary status	Y	Is the medicine listed in the national EML or formulary? Y = yes, N = no.
Therapeutic class	44:29	Categorizing medicines by therapeutic or pharmacologic class can be useful. Several systems exist, including the ATC, BNF, AFHS, and PAHO systems, and that used for the WHO Model List of Essential Medicines. (See Chapter 40 for further discussion of therapeutic category systems.)
Prescription status	POM	Status for retail sales. For example, POM = prescription-only medicine, OTC = over-the-counter.
Level of care	A	National EMLs may categorize medicines according to level of care. For example, A = all levels, B = all levels except dispensary, and so forth.
ABC classification	A	Classification of a product as A, B, or C according to the volume consumed and unit cost. (See Chapter 40 for discussion of ABC analysis.)
VEN classification	V	Classification of a product as V, E, or N, according to its therapeutic value as vital, essential, or nonessential. (See Chapter 40 for discussion of the VEN system.)
WHO status	M	Is the medicine on the WHO Model List of Essential Medicines? This entry can be listed as Y (yes) or N (no). It can also be listed as M (main), C (complementary), E (therapeutically equivalent), or N (not on the list).

Annex 50-1 Building a product master file in a database (continued)

SUMMARY

Human resources are central to planning, managing, and delivering health services, including pharmaceutical services. In most countries, personnel account for a high proportion of the national budget for the health sector—often 75 percent or more. Despite the critical importance of human resources to the functioning of pharmaceutical management programs, few concerted efforts have addressed the severe staff shortages facing the health sector in many countries. The HIV/AIDS pandemic has intensified this already serious situation.

In addition to staffing shortages, the health system faces many human resources challenges, including human resources planning, recruitment, deployment, training, staff motivation, and staff development. The root causes of these issues can be traced to years of neglect, low salaries, poor workplace climate, and limited capacity to train and update staff skills. Interventions needed to alleviate the human resources crisis include short-term actions, such as task shifting, while in the long term, countries need to expand their capacity to train enough staff to fill needs. Some issues need to be addressed at the national level (for example, compensation), but many can be addressed through better leadership and human resource management (HRM) at the facility level. In the pharmaceutical sector, the goal of HRM is to develop and sustain an adequate supply of skilled professionals who are motivated to provide a high level of pharmaceutical care.

Effectively addressing human resources challenges requires improved leadership and management at all levels. An expanded HRM role, especially at the facility level, is needed to transform the outdated view of human resources as mainly an administrative function to one where the human resources staff work closely with managers to support the health goals of the organization and to ensure that the right staff with the right skills are in place to meet these goals.

Managing people is an important and challenging task for any manager. Employees are motivated by many factors that can be affected by management. Receiving effective supervision, perceiving they are fairly treated, understanding their job priorities, getting feedback, feeling valued and appreciated, and having opportunities for professional development can all help staff perform better.

Developing and maintaining a fair, equitable, and effective HRM system can motivate staff and increase their level of job satisfaction and efficiency, which can result in improved service quality. An important part of a long-term strategy is creating an organizational and management structure for HRM that is implemented by managers and staff at all levels. A human resources partnership between senior managers, supervisors, human resources professionals, and individual staff members is what makes an HRM system work.

51.1 Recognizing the crisis in human resources for health

Countries throughout the world, especially developing countries, have long suffered from a severe lack of skilled health workers and managers. The delivery of health services is labor intensive, and the workforce is the primary determinant of health system effectiveness, yet strategies and systems for human capacity development in most ministries of health are inadequate to meet the needs of the population. In addition, the lack of health staff, including trained pharmacy staff, has compromised health care in rural areas. Moreover, the demands of scaling up antiretroviral treatment (ART) programs and the related time-consuming care have overburdened already weak systems for human resources development and management and drained personnel from other health services. Absenteeism and low morale are widespread, and work-related stress reduces health workers' productivity.

Countries with a high prevalence of HIV/AIDS that cannot address acute shortages in the short term are unable to

deliver effective services. In these countries, staff attrition rates are rising because of HIV infection, illness, and death as well as the migration of staff to urban areas or other countries. Vacancy rates in public-sector organizations are also rising, while the pool of skilled candidates to fill positions is still not deep enough. Results from a twelve-country survey showed that the problem is so serious that countries simply do not have the human resources capacity to absorb, deploy, and use additional funds that they are receiving to improve health (Kinfu et al. 2009). Estimates cited in the survey indicate that workforces in the most-affected countries would need to increase by up to 140 percent to attain health development targets.

The pharmaceutical personnel situation in many countries is dire; for example, countries such as Benin and Mali have less than one pharmaceutical worker for every 100,000 people, whereas France, in comparison, has more than 100 per 100,000 (Table 51-1). Uganda has an estimated 30 percent of the pharmacists it actually needs (Matsiko and Kiwanuka 2003). Some industrialized countries also have pharmacy staff shortages; many areas of the

^a Pharmaceutical personnel include pharmacists, pharmaceutical technicians, and pharmaceutical technologists.

United States have some difficulty filling pharmacist positions (FIP 2009).

The dynamics of entry and exit from the health workforce in many countries remains poorly understood, and many reasons—such as lack of investment in training, illness, and premature retirement and death—contribute to the shortage. This lack of understanding inhibits countries and development partners from developing and implementing appropriate interventions. Several factors, however, are recognized as important contributors to the shortage of trained pharmacy personnel and other health care workers, including—

Migration of health personnel: Migration contributes significantly to the loss of health workers from many countries. For example, almost two-thirds of Ghana's 140 pharmacy school graduates in 2003 migrated to a different country; between 2001 and 2004, Zimbabwe had about 150 new pharmacy graduates, while 100 Zimbabwean pharmacists registered to work in the United Kingdom during the same period (FIP 2006). Even relatively well-off countries like South Africa are losing trained health professionals to richer economies (FIP 2006).

Staff leaving the public sector: Health staff members leave the public sector to work for donor-funded projects that are flourishing from the large influx of money into Africa; in addition, health workers often choose to work in the private sector, where remuneration is often better.

For example, in Kenya, 58 percent of health facilities are in the public sector, whereas 86 percent of the pharmaceutical workforce is employed in the private sector (FIP 2009). [Country Study 51-1](#) shows how a public-private partnership in Namibia, where pharmacists prefer private-sector employment, successfully recruited and pharmacy professionals into public-sector service.

Poor distribution of staff: The predominance of health workers is in urban areas—where they earn more and have access to better opportunities—meaning that rural areas often suffer from acute shortages of trained workers. Uganda is a country that has less than one pharmacist per 100,000 people in its population, but almost 90 percent of the existing pharmacists are located in the Central region, while the other 10 percent are divided among the other four regions in the country (FIP 2006).

Insufficient preservice training: Many countries lack the ability to train enough pharmaceutical professionals to fill their needs; they may have no or only one accredited school of pharmacy, for example. Increasing the number of skilled workers requires capacity in the educational system—enough teachers, updated curriculum, and adequate infrastructure—which takes time to build. Even when graduates are available, retention is difficult unless good management exists to absorb, train, and support them.

51.2 Addressing the crisis in the short and long terms

Global action is required not only to address high-priority infectious diseases but also to meet the long-term human resources needs of health systems in developing countries. The greatest challenge is to begin addressing shortages of health personnel in an integrated and comprehensive fashion. Responses to the challenge must meet both the short-term necessities of providing lifesaving treatment and the long-term human resources needs of the health sector (see [Country Study 51-1](#)).

Short-term responses include implementing aggressive retention policies, such as improving terms and conditions of service for health workers, providing ART to health workers who need it to preserve their health and productivity, and encouraging temporary regional migration of workers from countries with surplus workers to countries with deficits. For example, Kenya has bilateral agreements with Namibia, Southern Sudan, and Lesotho to send nurses to work on short-term contracts in those countries.

Task shifting has been used extensively and often effectively to fill gaps in health care worker shortages, including in pharmacies (WHO Maximizing Positive Synergies Collaborative Group 2009). Often, lower-level pharmacy workers, such as pharmacy technicians, or other cadres,

Country Study 51-1**Using partnerships to improve human resources capacity to deliver pharmaceutical services in Namibia****Human resources crisis in pharmacy**

According to the World Health Organization's Global Atlas of the Health Workforce, in 2004, Namibia had fourteen pharmacists per 100,000 people, or half of South Africa's twenty-eight pharmacists per 100,000. Namibia's pharmacists are also poorly distributed—80 percent work in the private sector, leaving priority public health programs short of qualified staff. About half the pharmacists working in the public sector are located in Khomas region, particularly in Windhoek city, leaving the other twelve regions short of qualified personnel. Pharmacist assistants in most district hospitals occupy positions meant for more highly skilled pharmacists.

In 2006, of the forty-eight public-sector pharmacy posts available, only fourteen were filled—four of these were filled by Namibians.

Challenges in filling positions in Namibia

- Foreigners on two-to-three-year contracts fill 90 percent of pharmacist positions. Knowledge of local languages is critical; English speakers usually need translators to communicate with patients, while the many Cuban pharmacists have a hard time because of a lack of Spanish translators.
- No pharmacy school exists in Namibia, and an inadequate number of Namibian students pursue a pharmacy degree abroad. Those who do return from abroad choose careers in the private sector.
- Of 515 students pursuing health and social welfare training at the University of Namibia during 2003–04, only two were enrolled in the prepharmacy program.
- The Namibia National Health Training Center trained only about eight pharmacist assistants in a year.
- The public-sector recruitment process was time consuming; therefore, engaging pharmacists—particularly those from abroad—took a long time.

A partnership to expedite the recruitment of pharmacy staff

The Ministry of Health and Social Services (MoHSS) and the Rational Pharmaceutical Management Plus (RPM Plus) Program developed an intervention with the goal of increasing the number of facilities with qualified pharmaceutical staff. The partnership model comprised the following components—

- RPM Plus worked with the MoHSS to develop a mechanism to expedite the hire of pharmacists and pharmacist assistants for priority positions in the public sector; all target positions were identified and aligned with MoHSS priorities.
- Job descriptions for temporary staff were made commensurate with those in the public sector; work standards were set according to MoHSS policies.
- The MoHSS led the interview and selection process.
- Remuneration for recruited staff was set in accordance with the MoHSS scale.
- A local human resources company, Potentia Namibia Recruitment Consultancy, recruited successful personnel and managed their remuneration and benefits.
- The MoHSS directly supervised and evaluated the performance of recruited personnel.
- The MoHSS mobilized its own resources and systems to progressively absorb the newly appointed personnel into the government personnel structure.

Results of the partnership

In two years, twenty-eight pharmaceutical staff members (eleven pharmacists, one network administrator, and sixteen pharmacy assistants) were recruited; 64 percent of the staff positions have been absorbed into the public service (46 percent of the pharmacists and 81 percent of the pharmacy assistants). Despite Namibia's lucrative private sector, no pharmacist that the partnership recruited and supported has been lost to the private sector. Vacancy rates have been reduced by more than half, and evidence suggests that the quality of pharmaceutical care and services has improved. According to the Kunene regional director, "There is better ordering of pharmaceutical items and stock management has improved. The compilation of consumption pattern has been done, and it is easier to forecast needs of certain pharmaceutical items. The Regional and District Therapeutic Committees have been resuscitated and have begun to look more closely at pharmaceutical issues in the region and districts."

Lessons learned

The time and resources needed to manage staff before they were absorbed into the public sector proved higher than RPM Plus expected. Thus, contracting with a local human resources company to manage the seconded staff on behalf of the MoHSS and RPM Plus proved vital to the partnership's success. Additional steps that were critical to the process included working closely with the MoHSS

to identify its needs, complying with MoHSS policies and standards, and recruiting pharmacy assistants as they graduate and before they slip into the private sector.

Innovative partnerships between the public and private sectors can help national programs expand their human resources base more quickly; however, the success of such partnerships relies heavily on the explicit commitment of each partner, including the host government, the donor, and the technical assistance team. Human capac-

ity-building interventions should be based on existing government systems to ensure their eventual integration and sustainability. This innovative collaboration created a new mechanism for the government to fill priority pharmaceutical positions more quickly while allowing it to gradually absorb the positions into its existing structure—thereby addressing immediate program needs while ensuring long-term contributions.

such as nurses, are given the responsibility of running an entire dispensing site because no fully trained pharmacist is available to do so. Some countries are training community health workers to dispense certain medicines, especially for childhood illnesses. [Country Study 51-2](#) illustrates how Kenya supported pharmaceutical management task shifting to support ART scale-up. The World Health Organization (WHO), the U.S. President's Emergency Plan for AIDS Relief, and the Joint United Nations Programme on HIV/AIDS (WHO, PEPFAR, and UNAIDS 2008) have also collaborated on guidelines for task shifting in the health sector.

To address the lack of pharmaceutical workers in rural or peri-urban areas, countries such as Vietnam require students receiving government scholarships to work in underserved areas upon graduation. Vietnam also allows pharmacy schools to accept students from underserved provinces and rural areas without a competitive examination (FIP 2009). Other countries use financial incentives to boost recruitment in rural areas, but this strategy may not be sustainable if it relies on outside funds. Australia is tackling its shortage of pharmacists through a series of strategies known as the Rural Pharmacy Program. The framework is based on the belief that a combination of incentives to address these multiple factors is more likely to be successful than a single intervention and that the synergy among the interventions can improve both recruitment and retention (FIP 2009). [Table 51-2](#) shows examples of the types of strategies the program uses.

Countries are also enacting policies and incentives to recruit and retain more pharmaceutical personnel in the public sector. In Kenya, for example, improved policies and terms of service in the public sector have led to higher retention of pharmacy staff—from 433 in 2005 to 609 in 2008—and Sudan now requires pharmacist graduates to spend one year in government health institutions, which has increased the number of pharmacists in the public sector, particularly in rural areas (FIP 2009). Sudan has also created opportunities for postgraduate study to minimize attrition from the public sector (FIP 2009). WHO launched an initiative to increase access to health workers in remote and rural areas

through improved retention (see http://www.who.int/hrh/migration/expert_meeting/en/index.html).

Long-term solutions require national-level planning and strategies. Governments should work with professional organizations, regulatory bodies, training institutions, unions, and employers to develop long-term workforce plans. Strategies should strive for self-sufficiency rather than rely on foreign workers or educational institutions. Governments also need to ensure that legislation and regulations keep up with capacity-building strategies. For example, Sudan's Ribat University opened a new school and approved a three-year curriculum for pharmacy technicians; however, the pharmacy technician cadre was not defined in any policy or legislation, and how the cadre differs from that of pharmacy assistant or what its role is in pharmacy practice is unclear (FIP 2009).

More educational and preservice training opportunities are the key to solving long-term staffing problems. WHO and the International Pharmaceutical Federation (FIP) have established a task force to examine issues related to addressing pharmacy education as a means of increasing the number of pharmacists. [Box 51-1](#) includes the task force's plan of action. Namibia addressed its lack of pharmaceutical training capacity by expanding the ability of the National Health Training Centre to train pharmacy assistants by renovating classrooms and offices, revising curriculum, and providing tutors and training consultants. As a result, the center increased its yield of pharmacy assistant graduates by 100 percent in one year—from nine in 2009 to eighteen in 2010, with sixty more in line to graduate by 2012. The 2010 graduates were all recruited into the public sector.

In addition to using public institutions to help build pharmaceutical sector human resources, providing technical assistance to academic institutions in resource-limited countries and fostering regional collaboration are efficient ways to build institutional capacity. The Regional Technical Resource Collaboration for Pharmaceutical Management, described in [Country Study 51-3](#), is an example of such a regional approach to capacity building.

[Box 51-2](#) presents a human resources for health (HRH) framework that promotes a comprehensive and integrated

Country Study 51-2**Supporting task shifting to build HR capacity in pharmaceutical management in Kenya**

Only 38 to 45 percent of those in need have access to ART in Kenya. Because of the severe shortage of pharmaceutical professionals, Kenya's adoption of decentralized ART has resulted in other health cadres being used to manage pharmaceuticals; however, these other health care providers lack skills in pharmaceutical management, thus limiting ART scale-up.

The Strengthening Pharmaceutical Systems (SPS) Program collaborated with the National AIDS and STI Control Programme (NAS COP), training institutions, and other government agencies to develop and implement short- and long-term measures that support decentralization and task shifting, thereby strengthening human resources capacity and sustainability. Key interventions included training more than 1,500 health providers in pharmaceutical management and implementing a mentorship program. Training of trainers increased the pool of regional experts and created a mechanism to provide ongoing supervision.

SPS developed eleven job aids and eleven pharmaceutical standard operating procedures (SOPs) and guidelines,

which NAS COP adopted and disseminated to more than 400 ART sites to improve services and standardize practices. Decentralization of ART pharmaceutical services has been implemented successfully in more than 300 satellite sites. In addition, more than 2,500 public and private practitioners attended continuing professional development courses in pharmaceutical management. Advocacy for incorporating pharmaceutical management into preservice curricula culminated in 162 students at middle- and tertiary-level educational institutions receiving training. SPS is developing a pharmaceutical management orientation package for new providers at all levels of care and working with institutions to include pretested pharmaceutical management modules in preservice training curricula to promote sustainability.

Systematically implemented task shifting strategies that combine pre- and in-service training programs, job aids, reference guides, and SOPs have alleviated human resources challenges in a context of decentralized ART.

Box 51-1**FIP, UNESCO, and WHO Pharmacy Education Taskforce Action Plan 2008–10**

- To define pharmacy service competencies across all settings and levels of the health system
- To set educational objectives aligned with competencies and develop a framework that considers the entire pharmacy education continuum from undergraduate education through to continuing professional development at the postgraduate level
- To develop a global framework for quality assurance and the development of accreditation systems (e.g., development of standards for educational institutions and programs) in pharmacy education
- To gather and analyze data on the academic/faculty workforce, and review and develop capacity development strategies that meet local, regional, or global needs
- To guide stakeholders toward an accepted holistic vision for the entire continuum of pharmacy education at the global, regional, and local levels
- To provide advocacy and technical guidance to country-level stakeholders and educational institutions
- To establish a global platform for ongoing dialogue; sharing of evidence, practices, lessons learned, resources, and tools for pharmacy education; and workforce planning

FIP = International Pharmaceutical Federation; UNESCO = United Nations Educational, Scientific and Cultural Organization; WHO = World Health Organization.

approach to developing strategies to tackle both immediate and longer-term HRM challenges. The framework examines six components of planning and managing the workforce so that appropriately trained personnel are available in the right places at the right time: HRM, policy, finance, education, partnerships, and leadership. HRM systems are at the center of the diagram because of their importance in integrating all the other components. [Country Study 51-4](#) illustrates how the results of an HRM assessment of the pharmaceutical sector in Namibia were organized using the HRH framework.

51.3 Understanding the role of HRM at all levels of the health care system

Human resources management is the integrated use of systems, policies, and management practices to recruit, maintain, and develop employees so the organization can meet its desired goals (MSH 1999). Effective HRM should help managers make plans and hire trained staff, and help employees find meaningful work with avenues for career development. A comprehensive HRM system provides managers with a framework and tools to better plan, recruit, hire, deploy, motivate, and retain employees. At the national level, HRM involves developing health-sector strategies, policies, and practices to ensure a workforce that is balanced in numbers of staff, qualifications, and placement.

Initiatives such as the Global Fund to Fight AIDS, Tuberculosis and Malaria and the President's Emergency Plan for AIDS Relief, while adding more financial resources, are also putting pressure on human resources. Sometimes such initiatives can be an opportunity to advocate for better

salaries and working conditions, but these benefits must be equitable for all staff.

Even as policy makers adjust policy and regulatory frameworks at the national level, managers of district health services, nongovernmental organizations, public hospitals, or pharmacies can still do much to strengthen the HRM system. At the organizational level, where most program managers function, HRM involves linking management and development of human resources to an organization's strategic plan, goals, and objectives. Establishing these links is an essential management strategy.

An essential part of the overall management strategy should be to consider how HRM can help the organization fulfill its goals. Often people view HRM as having a limited, administrative role focused on documenting staff personnel actions. Although this administrative role is very important, the role of human resources should not be limited to these activities. In light of the new global initiatives resulting in scaled-up public health treatment programs for diseases such as HIV/AIDS and malaria, human resources should—

- Be a strategic partner in developing and attaining the goals of global initiatives
- Align human resources needs with the demand for new and old services
- Assess the need for task shifting and new job descriptions
- Develop incentives for staffing hard-to-reach areas
- Keep all employees informed about the changes taking place
- Create opportunities for staff to contribute ideas
- Encourage teamwork and team spirit

Box 51-2 The human resources for health framework

The World Health Organization and the U.S. Agency for International Development invited thirty-five representatives from various agencies, donor countries, nongovernmental organizations, and academia to draft a common technical framework to help governments and national planners understand the complex problems of human resources for health.

Meeting participants agreed that the framework should be scientifically based, tested in the field, and useful in a multisectoral and multistakeholder context. It had to capture the content and processes involved in develop-

ing and implementing a national strategy for human resources for health; be simple but comprehensive; and show the interdependencies among the various players, institutions, and labor markets involved in the health workforce.

The following figure and table illustrate and explain the final framework. Additional information on the development of the framework and how it can be used to develop a national strategy can be found in the publication *Tools for Planning and Developing Human Resources for HIV/AIDS and Other Health Services* (MSH/WHO 2006).

Framework components		
Component	Goal	Factors in achieving the goal
HRM systems	HRM systems are in place that result in adequate and timely staffing, staff retention, teamwork, effective planning, and good performance.	<ul style="list-style-type: none"> • HRM capacity in health facilities, local governments, and local health offices • Effective personnel systems: planning, recruitment, hiring, transfer, promotion, firing • Staff retention strategies • Training aligned with job requirements • Human resources information systems • Workplace programs for HIV prevention
Policy	Employment process in government is streamlined; appropriate HR policies are in place and enforced.	<ul style="list-style-type: none"> • National civil service rules • Government policies and structure for HRM (such as centralized hiring and firing) • Authorized scopes of practice for health cadres
Finance	Approved budget is adequate to sustain projected health workforce requirements. Allocation authority is aligned with technical and management planning and decision making.	<ul style="list-style-type: none"> • Health expenditures • Salary structures • Incentives to prevent migration of health staff • Support for preservice and in-service training • Administrative costs for recruitment, hiring • Supervision • Accountability
Education	Preservice training institutions have the capacity to meet demand for essential health workers and to adapt curricula as needed for new content requirements.	<ul style="list-style-type: none"> • Enough institutions to train all required health cadres • Adequate number of lecturers and tutors who meet quality standards for both content and teaching capacity • Training programs that match demand for health cadres and include essential content (clinic management, health management information systems, etc.) • Availability of equipment and supplies needed for preservice training
Partnerships	Planned links among sectors; districts; and nongovernmental, community, and religious organizations increase human capacity.	<ul style="list-style-type: none"> • Effective links among public-sector, private-sector, and community networks • Collaboration between ministry of health and ministries of finance and education
Leadership	Managers at all levels demonstrate that they value health workers and provide staff with leadership to face challenges and achieve results.	<ul style="list-style-type: none"> • Visionary leadership • Advocacy for reform of human resources policies • Leadership development for managers at all levels

Source: MSH/WHO 2006.

Furthermore, a strong and comprehensive HRM system has many benefits for managers and employees at all levels in both public- and private-sector organizations. Such a system can help ensure that staff members deliver quality health and pharmaceutical services to their client communities. [Box 51-3](#) lists the benefits of establishing a strong HRM system.

51.4 Assessing the strength of HRM in the organization

HRM is perhaps the most misunderstood and poorly used management system in the health sector. As a result, determining an organization's view of its human resources and how it should strengthen its systems can be a challenging task. One of the most important actions in establishing a

strong, comprehensive HRM system is gathering the information that will help plan for and implement the system. To do this, management needs to assess the organization's existing areas of strength and the areas that need strengthening. After it has identified the areas that require strengthening, management should prioritize them and develop an HRM action plan to address them.

By asking the following questions, a manager can begin to think about some of the issues involved and begin the process of establishing an HRM system that improves productivity and helps provide quality services—

- Do employees understand how their work specifically contributes to the mission and goals of the organization?
- Do employees view performance appraisals as an opportunity to learn about their skills and competencies and to discuss plans?

- Is the supervisor's role valued and supported by the organization?
- Are job descriptions up-to-date and readily available to all employees?
- Are employees routinely considered for job vacancies and other opportunities for promotion?
- Do employees understand the organization's policies on salaries and benefits and consider them fair and equitable?
- Can the organization engage in long-range planning, knowing it has or can develop the human resources required?
- Does the organization have strategies to provide meaningful jobs?
- Does the organization have a spirit of achievement and high performance?
- Do employees come to work on time and work productively for the full workday?
- Do managers spend less than 10 percent of their time dealing with grievances?
- Can the organization take on new objectives or tasks with cooperation from everyone?

Assuming the assessment identifies gaps that indicate the need to establish a stronger HRM system in the organization, several key issues should be considered, which include—

- Encouraging human resources leadership at the organizational level
- Assessing staffing requirements
- Developing and maintaining a performance management system
- Establishing a responsive supervisory system
- Improving staff motivation and performance through better human resources practices

Country Study 51-3

Using a regional resource to build capacity in pharmaceutical management

In addition to helping public institutions build pharmaceutical-sector human resources, providing technical assistance to academic institutions in resource-limited countries and fostering regional collaboration are efficient ways to build institutional capacity. The Regional Technical Resource Collaboration (RTRC) for Pharmaceutical Management comprises groups from Makerere University in Uganda, Muhimbili College of Health Sciences in Tanzania, the University of Nairobi in Kenya, and the National University of Rwanda. These institutions are leading in-country initiatives for building the capacity of health care workers to manage medicines by developing and adapting training materials, training health care workers, and developing effective approaches for skills building in low-resource settings.

Over a period of two years, the RTRC assessed pharmaceutical supply management systems and practices in Kenya, Rwanda, Tanzania, and Uganda. In a 2006 workshop in Uganda, the RTRC contributed to the development of comprehensive HIV/AIDS pharmaceutical management training materials, which are now widely available in all four countries. In Tanzania and Uganda, the RTRC has been involved with the training of more than 100 health care workers in HIV/AIDS pharmaceutical management. In Kenya, Tanzania, and Uganda, the RTRC has been conducting operations research to find solutions to those countries' skills-shortage problems.

A number of junior members of the academic staff within the mentioned institutions were targeted for

capacity building. This training allowed the system to build a significant pool of professionals with skills and competences in pharmaceutical supply management. At Tanzania's Muhimbili University College of Health and Allied Health, ten members of the academic staff— three senior staff members and seven junior staff members— have developed competences and skills in pharmaceutical management. Makerere University in Uganda has thirteen staff members who have developed competences in pharmaceutical management.

Following the development of training materials and the training of a number of academic staff members in pharmaceutical supply management, Makerere University's Department of Pharmacy has now adapted various components into its preservice pharmacy curriculum. In addition, the schools of pharmacy in both Tanzania and Uganda have plans to develop master of science programs in pharmaceutical supply management that draw largely from the initiative. In Rwanda, the Department of Pharmacy at the National University has revised its preservice curriculum to include components of pharmaceutical supply management.

The skills acquired by local institutions can be incorporated into both preservice and in-service teaching curricula to ensure long-term availability of skills in-country. The ability of trained institutions to mobilize their own resources for skills-building activities is crucial for the success and sustainability of these programs.

Box 51-3 Benefits of establishing a strong HRM system

Benefits to the organization

- Increases the organization's capacity to achieve its goals
- Increases the level of employee performance
- Uses employee skills and knowledge efficiently
- Saves costs through the improved efficiency and productivity of workers
- Improves the organization's ability to manage change

Benefits to the employee

- Improves equity between employee compensation and level of responsibility
- Helps employees understand how their work relates to the mission and values of the organization
- Helps employees feel more highly motivated
- Increases employee job satisfaction

These HRM areas are relevant in any organization, regardless of its size, purpose, and degree of complexity, and whether it is public or private. Carrying out a comprehensive HRM assessment will help address policy, planning, training, and management in an integrated way.

51.5 Encouraging human resources leadership at the organizational level

Many organizations treat HRM in a piecemeal fashion. Human resources leaders link all components of human resources to create one, integrated HRM system. When an organization's leaders create this type of integrated system, the effect on organizational performance can be profound. In supporting human resources by giving it a prominent and strategic role, managers and leaders are also sending a message to all staff that the organization will treat them fairly and will respect their contribution to its success. [Table 51-3](#) lists the components that contribute to developing a human resources system.

Every organization or program needs leadership at the highest level to support human resources. To take a leadership role in HRM, a manager should—

- Create a positive climate for human resources
- Create a management structure for human resources
- Define what needs to be done
- Forge new organizational arrangements that foster employee participation, teamwork, and growth
- Ensure that human resources activities are integrated throughout the organization
- Involve staff at all levels and from all departments in HRM
- Dedicate staff and budget to building human resources capacity within the organization
- Make learning an organizational priority
- Provide a link between internal HRM and external stakeholders

Table 51-3 Human resources development components

Component	Sample elements
HRM capacity	<ul style="list-style-type: none"> • HRM budget • HRM staff
HRM planning	<ul style="list-style-type: none"> • Organizational mission and goals • HRM planning
Personnel policy and practice	<ul style="list-style-type: none"> • Job classification system • Compensation and benefits system • Recruitment, hiring, transfer, and promotion • Orientation program • Policy manual • Discipline, termination, and grievance procedures • Relationships with unions • Labor law compliance
HRM data	<ul style="list-style-type: none"> • Employee data • Computerization of data • Personnel files
Performance management	<ul style="list-style-type: none"> • Job descriptions • Supervision • Work planning and performance review
Training	<ul style="list-style-type: none"> • Staff training • Management and leadership development • Links to external preservice training

- Influence health policy makers
- Influence the curricula offered by preservice training organizations

51.6 Assessing staffing requirements

Determining the staffing requirements of a pharmaceutical program means taking into account factors such as the size of the program and its goals, its geographic location, and its place within the agency of which it is a part. Three inter-related questions can be used for an initial determination of staffing requirements—

Country Study 51-4**Assessing Namibian pharmaceutical sector capacity to support the scale-up of HIV/AIDS programs**

The burden of HIV/AIDS on Namibia's health service delivery system and human resources is enormous. For example, in 2005, a referral hospital had 2,570 people on ART who must see the pharmacist every month. At that time, the ART pharmacy served approximately eighty people per day, staffed by one pharmacist and one pharmacist assistant. Staff had no computer system to track patients and no telephone or transport to find the patients who had started on ART but then stopped coming. Staff members at this hospital were barely coping with the demand; how they were going to be able to scale up ART services without additional pharmacy help was hard to imagine.

In 2005, an assessment in the Namibian pharmaceutical sector was the first step in identifying and implementing both short-term and long-term solutions to the shortage of pharmacists and pharmacist assistants in scaling up HIV/AIDS services in the national health system. The assessment and the resulting recommendations were seen as the first move toward strengthening the capacity of pharmaceutical personnel for the scale-up of HIV/AIDS as well as the delivery of health services in general.

Assessment team activities

- Reviewed all relevant human resources data and pre-service statistics
- Reviewed HIV/AIDS operational strategy, and identified the numbers and types of cadres required to implement it
- Conducted interviews with health staff, especially those linked to pharmacy, using a participatory tool and instrument with questions
- Held meetings and focus group discussions with a diverse range of human resources stakeholders in all sectors of the national health system
- Met with selected training institutions and interviewed managers and faculty
- Used the HRH framework to assess and analyze data collected in the assessment
- Formulated both short- and long-term recommendations and cost elements
- Debriefed stakeholders on draft findings and recommendations

Assessment results

Despite the different approaches used in establishing ART programs as rapidly as possible, the assessment showed that the pharmaceutical services in all of the hospitals had human resources constraints that compro-

mised their delivery of ART services. These constraints included—

- Vacant positions
- Reliance on foreign pharmacists, creating language barriers
- Small number of trained pharmacists and pharmacist assistants coming from the educational system
- Limited opportunities for in-service training and career mobility for pharmacists and pharmacist assistants
- Difficulty in retaining pharmacists and pharmacist assistants in the public sector
- Inability of pharmacists and pharmacist assistants to perform efficiently

Short- and long-term recommendations

The assessment team used the HRH framework as an approach to capture the recommendations made in their report (see [Box 51-2](#)). The HRH framework is based on the understanding that an integrated and comprehensive response is needed to address the global priority of scaling up HIV/AIDS treatment. Short-term solutions are needed to address emergency staffing issues, but longer-term strategies are critical to ensure an effective and sustainable health workforce over time.

HRM systems

In the short term—

- Contract a marketing firm to develop and implement a marketing campaign to recruit more candidates for the pharmacy program.
- Increase the number of pharmacist assistants being trained. Restart the program at another location.
- Contract with an outside recruitment firm to secure more foreign pharmacists. Provide a central-level monitoring mechanism.
- Implement the HIV/AIDS workplace program developed by the MoHSS.
- Use pharmacist assistants to counsel ART patients.
- Review the role pharmacists play in hospital pharmacy to make optimum use of the limited resources.
- Reconsider the staffing mix at medical stores to include more management skills.

In the long term—

- Provide a leadership development program for managers at all levels.
- Ensure that trained human resources professionals are in place throughout the health system.

Policy and financial

In the short term—

- Establish a minimum of ten bursaries or grants for students pursuing a pharmacy degree and two for pharmacist assistants.
- Develop a two-year community service requirement, in lieu of bonding.
- Permit part-time employment for pharmacists.
- Create a new cadre of pharmaceutical technician as promotional step for pharmacist assistants.
- Finalize a policy to permit pharmacists to work in both the private and public sectors.
- Increase the number of pharmacist assistant students that a pharmacist may supervise.
- Install computer tracking systems at ART sites.

In the long term—

- Streamline the employment process, and improve human resources links between the central and regional levels.

Education

In the short term—

- Install Internet facilities in all district hospitals to enhance learning.
- Review in-service training to improve availability and meet the needs of pharmacy staff.
- Introduce a best practices program for pharmacists and pharmacist assistants to share knowledge.

- Provide intensive English-language training for Cuban pharmacists.

In the long term—

- As a long-term measure, the MoHSS should introduce distance learning and computer-aided instruction to its in-service training capacity.

Leadership

In the short term—

- Implement leadership development programs to create a climate of teamwork and support at all ART sites.

In the long term—

- Improve multisector collaboration for strengthening human resources capacity in all areas of health.

Partnerships

In the short term—

- Partner with the Pharmaceutical Society of Namibia to market pharmacy and support more students in training.
- Enlist assistance of district councils to develop formal partnerships with community groups that can provide needed human capacity in ART.

In the long term—

- Work with the two education ministries and the University of Namibia to improve science education at the secondary level.

- What is the scope of the services to be offered in relation to the selection, procurement, distribution, and use of pharmaceuticals?
- What different types of workers are required at each level of the system?
- What is the optimal number of employees needed to deliver these services in the most efficient and effective manner?

Administrative arrangements can vary considerably, even within one agency or government. For example, medicine selection and use may fall under the purview of the ministry of health, whereas procurement and distribution may be handled by a different ministry, responsible for supplies. Also, many options exist in linking with pharmaceutical supply sources. If pharmaceutical procurement and distribution are provided directly by a government agency, then all jobs may be performed by government staff. If the central procurement office is limited to negotiating with commercial suppliers for direct delivery to health facilities, then

most of the importation, bulk inventory control, and bulk storage occur within the private sector.

An example of a large-scale human resources challenge is the integration of ART for HIV/AIDS into existing pharmacy services, which can easily double the volume of pharmaceutical products the staff handles and dramatically increase the number of patients served at the pharmacy. Pharmacy staff that dispenses antiretroviral drugs must spend more time counseling patients, especially new patients. In addition, because patients continue therapy for a lifetime, they need regular monitoring for treatment adherence, which adds to staff responsibility.

An analysis of information on human resources requirements for ART showed that the number of pharmacy staff needed depended on how dispensing and counseling activities were divided among different cadres; however, the average number of pharmacy staff was estimated at one to two per 1,000 ART patients (Hirschhorn et al. 2006). In Kenya, ART managers have addressed the shortage of pharmacists by developing a cluster of facilities that share the services

Box 51-4**Recruitment action checklist****1. Review staff requirements**

Take a broad view of your staffing needs and consider whether you really have a vacancy. For example, if an employee is leaving a clinic that you feel is already over-staffed, review the workload at that facility and decide whether a full-time permanent replacement is needed or whether an alternative option would be more appropriate. For example, would a part-time or temporary worker be sufficient? Should the job be restructured? What would the staffing implications of a restructured position be?

2. Consult with those involved

Always be sure to take any organizational policies and procedures into account. Authorization for a replacement or a new appointment may be needed from senior management, or in the case of most health ministries, from another government agency. Consult with your personnel or human resources department if you have one, because they will have expertise in this area.

3. Specify the sort of person you are looking for

List the duties, responsibilities, and relationships involved in the job role, and define the level of authority the post holder will have. Decide what qualifications and skills are required, what type and length of experience are needed, and which personal attributes will be important. This information will enable you to create an up-to-date job description and role specification. State the geographic location of the vacancy (hospital, clinic, etc.) and set a target start date.

4. Research the labor market

Depending on the nature of the job, you may want to review the job description and role specification and ask yourself whether you are likely to find what you are looking for in one person. If so, undertake some research to gauge the pay and benefits package you will need to offer. Salary surveys are usually expensive, but they are often summarized in the press at the time of publication. Monitoring job advertisements and networking with employers in your area and sector can also give you an idea of current pay rates for certain common job categories.

5. Comply with local labor laws and other legal requirements

In most countries, recruitment activities are covered by a growing body of legislation and codes of practice

designed to exclude favoritism, discrimination, and unfair treatment. As such, the entire recruitment team needs to be aware of and keep up-to-date with the latest developments to ensure that they follow good practice and do not infringe on the regulations.

6. Plan how to find and attract candidates

Again, depending on the position you want to fill, you may want to start within your organization. Are any employees suitable for promotion or reassignment? Even if you are doubtful, advertising internally as a courtesy to staff who may wish to apply is important, and keep in mind that they may have friends or relations who will be interested in the position.

Refer to your existing database of previous applicants, whether unsolicited or otherwise. Draw on any appropriate contacts.

Decide whether to use the services of a recruitment agency to identify and short-list candidates for you, weighing the costs incurred against the time and expertise at your disposal.

Consider whether electronic recruitment techniques, using either a government website (as in Kenya) or an online recruitment service, would be appropriate.

7. Decide where to advertise

If you decide to advertise independently rather than use an agency, think through the options and decide which is most likely to reach the kinds of candidates you have in mind: local or national press, bulletin boards of professional associations, Internet recruitment sites, or mailing lists. Research the costs involved, and decide what you can afford.

8. Write the advertisement

Decide if you or other staff members have the skills and knowledge required to draft an advertisement. If your organization has a human resources department, they will probably take on this task, but ensure that you are involved throughout the process. In the case of a senior post, or if you are recruiting in large numbers, you may wish to hire an advertising agency to draft the advertisement and place it appropriately. Naming your organization in the advertisement is preferable to using a box number unless you have particular reasons for secrecy. Ensure that the advertisement provides the following details clearly and succinctly—

- Duties and responsibilities of the job
- Qualifications and experience required
- Personal qualities sought
- Location
- Some indication of the salary range
- Form of reply you require (i.e., CV and covering letter, copies of relevant certificates, and testimonials)
- Deadline for the submission of applications and where the application should be sent

If you are asking applicants to complete an application form, check that it requests all the details you will need to help you assess the candidates. Asking a colleague to complete the form from the perspective of a candidate can also be helpful to ensure that the form is clear.

Source: Society for Human Resources Management (<http://www.shrm.org>).

of one ART-trained pharmacist, who floats among the clustered sites, while technicians or nurses take care of the routine responsibilities.

Calculating and justifying the number of pharmaceutical management staff needed can be difficult. The *norms approach*, which specifies a standard staffing level, or norm, for each staff cadre, quickly breaks down in practice. For example, a norm that says that each regional store needs three supplies officers will result in overstaffing at small regional stores and understaffing at busier stores.

The *workload approach* to staffing is based on the activities, volume of work (workload), and activity standards for each type of staff at each level. This is known as the WISN, or workload indicator of staffing need, approach (Shipp 1998). The WISN method is generally a much more realistic approach for determining staffing needs than the norms approach. Because it is based on actual workload, results from the WISN method are more readily explained and defended.

No matter how the organizational structure and contractual arrangements are defined, all the tasks and related jobs must be performed if the pharmaceutical supply system is to operate reliably and expeditiously. An organizational chart describing the relationships among different staff positions is very useful.

51.7 Recruiting and hiring needed workers

Effective recruitment processes are vital in ensuring that a ministry of health or any other health organization has the people it needs to implement its strategy and meet its objectives. Recruitment can be expensive, but so too is the appointment of an employee who is inadequately qualified, fails to perform well, or leaves the organization before he or she has been able to make a significant contribution. The time and effort invested in planning the process of recruitment carefully can help get the right person for the job, reduce turnover, build a strong team, and enhance organizational performance.

Recruitment is the process of attracting, assessing, selecting, and employing people to carry out the work activities

required by a health facility or organization. [Box 51-4](#) has a recruitment action checklist that focuses on planning and undertaking the initial stages of the process. In addition to assessing the need for additional or replacement staff, the process involves identifying the tasks to be carried out, specifying the kind of person needed, finding a pool of suitable candidates, drawing up a short list, conducting interviews, hiring, inducting the new hires, and deploying them.

[Country Study 51-5](#) describes how implementing emergency administrative reform allowed Kenya to fast-track recruitment and hiring into the public-sector health services.

51.8 Developing and maintaining a performance management system

One of the most important tasks for a manager is to support the establishment of an organization-wide performance management system that connects strategic and operational plans with performance measures for organizational units and for individuals. This system helps employees understand how their work contributes to the success of the organization, which may make them feel more motivated and be more productive. When implemented in a systematic way, performance management has the potential to improve both group and individual performance and to make organizations more successful.

Human resources elements of a performance management system include—

- A written job description for each position in the organization
- Defined supervisory relationships
- Regular work-planning meetings between supervisors and their staff
- Periodic performance review meetings
- Opportunities for training and staff development

Regular work planning is a key element in an effective performance management system. To do work planning, the supervisor and the employee jointly develop the

employee's workplan objectives for a designated period, often six months. They derive these objectives in part from the organization's annual workplan objectives. They should write the employee's workplan down and sign it. At the end of the designated period, they meet again to review the employee's performance against his or her performance objectives and to develop a workplan for the next period.

Work planning helps the staff member understand his or her work objectives and understand that he or she is accountable for achieving them. If an employee is unable to perform at a satisfactory level, a good HRM system provides personnel procedures for the supervisor to follow in providing opportunities to learn needed skills or in taking corrective actions.

Accountability, or being responsible for achieving agreed-upon work objectives, is an important element in a performance management system. A core set of people-centered values does not mean a lack of employee accountability. A human resources leader shows respect for people by building a performance management system that provides for assessing employee performance in an objective and constructive way and holds employees accountable for workplanning objectives. (See References and Further Readings for a list of performance management tools.)

As a way to promote accountability and deter unethical behavior in public servants or employees, some countries and organizations establish codes of conduct based on moral values and ethical principles. As part of its Good Governance for Medicines program, WHO (2006) has laid

out the framework for a code of conduct for public-sector employees—

- A public service is a trust that requires a public servant to place faithfulness to his/her moral contract with society and obedience to the laws and ethical principles above private gain.
- A public servant shall fulfill his/her lawful obligations to the government and the public with professionalism and integrity.
- A public servant shall perform his/her official duties with justice, truthfulness and with a spirit of service to the common good (public interest).
- A public servant shall perform his/her official duties with honesty, transparency, and accountability.
- A public servant shall respect the rights of the public and of his/her colleagues.
- A public servant shall disclose unethical practice and corruption to appropriate authorities.
- A public servant shall avoid any actions that may create the appearance of violating the law or ethical principles promoted by this code of conduct.

In addition, codes of conduct can specify actions that the employee must avoid to adhere to the code, such as avoiding conflicts of interest, not giving preferential treatment to an organization or person, or not engaging in private activities that would reflect poorly on the government or organization of employment.

Country Study 51-5

Instituting an emergency hiring plan in Kenya

Despite a large pool of unemployed health workers in Kenya, staffing levels at most facilities were only 50 percent, and poor geographic distribution of existing staff left many people without access to ART and other essential health services. Because filling vacant positions in the public sector can take one to two years, even when funding is available, an emergency approach was needed to fast-track the hiring and deployment process. Management Sciences for Health staff designed the Kenya Emergency Hiring Plan and led the difficult negotiations with senior health-sector leaders that eventually allowed the plan's successful implementation.

The emergency hiring plan incorporated a nongovernmental outsourcing mechanism to rapidly hire, train, and deploy workers on short-term contracts. Deloitte & Touche, Kenya, was selected to carry out most business functions, such as screening, recruitment, and benefits

management, while the African Medical and Research Foundation, the Kenya Medical Training College, and the Kenya Institute of Administration worked together to ensure that the newly hired health staff had the necessary knowledge and skills to provide appropriate services.

In the first six months, 890 health providers, including 129 pharmacy technologists, were hired for positions in critically underserved public-sector health facilities. The new hires were given three-year contracts after which they will become permanent government staff. After experiencing the initial success, the public health sector fully embraced the concept, and consequently, 3,000 health workers are working in rural health facilities on various kinds of contracts funded by both the government and donors.

51.9 Establishing a responsive supervisory system

The role of the supervisor in an effective human resources system is critical because he or she provides the bridge between the organization and the employee. The supervisor communicates the larger goals of the organization to the employee and, through the work-planning process, guides the work of the employee to directly support these goals. The supervisor needs to be aware of gaps in job readiness and to support the development of employee skills and capacity as needed. The supervisor must also be aware of problems in employee performance that cannot be solved through training or development activities and make decisions about how to address them in a positive and constructive manner.

Several characteristics are likely to define supervisors who are concerned about the developmental as well as the disciplinary aspects of supervision. These supervisors are—

- Knowledgeable and enthusiastic about the jobs they are supervising
- Sensitive to staff members' needs and feelings
- Capable of supporting and guiding without harassment
- Skilled in communication—good listeners, approachable, and open-minded about ideas that conflict with their own
- Ready to praise good work and quick to support their staff
- Willing, whenever possible and appropriate, to involve staff in making decisions, especially about matters directly affecting their own work
- Able to preserve harmony within the team and the workforce by minimizing personal jealousies and conflicts
- Able to organize effectively and to mobilize staff
- Able to allow staff to complete assigned duties without interference
- Willing to delegate tasks
- Scrupulous in making regular supervisory visits and punctual in keeping appointments
- Capable of appraising staff without bias and writing reports on the basis of work performance rather than hearsay or favoritism

Managers must allow supervisors adequate time to meet with and develop their supervisees for the supervisory process to be effective in meeting the needs of the staff and of the organization. In addition, the organization must fully integrate the supervisory process with other HRM components, such as performance management and personnel policy.

At all levels of the organization, supervisors in pharmaceutical management and other areas of the health sector

contribute to the delivery of high-quality health services to clients. They do so in two ways: through both individual and team supervision. For either supervisory approach, the role of the supervisor is to facilitate the work of individual employees or employee teams so they can effectively perform their job responsibilities. Staff members respond positively when they are given interesting and challenging work assignments by supervisors who are themselves clearly working hard toward fulfilling the organization's objectives.

Individual supervision involves supervising the performance of an individual employee on a one-to-one basis. It also involves periodic joint work planning and performance review meetings between the supervisor and the staff member. It can also involve day-to-day guidance, mentoring, and problem solving.

In team supervision, supervisors build and support a clinic team whose members work together to analyze and solve problems on an ongoing basis. A team approach to supervision emphasizes individual performance only as it relates to the ability of the team to achieve common goals. By using a team approach to supervision and by placing an emphasis on team problem solving, supervisors can overcome many of the shortcomings of traditional supervision, which can focus more narrowly on vertical programs or individual performance and may not be as supportive or facilitative (see MSH's *Improving Supervision: A Team Approach* in References and Further Readings).

An effective supervisory system—

- Describes all supervisory roles in writing
- Ensures that all supervisors and employees are aware of the system and the procedures
- Makes clear all individual performance objectives and also overall clinic objectives and desired results or outcomes
- Trains supervisors
- Provides adequate time and resources for supervisors and supervisees to meet and work together
- Fully integrates the supervisory system with the overall strategies and goals of the organization and the other components of the HRM system

51.10 Improving motivation, retention, and productivity through HRM

If staff members were asked to brainstorm on all the factors that affect their attitudes about work, the resulting “pressure map” might look something like [Figure 51-1](#). If staff members are then asked to say whether each of these pressures is positive or negative, they are likely to find more negatives than positives on the chart. Most will feel that they are poorly paid and are expected to handle heavy workloads with limited resources. Because advancement frequently

Figure 51-1 Staff pressure map

depends on formal educational qualifications or on “affiliations” rather than on the quality of work done, many may feel that they have low promotion prospects. Supervision is often constrained by lack of transport and other resources. If a staff member has extensive family responsibilities, he or she will be tempted to look outside the job for opportunities to increase income. In such circumstances, motivating staff members to perform their best may be difficult. Many of these factors are not within the control of individual managers. Some of these problems relate to a general lack of funds for running health services; other obstacles cannot easily be overcome within the constraints of typical budgeting and civil service procedures.

Conventional motivational approaches often rely on reward schemes, improved working conditions, or competition for promotions and pay increases. These approaches are not always easy to apply in resource-constrained settings. Although people need fair compensation, money alone does not improve performance. Meaningful work that is integral to the goals of the organization, has the respect of fellow employees, and provides opportunities to develop individual skills results in a more sustained level of employee performance. For example, senior staff from eleven pharmaceutical supply organizations in sub-Saharan Africa reported that the main factors contributing to staff motivation were team-building exercises, bonus schemes, staff appraisal systems, staff meetings, and church fellowship-related activities (WHO/EPN 2006).

As part of a joint initiative of several international health professional councils, including the FIP, the Global Health

Workforce Alliance (2008) commissioned a publication that extensively describes incentive plans for health workers. The guidelines include nonfinancial incentives, such as career development and positive working environments, as well as financial incentives, such as performance-linked payments. Such performance-based incentive plans are receiving increasing attention as successful mechanisms to improve service quality and worker satisfaction. [Country Study 51-6](#) describes how a performance-based financing scheme has affected health services in Rwanda.

A human resources system that integrates performance management with organizational goals will ensure that employees understand how their work relates to and contributes to the mission of their organization.

A carefully planned and implemented human resources system addresses the kinds of employee concerns that can affect motivation. These concerns are reflected in questions that employees frequently ask about their workplace, including—

- Am I being treated fairly?
- What am I supposed to do?
- How well am I doing it?
- Does my work matter to the organization?
- How can I develop myself within the organization?

HRM responsibility for fairness in the workplace

A major factor in employee motivation is people’s perception of fairness, which is especially important regarding sal-

ary and compensation. An employee may begin to develop his or her perception of fairness in the organization starting with the hiring process. Perceptions of fairness relate to the day-to-day application of personnel policies, the distribution of tasks and responsibilities among employees, the organization's salary policies, and the organization's support for and recognition of employees.

One important managerial responsibility is making sure that all managers and staff apply personnel policies on a day-to-day basis and distribute tasks and responsibilities fairly and equitably among employees. When developing an integrated HRM system, a manager should review the organization's job classifications and related salary scales to ensure that salaries are appropriate to the level of responsibility and are competitive when compared with local economic conditions. In some cases, correcting salary imbalances may be difficult, but every effort should be made to take corrective action internally to ensure that all staff members receive fair and equitable compensation.

A manager should also review the organization's personnel policies, update them as needed, and make the updated information available to all staff. In addition, all supervisors and managers should be informed about the new personnel policy and apply the rules fairly and equitably to all employees.

HRM responsibility for setting work priorities

People want to know exactly what is expected of them in their work. In many cases, job descriptions are not clear, supervisors have not specified their expectations, or man-

agers who have hired people for a specified job ask them to perform other duties. If employees do not understand their work priorities or if their supervisor changes their work priorities on a regular basis, employees find maintaining a consistent level of productivity and a sense of self-worth in the organization difficult.

One of the steps that can strengthen an HRM system is to make sure that all staff members have an up-to-date job description that provides them with information about their general duties and responsibilities. The description should clearly describe all job responsibilities and the supervisory relationship. The job description gives the supervisor a starting place in developing a workplan with the employee. See Section 51.12 for more detail on how to develop job descriptions.

Because the job description is general, it does not describe the specific responsibilities or performance objectives for which a supervisor may hold an employee accountable in a certain period. Most employees do not perform all the duties listed in their job description all the time, even if the job description is up-to-date, because work and organizational priorities change. As stated earlier, a supervisor and a staff member should conduct work-planning and performance review meetings on a semi-annual basis to allow them to jointly and systematically plan the specific performance objectives for which the employee will be responsible in a given six-month period. This joint work-planning process also helps the supervisor identify in a timely way the skills and resources that the employee needs to successfully perform the tasks required to meet his or her work objectives.

Country Study 51-6

Using performance-based financing to increase worker retention and service quality in Rwanda

Although most health workers recognize and appreciate the intrinsic rewards of providing quality services, historically, low wages and lack of resources have tended to make recruiting, retaining, and motivating health workers challenging. In Rwanda, Management Sciences for Health worked with health-sector leaders and the government of Rwanda to design and implement a groundbreaking performance-based financing (PBF) model. By decentralizing administrative structures and budgets and paying PBF funds directly into health facility accounts, facility directors and their teams at all levels of the system were empowered to improve performance. PBF starts with contracts that define the obligations of the government, development partners (the purchasers), and health care facilities (the providers). Health centers receive payment based on the number of health services they deliver, multiplied

by the fee set for those services, and adjusted by a quality score. Access to data monitoring and verification systems promotes accuracy, accountability, trust, and collaboration among all parties.

Since the introduction of PBF in 2005, the health workforce has grown by 250 percent and retention has improved. A World Bank evaluation of the scheme in 2008 showed that PBF also fostered teamwork and health worker participation in problem solving and improved quality of care. These improvements led to greater support from the community and increased use of health services. The result has been a self-sustaining process leading to improved health outcomes for the Rwandan people.

HRM responsibility for providing feedback on performance

Employees need ongoing feedback about their job performance. Anxiety about not performing well can directly affect an employee's motivation and productivity. This anxiety often results in denial and avoidance of responsibilities and in other work behaviors that reduce productivity.

An important element of a work-planning and performance review system is holding work-planning and performance review meetings on a regular basis. As discussed, the supervisor and employee agree on specific performance objectives during these meetings. These agreed-upon objectives become the basis of the next performance review. This system allows both the supervisor and the employee to evaluate performance and to plan for training or other career development activities, if needed. A work-planning and performance review system can improve individual performance and increase staff motivation. If the system is used for creating a staff development plan, it will also help align staff development efforts more closely with the organization's goals. Ongoing supervision between the semi-annual work-planning and performance review meetings is also key.

HRM responsibility for providing meaningful work

When employees feel that their work is meaningful to their organization and important to the people they serve, they work more productively. For many people, having skills and competencies and performing well is not motivating if the result does not contribute to the success of the organization. Therefore, communicating to employees that their work matters is an important element in an HRM strategy. Engaging in systematic planning and taking steps to make sure that people's day-to-day work directly supports the priorities of the organization is critical in meeting the organization's objectives. These objectives represent the strategic areas in which the organization has decided to focus in a given year, as identified during the organization's annual planning process. These objectives may vary on an annual basis, depending on changing organizational priorities.

A supervisor can link the work-planning and performance review process to the organization's annual work-planning cycle by using organization, department, or unit priorities as the basis of joint work planning with his or her staff. Such linkage will help ensure that the work of each person matters and that each person understands how his or her work is important to the organization.

HRM responsibility for professional development of staff

People feel motivated and challenged when they have opportunities to learn, develop new competencies, and assume

new responsibilities, and when they believe that their efforts will strengthen their careers. Providing these opportunities can also be an important way to recognize employees. Participating in training and other activities where people share learning and value each other's experience increases staff collaboration and teamwork and can increase overall performance and productivity.

Health organizations devote a significant portion of their funds and staff time to training, with the goal of improving the effectiveness and efficiency of their staff and their programs. Often, however, health organizations have designed and implemented this training without adequately diagnosing or planning for the needs of the organization or their employees, who hope that training will further their career development and credentials. As a result, whether the training has either solved individual performance problems or contributed to improving the organization's performance overall is not always clear. Furthermore, many health organizations are becoming reluctant to pay for expensive training until they see more tangible benefits to employees, the organization, and the community.

Making staff development a priority is an important component of a comprehensive HRM system. Posting job opportunities within the organization and supporting internal candidates will send a signal that the current experience of the staff is valued. A well-managed program of training and staff development can broaden the skills and competencies of staff and reap many payoffs. Formal, organized training, which is discussed below, is only one vehicle for staff development. Other staff development strategies include—

- On-the-job learning through mentoring relationships
- Cross-functional assignments
- Membership in task forces and committees
- Additional job assignments
- Technical presentations and discussions at staff meetings

These strategies can all provide the challenge and opportunity needed for personal and professional growth, as well as increase the knowledge that people have in common and expose them to new ways of thinking and doing.

Technology is also opening up a range of new ways to transfer knowledge. If staff have access to computers and the Internet, a variety of electronic training and educational resources is available that employees can use to develop skills without leaving their work site. Although these technologies have the potential to increase staff competency in some areas, how staff members can use these technologies in a productive and cost-efficient way is not always clear. As with traditional training programs, a manager should first determine the training needs and integrate training planning into the overall HRM system. Doing so will allow the effective use of electronic training to solve individual perfor-

Table 51-4 Comparison of communication channels

Channel	Examples	Positive aspects	Negative aspects
Controlling —used when telling someone what to do, giving an order, or making a criticism	“Do it this way.” “No, not that way, silly!”	Can provide necessary direction	Can result in inflexible dictating
Caring —used when expressing concern for someone’s welfare	“How are you today, Aziz?” “Don’t worry—it will be OK.”	Can be nurturing	May become smothering
Computing —used when giving, processing, or exchanging information; when reasoning, measuring, calculating; when thinking as opposed to feeling	“If we allow too many exemptions, the revolving drug fund will collapse.” “On average, how many patients attend this health center per day?”	Necessary calculations may provide an objective viewpoint	May come across as thoughtless lack of feeling or compassion
Complying —used in “editing” what we say; when conforming to the wishes of another person; when adapting our behavior in light of the likely reactions of the other person	“Would you mind if I . . . ?” “I’m sorry, I won’t do it again.”	May be polite accommodation	May be undignified subservience
Expressing —used when spontaneously expressing feelings of pleasure or pain; having fun, expressing humor, sharing a joke	“Great—that was really great!” “Ouch!”	Displays honest emotions	May result in selfishness and egotistical behavior

mance problems and contribute to improving the organization’s performance.

51.11 Using channels of communication

The previous sections on management and leadership imply that effective managers have good communication skills, but no set formula will work every time. Five main channels used in interpersonal communication are set out, with their positive and negative aspects, in [Table 51-4](#).

Choosing the channel

The key factor in communication is deciding which of the five channels should be used in any given situation. Two basic skills help in communicating with others: the ability to use all five channels and the sensitivity to choose the most appropriate channel on any particular occasion.

Nonverbal communication

Effective communicators have the ability to alternate among the five channels like nimble telephone switchboard operators. However, unlike using the telephone, where only the voice is important, interpersonal communication involves both words and body language. Therefore, a good manager must be aware of factors such as posture, gestures, and facial expressions.

Improving communication

A manager can improve communication with staff in a number of ways—

Clarify ideas before attempting to communicate them:

Good communication depends on clear thinking. Think about how best to express the idea and what format to use (for example, a formal circular, an informal memo, or a talk), and try to assess its likely impact.

Follow up on any communication: Good communication depends on feedback. Ask questions and encourage reactions.

Be a good listener: Good communication also depends on good listening. Careful attention to what people say helps one know what is best to say to them.

Feedback skills

Good managers try to provide feedback as a regular feature of the work experience. Done well, feedback both enhances individual performance and improves teamwork.

When giving feedback, consider the following recommendations—

- Deal only with what is known for certain.
- Describe actual behavior (“You did not attend the last two meetings”) rather than making judgmental comments (“You are irresponsible”).
- Start with positive feedback before giving negative feedback.
- Do not exaggerate.
- Listen as well as talk.

Techniques found to be successful in prompting discussion of problem areas include the following—

- Ask open rather than closed questions, avoiding those that can be answered with a simple yes or no. (“What is

your experience in this matter?”)

- Present possible scenarios that encourage concrete descriptions. (“If you were faced with such a problem, how would you tackle it?”)
- Rephrase the speaker’s words. (“You are saying that you feel that you are not trusted, because you are not allowed to handle the finances for the workshops—am I right?”)
- Acknowledge the other person’s feelings. (“You seem to be very worried about this matter—am I right?”)
- Concentrate on what is being implied as well as what is being said. People are much more willing to talk if they are convinced that they are really being heard.

Clearly, such techniques go well beyond simple criticism or interrogation.

The rest of this chapter addresses some of the common functions of human resources management—developing job descriptions, disciplining staff, resolving conflict, and conducting meetings—in light of what has been said about leadership and communication.

51.12 Preparing job descriptions

One of the most important functions of a pharmaceutical supplies manager is to ensure that the tasks of the organization are distributed equitably. This involves matching the jobs that need to be done with the skills and abilities of the individuals who make up the workforce. Each position should have a written job description and a summary of duties and responsibilities.

Job descriptions are important management tools. They are helpful in—

- Determining job qualifications, because the tasks to be performed in a particular job determine the necessary skills and experience
- Orienting new employees, because the written job description explains basic duties to new employees
- Establishing performance expectations and supervising staff

Job descriptions have no fixed format, but most have five distinct sections—

Job title: The title gives only the briefest information needed to identify the job, for example, “director of pharmaceutical services” or “chief supplies officer.”

Job summary: A brief paragraph summarizes the main responsibilities of the job.

Duties and responsibilities: The core of the job description is a more detailed description of the work to be performed and the activities for which the employee is responsible.

Qualifications: This section comprises a statement of the qualifications and requirements necessary for satisfactory job performance, including education, experience, knowledge, skills, and abilities.

Reporting relationship: The person’s supervisor should be listed. Adding a chart that indicates the structure of the organization can be useful, particularly if it shows reporting relationships.

Developing a job description

When a job description is outdated or nonexistent, the situation can be remedied by compiling and analyzing information, writing a job description, assigning time allocations, and obtaining agreement on the job description among the employee doing the job, the supervisor, and others who may have a say, such as the human resources manager.

Compile information. The information needed to build a job description can be obtained in several ways—

- Having the employee complete a questionnaire about key aspects of the job
- Observing and interviewing the employee while various tasks are being performed
- Conducting a group interview when a number of employees perform the same job
- Having the employee keep a daily record of work done, in the form of a log or diary

Analyze information. Identify the major tasks and related clusters of minor ones. Review each cluster to ensure that it accurately represents the tasks to be performed. Arrange the main tasks and related minor ones in a logical sequence, to give a clear overview of the job.

Write the job description. Group activities related to one duty, such as planning, budgeting, or supervising. In writing the descriptive statements, use active verbs and be concise. Try to avoid any ambiguity or vagueness. If someone is responsible for signing the pharmaceutical supplies order, state “signs the supply order” rather than “approves the supplies order.”

Each statement should describe one functional element of the job and be able to stand by itself. Normally, duties should be arranged in order of priority.

Obtain agreement. In updating a current employee job description, as part of good management practice, the immediate supervisor should review the job description with the employee to ensure that the listed duties and responsibilities are mutually understood and accepted. The job description form should include space for both the supervisor’s and the employee’s signatures to formalize this process.

An example of a job description for a chief pharmaceutical supplies officer is presented in [Figure 51-2](#).

Staff orientation

Every organization has its own culture; set of goals and expectations, policies and procedures; and norms and standards. Sometimes these are not made explicit, and a written job description alone can never convey all the nuances of a job. It is only one tool in the broader process of orientation and training.

New managers especially need to become familiar with the organization they have joined. Three essential steps help accomplish this—

1. Explore the new work environment. This step means getting acquainted with staff members (both senior and junior) as well as the physical location of job sites, outreach services, and training facilities.
2. Review the mission and strategy of the organization. This step involves acquiring a sound understanding of the long- and short-term goals; the organizational structure and general mode of operation; and the roles, responsibilities, and functions of the individual members of the workforce.
3. Identify training needs and opportunities. Managers need to do this for themselves and for their subordinates.

Before questioning others, good managers need to ask the following questions of themselves—

- Do I have a job description?
- Have I discussed it with my supervisor?
- Am I clear about the objectives of the organization? Can I explain them to others?
- How does my department relate to other departments? Can I explain how they relate to mine?
- What resources do I have at my disposal to achieve the organizational objectives? Consider buildings, facilities, transport, utilities, medical supplies, finances, and personnel.
- Do I have a staff development plan and a personal development plan?

Staff procedures handbook

The regulations and rules governing work should be gathered in a staff handbook that is regularly updated and includes information on—

- Organizational purpose and objectives
- Organizational structure
- Activities
- Address and telephone lists
- Safety and health policies
- Personnel classifications
- Hours of work

- Personnel policies, including recruitment, performance planning, and review of records
- Ethical standards
- Grievance, disciplinary, and termination policies
- Salary policies, including overtime
- Vacation, holidays, and other leave
- Pension and insurance benefits
- Administrative procedures, including communication, travel, procurement, and parking

Producing a handbook takes time and effort, but both supervisors and staff need to know the policies and procedures of the organization, and the handbook may be essential backup when disputes arise.

51.13 Disciplining staff

A good manager should not shirk the responsibility of disciplining staff when necessary. However, in a pharmaceutical supply program within a ministry of health or as part of a larger nongovernmental organization or private operation, a manager may be able to do little beyond submitting a report to higher authorities recommending disciplinary action. Measures such as indictment, suspension, transfer, or dismissal are normally outside the powers of a program manager. Nevertheless, maintaining fairness and dignity is important in coping with situations that might lead to making disciplinary recommendations. The following guidelines are suggested—

- If taking disciplinary action is necessary (whether a verbal warning, a written warning, or a report to higher authorities), the action should be immediate. Discipline that follows soon after the offense is more likely to be associated with the offense itself than with the manager. A delayed action can lead to resentment and a lack of trust.
- Advance warning should be given. Unexpected discipline is usually regarded as unfair. Staff members are more likely to understand and accept the need for disciplinary action if they are given a clear presentation of the rules, followed by a warning that disciplinary measures will be taken if the rules are infringed.
- Discipline should be consistent. If it is imposed differently under the same conditions, staff will be confused or frustrated, and the manager will quickly lose staff respect.
- Discipline should be impartial. It should be clear that a particular behavior is being challenged and not the personality of the individual staff member.

Of course, dealing with problematic situations before they become crises that call for formal disciplinary proce-

Figure 51-2 Sample job description for a chief pharmaceutical supplies officer

JOB DESCRIPTION	
JOB TITLE:	Chief pharmaceutical supplies officer, Pharmaceutical Service, Ministry of Health
JOB SUMMARY:	Responsible for the overall operation of the central medical stores unit; ordering and distributing medicines, medical supplies, and other related products; supervising stock control; providing technical inputs to the national formulary committee and tender board; and preparing reports on all aspects of the operation of the service
DUTIES AND RESPONSIBILITIES: (In order of priority)	<ol style="list-style-type: none"> 1. Provide medicines, medical supplies, and other products to all government health institutions by <ul style="list-style-type: none"> • Estimating requirements for medicine and nonmedicine products • Supervising preparation of medicine orders • Monitoring distribution of medicines and other supplies • Preparing monthly, quarterly, and annual reports on the status of the service 2. Supervise the control of medicines and other supplies to ensure continuous availability by <ul style="list-style-type: none"> • Maintaining an up-to-date inventory-control system • Continually evaluating the logistics management system • Implementing stock management guidelines and procedures • Liaising with a drug testing laboratory to monitor medicine quality 3. Provide technical inputs to management, as well as other agencies involved in monitoring the supply of medicines and other products, by <ul style="list-style-type: none"> • Functioning as a standing representative of the central traders' committee • Serving as a member of the national formulary committee • Providing technical information to these committees as required 4. Administer the dangerous drug component of the pharmaceutical supplies program by <ul style="list-style-type: none"> • Issuing import certificates covering dangerous drugs • Ordering, distributing, and monitoring psychotropic and narcotic drugs for government institutions • Preparing monthly, quarterly, and annual reports on the use of these medicines
QUALIFICATIONS:	<p>Education:</p> <ul style="list-style-type: none"> • Pharmacy degree • Certificate in management <p>Knowledge and experience required:</p> <ul style="list-style-type: none"> • Pharmaceutical principles and practices • Pharmaceutical supplies management • Sources of supply for medical and nonmedical drugs • Procedures for the estimation and importation of narcotic drugs <p>Abilities required:</p> <ul style="list-style-type: none"> • Forecasting pharmaceutical supply requirements • Coordinating pharmaceutical supply services • Monitoring the quality of work of others • Using computers <p>Working conditions:</p> <ul style="list-style-type: none"> • Work is performed at the central medical stores department.
REPORTING RELATIONSHIP:	Responsible to the director of pharmaceutical services
SIGNATURES:	
Incumbent: _____	Date: _____
Director of pharmaceutical services: _____	Date: _____

dures is always preferable. If someone is making mistakes, a good manager takes that person aside for a talk. Criticizing someone's behavior is perhaps one of the most difficult tasks a manager faces. The challenge is to remain objective and avoid blaming. The manager must—

- Present the perceived problem clearly
- Ask for the other person's point of view and listen when it is given
- Avoid expressing anger or frustration and remain calm and firm
- Focus on possible solutions rather than dwell on mistakes
- Discuss ways to resolve the issue and how such problems might be avoided in the future

51.14 Handling conflict

Conflicts can occur when employees feel that their needs are not being met or their concerns are being ignored. Conflicts inevitably occur in the struggle to secure adequate resources for effective pharmaceutical supply systems. This section reviews conflict resolution strategies that harmonize with the consultative, participatory approaches emphasized in this chapter.

Two forces determine how conflicts play out—

1. *Assertiveness*: the extent to which a person attempts to satisfy his or her own needs
2. *Cooperation*: the extent to which a person attempts to satisfy the needs of others

Individuals or groups manage conflict using a number of styles, but each can be understood as an interplay between these two driving forces. The two dimensions of assertiveness and cooperation define a model that provides a framework for describing various styles of conflict management and for assessing their relative strengths and weaknesses.

Competing style

The competing style involves maximum assertiveness and minimum cooperation. Competitors try to satisfy their own needs at the expense of other parties, using whatever powers are at their disposal. They try to gain power through direct confrontation or manipulation. A competitive style is not necessarily bad; it depends on the circumstances. In situations where life is threatened (an outbreak of cholera, for example, where quick decision making can save lives), a manager might need to take quick and decisive action, even if it means riding roughshod over those who challenge his or her policies.

Strengths. A competitive strategy might be appropriate when—

- Quick, decisive action is vital
- An unpopular decision needs to be made
- No doubt exists about the right course of action
- Defensive measures are urgently required

Weaknesses. A competitive strategy can lead to—

- Lost opportunities for collaboration or compromise
- Degeneration into stubborn opposition
- Low morale among employees, who may feel they have no input in decision making

Accommodating style

Accommodation is at the opposite pole from competition; it is characterized by unassertive and totally cooperative behavior. Accommodation means putting the other party's needs above one's own.

Strengths. Accommodation is an appropriate strategy when—

- The other party is clearly in the right
- Preserving harmony is the most important consideration
- Gaining goodwill is the most important outcome

Weaknesses. Too much accommodation can lead to—

- Reduced influence, respect, and recognition (someone who earns the label “accommodator” will always be expected to give in)
- People taking advantage of a perceived weakness

Avoiding style

Avoiding is characterized by zero assertiveness and zero cooperation—it means choosing not to engage. The avoider evades the issue, withdraws from the discussion, and never bothers to press for a resolution. Avoiding can sometimes be used effectively as an interim strategy.

Strengths. Avoidance may be appropriate when—

- Discussions become overheated and a cooling-off period is advisable
- A conflict should be delayed until more information is gathered or a closer analysis can be made
- The issue is relatively unimportant
- There is not enough time to come to a resolution
- The issue is identified as only a symptom of a substantial and extensive problem that needs to be dealt with later

Weaknesses. An inappropriate use of avoidance procedures can lead to—

- Communication breakdown, as when staff “left in the dark” stop taking initiatives
- Reduced effectiveness, as decisions are made by default
- Conflicts persisting and then flaring up later

Collaborating style

In the collaborating style, maximum use is made of both assertiveness and cooperation. Those using this style seek to satisfy the needs of all parties concerned. Collaboration is the best way to develop consensus solutions to problems and achieve a commitment to those solutions. Neither side feels that it has lost out in any way, so this is an ideal management style.

Strengths. The collaborating style is most effectively used when—

- The needs and concerns of the parties are sufficiently important to warrant the time and energy it takes to collaborate properly
- All parties agree to combine resources and efforts for a more effective outcome

Weaknesses. This is the most time-consuming and energy-sapping style. It can result in—

- Relatively unimportant matters getting too much attention
- The establishment of cumbersome procedures, which may lead to frustrating delays in making decisions and taking action

Compromising style

Compromise is an intermediate strategy, midway between competition and collaboration, avoidance and accommodation. The objective is to find a solution that partly satisfies both parties—by “splitting the difference.”

Strengths. Compromise solutions are appropriate when—

- The parties are strongly committed to mutually exclusive goals, and it is clear that no solution will be wholly satisfactory to both of them
- The goals of both parties are important but not worth the effort needed for collaboration
- Temporary solutions are sought for complex issues because the time for decision making is short

Weaknesses. If compromises are made too readily or casually—

- Important principles may be disregarded
- The value of the enterprise may be diminished

In conflict situations, the best approach to take depends on the circumstances. A good manager is in command of all the channels of communication, is sensitive to the needs of the situation, and can select the correct approach. Unfortunately, what tends to happen is that individual managers and groups become locked into one preferred style of conflict management and use it in almost every situation.

Collaboration and compromise are the styles that match the consulting, all-channels-open, problem-solving management approaches explored in this chapter.

51.15 Delegating

Effective delegation enables managers to become much more productive and, therefore, more successful. Unfortunately, many managers have never learned how to delegate effectively. A sure sign of trust between manager and staff is the manager’s willingness to delegate responsibilities. If delegation happens consistently and properly, the effectiveness of a team can be greatly enhanced.

Delegation is more than simply assigning tasks to subordinates. Delegation skills involve the following steps—

1. *Selecting the right person for the job.* Delegation works well only when the person to whom work is being delegated is capable of handling the task. Delegating to the wrong person invites failure.
2. *Clearly specifying the assignment being delegated.* Unless the assignment is clear, the staff member may do too much or too little.
3. *Defining the level of authority being delegated.* Is the staff member being asked to investigate a problem and then report back to the manager for a decision and action? Is the staff member to investigate, see the manager for a decision, and then act? Or is the staff member to investigate, decide, and act—informing the manager afterward? Both manager and staff member risk anger or frustration if the level of authority is not made clear.
4. *Informing concerned parties.* Unless other staff members are informed of what assignments have been delegated and to whom, they may feel that a staff member’s actions are inappropriate. They may think that the staff member is trying to take over the manager’s job rather than acting on the manager’s behalf.
5. *Monitoring without meddling.* Once an assignment has been delegated, monitoring progress is important. The manager may need to advise the staff member of possible problems. But if the manager intrudes, short-circuits, undercuts, goes around, or otherwise

meddles in the assignment, the staff member will lose interest in doing a good job. Accepting that the assignment will probably be done differently from the way the manager would have done it is part of delegating. Different is not necessarily worse. Staff members often have more time or other insights that allow them to do the task better than the manager would have.

6. *Completing the delegation neatly.* When the assignment has been completed, the staff member should brief the manager. Necessary follow-up actions should be identified. Most important, the staff member should receive positive feedback if the assignment went well and clear and direct negative feedback if the assignment did not turn out well. The manager should suggest specific corrective action.

When these basic steps are not followed, the result is often confusion, poor decision making, mistrust, and frustration. Managers are afraid to delegate because “the staff will mess it up,” and staff are afraid to take the initiative because “the boss will tell me I messed up.”

Directing managers have trouble delegating because they do not like to give up control. Avoiding managers have trouble delegating because they do not provide clear guidance and feedback. Consulting managers generally do the best job of delegating.

Delegation has three main benefits. First, it provides subordinates with the opportunity to accumulate valuable experience and develop new skills. Second, delegation prevents managers from being overworked, a condition that can cause delays in decision making. Finally, delegation frees senior managers to concentrate on long-term planning activities.

51.16 Conducting meetings

Properly run meetings can be vital to the effectiveness of an organization: they are forums for gathering information, reviewing progress, discussing ideas, planning actions, and resolving conflicts. Improperly run meetings can be a colossal waste of time.

Meetings are appropriate if—

- An issue affecting the work team needs to be clarified
- Concerns should be shared with a group
- The group needs to be involved in a problem-solving and decision-making activity
- A group has asked for a meeting

Meetings are inappropriate if—

- The decisions have already been made

- The calendar says that a meeting is due, but no urgent matters need discussion

Conditions for effective meetings

However informal and lively the interaction, effective meetings are usually the result of careful planning. The following are some of the most important factors that contribute to a meeting's success—

Purpose: The objectives of the meeting should be clear to all participants.

Preparation: The members should be knowledgeable about the topics under discussion. Relevant papers may need to be circulated beforehand.

Control: The chairperson should be in authority but not *the* authority and responsible for the conduct of the meeting but not the only decision maker in the group.

Size: The group should be small enough for everyone to make a contribution, unless the meeting is merely a gathering for dispensing information.

Setting: The seating should be arranged so that everyone has eye contact with everyone else.

Atmosphere: The climate should be such that participants feel free to offer ideas and to challenge and be challenged.

Summary: The meeting should end with a statement of what has been achieved.

Record: Taking accurate minutes of the meeting is important so that efficient monitoring can take place and those responsible for arranged actions can be held accountable.

Time: The meeting should begin on time and last for a predetermined length of time.

Skills of chairing

The success of meetings depends on the kind of control exercised by the chairperson. Some of the main techniques used to facilitate open and purposeful discussion and decision making are—

Initiating: Start by ensuring that all members know the objectives and agenda of the meeting.

Seeking opinions: Invite participation by bringing members in when you know that they will have something to contribute.

Clarifying: Rephrase or illustrate points so they can be understood by all members.

Steering: Bring the discussion back on track when it veers off course.

Summarizing: Pull together the ideas that have been expressed and sum up the conclusions that have been reached.

Keeping time: End the meeting on time.

ASSESSMENT GUIDE

In addition to the HRM system assessment questions in Section 51.4, the following questions can be used to assess an organization's human resources components—

- Do experienced HRM staff in your organization maintain human resources functions?
- Does an annual human resources plan exist? Is it monitored?
- Is a human resources information system in place to gather employee data that can be used in human resources planning and forecasting?
- Do personnel files exist for all staff? Do staff members have access to these files?
- Is a job classification system in place?
- Is a system in place to determine salaries and to determine upgrades and merit awards?
- Is orientation offered to all new employees?
- Does an updated personnel policy manual exist? Is it used by managers and supervisors to address employment questions?
- Are formal procedures in place for addressing discipline and termination issues?
- Does an organizational chart of staffing positions and relationships exist? When was it last revised?
- Do job descriptions exist for these positions? When were they last revised? Does each staff member have a copy of his or her job description?
- Is a training plan in place? Does it include a plan for management and leadership development?
- Does the organization have links to preservice training institutions?

Finally, the conclusions of most meetings can be encapsulated in a brief plan of action, recording what is to be done, by whom, and by when. ■

SUMMARY

Training is any planned activity to transfer or modify knowledge, skills, and attitudes through learning experiences. Personnel may require training for a variety of reasons, including the need to maintain levels of competence and respond to the demands of changing circumstances and new approaches and technologies. Training by itself cannot solve structural, organizational, or policy problems within an organization, although supportive supervision and the use of motivational strategies can help sustain performance improvement derived from training.

The first step in the design of training involves an assessment of training needs. The assessment comprises—

- Observing workers performing normal duties
- Interviewing workers and others
- Studying routine reports or performance reviews, along with job descriptions
- Identifying performance problems

The second step involves defining the training program's learning objectives. The learning objectives, which are derived from the needs assessment, specify the observable, measurable actions that each learner will be able to demonstrate as a result of participating in the training activities.

The third step is the creation and implementation of a training program to improve performance, taking into account the experience and educational levels of the personnel and the time and resources available for training. Options range from short courses to long-term placements in academic institutions in the country, in the region, or overseas, and non-classroom-based interventions, such as on-the-job training, coaching, and mentoring. All options must be weighed against the immediate operational needs of the program or institution, because facilities may not have enough personnel to operate when staff members go for training.

The learning outcomes that must be achieved, along with the training environment, audience characteristics, and the experience of the trainer, all determine the mix of learning methods and media that will achieve maximum effectiveness. Methods and media may include lecture, discussion, case study, role-playing, group exercise, simulation games, brainstorming, and demonstration. If no published training materials—including audiovisual aids—are available, the trainer must develop them.

Development of the training program also includes design of the training evaluation, which is carried out during the course as well as at its conclusion. During the course, trainers monitor learner progress and satisfaction

to identify where they may need to make adjustments to the training program. At the end of the course, trainers should collect data on how well the learners achieved the course objectives and how satisfied they were with the training experience. Whenever possible, the trainer should follow up with participants after they return to their work situations to assess the impact of training on performance. Data collected during follow-up can help identify the need for additional training or reinforcement of newly acquired skills, as well as inform review and revision of the training materials.

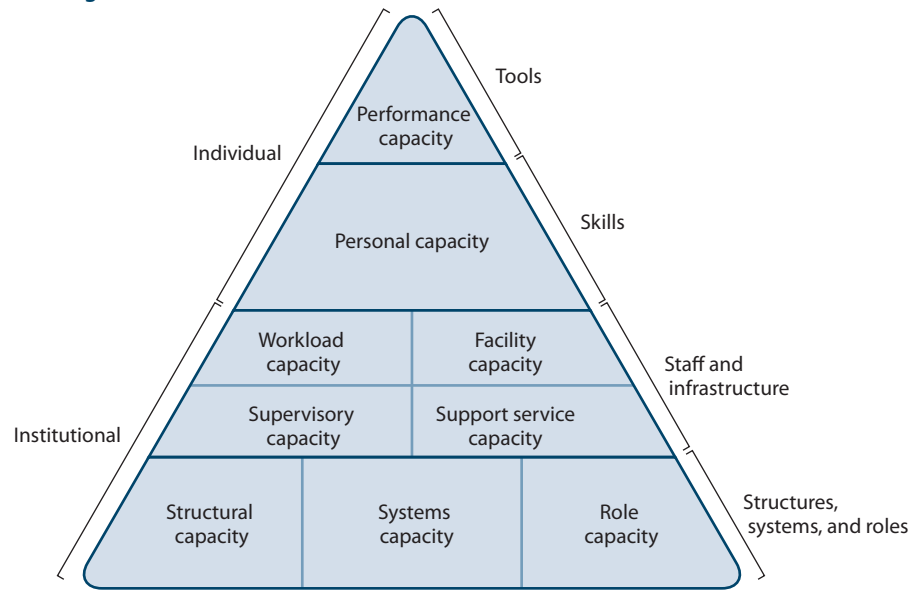

In some countries, availability of basic training and continuous professional development programs is limited; therefore, many health workers lack access to formal training opportunities and new ideas and approaches that can improve their work performance. Well-designed in-service training programs can help fill this need.

Training should be put into a context of continuous performance improvement. Changing and improving practices require an environment conducive to work, the appropriate learning resources, and the continuous use of motivational strategies. Training should be based on competencies: the abilities required to do work to the standards expected. Therefore, training should result in changes in work behavior that lead to an improved, efficiently functioning pharmaceutical management system. At the same time, training alone is unlikely to change overall supply system performance unless the environment and supervisory systems support change (see [Chapter 37](#)) and unless individuals are encouraged to maintain changes (see [Chapter 51](#)).

Learning requires active involvement. People prefer to learn in different ways—through visual stimuli, verbal interactions, and learning by doing. Therefore, offering a variety of training opportunities and training techniques is usually more effective than using only one approach. Training can be formal or informal, academic or applied, guided or self-directed, or provided in public agencies or private institutions.

Training alone is often not sufficient to change behavior or improve performance. Improved performance, changed attitudes, and new skills acquired during training may need to be complemented by and maintained through continuing education, supportive supervision, and adequate motivational incentives. In many cases, structural changes, such as workspace improvements and increased access to supplies and equipment may be needed to support improved performance.

Figure 52-1 Capacity-building framework

Source: Adapted from Potter and Brough 2004.

52.1 Objectives of training

The training of personnel in pharmaceutical management has four major objectives—

1. Increase knowledge about the special considerations related to pharmaceutical systems
2. Improve attitudes about the importance of pharmaceutical management, thus improving the environment for change
3. Build and strengthen skills in the specific tasks to be completed for efficient functioning of the pharmaceutical system
4. Improve work behavior, so that people function better at assigned activities and fulfill their potential

The goal of these objectives is to increase access to quality pharmaceutical products and services.

Training should address the needs of three levels of personnel, because it takes all three groups to effect sustainable change—

1. Policy makers, who are responsible for creating the environment needed for improved pharmaceutical management
2. Midlevel managers, who are responsible for planning and supervising activities required in the management and use of medicines
3. Line or operations-level personnel, who are responsible for carrying out the work of pharmaceutical management

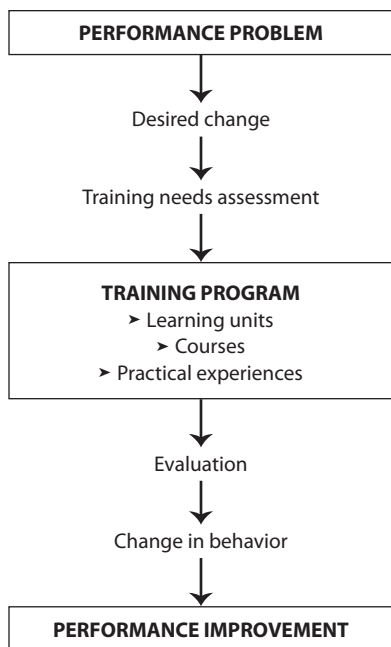

A country's national pharmaceutical program alone is not in a position to handle comprehensive training for policy makers and midlevel managers; many of their learning objectives are best handled through general management training. However, it is still possible and necessary to reorient this group on pharmaceutical policies and issues through information exchange, reports, and seminars. Training for operations-level personnel is critical because they often lack the basic knowledge and skills necessary to be effective at their jobs.

Finally, training alone will not result in significantly improved performance unless it is linked to an enabling institutional environment. This is illustrated by Figure 52-1, which is a conceptual framework for building in-country capacity for pharmaceutical management services. It illustrates the concept that health structures, systems, and roles, staff and infrastructure, skills, and tools must all be addressed to strengthen a country's ability to effectively provide pharmaceutical services.

52.2 Developing a comprehensive training program

A training program is composed of a schedule of activities with training goals, learning objectives, subject areas, methods, trainers, trainees, methods of assessment, and locations. A good training program is designed to address performance problems, such as long delays in getting medicines from suppliers to the main stores, delays in distributing medicines from midlevel stores to end-user units, or

Figure 52-2 The training process for improved performance

failure to ensure quality of medicines. [Figure 52-2](#) shows how a training program is developed, proceeding from problem identification, through needs assessment, training, and evaluation, to a change in behavior that results in better performance.

The key elements of a training program include needs assessment, course work, learning tasks, and practical application. Facilitators introduce new information to trainees through course work or lectures. Learning tasks or activities, such as case studies or role-plays, provide individuals with opportunities to work with the new information in a small-group setting. Practical experiences and application give the trainees the opportunity to apply the knowledge and skills learned in a real-life or simulated situation.

The current level of the trainees' skills will guide decisions on developing a training program specifically for the group. For example, the objectives and goals for a program to train new employees will differ dramatically from those for a program geared toward experienced technicians learning a new technique.

Conducting needs and knowledge assessments

A training needs assessment and a pretraining knowledge and skills assessment are required to help plan an effective training program. The needs assessment should encompass the overall working environment, including the supervisory structure and the level of employee motivation. Pharmaceutical management training will be effective only

if all areas of the pharmaceutical supply system are assessed frankly and carefully.

A knowledge and skills assessment evaluates the participants' level of prior knowledge, as well as previous training and experience, in the area of interest. The results of this assessment are used to develop the training learning objectives, and ultimately, the content.

Methods for assessing training needs are outlined below. The optimal method depends on the goals of the assessment and the cadre of the individuals being assessed.

A knowledge assessment can be based on observation of a worker performing routine duties. This review uncovers both strengths and weaknesses, but the presence of an observer may influence the behavior observed. For example, a clinical worker examining a patient is likely to be more thorough than usual if someone is watching. Specific training needs can be determined more clearly by using well-established indicators, such as those on performance monitoring and evaluation described in [Chapter 48](#), and observation methods, such as those described in [Chapter 28](#).

Interviews with supervisors, administrators, users of services, and workers can help determine where performance problems might exist and what skills need to be taught or improved. If workers fear reprisals from management, reassurances about confidentiality of information will be necessary to obtain good data. In some situations, a training needs analysis can be done by conducting a group interview in which the staff are invited to identify competencies in terms of knowledge, attitudes, and skills. Staff members rate themselves on a graph in relation to each of a set of competencies. Exit interviews with workers leaving their jobs can also be useful. Finally, interviews with users of the services can help in assessing levels of satisfaction.

Analyses of job and task descriptions may reveal special training needs. Self-administered, anonymous questionnaires for both managers and workers can also be valuable.

Several types of reports are useful needs assessment tools—

- Organizational reports, for an overview of the performance of the organization and personnel
- External evaluation or appraisal reports, for an outsider's view of the organization and its training needs (and performance)
- Annual or semiannual performance reviews

Selecting subject areas and setting learning objectives

A training needs assessment should indicate which subject area, topic, or target group should be given priority ([Table 52-1](#)). In many countries, some subject areas require more attention than others, but certain basics must be provided: the selection process needs to be well managed and par-

Table 52-1 Subject areas, training topics, and target groups

Subject area	Training topics	Target groups
Selection	<ul style="list-style-type: none"> • Essential medicines lists • Public formulary • Sources of information • Safety and efficacy • Cost comparisons • Levels of use • Hospital formularies • National pharmaceutical policy 	<ul style="list-style-type: none"> • Policy and decision makers in ministry of health (MOH), ministry of finance (MOF), other ministries • Service providers: doctors, nurses • Auxiliary personnel • Pharmacists and dispensers • Hospital administrators
Procurement	<ul style="list-style-type: none"> • Procurement cycle • Purchasing methods • Quantification of pharmaceutical needs • Scheduling of purchases • Terms of payment • Selection of suppliers • Payment mechanisms • Organization of procurement services • Quality assurance • Make-or-buy decisions • Shipment specifications • Contracting 	<ul style="list-style-type: none"> • Division of planning, MOH • Division of finance, MOH • Division of administration or purchasing, MOH • MOF • Central procurement service (if it exists) • Central laboratories, MOH • Pharmaceutical quality laboratories • Drug regulatory bodies • Senior MOH/MOF officials for policy decisions (such as make-or-buy)
Distribution	<ul style="list-style-type: none"> • Distribution cycle • Information system • Port clearing • Warehouse operations • Packaging and repackaging • Transportation • Security 	<ul style="list-style-type: none"> • Division of planning, MOH • Division of administration, MOH • Operations personnel in port and warehouses (central, regional, and district) • Transportation
Use	<ul style="list-style-type: none"> • Promotion of appropriate therapy • Training of health workers • Dispensing practices • Patient education • Information systems • Patient adherence • Rational-medicine-use indicators 	<ul style="list-style-type: none"> • Program directors • Program supervisors • Doctors • Nurses • Pharmacists • Dispensers • Auxiliary and community health workers • Drug sellers • Patients and clients

ticipatory; procurement officers need training in efficient purchasing methods and quantification of pharmaceutical needs; distribution—proper storage, efficient transportation, and security of medicines—is a continuing concern; and rational use is becoming a major focus of many pharmaceutical programs.

In addition to these basic pharmaceutical management skills, staff will benefit from training in other areas, including—

- General management
- Financial management, budgeting, and accounting
- Computer systems and information management
- Training program development and management
- Training materials development
- Patient and public communications
- Personnel planning and management
- Program planning, monitoring, and evaluation
- Proposal development and writing

Pharmaceutical supply systems often run into difficulty not because they lack staff members with technical expertise but because they lack staff members who have critical management skills. Thus, when considering subject areas, thinking broadly about which skills are most needed to improve the performance of the organization is important.

After determining which tasks and competencies are required by staff for a particular situation, training goals should be established and learning objectives should be set. Goals will be broad statements about what the training intends to achieve: for example, “This course aims to provide medical stores personnel with the knowledge and skills to accurately estimate quantities of medicines and related commodities to order.”

Objectives, on the other hand, should clearly state what the participant must be able to do at the end of the training. They must be clear, concise, relevant, easily understood, and measurable—in other words—SMART (specific, measurable, achievable, realistic, and time-bound) (CDC 2009).

They are, in fact, indicators by which course output and performance can be assessed. For example—

On completion of the course, participants should be able to—

- State the rationale and uses for quantification of pharmaceuticals and other related commodities
- Describe the attributes, uses, and limitations of various quantification methods
- Identify the data required for each of the quantification methods

Because objectives must be measurable, terms such as “understand” or “know” are not acceptable.

Learning methods

A variety of learning experiences can be used in training, including—

Brainstorming: Members of a small or large group are encouraged to contribute any suggestion that comes into their heads on a given subject, initially with no criticism, but later with a sifting and assessment of all ideas. (Because brainstorming is such a versatile but sometimes misunderstood method, it is described in detail in [Box 52-1](#).)

Case study: A real situation is presented in a brief paper or presentation, then analyzed by participants.

Demonstration: The facilitator shows learners how and what should be done while explaining why, when, and where an action is taken; participants then perform the action.

Discussion: A method in which the participants learn from one another, usually with guidance from a facilitator.

Distance learning: A system designed to build knowledge and skills of learners who are not physically on-site to receive training. Facilitators and students may communicate at times of their own choosing by exchanging printed or electronic media or through technology that allows them to communicate in real time.

Box 52-1

Brainstorming: A versatile technique for training, planning, and problem solving

Brainstorming is a group technique that is useful in training situations. It also helps work groups be more creative in decision making and problem solving. The basic process is easy. The facilitator writes the topic or questions on a flip chart, whiteboard, or blackboard. Group members are asked to call out their ideas in short phrases that can be written down readily. To keep the discussion moving, a tight time limit is usually set—typically, five to ten minutes. The facilitator should be prepared to stimulate brainstorming with a few examples or prompting questions.

The creativity of brainstorming is enhanced by giving the group the following short set of guidelines before starting—

No idea is a bad idea: No matter how odd, unconventional, or silly an idea may seem, no idea should be ignored.

No discussion of ideas is allowed: Discussion of ideas can come later. Grimaces, groans, and other nonverbal judgments discourage creative thinking and should be avoided.

Everybody is encouraged to contribute: The facilitator should try to get everyone to make at least one suggestion.

Go for quantity: This encourages the maximum contribution and discourages people from screening out potentially good ideas before suggesting them.

Build on other people’s ideas: Although discussion of ideas is discouraged, generating new ideas from those already suggested is fine.

After the brainstorming session, ideas are usually typed up, organized in some way, and brought back to the group for discussion.

Although brainstorming can generate many creative ideas, it is not always successful. Some people may be discouraged from contributing, and inhibitions may exist about raising certain ideas. Brainstorming may also be dominated by certain individuals or get stuck on one part of the topic. Sticking to the preceding guidelines will help. In addition, methods to make brainstorming more productive include—

- Prepare a broad range of prompts that can be used to direct the group’s thinking into new areas if suggestions consistently concern one area.
- Begin by asking each person to brainstorm individually for a few minutes and write down ideas.
- Divide the group into several smaller groups to brainstorm on the same topic. Then compile and discuss the topics in a larger group.
- Limit the number of suggestions by an individual group member. Generally, this degree of directness should be reserved for situations in which one group member dominates the brainstorming session.

e-learning: Participants interact with facilitators through the use of some of the many electronic, computer-based learning materials that are now available, ranging from CD-ROMs to Web-based systems.

Group exercise: A number of participants undertake an activity together, followed by a critical analysis of the process involved.

Lecture: A direct talk with or without learning aids but without group participation.

Role-playing: Participants act out the roles of those represented in a given situation.

Self-paced: Participants are allowed to learn anywhere, anytime, and at a pace that suits their levels of skills, knowledge, and aptitudes.

Simulation game: A more advanced version of a case study, where participants are given more detailed information on a situation, including data sets to analyze. On the basis of their analyses, participants develop and defend a plan of action.

Worksheet: A step-by-step approach to identifying problems or solutions through written questions or problems, with space provided for answers.

The uses, advantages, disadvantages, and trainers' role for some of these methods are summarized in [Table 52-2](#). Some of the methods are more suitable for adult participatory training, and others work well in formal academic settings (such as lectures or seminars). Most people learn better in an active rather than a passive fashion. A combination of methods is likely to be more effective than the exclusive use of one method.

Sequencing topics. *Sequencing* means arranging topics in a logical order during training. In doing so, bear in mind that most people prefer to learn in easy and progressive stages. Adults, especially experienced trainees, usually prefer to start with an overview of the whole course before concentrating on particulars. The best approach is to sequence topics to build on previously completed content and learning experiences. In addition, *spiraling* the curriculum revisits the basic concepts repeatedly, while building on them. The trainer should, however, be aware of training fatigue and not leave the most complex topic for the end of the course, when learners are likely to be more tired.

Developing teaching materials. Training materials may not be available for the kind of in-service training that would best suit a particular pharmaceutical management program. Many countries, however, have developed their own teaching materials using a number of approaches. These materials can be requested and used as is or can be adapted to suit specific needs. Materials from international sources are listed in [Annex 52-1](#).

Manuals. Many countries have training manuals that are not being used effectively by their health workers, often

Box 52-2 Outline of trainers' and participants' guides for workshops

Trainers' guides

Summary

- Learning objectives and content of the unit

Session notes (containing basic technical information, including definitions of essential terms)

Session activities (with worksheets and instructions)

because the workers were not involved or consulted in developing them. A better approach is to ask knowledgeable persons to write on one or two topics; circulate drafts among selected end users; and develop the final version in a workshop involving end-users, the authors, and national pharmaceutical management program officers. This approach creates a sense of ownership, which leads to increased acceptance and use of the materials developed. The topics can be compiled inside one cover or distributed as a series of individual modules.

Trainers' and participants' guides. Training materials should include guides for both trainers and participants, as well as audiovisual aids. Some of these materials may be obtained from established programs. Typical contents of trainers' and participants' guides are outlined in [Box 52-2](#). Both provide structured but adaptable notes and exercises for each unit. The participants' guide should contain the technical content for the unit, including definitions of all

Table 52-2 Comparison of training methods

Method	Useful for	Advantages	Disadvantages	Trainer's role
Lecture	<ul style="list-style-type: none"> • Passing on information and facts • Giving specific information related to occupation, job, or task 	<ul style="list-style-type: none"> • Allows much material to be delivered in a short time • Handles a large number of participants • Permits lecturer to be in full control 	<ul style="list-style-type: none"> • Learner is passive • Little of what is said is remembered • Lecturer receives little feedback 	<ul style="list-style-type: none"> • Provide information • Answer questions
Discussion	<ul style="list-style-type: none"> • Stimulating interest and thought • Generating possible solutions to problems • Consolidating other types of learning • Developing consensus 	<ul style="list-style-type: none"> • Stimulates learners' interest • Involves learners actively • Allows sharing of learners' experiences with others 	<ul style="list-style-type: none"> • Time-consuming • Requires learners to have facts about the topic • Needs to be well controlled to have value • Can be dominated by a few active persons 	<ul style="list-style-type: none"> • Establish small groups early in course • Help groups select moderators and rapporteur • Clearly specify tasks for each group • Assign time limits for each task and enforce them
Case study	<ul style="list-style-type: none"> • Solving problems • Changing attitudes • Building analytical skills 	<ul style="list-style-type: none"> • Involves learners actively • Allows sharing of learners' experiences with others • Stimulates ideas and discussions of concrete subject 	<ul style="list-style-type: none"> • Time-consuming to prepare • Not easy to validate • Discussion may focus on areas different from those intended by trainer 	<ul style="list-style-type: none"> • Carefully prepare or read case and relevant material • Ask provocative questions to provide key issues for discussion • Guide discussion to achieve analysis, possible solution, recommendations for action
Role-playing	<ul style="list-style-type: none"> • Developing interactive knowledge and modifying attitudes • Introducing humor and liveliness into training 	<ul style="list-style-type: none"> • Stimulates interest • Is fun • Is active • Uses participants' experiences 	<ul style="list-style-type: none"> • Time-consuming to prepare • Observers may be passive • Some key points may not be addressed • Those engaged in role-playing may learn more than observers 	<ul style="list-style-type: none"> • Choose a suitable story to illustrate key points • Debrief (discuss insights gained from role-playing)
Group exercise	<ul style="list-style-type: none"> • Team building • Developing interactive skills • Studying group dynamics 	<ul style="list-style-type: none"> • Facilitates high participation of motivated learners 	<ul style="list-style-type: none"> • Trainer's skills required to guide the exercise • Takes time for group to work in harmony 	<ul style="list-style-type: none"> • Prepare carefully to ensure that everything is organized
Brainstorming	<ul style="list-style-type: none"> • Stimulating creative thinking • Generating possible solutions • Consolidating past learning • Providing diversion 	<ul style="list-style-type: none"> • Promotes active participation of learners • Uses learners' experiences and ideas 	<ul style="list-style-type: none"> • Time-consuming • Some learners may be passive • Requires high-level trainers' skills 	<ul style="list-style-type: none"> • Record suggestions • Reorganize into groups • Lead discussion at end
Demonstration	<ul style="list-style-type: none"> • Showing correct procedures and required standards 	<ul style="list-style-type: none"> • Stimulates a lot of interest • Can be used for large groups 	<ul style="list-style-type: none"> • Takes effort to produce • Good viewing by learners is difficult in a large group 	<ul style="list-style-type: none"> • Arrange for demonstration materials in advance • Do demonstration alone to ensure that everything works • Observe participant demonstrations • Correct mistakes promptly • Encourage slow learners
Worksheet	<ul style="list-style-type: none"> • Performing quantitative exercises requiring calculations • Working out solutions for issues of case studies 	<ul style="list-style-type: none"> • Helps learners relate their general learning to some specific area of their work 	<ul style="list-style-type: none"> • Time-consuming • Difficult to prepare 	<ul style="list-style-type: none"> • Prepare a worksheet based on real situations to show difficulties and successes • Guide the learners but leave most responsibility with participants
E-learning	<ul style="list-style-type: none"> • Individual study • Passing on information and facts • Showing correct procedures • Working out quantitative exercises requiring calculations 	<ul style="list-style-type: none"> • Allows materials to be passed on quickly • Allows participants to study at their own locations, at their own pace • Some Web-based systems allow for communication between participants working on the same module at the same time 	<ul style="list-style-type: none"> • Expensive and time-consuming to prepare • Participants may not have computer equipment or communications links capable of handling some forms of electronic platforms (e.g., Web-based) 	<ul style="list-style-type: none"> • Provide backup support for tutoring, coaching through various means, including telephone, chat room, and Listserv

essential terms and concepts. The trainers' guide should provide guidance on how the session should be taught.

Audiovisual aids. Audiovisual aids are useful because they stimulate the trainee and help reinforce the ideas presented. However, poor visual aids can confuse participants.

Common visual aids include posters, wall charts, chalkboards, flip charts, overhead projections, and computer-projected presentation slides. CDs and tapes are common audio aids. Videotapes, DVDs, and films are good audiovisual aids, but their expense often makes them impractical. The equipment and technology support required for some of these approaches may limit their use in certain settings. If relying on equipment or technology that requires electricity, having a backup option that does not need electricity is an important consideration.

52.3 Implementing a training program

There are two basic approaches to implementing a training program: one is centered on the trainer, who controls learning contents and experiences; the other is centered on the learner, with the trainer acting as a guide and providing resources. This approach assumes that people are able and willing to learn if they are given the proper materials in an atmosphere that is conducive to learning. This method is preferred because it is participatory, learners' experiences are shared, and participants have more freedom to learn at their own speed.

An important aspect to include in a training package is follow-up support to the participants and evaluation of the training outcome. This support, which should be included in the training budget, may be in the form of supervision, coaching, mentoring, setting up a network support group, or simply providing a source of ongoing information. Follow-up activities may be conducted in person but may also be provided by telephone or e-mail. [Country Study 52-1](#) shows how a follow-up plan is used to track participants' progress in developing drug and therapeutics committees.

Strategies

Training strategies must be appropriate to the educational level of personnel being trained and to the resources available in the country, feasible in terms of the amount of time and travel involved, and relevant to the job. In some countries, governments often place officials in jobs that require a higher degree of technical capacity than they possess. In such cases, managers and trainers need to work together to close the gap between requirements and ability.

Training programs must consider the resources available. For example, an individual working in a central medical store that uses a simple card system for inventory control

THE PROFESSIONAL WORKSHOPPER

should be trained in the operation of that system rather than a computerized system that may never be installed.

Training programs must be feasible. Governments may not be able to allow a senior official to take an extended training leave, regardless of potential long-term benefits. Some officials may not be able to be absent from work for more than one week. Similarly, health care providers may not be able to be away from the patient population they serve if no backup staff support is available. This factor is of particular concern in the private sector, where having staff away from work will result in facilities' losing revenues and in providers' losing income.

Preservice training is conducted at established training institutions and is often a prerequisite for hiring. In-service training may be offered in a classroom setting or in the work environment, either as part of a planned staff development program or after an assessment of deficiencies has determined what training is needed at the workplace.

Continuing professional development allows cadres of professionals to maintain and improve their knowledge and professional competence throughout their careers. Professional associations often develop and sponsor continuing professional development courses and accreditation. A recognized credential can be a powerful incentive for seeking professional development; for example, Tanzania created a new cadre of private-sector drug dispenser, who may earn a license to work in a government-accredited drug dispensing outlet after completing a training program and examination.

The decision about the kind of training program to use depends on the issues raised in [Table 52-3](#), as well as the criteria of appropriateness, feasibility, and relevance. A comprehensive training program is likely to include a combination of long- and short-term training, observation trips,

Country Study 52-1**Follow-up activities to support a drug and therapeutics committee course for professionals in developing countries**

Drug and therapeutics committees (DTCs) are effective in promoting rational medicine use, but DTCs have been underused in developing countries. The Rational Pharmaceutical Management (RPM) Plus Program and World Health Organization (WHO) designed a course, training materials, and a manual to train health care providers and administrators who would be involved in DTC activities in developing countries. The course includes fifteen training modules and a field trip to hospitals where participants assess the hospital DTCs, conduct medicine use evaluations, and review the formulary process. The course ends with each participant making a workplan for future DTC-related activities.

A common problem with training courses is that when participants go back to their places of work, they may have difficulty maintaining their new skills without ongoing support. The RPM Plus follow-on program, Strengthening Pharmaceutical Systems (SPS), addresses that issue through an innovative follow-up program designed to help participants carry out their DTC workplans and become DTC advocates. The workplans developed in the training are made available on a DTC Learning Center website. The follow-up program provides specific technical assistance and support for all DTC course participants and local organizations to implement a DTC and related activities. Participants' activities are monitored on the website and through regular e-mail follow-up and support. Technical assistance and support for implementing their workplan activities are made available to all participants, and through this post-training support mechanism, participants can share the problems they encounter in their work and brainstorm possible solutions.

Between 2001 and 2010, 24 courses were conducted in Asia, Africa, Latin America, and Eastern Europe for 945

people from 70 countries. Follow-up e-mail contact with participants showed that they initiated almost 400 activities based on the training.

The RPM Plus/SPS process for promoting and supporting DTCs through training and follow-up of course participants has paid measurable dividends in many countries. The following examples show the wide range of accomplishments by course participants and other in-country stakeholders—

- Reduced the percentage of outpatients receiving antibiotics at each visit from 90 to 60 percent (Kenya)
- Established a system that monitors prescribing patterns for certain high-use antibiotics (Malaysia)
- Developed a generic substitution policy that allows the pharmacy to substitute equivalent products, which decreased the average prescription cost by 20 percent (Kenya)
- Created an adverse drug reaction reporting system (Pakistan)
- Analyzed cost of pneumonia treatment, resulting in institution of new standard treatment guidelines and medical records review to assess physician adherence (Paraguay)
- Performed ABC analysis, resulting in changes in the formulary and in the suppliers of several drugs (India)

Training courses can promote the use of DTCs and related activities in developing countries, but increased support at the country level plus post-training support and technical assistance are needed to help course participants achieve their objectives. In addition, more intensive course follow-up appears to produce enhanced results in a very short period.

Source: MSH/SPS 2010.

conferences and seminars, and in-country counterpart training.

Long-term training. Long-term training is often obtained in an institution of higher learning (sometimes in overseas institutions). Such training, whether in academic or nonacademic settings, is most useful for highly technical areas, such as research and development of new drugs, quality assurance, pharmaceutical production, improved manufacturing practices, or advanced areas of patient care. The provision of fellowships for doctors, pharmacists, industrial

engineers, and other technical professionals is most appropriate here.

This approach is limited because a pharmaceutical program does not have the specific duty to provide basic training, and most programs cannot afford to have top personnel away for a long time. In addition, if personnel fail to return to their job, the costs for training new personnel can be high.

Short-term training. Short-term training is usually conducted over a period of one to three months in an academic or nonacademic setting. To work effectively, the trainee

Table 52-3 Issues to consider when designing training programs

Audience	Mode	Length	Location	Funding source
<ul style="list-style-type: none"> Trainers to be trained Senior government officials Administrators in government ministries Managers of donor programs, nongovernmental organizations Managers of facilities in decentralized settings Line or operations-level personnel 	<ul style="list-style-type: none"> Preservice training On-site job training, counterpart training Classroom (off-site, in-service training) Tours, observational trips Workshops and seminars Courses (short or long term) 	<ul style="list-style-type: none"> Seminar (two weeks or less) Short-term course (two weeks to three months) Long-term course (six to twenty-four or more months) 	<ul style="list-style-type: none"> Local college or university National management institute (where one exists) International sponsor (for example, WHO, UNICEF, USAID, Danida, SIDA, KfW, and GTZ) Business Independent private group Government agency 	<ul style="list-style-type: none"> Government Private organizations Industry University Self Donors <ul style="list-style-type: none"> International organizations National government donor agencies Foundations Private charity, such as a church group

needs to be separated from everyday work responsibilities. Sometimes, when staff members have difficulty getting away for an entire week, training may occur on a series of Saturdays.

This approach is appropriate for most training needs in pharmaceutical management, especially for top- and middle-level personnel. Prerequisites for effective short-term training include—

- A sufficient supply of people with appropriate background or education
- Courses available in the language of the participants
- Course design that uses training modules to allow for flexible curricula to meet the needs of target groups
- Intensive, practical training so that participants gain a good mix of information and skills in a short time
- Adequate follow-up of graduates, including provision of continuing education programs, to ensure that they continue to function effectively

In addition to training the target groups outlined in [Table 52-1](#), this type of program is suitable for the training of trainers (often referred to by the acronym TOT) who will return to their jobs and train others in the techniques and skills they have learned. Thus, short-term training should include pedagogical and leadership skills and provide some institution-building capacities. [Annex 52-2](#) provides further information on workshop logistics and evaluation.

An example of an innovative type of training is the monitoring-training-planning (MTP) methodology, which puts into place an ongoing process to deal with individual training issues in the short term. MTP puts the tools and responsibility for training into the hands of local staff, who tackle specific problems in concise, monthly sessions. See [Country Study 52-2](#) for an introduction and example of the MTP methodology being used in the Lao People's Democratic Republic (P.D.R.).

A number of institutions have developed training materials and can provide training at the regional or international level. Some private nongovernmental institutions in the United States, such as Management Sciences for Health, and quasi-governmental institutions, such as the Eastern and Southern African Management Institute in Arusha, Tanzania, offer training in individual countries. In addition, some institutions are beginning to develop regional training centers in management; [Country Study 52-3](#) illustrates a regional approach to technical assistance and capacity building in East Africa.

Observation trips. Countries that do not have formal training programs but have successfully implemented essential medicines programs can offer useful and practical examples for personnel from other countries. In addition, some multinational and national pharmaceutical manufacturers have regional or local warehouses, manufacturing plants, and laboratories that are good sites for visits. Observation trips work best when combined with short-term training, to reinforce in a practical way the skills learned. Such programs can benefit both the visitors and the institution visited, especially if the trainer accompanies the trainees.

Conferences and seminars. Standardized curricula prepared by an international institution can be used to present at regional conferences and seminars. This approach works well for focusing on particular components, such as pharmaceutical distribution or use. It is also an effective way to promote longer training programs, information sharing among developing-country personnel, desire for improvement, and general sensitization of policy makers to the importance of pharmaceutical management.

In-country counterpart training. An outside consultant with expertise in an aspect of pharmaceutical management, such as computerized inventory, can train counterparts by working on-site for a period of weeks or months. Short-term consultancies work best when they are focused on a specific activity (for example, a pharmaceutical packaging process or the development of an operations manual). Longer periods (from two to four years) are required for overall systems

renovation. Meaningful improvements in pharmaceutical management systems can be made using long-term, on-site consultants. The major limitations are—

Expense: International agencies characteristically spend a significant amount of money a month to support an in-country consultant.

Lack of regional effect: Only the individual country benefits, although participants in a program could train others.

Lack of appropriate institutional capacity building: The host country may not be able to continue innovations after the departure of the consultant.

Assistance for the design and implementation of training courses

Ideally, training courses are best developed by educators skilled in instructional design who have a solid background in and knowledge of the topic areas. However, the skills

Country Study 52-2 Using the MTP methodology in Lao P.D.R.

The monitoring-training-planning methodology uses a sequence of steps involving techniques to implement a sustainable health project or program. MTP places the tools and responsibility for programs in the hands of local staff, who learn how to mobilize their own resources, carry out the MTP program, and improve pharmaceutical management in their health facilities. Central- and regional-level managers accompany and monitor the staff as they implement the new pharmaceutical management programs.

The MTP tool relies on the following principles—

- The program is continuous, stepwise, and implemented in a structured fashion.
- Every implementation step is planned in advance and detailed in the instructions and materials.
- The programs lead to concrete products that are shared among peers.
- Because MTP participants are usually volunteers, the institution should recognize their efforts.
- Work is spread among the team of participants so that everyone takes part.
- Supervision by all participants of each other's responsibilities and tasks increases accountability and improves problem-solving skills.
- Sessions must be short and punctual so time and travel commitments are minimized.
- Materials and approach should allow for adaptation to the particular needs of each locale.

MTP is unique in that it incorporates monitoring, training, and planning into a single monthly session that achieves tangible results. For one day or less on a monthly basis, participants first review achievements from the previous session, analyze information about their own situation, study how to take action, and then plan short-term activities. Each segment sets the stage for the succeeding segment; the planning segment of one

module flows into the monitoring section of the next. For example, if an organization launches a program to improve warehouse management at the local level, the program designers may organize a session on evaluating storerooms, one on improving storage conditions, and another on inventory control. Each session begins with a report on the planned activities from the previous month; contains a concrete product, such as an evaluation, correct storage practices, or an operating inventory system; and ends with participants knowing their responsibilities and tasks for the next month.

The Lao P.D.R. National Drug Policy Program promotes rational medicine prescribing in hospitals through the activities of Drug and Therapeutics Committees; however, when some problems did not respond well to that approach, MTP was implemented to handle small-scale training issues. The use of the MTP approach in the Lao P.D.R. involved a series of small-group discussions among prescribers in individual hospital departments. After being trained in the MTP methodology, these groups defined their problem of interest, selected targets they wanted to achieve, applied a problem-solving approach, and monitored indicators to observe the response. By using MTP, groups frequently met defined targets within two to three monthly training cycles. For example, within three months, Vientiane Hospital reduced postoperative antibiotic prescription from 60 percent to 49 percent, close to its goal of 45 percent; Mittaphap Hospital reduced intravenous fluid use for gastritis from 78 percent to 46 percent and antibiotic use from 40 percent to 20 percent; and Oudomxay Hospital reduced antibiotic use in outpatients from 60 percent to 45 percent. Initially implemented in eleven provincial hospitals, the MTP methodology has been extended to fourteen provincial and fourteen district hospitals and will be extended to all hospitals in the country.

Country Study 52-3

Creating a pharmaceutical management training network in East Africa

As a result of major global funding initiatives, countries in Africa have experienced a tremendous increase in the volume of pharmaceuticals and health commodities to manage. However, the weakness in the region's pharmaceutical management has required interventions to help build in-country and regional capacity to support the scale-up of treatment programs.

With help from the Rational Pharmaceutical Management (RPM) Plus Program, the Makerere University in Uganda began coordinating a network of institutions from Uganda, Kenya, Tanzania, and Rwanda to develop capacity for pharmaceutical management. The idea behind the Regional Technical Resource Collaboration (RTRC) for Pharmaceutical Management initiative is to create a collaborative group that offers regional and country advisers with expertise in the supply, management, and use of antiretrovirals and other medicines. Each country core group is multidisciplinary and includes pharmacists, social scientists, and representatives from academic institutions, ministries of health, and nonprofit organizations. In the long term, the RTRC plans to incorporate institutions from other countries, such as Ethiopia and Zambia.

Each country's core group assumes a role in the country's national pharmaceutical management activities. For example, by conducting national assessments of the pharmaceutical sectors, each group identified key areas in which to develop and consolidate specific skills in the

supply, management, and use of medicines in their countries. The country groups then take a regional lead in a specific area and offer assistance to other groups related to this area of expertise. In addition, the groups consult with ministries of health and other stakeholders regarding research activities and the monitoring and evaluation of pharmaceutical management initiatives.

The RTRC's first activity was to assess management of HIV/AIDS pharmaceuticals and commodities in each of the four countries. The assessments identified many problems, among them inadequate human resource capacity to handle the basic functions of pharmaceutical management, such as selecting, quantifying, and distributing AIDS-related commodities, including rational prescribing. As a result, the RTRC has placed priority on training health care workers on how to manage AIDS-related pharmaceuticals.

As a next step, RPM Plus developed generic HIV/AIDS pharmaceutical training materials that can be easily adapted to train pharmacists, pharmaceutical technologists and technicians, pharmacist assistants, nurses, and storekeepers. The training materials were developed with a diverse audience in mind, with content that is neither too complicated nor too basic. The training process is as practical as possible to help trainees apply the lessons learned in their daily work. The RTRC countries are also incorporating the monitoring-training-planning approach in their training programs (see [Country Study 52-2](#)).

involved in designing and implementing a training program can be learned by observing good trainers and paying attention to how they use different methods. Many pharmaceutical programs rely on outside organizations, such as Management Sciences for Health, i+Solutions (previously the International Dispensary Association), and WHO to help them develop local training programs or provide training opportunities for staff (see [Annex 52-1](#)). Training-of-trainers courses are also frequently offered by local, regional, or international training institutes.

Another valuable resource for a training program is the practical experience of organizations and institutions in the pharmaceutical supply process. Among these are international organizations, governmental and nongovernmental organizations, universities, developing-country institutions, and programs already operating in developing countries.

With few exceptions, however, these organizations have made technical assistance rather than training their high-

est priority. Training programs have usually been established on an ad hoc basis to fulfill a specific need rather than in a systematic and comprehensive way. But some programs address specific areas for a particular level in the supply system or for multiple levels in a vertical disease control program.

[Annex 52-1](#) lists selected organizations that have practical experience in the design or implementation of training programs, or both. These organizations are invaluable resources for the development of many types of training programs.

Training and presentation skills

A trainer is expected to be knowledgeable, possess excellent communication skills, and be able to communicate at the level and in the language of the participants (consecutive or simultaneous translation may be appropriate for certain situations). To be effective, the trainer should take into account

Figure 52-3 Seating arrangements for various training applications

Source: Adapted from McMahon et al. 1992.
Key: ★ = Trainer or presenter.

Country Study 52-4**Measuring the effect of training on pharmaceutical supply management at primary health care clinics in South Africa**

Training in pharmaceutical supply management was introduced as part of the Essential Drugs Program in Mpumalanga province in South Africa. To study the effect of the training, a pre- and post-intervention study was conducted comparing six randomly chosen primary health care clinics that received training to six primary health care clinics that did not receive training. The three-day workshop was part of a provincial pharmaceutical supply management training cascade.

The evaluation included a pre-intervention survey, the training workshop for staff of the study group clinics, a post-intervention survey one month after the training, and a second survey three months after the training. The study measured not only supply management outcomes,

such as organization of supplies, record keeping, ordering and stock control, labeling of medicines, but also rational-medicine-use indicators, such as patient knowledge and advice received from staff and appropriate use of the essential medicines list. The results of the evaluation showed significant improvements across the range of outcome measures in the intervention group, and the improvements were sustained and even increased in some instances from the first to the second post-intervention survey. The pharmaceutical supply management training not only affected the pharmaceutical management indicators, but also improved patient care and raised the level of use of the essential medicines list.

the nature of the target group or audience (who are they? are they senior or line managers?) and their level of knowledge and skill (have participants been trained in the subject to be presented or related subjects?).

Preparation. Time used in preparation is time well spent. On average, the amount of time spent preparing the first presentation of a course or training session by a person knowledgeable on the topic equals four times that spent presenting it. So a one-week course would require four weeks of preparation. After looking up information and consulting manuals and other resources that are relevant to the subjects (identified in the needs assessment), the trainer chooses appropriate learning methods and puts together a session plan. He or she takes steps to acquire or prepare appropriate participants' guides and audiovisual aids well in advance of the targeted training date. The trainer should have the draft materials peer reviewed by someone who is technically competent in the subject area. Also, if possible, the trainer should rehearse the presentation before colleagues, keeping in mind issues of time and clarity.

Presentation. The trainer should always come to the training venue and the session early to check out the room, the seating arrangements, and the audiovisual equipment (Figure 52-3). A friendly chat with participants before the session creates a more comfortable environment.

Formal introductions should take place at the beginning of the first session. One way to do this is to ask pairs of participants to interview each other; then each presents the other to the group or records the information on a wall chart for all to see.

The actual session should begin with the trainer presenting the objectives of the course or session and summarizing

its main points. These main points are then expanded using the chosen learning methods. At the end of the session, the trainer should always summarize the discussion, making sure to allow time for questions and clarification.

In developing visual aids, the following points should be kept in mind—

- Use only one idea per visual aid to avoid crowding.
- Use large letters and clear drawings.
- Do not include too much information on one slide (seven lines with seven words per line is a maximum guideline).
- Do not use multiple fonts, sizes, and colors.
- Allow plenty of time for preparing the visual aids and time for obtaining and testing the equipment.
- Test the materials in a rehearsal before the session, preferably in front of critical colleagues.

When using visual aids, the trainer should take care to—

- Check the visual aids and equipment a few minutes before the session begins.
- Always face the audience, without obstructing their view, and use a pointer.
- Switch off the equipment during discussions.

Trainers' personal style. Personal appearance and style can make a difference in keeping participants' interest during a session. The trainer should maintain eye contact with the group and make sure that his or her voice is clear and can be heard by everybody. When interest appears to be flagging, the trainer needs to be flexible and willing to

change the schedule, perhaps by introducing a role-play or arranging a short field visit or by inserting an unscheduled break to allow participants to stretch or get refreshments. A good story or joke can help revive interest. In a session in which participants are divided into small groups, having the trainer move from group to group stimulates interest. During a long course, allocating time for dinners and other social activities is important.

Monitoring and evaluation

Monitoring and evaluation to assess the performance and progress of the participants is one of the trainer's key roles. These assessments should be done as formative evaluations while the course is in progress (for midcourse adjustments and fine-tuning), as summative evaluations at the end of the course (to make the course better in the future), and as periodic follow-ups after the training is over to monitor outcomes and assess the continuing performance of the trainees. The training outcomes should be measurable, performance-based, and directly related to the objectives of the training program. For example, if the goal of the training is for the participants to be able to institute a post-exposure prophylaxis program in their workplaces, a relevant outcome measure would be the completion of this activity within a reasonable time frame. Curriculum mapping is a method to evaluate the links between course content and outcomes (Plaza et al. 2007).

Country Study 52-4 details a study designed to assess the effect of pharmaceutical management training on clinics in South Africa.

In training, formative assessment is important, because the aim of the course is to improve performance, not to grade the participants. The trainer can help them learn more quickly and more completely by providing them with constructive criticism during the course. The trainer can also use the feedback from evaluations to adjust the content and methods of the training to better meet participants' needs. ■

ASSESSMENT GUIDE

Training programs

- Was a needs assessment conducted before the training programs were developed?
- Were performance indicators established? If so, how were they established and who was involved?
- Do the performance indicators include process, output, performance, and impact indicators? Are they both quantitative and qualitative?
- What training programs have been held?
- How many people of each target group have been trained? What percentage is that of the total target number?
- What methods were used for the training?
- What feedback did the participants give on the training?
- What were the evaluation results for knowledge change? Work performance change?
- How much money has been spent on training activities (if possible, compare budget to actual expenditures)? What percentage of the overall program budget is this?

Sites and institutions

- Which institutions provide training for staff working in the pharmaceutical sector?
- Over the past two years, where has training occurred? For whom?

Trainers

- At each of the institutions identified, how many trainers are there?
- How many of these people have been formally trained as trainers?
- In the courses undertaken, what were the evaluation ratings of the trainers?

Materials

- What training materials were used for the training courses?
- Where and how were the materials developed? When were they last updated?
- How widely available are the training materials?
- Do the training materials correspond with current policies?

Annex 52-1 Sources of assistance for training programs to improve pharmaceutical management

The following organizations and institutions offer training in selected activities relevant to the pharmaceutical supply process. This listing is not exhaustive, nor is it an endorsement of these training programs. For details, these organizations should be contacted directly.

International organizations are listed first, followed by national and private organizations and institutions. Also included is a list of short courses on pharmaceutical policy, pharmaceutical management, rational medicine use, and related subjects.

International organizations

World Health Organization (WHO), 20 Avenue Appia, CH 1211 Geneva 27, Switzerland; telephone: 41 22 791 21 11

Department of Essential Medicines and Pharmaceutical Policies; website: <http://www.who.int/medicines>

Assists member states in the development and implementation of pharmaceutical policies, the supply of essential medicines of good quality at the lowest possible cost, and the development of training in the rational use of medicines. Works closely with WHO collaborating centers on pharmaceutical regulation and quality assurance and control. Provides training in product registration and computerization of drug regulatory data, as well as good manufacturing practices (GMPs), analytical control, and preparation of chemical reference substances.

WHO's medicines department provide training programs to support policy makers, ministry of health officials, nongovernmental organizations (NGOs), professional associations, and other stakeholders in managing medicines supply and rational pharmaceutical management. WHO participates in regional and national training courses for drug regulators.

WHO/EMP maintains a list of training resources on its website at <http://www.who.int/medicines/training/en>.

United Nations Children's Fund (UNICEF), Supply Division, UNICEF Plads, Freeport, 2100 Copenhagen Ø, Denmark; telephone: 45 3527 3527; fax: 45 3526 9421; website: www.unicef.org/supply

The Supply Division conducts training on vaccine forecasting at regional immunization meetings and has developed a complete suite of training modules on supply chain management. Through its Procurement Services, the Supply Division can arrange for training in procurement and supply upon request.

United Nations Institute for Training and Research (UNITAR), International Environment House, 11–13 Chemin des Anemones, CH 1219 Chatelaine Geneva; telephone: 41 22 917 84 00; fax: 41 22 917 80 47; website: <http://www.unitar.org>

Conducts training and workshops on many areas, including social and economic management, although not specific to pharmaceuticals. Offers a number of online training courses.

National and private organizations and institutions

Commonwealth Pharmacists Association, 1 Lambeth High Street, London SE1 7JN, United Kingdom; telephone: 44 20 7572 2364;

fax: 44 20 7572 2508; e-mail: admin@commonwealthpharmacy.org; website: www.commonwealthpharmacy.org

Offers the Management of Pharmaceutical Supply, a distance learning program for all pharmacist and nonpharmacist managers involved with pharmaceutical supply procurement and management, especially at the regional level. The course does not require the student to take leave from his or her employment.

Crown Agents, St. Nicholas House, St. Nicholas Road, Sutton, Surrey, SM1 1EL United Kingdom; telephone: 44 20 8710 6771; fax: 44 20 8770 0479; e-mail: TrainingEnquiries@crownagents.co.uk; website: <http://www.crownagents.com/Training/CrownAgentsTraining.aspx>

Crown Agents offers a number of short courses on general management and finance topics and in procurement and supply management, including a Certificate in Health Supply Chain Management. Courses are held in the United Kingdom and in a number of other countries, including some in Africa and Asia.

Fédération Internationale Pharmaceutique/International Pharmaceutical Federation (FIP), P.O. Box 84200, 2508 AE, The Hague, The Netherlands; telephone: 31 70 302 1970; fax: 31 70 302 1999; e-mail: fip@fip.org; website: www.fip.org

Provides contact information on more than 900 pharmacy schools worldwide as well as an extensive list of organizations offering continuing education and online and distance learning courses on pharmacy topics. The FIP Foundation for Education and Research provides a certain number of scholarships, fellowships, and grants every year to assist in the development of individuals or groups in the fields of pharmacy practice and pharmaceutical science.

Eastern and Southern Africa Management Institute (ESAMI), P.O. Box 3030, Arusha, Tanzania; website: <http://www.esami-africa.org>

A regional institution that was designated by the UN Economic Commission for Africa as the African Centre of Excellence in Management Development, ESAMI has nine program areas, including training in general financial management and health management. Clients come from governments, parastatals, the private sector, NGOs, and national and regional institutions in Africa.

i+Solutions, Westdam 3b, 3441 GA Woerden, The Netherlands; telephone: 31 34 848 9630; fax: 31 34 848 9659; e-mail: info@iplussolutions.org; website: <http://www.iplussolutions.org>

i+Solutions is a not-for-profit organization specializing in pharmaceutical supply chain management for low- and middle-income countries. i+Solutions offers a variety of courses and training programs in pharmaceutical management.

Mahidol University, Faculty of Pharmacy, Sri-ayudhaya Road, Rajadhevi, Bangkok 10400, Thailand; telephone: 66 02 644 8677 91, ext. 1301; fax: 66 02 354 4326; website: <http://www.pharmacy.mahidol.ac.th/eng>

Offers short courses on pharmaceutical management, including use of essential medicines, GMP training, and pharmaceutical economics. Organizes professional meetings, conferences, and symposia as a means of professional continuing education.

Management Sciences for Health (MSH), 784 Memorial Drive, Cambridge, Mass. 02139-4613 USA; telephone: 1 617 250 9500; fax: 1 617 250 9090; website: www.msh.org

Center for Pharmaceutical Management, 4301 North Fairfax Drive, Suite 400, Arlington, Va. 22203 USA; telephone: 1 703 524 6575; fax: 1 703 524 7898; e-mail: cpm@msh.org

Offers short-term courses in multiple languages on rational medicine use and other aspects of pharmaceutical management and on other topics, including pharmacovigilance, management information systems, and disease-specific pharmaceutical management—such as HIV/AIDS, malaria, and tuberculosis. In more than thirty years, thousands of health professionals have participated in MSH courses in the United States and other countries.

Robert Gordon University, School of Pharmacy, Schoolhill, Aberdeen AB10 1FR, Scotland, United Kingdom; telephone: 44 1224 262 502; website: www.rgu.ac.uk/pharmacy

The School of Pharmacy offers postgraduate distance learning courses and certificates for health care professionals to develop

an advanced therapeutic knowledge base and the necessary practical skills to ensure rational prescribing.

Swiss Tropical and Public Health Institute, Course Secretariat, Socinstrasse 57, CH 4002, Basel, Switzerland; telephone: 41 61 284 82 80; fax: 41 61 284 81 06; website: <http://www.sti.ch>

Offers the two-week course Rational Management of Medicines—A Focus on HIV/AIDS, Tuberculosis and Malaria. Conducted in English. Other courses in international health include Health Care and Management in Tropical Countries.

University of Heidelberg, Institute of Public Health, Course information: Im Neuenheimer Feld 365, 69120, Heidelberg, Germany; telephone: 49 62 21 56 50 48; fax: 49 62 21 56 49 18; website: <http://www.klinikum.uni-heidelberg.de/Short-Courses.109912.0.html>

Offers short courses in international health. Most of the courses are post graduate, advanced level, one- and two-week long programs conducted in English. The institute also offers a one-year master's of science in international health.

Annex 52-2 Workshop logistics

Workshop and support checklist

Advance planning

- Goals
- Objectives, expected outcomes
- Needs assessments
- Content, topics, session
- Length, time frame
- Number of participants
- Implementation approach (e.g., small-group interaction versus large-group presentations)
- Materials, including prereading for the participants, participants' and facilitators' guides, handouts
- Participant list
- Short-term consultants, facilitators or presenters (choosing the best people to present each topic)
- Budget, including materials, travel, accommodations
- Venue: reservations, deposit, other concerns
- Invitations to participants and follow-up phone calls

Workshop material

- Ruled writing pads, pens, pencils with erasers
- Document binders
- Flip charts, pens, and markers
- Blank overhead transparencies and pens
- Masking tape and transparent tape
- Stapler and staples
- Hole punch
- Photocopying paper
- Computer paper, printer ribbon, blank diskettes, multiplug adapter
- Letterhead stationery and envelopes
- Paper clips, scissors, Post-it pads, rubber bands, Wite-out, glue
- Calculator
- Name badges

Workshop support responsibility

- Logistics: supervision of conference site, meals, breaks, and accommodations
- Finances: payment of cash food allowances, paperwork, and reimbursement for transportation expenses
- Secretary for word processing
- Vehicle and driver
- Messenger and photocopier

Workshop support facilities

- Telephone access (incoming and outgoing) for facilitators
- On-site (or easily accessible) photocopier machine (with toner and paper) for low-volume copies
- Photocopy service site for high-volume copies
- Computer and printer
- Overhead projector, extra bulb, extension cord of adequate length
- LCD projector and projection screen
- Sound system and microphones (if needed)

Setup of main meeting room

- Opening session and plenary sessions: horseshoe versus classroom-style seating with extra chairs
- Tables for small group work

- Break room(s) or area(s)
- Groups of approximately equal size
- Overhead and slide projector check: screen that all participants can see, projector proper distance and angle from screen, sufficiently long electric cord, extra bulb
- Transparencies and pens
- Flip charts and pens available for plenary and small groups

Daily preparation of meeting room

- Projectors: position, cord, spare bulb, transparencies, pens
- Blackboard or whiteboard: cleaner, pens
- Flip charts: location, paper, pens

Workshop administration checklist

- Upon arrival at the training site, make sure that the conference room is arranged properly and note any changes that need to be made. Find out if additional rooms are available for small-group discussions. Set up a registration desk near the entrance and a working table where appropriate. Arrange the handouts on a separate table where they are readily accessible.
- Set up the projector and test it. Make sure that the projection screen can be seen easily by all participants.
- Put the writing pads, pens, and programs into document binders and place them on the tables.
- Inform the management of the site about all the practical arrangements.
- Put up a signboard at reception displaying the location of the conference room and registration time.
- Using the list of participants, prepare the name tags and spread them out on the registration desk so that the participants can collect them as they register. This step can be done either the evening before or in the morning before registration begins.
- Give a copy of the program to the management so that they know when to serve tea or coffee and meals.
- During the introductory session, make administrative announcements: when allowances will be paid (night-out allowances are normally paid at the end of day one; reimbursements for travel expenses are normally paid at the break on the last day, upon presentation of receipts as documentation).
- As soon as the last person has registered, type out the participant list and start preparing the receipts for participants to sign when receiving allowances. Use a duplicate receipt book with a carbon. Mark the receipt number against the participant's name on the list to make paying easier.
- Type out a separate list for reimbursing transport expenses and make out payment receipts. Fuel and other travel receipts can be collected on day one when paying out allowances.
- Give a copy of the participant list to hotel management, indicating the participants who are not staying at the site so that they know how many extra teas and lunches to charge for. Also, give management the names of the people who are settling their own bills (facilitators, secretaries) so that they will not be included in the main bill.
- On the last day, have the hotel management prepare the detailed bill and check it against the participant list.
