Preface

It is my great pleasure to present *MDS-3: Managing Access to Medicines and Health Technologies*. In the thirty years since the original publication of *Managing Drug Supply*, the world has experienced remarkable changes as the global health context has evolved. Think, for example, about the profound impact that HIV/AIDS alone has had. Advances in science and medicine, donor funding for vast global health initiatives, the advent of innovative information technologies, and a greater focus on building strong health systems have fundamentally affected our work. What has not changed over the years is MSH's commitment to identifying problems in access to and use of medicines and designing and implementing relevant, effective responses. We hope that *MDS-3* will be a valuable tool in the effort to ensure universal access to quality medicines and health technologies and their appropriate use.

The new and updated information in *MDS-3* reflects the dramatic changes in the public health landscape. Nearly 100 experts from a wide range of disciplines and virtually every corner of the world have contributed to this third edition. In addition to new country studies, references, and extensive revisions, *MDS-3* offers new chapters on areas such as pharmaceutical benefits in insurance programs, pricing, intellectual property, drug seller initiatives, and traditional and complementary medicine. The revisions and new chapters echo the wide variety of issues that are important to health practitioners and policy makers today. Even the book's new title depicts the need to broaden our focus from medicines to include *health technologies*, such as test kits and laboratory supplies, and to embrace the concept of *access*. Too often people assume that if medicines and technologies are available, positive health outcomes will naturally result. Access, however, encompasses not only product availability, but also the need to provide medicines and pharmaceutical services that are safe, efficacious, cost-effective, and high quality. Equally important are affordability and acceptability, including cultural and personal preferences.

We hope that *MDS-3* will be used widely by those with an interest in improving access to medicines and health technologies. To make the book accessible to as many users as possible, we are making the content available in several formats. The easiest way to access *MDS-3* is online at <http://www.mds-online.org>. The entire book can be searched online, and individual chapters can be downloaded. *MDS-3* is also available directly from MSH on flash drive or CD-ROM for those without reliable Internet access or who prefer these media. We are working on an arrangement to make print copies available as well.

As users of *MDS-3*, you are vital to ensuring that it remains a valuable and dynamic resource. Your suggestions for enriching and updating the information and improving its presentation are greatly welcome. We will update individual chapters as needed to provide new material in a timely manner. Please send suggestions to us at mds@msh.org.

We acknowledge with great appreciation all the authors, reviewers, and others whose efforts are reflected in *MDS-3*. Any contribution that *MDS-3* makes is a direct result of their knowledge, experience, and deep dedication—and of the hard work of those around the world who each day strive to help their countries and their programs realize the full health impact of ensuring access to medicines and health technologies for all.

Jonathan D. Quick, MD, MPH
President and Chief Executive Officer
Management Sciences for Health
February 2012

How to Use *MDS-3*

MDS-3: Managing Access to Medicines and Health Technologies may seem intimidating, but you do not need to read it from cover to cover. To ease accessibility, we have organized its content to present a sequential overview of major topics and then within each section to provide more detailed explanations of fundamental concepts, definitions of basic terms, and practical ideas for designing and implementing effective changes in pharmaceutical management systems.

The following features make the material accessible to readers looking for information in specific areas.

Overview chapters. Starting with Part II, Pharmaceutical Management, overview chapters introduce each element in the pharmaceutical management framework: selection (Chapter 16), procurement (Chapter 18), distribution (Chapter 22), use (Chapter 27), and management (Chapter 37). These overview chapters provide background information that lays the foundation for more detailed discussions of specific topics in the chapters that follow them.

Chapter summaries. Each chapter begins with a summary of its contents. Readers who are interested in a brief overview of an area or of all aspects of managing access to medicines can read the relevant summaries.

Country studies. Reports of experiences in various countries illustrate points in the text. Although conditions in some countries may have changed since these country studies were written, they provide useful examples of the ways in which the pharmaceutical management process can operate, and in some cases, how it should not operate.

Boxes. Boxes are used to make information, such as the steps of a process, easy to locate and use. In addition, some boxes contain general experiences or descriptions of relevant initiatives or resources.

Glossaries. Glossaries are included for the chapters on intellectual property (Chapter 3), insurance (Chapter 12), selection (Chapter 16), procurement (Chapter 18), distribution (Chapter 22), use (Chapter 27), management (Chapter 37), analyzing expenditures (Chapter 40), financial management (Chapter 41), storage facilities (Chapter 42), and computers (Chapter 51).

References and further readings. Each chapter contains a list of references cited in the text or that relate to topics the chapter covers. Particularly useful references are indicated by a star.

Chapter annexes. Annexes provide sources of additional information and samples of pharmaceutical management forms currently in use in various parts of the world.

- CS 1-1 Working with the private sector to improve malaria outcomes in Tanzania, Ghana, and Nigeria 1.16

SUMMARY

Most leading causes of death and disability in developing countries can be prevented, treated, or at least alleviated with cost-effective essential medicines. Despite this fact, hundreds of millions of people do not have regular access to essential medicines. Many of those who do have access are given the wrong treatment, receive too little medicine for their illness, or do not use the medicine correctly.

MDS-3 addresses practical ways in which government policy makers, essential medicines program managers, nongovernmental organizations (NGOs), donors, and others can work to ensure that high-quality essential medicines are available, affordable, and used rationally. Medicines are of particular importance because they can save lives and improve health, and they promote trust and participation in health services. They are costly, and special concerns make medicines different from other consumer products. Moreover, substantive improvements in the supply and use of pharmaceuticals are possible.

Within a decade after the first modern pharmaceuticals became available, efforts began to ensure their widespread availability. From the mid-1950s to the mid-1970s, basic pharmaceutical management concepts began to evolve in countries as diverse as Cuba, Norway, Papua New Guinea, Peru, and Sri Lanka.

In 1975, the World Health Organization (WHO) defined *essential medicines* as those medicines that meet the health needs of the majority of the population. In 1982, Management Sciences for Health published the first edition of *Managing Drug Supply*, which incorporated the essential medicines concept and has become known as the seminal guide to managing pharmaceuticals in developing countries. Over the last thirty years, countries have acquired considerable experience in managing pharmaceutical supply. Broad lessons that have emerged from this experience include the following—

- National medicine policy provides a sound foundation for managing pharmaceutical supply.
- Wise medicine selection underlies all other improvements.
- Effective management saves money and improves performance.
- Rational medicine use requires more than medicine information.
- Systematic assessment and monitoring are essential.

Although much has been achieved, challenges remain—

- Achieving financial sustainability through greater efficiency and financing mechanisms that increase

availability while ensuring equity (financing options include public financing, health insurance, voluntary and other local financing, and donor financing)

- Improving efficiency in public pharmaceutical supply through strategies that build on public-sector strengths while incorporating greater flexibility and competitiveness
- Changing the behavior of providers, patients, and the public to promote effective, safe, and economical prescribing, dispensing, and patient use of medicines
- Reorienting the role of government to improve the availability, affordability, and rational use of medicines in the private sector, which supplies 60 to 90 percent of the medicines consumed in many developing countries
- Regulating safety, efficacy, and quality through adoption and enforcement of legislation and regulations that ensure that all medicines meet basic quality standards

MDS-3 is organized around the four basic functions of the pharmaceutical supply management framework—

- Selection
- Procurement
- Distribution
- Use

These functions are supported by a core of management support systems—

- Planning and administration
- Organization and management
- Information management
- Human resources management

Effective pharmaceutical management rests on a policy and legal framework that establishes and supports the public commitment to essential medicines supply and is influenced by economic issues (Part I of this manual). Other major sections of the manual are devoted to each of the main functions of the pharmaceutical management framework (Part II) and management support (Part III).

This manual provides concepts and approaches that can produce measurable health improvements through greater access to and more rational use of medicines. Governments, private organizations, donors, and others who use this manual must provide the will and the resources to put these concepts and approaches into action.

1.1 Introduction

Interest in human health and illness is as old as humanity. Scientific study of human anatomy and human diseases can be traced to the Greek physician Hippocrates and earlier. Yet as recently as one hundred years ago, the best that medicine could offer was a handful of demonstrably effective preparations. Penicillin, one of the first antibiotics, and chloroquine, the first modern antimalarial, are about seventy years old. Medicines for common conditions such as diabetes are only fifty years old. Oral contraceptives have been generally available for only forty years.

In industrialized countries, the age of modern pharmaceuticals has eliminated or dramatically reduced mortality from most common infections, allowed families to plan their growth, extended the lives of millions of people suffering from chronic illnesses, and provided relief from pain and suffering for hundreds of millions more people. From the first mass production of penicillin in the 1940s has grown a pharmaceutical industry valued at 600 billion U.S. dollars (USD) annually. The research efforts of that industry continually provide safer, more effective products. The industry's distribution networks ensure ready access to thousands of products for people throughout the industrialized world.

In many other parts of the world, however, people have not fully benefited from these medical advances. In the late 1970s, 60 to 80 percent of people in developing countries were estimated as lacking regular access to even the most essential medicines. By 2003, WHO estimated that less than half the citizens in 32 percent of the world's poorest countries lacked regular access to essential medicines, which improved on 1999 access estimates (WHO 2006c). Lack of access is directly related to income—81 percent of the countries with the lowest access to medicines also had the lowest incomes (WHO 2006c).

The large share of the world's population that does not benefit from simple, safe, effective pharmaceuticals—and the millions of children and adults who die each year from common conditions that can be prevented or treated with modern medicines—signal a fundamental failure of health care systems.

Those who do have access to essential medicines often receive the wrong medicine, the wrong dosage, or a quantity insufficient for their needs. In some countries, many modern medicines are dispensed without prescription by untrained and unlicensed drug sellers. Even when patients and consumers receive the correct medicine, half do not consume it correctly (WHO 2002).

MDS-3 is concerned with practical ways in which government policy makers, essential medicines program managers, NGOs, donors, and others can work to close the huge gap between the need for essential medicines and public access to them—between the vast number of

people who could benefit from modern pharmaceuticals and the much smaller number of people who actually do benefit. This manual is also concerned with closing the gap between the availability of medicines and their rational use.

This chapter focuses on the role of medicines in health care and health policy. It describes the essential medicines concept, reviews major lessons in pharmaceutical management since the 1980s, and summarizes major challenges still facing the pharmaceutical sector.

1.2 Why worry about medicines?

To clinicians facing the sick and injured on a daily basis, the importance of medicines is obvious. Nonetheless, summarizing the reasons that ministers of health, directors of health programs, donors, and others involved in the health sector should be concerned with medicines is useful. Accessible health services and qualified staff are necessary components of any health care system, but medicines have special importance for at least five reasons—

- Medicines save lives and improve health.
- Medicines promote trust and participation in health services.
- Medicines are costly.
- Medicines are different from other consumer products.
- Substantive improvements in the supply and use of medicines are possible.

These observations were the primary motivation for preparing this manual. The following chapters focus on the richness and diversity of opportunities for practical, effective improvements in pharmaceutical supply and use.

Medicines save lives and improve health

Most leading causes of discomfort, disability, and premature death can be prevented, treated, or at least alleviated with cost-effective essential medicines. Although the relative frequencies of specific conditions vary among countries, outpatient services throughout the world are presented with a fairly common set of health problems for which essential medicines have an important role: acute infections, skin diseases, gastrointestinal complaints, musculoskeletal conditions, and injuries.

Mortality figures across developing regions (see [Table 1-1](#)) reflect a huge burden of illness that can be substantially reduced if carefully selected, low-cost pharmaceuticals are available and appropriately used. Essential medicines significantly affect the common causes of morbidity and mortality, including acute respiratory infections, diarrheal diseases, HIV/AIDS, measles, malaria, maternal

Table 1-1 Mortality from infectious, chronic, and other conditions in WHO member countries worldwide and in select WHO regions, 2004

Conditions	All WHO member countries	Africa	Southeast Asia
Respiratory infections	4,259	1,437	1,416
Diarrheal diseases	2,163	1,005	684
Tuberculosis	1,464	405	519
Malaria	889	806	36
HIV/AIDS	2,040	1,651	206
Other infections and parasites	2,963	982	1,229
Nutritional deficits	487	159	179
Cardiovascular disease	17,073	7,175	3,875
Diabetes mellitus	1,141	172	280
Malignant neoplasms	7,424	480	1,195
Maternal and perinatal conditions	3,707	1,236	1,367

Source: WHO 2008a.

and perinatal mortality, tuberculosis, and cardiovascular and other chronic diseases (see [Box 1-1](#)).

Not only are essential medicines effective against common health problems, they are also cost-effective. Undeniably, long-term health gains can be made by investing in prevention through health education and other programs to improve nutrition, sanitation, water supply, housing, environment, and personal health habits. At the same time, essential medicines provide a direct, low-cost response for many diseases.

Medicines promote trust and participation in health services

The credibility of health workers depends on their ability to save a dying village elder with a course of penicillin, to restore life to a limp child with oral rehydration, or to relieve an irritating skin infection with a simple ointment. In addition to the direct effect on health, the availability of essential medicines attracts patients, who can then also receive preventive and public health messages. The provision of essential medicines is one element of primary health care that families everywhere take an interest in and that brings them to health facilities.

Over the years, household and patient surveys around the world have found that pharmaceutical availability is a major determinant of where patients go for health care and how satisfied they are with that care. Availability of medicines and supplies also affects the productivity of health staff. When pharmaceutical supplies fail to arrive, patient volume drops, and health workers are left idle. Irregular pharmaceutical supply can be a greater constraint on program effectiveness than inadequate numbers or inadequate training of health workers.

Medicines are costly

Although medicines are cost-effective, they can be quite costly for an individual, a household, a government health system, or a country.

At the individual and household levels, medicines represent the major out-of-pocket health expenditure; 60 to 90 percent of household health spending may go toward medicines (WHO 2000). In northern India, at least 57 percent of a family's average out-of-pocket cost of a newborn's illness was for medicines (Srivastava et al. 2009). The trend of private spending by households as the principal source of worldwide pharmaceutical spending increased during the 1990s (WHO 2004c). In addition to those direct costs, income is lost when family members are sick, and this loss reinforces the poverty-illness cycle. Women are especially vulnerable because they are usually the main family caregivers.

For ministries of health in most developing countries, expenditures on medicines are second only to those made on staff salaries and benefits, which can cost up to half of total health expenditures (WHO 2006d). Payment of personnel costs is largely unavoidable as long as staff are employed. Medicine expenditures, therefore, represent the largest expenditure over which ministries have year-to-year discretionary control. This fact makes medicine expenditures both extremely important and extremely vulnerable—particularly to fluctuations in the availability of public funding as well as to various political and economic pressures, such as rampant inflation and currency fluctuations.

At the national level, pharmaceuticals represent 10 to 20 percent of health expenditures for leading industrialized countries. But for most developing countries, they may

Box 1-1**Impact of essential medicines on common causes of morbidity and mortality**

HIV/AIDS still kills about 2 million people per year, even though global initiatives to combat the epidemic have increased dramatically. The widespread treatment of HIV/AIDS with antiretrovirals (ARVs) in resource-limited settings is relatively new, and prices for treatment have dropped dramatically in recent years making it available to far more people. Even with the increase in ARV treatment, however, medicines to treat opportunistic infections are still an important aspect of treating patients with HIV/AIDS.

Respiratory infections, which accounted for more than 4.25 million deaths in 2004, are usually cured readily with inexpensive oral antibiotics. About 20 percent of all deaths in children under five years of age are caused by acute lower respiratory infections (pneumonia, bronchiolitis, and bronchitis); 90 percent of these deaths are caused by pneumonia.

Diarrheal diseases, a top cause of childhood mortality, can be prevented through improved water and sanitation. Diarrhea can be treated in the home with simple oral rehydration solution and selective use of antimicrobial medicines. Recent case management advances such as reformulated oral rehydration solution and zinc supplementation have helped significantly decrease mortality caused by diarrhea.

Measles, another leading cause of childhood mortality, is preventable through immunization. But when immunization is missed, much of the resulting mortality can still be eliminated through the treatment of respiratory, diarrheal, and other potentially fatal complications.

Malaria threatens almost half the world's population and is responsible for nearly 1 million deaths each year; over

80 percent of fatal cases are in African children under four years of age. Early diagnosis and treatment with effective medicines can cure infections and save lives.

Maternal and perinatal mortality can be reduced through prenatal care and nonmedicine interventions such as high-risk case management. Postpartum hemorrhage can be avoided with the use of oxytocic drugs, and maternal anemia, a major contributing factor to maternal and perinatal morbidity and mortality, can be reduced with preventive doses of iron folate preparations. In addition, spacing the birth of children through family planning (using largely oral, injectable, and implanted contraceptives) improves both maternal and neonatal outcomes.

Tuberculosis (TB), once on the decline, is now a leading cause of death worldwide from an infectious disease. Although drug resistance is growing and second-line TB drugs are costly, short-course chemotherapy is curative, and the investment is highly cost-effective. Other strategies to bring TB under control include testing for TB drug resistance and treating TB/HIV co-infection.

Cardiovascular and other chronic diseases are rapidly increasing in developing countries as socioeconomic development, immunization, and other improvements increase life expectancy. In some countries, such as Russia, life expectancy has declined because of cardiovascular disease. Health services are facing a growing demand for essential medicines to treat hypertension, ischemic heart disease, diabetes, and other chronic diseases.

represent 20 to 40 percent of total public and private health expenditures (WHO 2006b).

In absolute figures, the sums that countries spend on pharmaceuticals vary tremendously. In 2000, the world's population in low-income countries spent an average of USD 4.4 per capita per year, whereas the population in high-income countries spent an average of USD 396 per capita (WHO 2004c). For example, Afghanistan spent USD 9 on pharmaceuticals, Cambodia spent USD 11, and Haiti spent USD 3; for industrialized countries in the same year, the figure ranged from USD 272 in Norway and USD 253 in the United Kingdom to USD 382 in Switzerland and USD 528 in Japan (WHO 2004c) (Table 1-2). In general,

medicine expenditures increase with gross national product (GNP).

Medicines are different from other consumer products

Because pharmaceuticals are produced by a competitive industry that responds primarily to economic demand, one might expect their production and sale could be left almost wholly to the play of market forces (see Chapter 10). In that case, politicians and lawmakers would have only the same sorts of concerns that apply to other forms of trade—prevention of fraud, protection of trademarks, and so forth.

Table 1-2 Per capita pharmaceutical and health expenditures in selected developing countries, 1990 and 2000

Country	Per capita expenditures (USD)			
	1990		2000	
	Medicines	Health	Medicines	Health
Bangladesh	2	6	5	14
Brazil	16	146	61	265

But medicines are different and require special attention, because—

- The consumer (patient or parent) often does not choose the medicine—it is prescribed by a clinician or recommended by pharmacy staff.
- Even when the consumer chooses the medicine, he or she is not trained to judge its appropriateness, safety, quality, or value for money.
- Neither the average medical practitioner nor the average pharmacist is equipped to independently assess the quality, safety, or efficacy of each new medicine.
- Fear of illness can lead patients to demand costly medicines from health workers, or to buy such medicines for themselves, when cheaper medicines—or no medicines—would achieve the same result.
- The consumer often cannot judge the likely consequences of not obtaining a needed medicine. This problem is most troublesome when the decision maker is a parent and the patient is a child.

These knowledge gaps, anxieties, and uncertainties associated with both acute and chronic illnesses create special concerns about the supply and use of medicines.

The issues that make medicines different from other consumer products also help make the pharmaceutical sector a likely target for mismanagement, bribery, and fraud. Contributing factors to this vulnerability to corrup-

tion include knowledge gaps and information imbalances between manufacturers, regulators, health care providers, and consumers; a lack of legislation or regulation or enforcement mechanisms; and the high value and volume of medicines in the marketplace (see Cohen 2006 and WHO 2009).

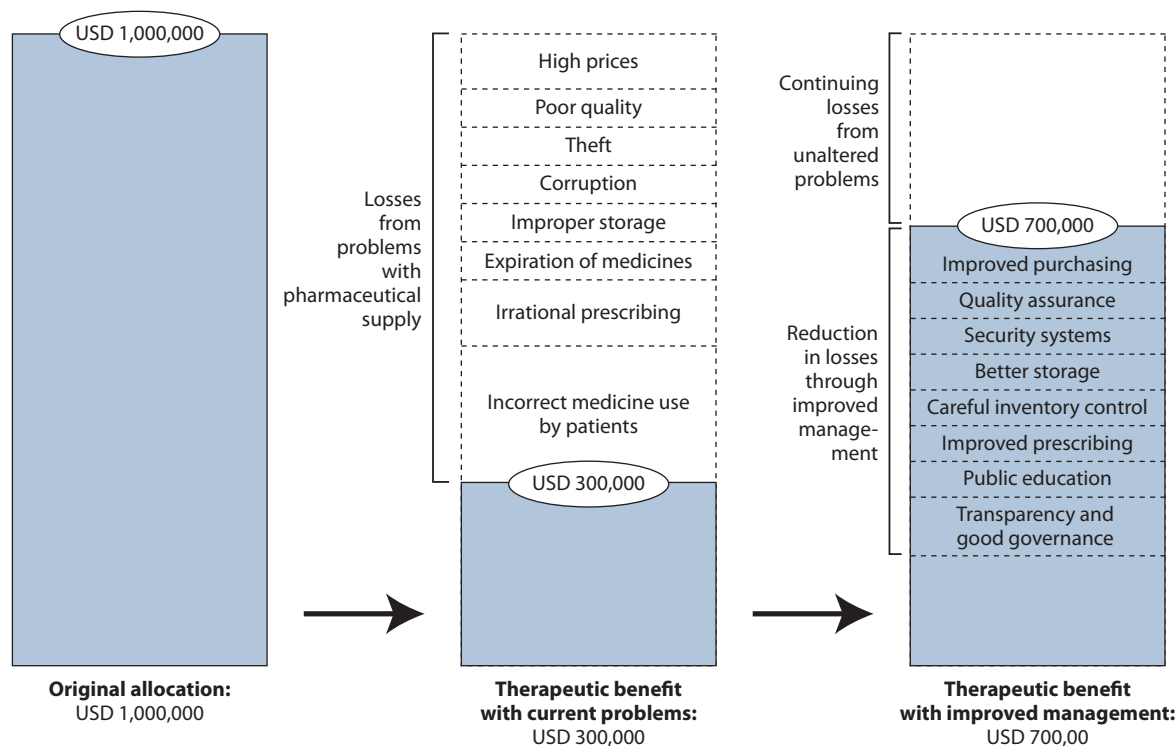

Substantive improvements are possible

In most health systems, the potential for improving the supply process is tremendous, reflecting in part the magnitude of current inefficiencies and waste.

Figure 1-1 shows a hypothetical program in which an annual expenditure of USD 1 million on pharmaceutical supply results in only USD 300,000 worth of therapeutic benefit to the patient. Lack of careful selection, incorrect quantification, high prices, poor quality, theft, improper storage, expiration of medicines, irrational prescribing, corruption, and incorrect medicine use by patients cause losses totaling 70 percent of the original expenditure.

However, much can be accomplished with substantial effort, a moderate amount of know-how, and relatively little additional funding. Some pharmaceutical management improvements require an initial investment in systems development, training, physical infrastructure, and other development initiatives, but the potential cost reductions and therapeutic improvements are dramatic. Even small improvements, when made in a number of related areas of

Figure 1-1 Waste in pharmaceutical management and potential for improvement

pharmaceutical management, can yield substantial overall savings.

1.3 Public health objectives and the essential medicines concept

Public health programs are concerned with using available resources to achieve maximum health improvements for the population. The perspective is not that of the individual patient, who may well benefit from a costly medicine, but of the entire community or population, which will benefit most if safe, effective medicines are accessible to all who need them.

Within a decade after the first modern pharmaceuticals became available, efforts began to ensure their widespread availability. From the mid-1950s to the mid-1970s, basic medicine management concepts began to evolve in countries as diverse as Cuba, Norway, Papua New Guinea, Peru, and Sri Lanka. In 1975, WHO defined *essential medicines* as “indispensable and necessary for the health needs of the population. They should be available at all times, in the proper dosage forms, to all segments of society.” In 1978, the International Conference on Primary Health Care at Alma-Ata, Kazakhstan, recognized essential medicines as one of the eight elements of primary health care. (See [Chapter 2](#) for additional historical background.)

The first WHO Model List of Essential Drugs, containing about 200 products and a description of the essential medicines concept, was published in 1977. Since 1977, the WHO model list has been revised every two to three years, and as of 2007, at least 156 countries had adopted essential medicines lists (WHO 2007a).

Consistent with a public health perspective, the essential medicines concept embraces the following guiding principles—

- The vast majority of health problems for most members of the population can be treated with a small, carefully selected number of medicines.
- In practice, most doctors and other health professionals routinely use a small fraction of medicines produced. Training and clinical experience should focus on the proper use of these few medicines.
- Procurement, distribution, and other supply activities can be carried out most economically and most efficiently for a limited list of pharmaceutical products.
- Patients can be better informed about the effective use of medicines when the number of medicines they are confronted with is limited.

Implementation of these principles occurs through the adoption of national medicine policies and through

practical pharmaceutical management initiatives. The major goals of such initiatives are outlined in [Box 1-2](#).

1.4 A paradigm for defining and improving access to medicines

Access to health care, including essential medicines, is a fundamental human right. Realization of this right may involve various combinations of public and private financing and service provision. The public health challenge is to work with the private sector and NGOs to achieve universal access to essential medicines and rational use of medicines. This work involves building mutual understanding, constructive partnerships, and the right incentives.

Access to health care can be defined as a construct that encompasses distinct dimensions, which are distinguished by sets of specific relationships (CPM 2003) ([Figure 1-2](#)). Four dimensions of access have particular relevance to essential medicines, vaccines, and other health commodities—

- *Availability*, defined by the relationship between the type and quantity of product or service needed, and the type and quantity of product or service provided
- *Affordability*, defined by the relationship between prices of the products or services and the user's ability to pay for them
- *Accessibility*, defined by the relationship between the location of the product or service and the location of the eventual user of the product or service
- *Acceptability* (or satisfaction), defined by the relationship between the user's attitudes and expectations

about the products and services and the actual characteristics of products and services

In addition, a cross-cutting characteristic of access is—

- *Quality of products and services*, an essential component of access cutting across all the dimensions, but which specifically applies to products in terms of their safety, efficacy, and cost-effectiveness

Indicators for measuring these dimensions of access are described in [Chapter 36](#).

The pharmaceutical management framework ([Figure 1-3](#)) provides the underpinning for improving access to medicines as described in the paradigm above. Pharmaceutical management involves four basic functions: selection, procurement, distribution, and use. Selection involves reviewing the prevalent health problems, identifying treatments of choice, choosing individual medicines and dosage forms, and deciding which medicines will be available at each level of a health care system. Procurement includes quantifying medicine requirements, selecting procurement methods, managing tenders, establishing contract terms, assuring pharmaceutical quality, and ensuring adherence to contract terms. Distribution encompasses clearing customs, stock control, stores management, and delivery to drug depots and health facilities. Use comprises diagnosing, prescribing, dispensing, and proper consumption by the patient.

In the pharmaceutical management framework ([Figure 1-3](#)), each major function builds on the previous function and leads logically to the next. Selection should be based on actual experience with health needs and medicine use, procurement requirements follow from selection decisions, and so forth. A breakdown in one part of the framework leads to

Box 1-2

Goals for national medicine policies and pharmaceutical management initiatives

Health-related goals

- Make essential medicines physically available and geographically accessible to the entire population.
- Ensure the safety, efficacy, and quality of medicines manufactured and distributed in the country.
- Increase attendance at health facilities by increasing the credibility and acceptance of the health system.
- Promote rational prescription, dispensing, and patient use of medicines.

Economic goals

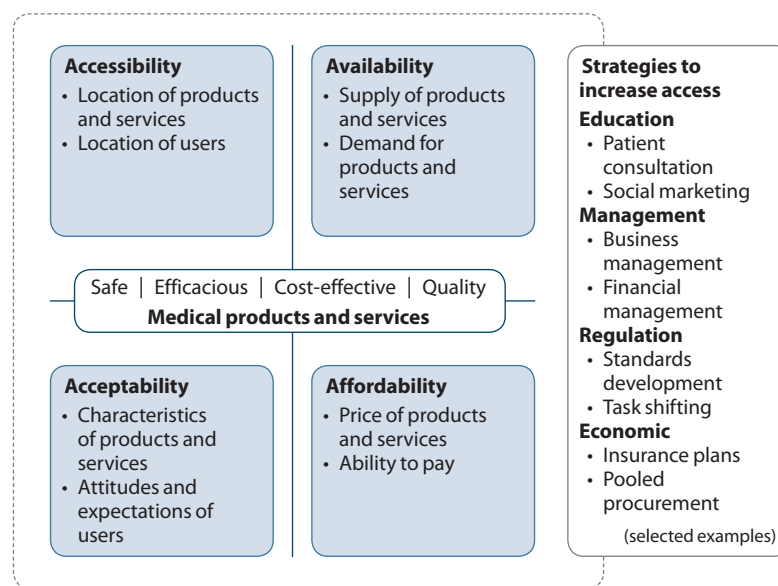

- Lower the cost of medicines to the government, other health care providers, and the public.

- Reduce foreign exchange expenditures for pharmaceuticals without reducing the supply.
- Attain sustainable financing through equitable funding mechanisms such as government revenues or social health insurance.
- Provide jobs in pharmaceutical supply and possibly production.

National development goals

- Increase skills of personnel in management, pharmacy, and medicine.
- Improve internal communication systems.
- Create reliable supply systems that incorporate a mix of public and private supply services.

Figure 1-2 Increasing access framework

failure of the whole pharmaceutical management process. Costs rise, shortages become common, and patients suffer when the separate tasks are performed not as part of a system but independently and disjointedly.

At the center of the pharmaceutical management framework is a core of management support systems: organization, financing and sustainability, information management, and human resources management. These management support systems hold the pharmaceutical management framework together. Although individual parts of the framework may function independently for a short time, the framework as a whole will soon cease to operate, and patient care will suffer without a functional organizational structure, adequate financing, reliable information management, and motivated staff.

Finally, the entire framework relies on policies, laws, and regulations, which when supported by good governance, establish and support the public commitment to essential medicine supply.

1.5 Lessons learned in pharmaceutical management

Since the 1980s, countries have acquired considerable experience in managing pharmaceutical supply. Although many important lessons have emerged from this experience, five broad themes capture the most important insights—

- National medicine policy (NMP) provides a sound foundation for managing pharmaceutical supply.

- Wise medicine selection underlies all other improvements.
- Effective management and good governance save money and improve performance.
- Rational medicine use requires more than just the dissemination of medicine information.
- Systematic assessment and monitoring are essential.

These five broad areas contain many specific lessons, some of which follow and most of which are covered in detail in the rest of the manual.

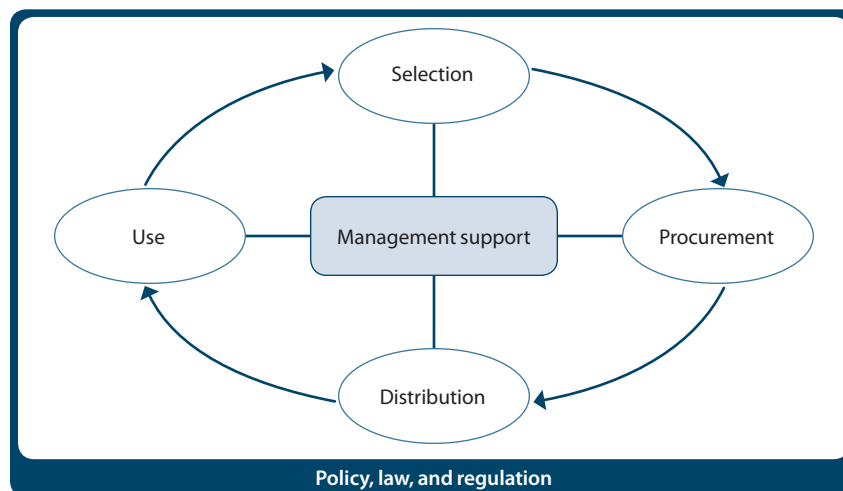

National medicine policy provides a sound foundation for managing pharmaceutical supply

A national medicine policy is a guide for action; it is generally a document containing the goals set by the government for the pharmaceutical sector and the main strategies for reaching those goals. It provides a framework to coordinate activities by the various actors in the pharmaceutical sector: the public sector, NGOs, the private sector, donors, and other interested parties (see [Chapter 4](#)).

The NMP concept began receiving support during the 1980s, when piecemeal approaches to policy were leaving important problems unsolved. A focused NMP, suited to the needs of the particular country and with clear priorities, was found to significantly affect the availability and use of pharmaceuticals in such countries as Australia, Bangladesh, Colombia, and the Philippines.

Comprehensive, officially adopted policies can focus efforts to improve access to medicines, medicine use, and

Figure 1-3 Pharmaceutical management framework

Source: CPM/MSH 2011.

medicine quality. Sometimes, however, the policy formulation process engenders such strong opposition that all energy becomes focused on the policy, effectively stalling other useful but less controversial efforts to improve the availability and use of medicines.

Formal NMPs provide a sound foundation for managing essential medicines programs. Of equal or greater importance, however, is the underlying strategic planning process: What are the long-term goals for the pharmaceutical sector? What strategies should be involved? How can key stakeholders be engaged in the process? The experiences of the last three decades suggest that governments and programs with clear objectives and strategies can make progress in the pharmaceutical sector.

Wise medicine selection underlies all other improvements

Establishing and using a limited list of carefully selected essential medicines is perhaps the single most cost-effective action that any health care system or health care provider can take to promote regular supply and rational use of medicines (Chapter 16).

As mentioned, more than 150 countries reported having adopted national essential medicines lists (WHO 2007a). In contrast, in the mid-1970s, few countries had selective medicine lists organized by generic name. Many of the national formularies that did exist were unselective and often contained more than one thousand products. Ministry of health procurement lists were commonly dominated by brand-name medicines.

Studies of the economic effect of essential medicines lists and formulary lists demonstrate that considerable savings can be achieved, primarily through careful choices for those few high-unit-cost and high-volume items that consume

the major share of the pharmaceutical budget. Chapter 40 describes how to analyze medicine expenditures.

An essential medicines list or formulary list that identifies medicines by level of care becomes the basis for training in therapeutics; for estimating pharmaceutical requirements; for competitive procurement by generic name; for planning distribution to health facilities; and for efforts to promote rational, cost-effective medicine use. The national essential medicines list or formulary list can also guide public education efforts, local production, and private-sector medicine management. The list, based on WHO criteria, should be updated regularly (usually every two to three years), divided by level of care, and accompanied by a clear policy on its application for procurement, distribution, and use of medicines (see Chapter 17).

Changing national policies to add or substitute a new treatment or diagnostic tool is a complex decision for a country's ministry of health. Major policy changes, such as switching to artemisinin-based combination therapy (ACT) for malaria, require intensive preparation and planning that involve multiple national and international stakeholders. For example, fluctuations in the demand for ACTs as countries changed their first-line treatment policies, then a delay in implementation, resulted in a global shortage of medicine that could have been allayed with better planning and communication.

Effective management and good governance save money and improve performance

Effective management and good governance make a vital difference in all aspects of pharmaceutical supply, especially with respect to the procurement and distribution of essential medicines. The basic principles of efficient procurement and distribution have been known for several decades, but

the view of the public sector as the lead player in a country's pharmaceutical supply has evolved. Countries are increasingly adopting the concept of multisector collaboration among public, NGO, and private entities to improve efficiencies in supplying pharmaceuticals.

Examples of the positive consequences of good management at the national level include savings in pharmaceutical costs through competitive procurement in El Salvador, Ghana, and the eastern Caribbean; improved medicine availability as a result of better quantification in Namibia and Kenya; and more reliable delivery as a result of redesigned distribution systems in South Africa.

Good pharmaceutical procurement practices include restriction of purchases to the essential medicines list (national formulary list), determination of order quantities based on reliable needs estimation, competitive tendering from qualified suppliers, separation of key functions, prompt payment, regular audits, and a formal system of supplier qualification and monitoring (Chapter 18). WHO has developed an assessment to measure transparency and governance in a country's pharmaceutical sector, including procurement procedures; for example, an assessment showed that four Southeast Asian countries all used an objective quantification method and that the post-tender system to monitor and report suppliers' performance was effective. However, WHO recommended that the appeals process for rejected tender applicants be instigated or strengthened, and noted that the procurement auditing process was weak (WHO 2006a).

Effective distribution management comes from—

- Defining appropriate roles in the distribution system for the public and private sectors
- Designing an efficient network of storage facilities with the fewest number of levels appropriate to the country's geography
- Selecting the appropriate strategy for delivery
- Keeping reliable records of medicine stocks and consumption
- Allocating supplies based on actual workload and treatment needs
- Maintaining accountability procedures and secure storage at each level of the system
- Constructing or renovating facilities appropriate for storing medicines
- Managing storage facilities to maintain pharmaceutical quality and efficiently serve health units
- Making reliable transport arrangements
- Reinforcing reporting and supervision arrangements

As mentioned, the most efficient system may result from collaboration among the public, private, and NGO sectors. Kit system distribution has both benefits and costs; it should be used only when necessary to ensure that supplies reach

lower levels of the system. Chapter 26 describes how kit systems are used to distribute pharmaceuticals.

Rational medicine use requires more than medicine information

Although 50 percent or more of pharmaceutical expenditures may be wasted through irrational prescribing, dispensing, and patient use of medicines, many methods for promoting rational medicine use have never been scientifically evaluated (Le Grand, Hogerzeil, and Haaijer-Ruskamp 1999). Among those methods that have been properly studied, not many have had much measurable effect on medicine use when implemented individually (Arnold and Straus 2005).

The actual use of pharmaceuticals is influenced by a wide range of factors, including pharmaceutical availability, provider experience, economic influences, cultural factors, community belief systems and patient attitudes, and the complex interactions among these factors. Medicine use patterns reflect human behavior and must be viewed from a social-science perspective rather than a biomedical perspective.

Pharmaceutical companies succeed in changing the habits of doctors and patients because they understand what influences these habits. Interventions to promote rational medicine use often fail because they are based on the notion that simply improving knowledge will improve medicine use. Examples of interventions that are likely to fail include dull medicine bulletins that drily present “the facts,” standard treatment manuals distributed to health staff without an active orientation, withdrawal of dangerous or ineffective products with no advice for prescribers on substitutions, and campaigns to discourage injection use that do not address the reasons why many patients prefer injections.

Fortunately, we have learned much in recent years about principles for promoting rational medicine use. These principles involve informed, focused, active, and engaging approaches for changing medicine-use practices by prescribers, dispensers, and patients (Laing, Hogerzeil, and Ross-Degnan 2001). Box 1-3 lists WHO's recommended interventions to promote the rational use of medicines.

Systematic assessment and monitoring are essential

One of the most basic, yet most significant, advances in pharmaceutical management has been the introduction of objective standard indicators for assessing, comparing, and monitoring medicine policies and management effectiveness. Since their introduction in the early 1990s, medicine-use indicators have been developed to assess virtually all key aspects of pharmaceutical management and NMPs. Examples of standard indicators include the percentage of government pharmaceutical purchases conforming to the national essential medicines list, the ratio of local

Box 1-3**Recommended interventions to promote the rational use of medicines**

- Establishing a mandated multidisciplinary national body to coordinate policies on medicine use and monitor their impact
- Formulating and using evidence-based clinical guidelines for training, supervision, and supporting critical decision making about medicines
- Selecting on the basis of “treatments of choice” lists of essential medicines that are used in drug procurement and insurance reimbursement
- Setting up drug and therapeutics committees in districts and hospitals and giving them the authority to improve the use of medicines
- Promoting problem-based training in pharmacotherapy in undergraduate curricula
- Making continuing in-service medical education a requirement of licensure
- Promoting systems of supervision, audit, and feedback in institutional settings
- Providing independent information (including comparative data) about medicines
- Promoting public education about medicines
- Eliminating perverse financial incentives that lead to irrational prescribing
- Drawing up and enforcing appropriate regulation, including that of promotional activities for medicines
- Reserving sufficient governmental expenditure to ensure equitable availability of medicines and health personnel

Source: WHO 2006c.

pharmaceutical prices to world market prices, the number of medicines per patient prescription, and the percentage of key medicines available at health facilities (see, for example, MSH/RPM 1995; CPM 2003; WHO 2007b).

Measured at one point in time, such indicators allow a program to compare itself to a target level of performance, to identify areas of relative strength and weakness, and to make comparisons with other programs for which data are available. Measured over time, such indicators can be used to set and monitor performance targets for pharmaceutical sector improvements.

Systematic assessment and monitoring based on standard indicators are a routine part of planning, program management, and donor evaluation in the field of essential medicines and pharmaceutical management. For example, the Global Fund to Fight AIDS, Tuberculosis and Malaria requires that grantees meet targets on certain indicators to receive additional funds. Each country and program needs to select, develop, and adapt indicators to suit local circumstances and needs, but the basic concept of objective indicators should be incorporated into any essential medicines program (see [Chapter 48](#)).

1.6 Challenges for pharmaceutical management

Major challenges for policy makers and managers include achieving financial sustainability; improving efficiency in public pharmaceutical supply; changing the perceptions and behaviors of providers, patients, and the public; reorienting the role of government and the private sector to improve

access to medicines; and regulating safety, efficacy, and quality, which may be the biggest challenge of all.

Achieving financial sustainability

Financial sustainability is achieved only when expenditures and financial resources balance and are sufficient to support a given level of demand. If demand for medicines exceeds the available resources, the health system is left with only four options: improve efficiency, increase financial resources, reduce demand, or accept a decline in quality of care. When the components of financial sustainability are not in balance, it simply defies economic reality to promise constant availability of high-quality essential medicines without improving efficiency, increasing financing, or limiting demand.

Efficiency means getting the most benefit from available resources. Much of this manual is devoted to improving therapeutic efficiency through better selection and use of medicines and improving operational efficiency through better organization, procurement, and distribution of medicines.

To achieve financial sustainability, policy makers and managers of essential medicines programs must become familiar with economic concepts and methods related to cost containment, efficiency, cost-effectiveness analysis, public expenditure decisions, the roles of the public and private sectors, and the economics of regulation. High-income countries increasingly rely on economic methods and perspectives. Countries with more limited resources must also make maximum use of the insights offered by the field of pharmaco-economics.

Health-sector reform is concerned with improving efficiency through changes in the organization and allocation of health care resources. It is also concerned with health care financing.

People pay for health care in different ways: collectively, through national health insurance or through the taxes they pay on goods, services, or income; in groups, through premiums paid for voluntary health insurance; or individually, through user fees at government facilities or private out-of-pocket health expenditures. In most countries, the primary burden for health financing falls directly or indirectly on the people of the country; the proportion of health care that is paid out of pocket actually increases in many low-income countries, where more than 60 percent of the total health spending comes from out of pocket (Gottret and Schieber 2006).

Local funding for recurrent health expenditures is often supplemented by external development assistance. In fact, the poorest countries may find it impossible to provide certain basic health services, including essential medicines, without some external assistance. External funding is a growing source of financing in low-income countries, especially in sub-Saharan Africa and South Asia. Although health aid increased from USD 2.6 billion in 1990 to USD 10 billion in 2003, experts are calling for increases in external assistance ranging from USD 25 billion to 70 billion a year to reach the UN Millennium Development Goals and other, disease-specific treatment goals (Gottret and Schieber 2006). For example, the U.S. Institute of Medicine estimated that instituting ACT for malaria worldwide would require USD 300 million to 500 million each year (Committee on the Economics of Antimalarial Drugs 2004), which would clearly be impossible for developing countries to cover with local funds.

Public financing provides an essential foundation for a country's health system and, in particular, for health promotion and preventive services. But providing free medicines through public resources has proved unsustainable in many developing as well as developed countries. Government budgets are squeezed, and donor funds are directed to a variety of other worthy causes. The policy of free medicines is often, in practice, a policy of shortages. Although global initiatives to provide ARVs to people in developing countries have brought free HIV/AIDS treatment to many, the sustainability of this arrangement is unknown. Most agree that, even with the introduction of lower-priced ARVs, HIV/AIDS treatment in developing countries will continue only as long as external funding continues.

Full or partial cost recovery through user fees is one way to supplement public financing. Revolving pharmaceutical funds and community medicine schemes linked to strengthening primary health care have been tried in countries in Africa, Asia, and Latin America. Some programs have led to a serious decline in utilization, with no visible improvement

in pharmaceutical availability. Yet some user-fee programs increased both equity of access and quality. Some global development organizations have called for the abolition of user fees as a barrier to access to poor people (UNMP 2005), but others point out that if the removal of user fees is not compensated for by other funding, patients may be forced to spend more on medicines or health care services in the private sector (Gottret and Schieber 2006).

Social health insurance (compulsory health insurance or social security), private health insurance, and community health insurance schemes finance pharmaceutical supply for a small but growing portion of the population in developing countries. People in most high-income countries are already covered by some form of public or private health insurance; however, the median coverage is only 35 percent in Latin America, 10 percent in Asia, and 8 percent in Africa (WHO 2004a). Health insurance coverage that includes pharmaceuticals has expanded access to medicines in many countries, including Argentina, China, Egypt, South Africa, and Vietnam (WHO 2004b). WHO has committed to promoting the provision of medicines benefits through social health insurance and prepayment schemes (WHO 2004b). [Chapter 12](#) discusses health financing through insurance in detail.

In the face of changing epidemiologic patterns, increasing demand for modern health care, and growing populations, the challenge for countries is to implement those pharmaceutical financing strategies that best ensure equity of access and a continuous supply of medicines. For many countries, reaching this goal means taking a pluralistic approach—one that uses different ways to serve different needs and different groups and that combines the benefits of public financing, health insurance, voluntary financing mechanisms, and donor support.

Improving governance and efficiency in public pharmaceutical supply

Aside from the problem of financing, public-sector pharmaceutical supply in many countries continues to be plagued by ineffective management systems. They often lack sufficient qualified human resources and are characterized by systems that are not transparent and do not promote accountability. As such, they become susceptible to political pressures, fraud, and abuse.

In fact, corruption is increasingly recognized as a barrier to social and economic development, and many governments and international development organizations are placing the issue high on development and health agendas. For example, in 2004, WHO launched its program on good governance in pharmaceutical systems (see [Box 1.4](#)); the United Nations Convention Against Corruption became effective in 2005; Transparency International's Global Corruption Report for 2006 focused on health systems; and the Medicines Transparency Alliance came together in

2007. Figure 1-4 shows a framework for improving governance and accountability.

The international donor community has recognized and is addressing the need to increase access to lifesaving medicines: new funding sources, such as the U.S. President's Emergency Plan for AIDS Relief, the President's Malaria Initiative, UNITAID, and the Global Fund to Fight AIDS, Tuberculosis and Malaria, are making unprecedented sums of money available to procure medicines for deadly diseases. However, the two greatest threats to successfully increasing access to medicines are weak and vulnerable pharmaceutical supply systems and the worsening human resources crisis. The scope of the challenge to countries in terms of the

drastic effect the new funding is having on pharmaceutical systems is unparalleled.

Sustainability is the extent to which a program will continue to achieve its policy and pharmaceutical supply objectives without additional outside financial or technical support. Key factors for program sustainability, in addition to financing, are motivated, capable staff; effective management systems; and political support. Low pay, inadequate training, lack of incentives, inappropriate recruitment, and ineffective disciplinary measures undermine staff performance, which is already decimated in many countries by the loss of trained human resources from "brain drain" and HIV/AIDS.

Box 1-4 WHO's Good Governance for Medicines program

The pharmaceutical sector is highly vulnerable to corruption and unethical practices, in part because pharmaceuticals have a high market value; regulating and procuring pharmaceuticals is complex; and the sector involves many international, national, and local entities.

Poor governance in the pharmaceutical system can lead to severe health and economic consequences. For example, corruption in the regulatory system can result in approval of medicines that are inappropriate because of safety, efficacy, quality, or price. Similarly, if inspection, postmarketing surveillance, or quality-control systems are corrupt, counterfeit and substandard medicines can easily enter the marketplace, causing harm or even death. Waste associated with corruption can also be a major drain on the public budget and decrease the resources available not only to buy medicines but also to pay health care workers. Corruption affects the public's trust in the government as well as in the whole health profession.

Recognizing how these problems affect the health sector negatively, WHO initiated the Good Governance for Medicines program in late 2004. The program offers a technical-support package for governments to tackle unethical practices in the public pharmaceutical sector. The goal of the program is to curb corruption in pharmaceutical systems by applying transparent and accountable administrative procedures and promoting ethical practices among health professionals.

Tackling corruption in the pharmaceutical sector requires a long-term strategy. WHO has identified a three-step approach—

1. Assess the level of transparency and vulnerability to corruption of key functions in national pharmaceutical regulation and management systems.

2. Use a national consultation process to develop a national program on good governance for medicines that increases transparency and accountability in the pharmaceutical sector and promotes ethical practices.
3. Implement and promote the national good governance for medicines program.

From 2004 to 2007, WHO gradually introduced the project in ten countries: Bolivia, Cambodia, Indonesia, the Lao People's Democratic Republic, Malawi, Malaysia, Mongolia, Papua New Guinea, the Philippines, and Thailand. National assessors used the WHO transparency assessment tool to measure the level of transparency in national medicines regulation and public-sector pharmaceutical procurement systems.

Information collected from the first four countries where the program was introduced—the Lao People's Democratic Republic, Malaysia, the Philippines, and Thailand—revealed that although they have different public-sector procurement and medicines regulation profiles, they have some common strengths and weaknesses. For example, all have publicly available standard operating procedures for procurement, but none requires members of the registration or selection committees to fill out a conflict-of-interest form.

WHO will continue to work with governments and WHO regional offices to select new countries and activities related to the Good Governance initiative.

For additional information, access WHO's Good Governance website at <http://www.who.int/medicines/ggm/en/index.html>.

Figure 1-4 Governance framework

Source: Adapted from United Nations Development Programme (UNDP), *Governance for Sustainable Human Development*, <http://mirror.undp.org/magnet/policy/> (Geneva, 1997).

Growing pressure to scale up access to medicines, combined with the influx of funds mentioned above, is exposing weaknesses in how developing countries procure and distribute pharmaceuticals to their citizens. Examples abound in which the conventional central medical stores (CMS) approach to pharmaceutical procurement and distribution continues to result in chronic medicine shortages—even after considerable investment has been made in training, management systems, and physical infrastructure. Public-sector supply systems in affected countries—primarily in Africa—have to adapt existing systems to manage hugely increased volumes of medicines and commodities. Alternative strategies for public pharmaceutical supply are attracting interest. They include formation of an autonomous supply agency, direct delivery, the primary distributor system, various privatized models, and mixed systems. Successful scaling up will require a dramatic transformation of the systems traditionally used for procurement and supply of medicines. Alternative strategies for public pharmaceutical supply have been implemented with varying degrees of success in countries such as Benin, Botswana, Colombia, Guatemala, South Africa, Tanzania, and Zambia.

With an autonomous supply system, an autonomous or semi-autonomous agency manages bulk procurement, storage, and distribution. With the direct delivery (non-CMS) system, the government tenders to establish prices and suppliers for essential medicines, which are then delivered directly by suppliers to districts and major health facilities. With the primary distributor system (another non-CMS system), the government pharmaceutical procurement office establishes a contract with a single primary distributor as well as separate procurement contracts with pharmaceutical suppliers. The primary distributor is contracted to manage pharmaceutical distribution by receiving medicines

from the suppliers and then storing and distributing them to districts and major facilities. In fully privatized models, public administration of pharmaceutical supply is minimized, with independent pharmacies or other mechanisms providing medicines within or outside government facilities; various financing and reimbursement arrangements can be used. Chapter 8 covers supply strategies in detail.

Selection, procurement, and distribution can each be carried out in centralized, partially decentralized, or fully decentralized systems. Decentralization aims to improve the responsiveness, quality, and efficiency of health services. Improvements are far from certain, however. Problems with attempts to decentralize pharmaceutical management functions have included lack of local management and supervisory capacity, increased costs (caused by loss of savings from bulk purchasing), lack of local staff trained in pharmaceutical management, inadequate financial resources, self-interested interference by local officials, and poor pharmaceutical quality (caused by difficulty in selecting and monitoring suppliers).

For managing pharmaceutical supply, a task-specific approach to decentralization may be useful. Examples of tasks that may be better performed centrally include development of essential medicines lists, preparation of standard treatment guidelines, management of competitive tenders, selection and monitoring of suppliers, quality assurance, and development of training programs in rational medicine use. Tasks that can be decentralized include those that do not require uncommon technical skills. Decentralization is advisable when local information is required, local circumstances are important and variable throughout the country, and local interests favor improved performance. Examples of such tasks include adapting medicine lists or standard treatments to local needs, quantifying medicine requirements, coordinating local distribution, conducting training

Country Study 1-1**Working with the private sector to improve malaria outcomes in Tanzania, Ghana, and Nigeria**

In many African countries, informal medicine sellers are the first point of contact for caregivers seeking treatment for childhood illnesses. These individuals typically have little or no health training and frequently misdiagnose malaria, provide inappropriate treatment, give an incorrect dose, and/or give inaccurate advice. Several programs designed to improve practices among this group for treating childhood illnesses have shown promising results.

Tanzania

Management Sciences for Health's Strategies for Enhancing Access to Medicines (SEAM) Program, in collaboration with the Tanzanian government, created a new category of accredited drug dispensing outlet (ADDO) to improve access to affordable, quality medicines and pharmaceutical services in retail drug outlets in rural or peri-urban areas where there are few or no registered pharmacies. To achieve this goal, the SEAM Program took a holistic approach that combined changing the behavior and expectations of individuals and groups who use, own, regulate, or work in retail drug shops as well as that of community members. Major program activities included changing behavior of dispensing staff through training, education, and supervision; improving awareness of community members regarding quality and the importance of treatment adherence through marketing and public education; and focusing on regulation and inspection and improving local regulatory capacity.

Postintervention assessment results showed that—

- Thirty-two percent of malaria treatment encounters at ADDOs included the sale of an appropriate first-line antimalarial, compared with only 16 percent at baseline. Twenty-four percent of encounters were dispensed exactly according to standard treatment guidelines, compared with 6 percent at baseline.

- The average availability of antimalarials increased from 74 to 90 percent in the ADDO region compared with 71 percent availability in the control region.

After the SEAM Program ended, the government of Tanzania adopted the ADDO program and announced the program's nationwide rollout.

Ghana

The strategy in Ghana involved implementing a franchise system called CAREshops among participating chemical sellers' shops to establish uniform standards, train personnel, monitor adherence to franchise standards, and create business incentives for adherence to those standards. The goal of this initiative was to improve access to reasonably priced, quality-assured essential medicines and health supplies and high-quality dispensing services in underserved rural areas. Other key elements of the franchising program include a ten-week, five-module training program, including appropriate dispensing practices in malaria management, designed and delivered to the selected group of licensed chemical sellers.

Postintervention assessment results showed that—

- At endline, there was an increase from 50 percent to 62 percent in dispensing any antimalarial to simulated malaria clients at CAREshops (compared with a decrease from 58 percent to 55 percent in the control regions).
- However, only 18 percent of CAREshop facilities dispensed the antimalarial exactly according to treatment guidelines at endline, compared with 10 percent and 13 percent of chemical sellers in two control regions. Clearly, additional training, supervision, and monitoring are still necessary.

in rational medicine use, and monitoring medicine use at health facilities.

The effectiveness of the pharmaceutical supply system in achieving a reliable supply of essential medicines must be continually and objectively assessed. Fundamental restructuring of pharmaceutical supply arrangements challenges the status quo and may threaten a variety of interests. But continuing to support an ineffective supply system wastes precious resources and denies patients access to lifesaving essential medicines.

Changing the perceptions and behaviors of providers, patients, and the public

One of the greatest challenges is to change the way in which providers, patients, and the public view and use pharmaceuticals. Major problems, noted earlier, include prescribing and dispensing incorrect, harmful, or unnecessary medicines; failure by patients to use needed medications correctly; and wasteful or harmful self-medication practices.

However, three years after implementation, the franchise organization had not reached the break-even point and continued to lose money, although many shops were independently performing well. Discussions between the original implementing organization and an outside organization to restructure the franchise business plan were unsuccessful, and by the end of 2008, the head of the implementing organization said that the franchise was in serious financial peril.

Nigeria

The Basic Support for Institutionalizing Child Survival (BASICS) Program designed an intervention in Nigeria that combined a short, highly focused training for private-sector patent-medicine vendors with the promotion of age-specific, color-coded, prepackaged antimalarials for children under five. These activities were supported by a comprehensive social marketing and behavior-

change strategy, which included mass media promoting the new prepackaged antimalarials and medicine sellers displaying shop identifiers from the training. More than eight hundred patent-medicine vendors were trained in a two-month period at the relatively low cost of approximately USD 8 each. Training materials focused on immediate treatment of children under five with fever using an appropriate-dose (preferably prepackaged) antimalarial.

Postintervention assessment results showed that—

- The number of patent-medicine vendors giving the correct antimalarial and dose increased from 9 percent to 53 percent.
- Patent-medicine vendor knowledge about the need to use insecticide-treated nets tripled (from 21 percent to 65 percent) between pre- and postintervention surveys.

Given the huge share of public and private pharmaceutical expenditures that may be wasted through irrational medicine use, governments, NGOs, and others must continue to explore effective, sustainable ways of improving medicine-use patterns. For example, the International Conferences on Improving the Use of Medicines in 1997 and 2004 brought together leading national and international policy makers, program managers, researchers, clinicians, and other stakeholders to produce state-of-the-art consensus on interventions to improve medicines use in nonindustrialized countries, to define evidence-based recommendations for program implementation, and to generate global research agendas to fill gaps in knowledge ([www.icium.org](#)). See also [Chapters 29](#) and [33](#), which address rational prescribing and use by the public.

Reorienting the role of government

Access to health care, including essential medicines, is a fundamental human right. Realization of this right may involve various combinations of public and private financing and service provision. In high-income countries, public financing of pharmaceuticals predominates. In low- and middle-income countries, the public-private mix varies remarkably, from over 90 percent public provision of medicines in Slovakia and the Solomon Islands to roughly 90 percent private market supply and financing of pharmaceuticals in Cambodia and Georgia (WHO 2004c).

From a public health perspective, therefore, the specific concerns with improving access to medicines in the private pharmaceutical market are improving the availability, geographic accessibility, affordability, and accept-

ability of quality medicines and related services. Measures to improve *availability* include certification and training of pharmacy aides and other drug sellers; focus on efficiency in the supply chain, including the private sector; licensing and incentives for wholesalers, pharmacies, and other drug outlets; and community-based medicine schemes. Innovative franchising and accreditation initiatives have been used successfully to increase the quality of medicines and pharmaceutical services from retail drug sellers, which are often more *geographically accessible* and therefore people's first source of health care ([Country Study 1-1](#)). *Affordability* can be improved with greater insurance coverage, better price information, competitive procurement and price competition through generic substitution, regulation of producer and resale prices, and modification of retail sales margins. *Acceptability* can be promoted by regulating medicine information and marketing; including essential medicines concepts in basic medical education; providing focused continuing education for health professionals; and actively educating the public and patients. Finally, *quality* of services is increased by enforcing licensing requirements for doctors, pharmacists, and other health professionals, and *quality* of products is improved by putting into place good procurement practices, such as using prequalified suppliers, and an effective regulatory system that includes monitoring, testing, and enforcement ([Chapter 6](#)).

The public health challenge is to work with the private sector and NGOs to achieve universal access to essential medicines and rational use of medicines. This work involves building mutual understanding, constructive partnerships, and the right incentives.

Regulating safety, efficacy, and quality

Regulatory control, often neglected in the pharmaceutical sector of developing countries, is an indispensable foundation for ensuring the safety, efficacy, and quality of pharmaceuticals in a country. Governments must ensure that all pharmaceuticals available on the local market meet basic standards. Moreover, the same quality standards applied to the open market must be applied to medicines procured through the public sector. Pharmaceutical legislation and regulation should also establish basic professional standards in both the public and the private sectors.

In industrialized countries, regulatory capacity has developed in phases over many decades. Most developing countries also will require time to develop effective regulatory capacity. Such capacity requires a firm legislative basis, trained personnel, specific technical resources, adequate funding, and—perhaps most important—public commitment to establishing and enforcing basic standards (Chapter 6).

1.7 Managing pharmaceutical sector improvements

This manual is meant to provide policy makers and managers with practical, accessible advice on a wide range of topics relevant to managing pharmaceutical supply. The basic functions of management are planning, implementation, and monitoring. Effective planning requires thoughtful reflection on basic goals, systematic assessment of the current situation, identification of root causes of problems, creative consideration of all reasonable strategies for improvement, and selection of strategies based on defined criteria.

Program implementation is an interactive process that involves organizing people, finances, and other resources to achieve the desired results. The test of any policy or plan is in its implementation. Gradual phasing-in of new initiatives can help build management systems, which can then support full-scale implementation. Active decision making and problem solving are fundamental to the implementation process.

Finally, ongoing monitoring and periodic evaluation are needed to measure progress, to adjust implementation plans, and to assess the effect of pharmaceutical management improvements. Objective indicators and specific program targets provide concrete measures against which actual performance can be compared. Without such indicators, judging the success and, therefore, the value of human and financial investments in pharmaceutical sector improvements is difficult.

The experiences of countless countries and programs demonstrate that substantive, sustainable improvements in the supply and use of medicines are possible. But an equal

or greater number of negative experiences demonstrate that success is by no means assured. Clear goals, sound plans, effective implementation, and systematic monitoring of performance are essential ingredients in pharmaceutical sector development. ■

SUMMARY

Concerns about medicines—or lack of medicines—can be traced back for centuries. The discovery of “wonder drugs” about the time of World War II, however, was a milestone in pharmaceutical management. The dramatic effectiveness of some new pharmaceuticals and the intensive marketing of many others combined to catalyze widespread use of modern medicines. A rapidly growing and profitable industry, together with an enthusiastic but largely uninformed public and an often inadequately regulated marketplace, resulted in excesses of promotion and consumption, along with substantial levels of expenditure that necessitated new policy measures.

Despite the advent of wonder drugs, however, it had become clear by the 1970s that the least-advantaged nations were not even meeting the basic needs of their people for essential lifesaving and health-promoting medicines. Through the 1970s and 1980s, governments and international organizations such as the World Health Organization (WHO) began to redress this imbalance, with support from nongovernmental organizations (NGOs), largely through the promotion of essential medicines programs.

In the 1990s and 2000s, the devastation caused by the HIV/AIDS pandemic specifically helped draw atten-

tion to the plight of people living in resource-limited areas—especially sub-Saharan Africa—and the increased interest in health care and funding for treatment in developing countries spawned a number of significant global initiatives to address inequities and increase access to health care and essential medicines in the most-affected countries. As the world responds with dramatically increased financial assistance to provide affordable medicines for HIV/AIDS, tuberculosis (TB), and malaria, there has been growing recognition that the effectiveness of these multimillion-dollar initiatives is limited by the capacity of health care and pharmaceutical supply systems at the national and local levels. Constraints to improving access to medicines include inadequate infrastructure in facilities and a lack of trained staff and equipment for those facilities.

Although differences have always existed between the way pharmaceutical policies have developed in industrialized countries, on the one hand, and developing countries, on the other, many elements of pharmaceutical policy are applicable everywhere. The increasingly globalized economy is driving more uniform approaches to pharmaceutical policy, especially as the many parties engaged in the pharmaceutical arena work together in global programs for the benefit of all.

2.1 The discovery of miracle medicines

During and soon after World War II, new and powerful medicines began to emerge in rapid succession from laboratories around the world. Penicillin was isolated and first used clinically in 1941; chloroquine, first investigated in the mid-1930s, was released for trial against malaria in 1943; and streptomycin followed in 1944 as the first effective medicine for tuberculosis. Adding to the earlier benefits of smallpox and typhoid immunizations, diphtheria and tetanus toxoid vaccines were first adopted during the war for use in large military populations. Tetracycline and chloramphenicol were introduced in 1948, isoniazid in 1951, and erythromycin in 1952. Chlorpromazine signaled a new era of mental health medicine therapy in the same year. In 1954, the sulfonylureas became the first oral preparations for treating diabetes, and nystatin emerged as an antifungal agent. In 1955, field trials of oral contraceptives took place in Puerto Rico, leading to a virtual revolution that enabled women to begin to effectively control family size.

In just over a decade, the whole field of therapeutics was revolutionized, putting into the hands of practitioners and consumers new pharmaceutical compounds that could

cure or control problems in ways largely unknown in earlier times. As both scientific and anecdotal evidence spread, practitioners and patients demanded, and were willing to pay for, the innovative and powerful products that the pharmaceutical industry was patenting and producing.

2.2 The increasing gap in access to medicines

In this exciting period during the middle of the twentieth century, many authors of popular books on pharmaceuticals wrote of the revolution in medical care that modern medicines had made possible: antibiotics seemed on the verge of controlling deadly infections such as pneumonia and septicemia; cortisone had arrived to suppress painful inflammation; asthma was yielding to isoprenaline; one vaccine after another was appearing to stop fatal epidemics. *Miracle* was the word many authors used to describe these effects.

From the global perspective, however, such miracles were for the minority. Affluent countries stood in stark contrast to the rest of the world, where entire populations had little access to medicines or were struggling to cope with a maze of competitive products, many of which were obscure,

overpriced, outdated, ineffective, or, frankly, dangerous. In many countries, two contrasting problems existed side by side: no medicines at all in the countryside, but hundreds or thousands of medicines competing for prescribers' and customers' attention in the cities. Medical and nursing staff in some areas worked without the medicines they needed, while practitioners in other areas faced a flood of expensive products about which they had no reliable information or that their patients could not afford.

2.3 The rise of the essential medicines concept

An idea gradually emerged: why not concentrate first on a basic list of reliable medicines to meet the most vital needs—understanding them, finding ways to pay for them, supplying them to the people? The idea of working with a limited range of medicines had long been used in places where no alternative existed; doctors had learned to carry twenty vital medicines in their bags, oceangoing ships commonly carried 100 or fewer medicines, and in later years, some airlines designed medicine kits for use in emergencies on long-distance flights.

The idea was first applied on a national scale before World War II in Norway, which was then a poor country. Norway decided to limit its list of approved medicines to those most needed in medical practice and most affordable for the population, avoiding unnecessary duplication. In the developing world, Papua New Guinea had a policy based on “essential drugs” by the early 1950s, Sri Lanka followed in 1959, and Cuba had a list of essential medicines by 1963.

How many medicines were needed for such a list? Sri Lanka chose 500, similar in number to Norway's original list. Whatever choice was made, it provided a starting point; one day, money might be available for more. Newly independent countries, committed to providing universal health care yet desperately short of resources, saw an essential medicines policy as a means of moving ahead despite stubborn obstacles.

It became clear that focusing on an essential medicines list could also make better use of limited financial resources. The most basic medicines were often well established through longtime use, and because patents on many of them had expired, several competing manufacturers were making them and selling them at lower prices. Often, a low-cost medicine was as good as a newer product being sold at a cost ten or fifty times higher.

By the mid-1970s, the essential medicines concept had evolved into a practical policy suitable for worldwide use, with one important modification. Rather than the view that only essential medicines should be allowed on the market, the view was now that any safe and efficacious medicine should be allowed for sale, but that essential medicines

should be given priority. At this point WHO adopted the concept. In 1975, WHO's Director General defined essential medicines as “those considered to be of utmost importance and hence basic, indispensable, and necessary for the health needs of the population. They should be available at all times, in the proper dosage forms, to all segments of society.”

Two years later, WHO issued its first model list of 224 “essential drugs” (including vaccines). By then, many countries were finding the cost of medicines a concern; for example, the government of Bangladesh was spending 60 percent of its entire public health budget on medicines, yet much of the poor population could still not get access to affordable treatment. Often, pharmaceuticals and raw materials had to be imported from high-cost countries, and their prices were further inflated by substantial markups imposed by importers, wholesalers, and retailers. In addition, thousands of brand-name combination products, often of questionable efficacy and safety, were flooding the private sector. Now, realizing that a limited list of essential medicines could help solve most of those problems, public health services could base their purchasing, supply, and training primarily on items that were most needed and most affordable.

The pharmaceutical industry grew rapidly in the postwar era. Substances that cured, prevented, or ameliorated many problems were formulated into products that were protected by patents, giving producers a long period in which to establish a dominant market presence and accumulate profits. Sophisticated production and testing methods allowed the formation of efficient, largely automated, high-volume manufacturing processes, resulting in large profits that could be plowed back into new-product research and the acquisition of smaller firms. These forces created an increasingly concentrated multinational industry.

Developing countries had another reason to give priority to essential medicines. The rush to get new products to the market resulted in inadequately tested medicines and many cases of serious or fatal medicine-induced diseases. In 1960, the introduction in Europe of the sleeping aid thalidomide resulted in the birth of thousands of deformed children. In 1973, clioquinol, used to suppress diarrhea in Japan, was found to cause blindness and paralysis. Even some widely used and valuable medicines brought unexpected problems. For example, the antibiotic chloramphenicol, misused widely in Latin America, caused aplastic anemia. These examples generated a growing recognition that pharmaceuticals often brought problems as well as great promise.

UN agencies and WHO lead the way

Although WHO's role in promoting the idea of essential medicines was historic, it was only the starting point for a much broader trend involving other international organizations. By the 1970s, UN member states were urging international agencies to take up the problems of imbalances in

growth, inequities, and redistribution of resources in developing countries. In 1974, the International Labor Office adopted the idea of defining and meeting “basic needs” in the developing world as a whole, not limited to medicines alone. WHO also urged a broader approach aimed at improving the health of rural and peri-urban populations. In Alma Ata in 1978, the WHO/UN Children’s Fund (UNICEF) Conference on Primary Health Care adopted the essential medicines concept as one of its basic tools. In Geneva, the Division of Drug Policy and Management came into being to develop the concept as part of national pharmaceutical policy for member states. Important backing also came from an interagency task force set up by the United Nations (UN), which by 1979 recommended the adoption of national medicines lists using generic names.

By this time, other UN agencies were also focusing on medicines. The UN Conference on Trade and Development (UNCTAD) supported the use of generic names, competitive procurement, and cooperative purchasing arrangements. The UN Industrial Development Organization (UNIDO) emphasized local and regional cooperative production. UNICEF, long active in directly providing medicines through its supply division, embraced the essential medicines idea with WHO in the late 1970s. Finally, the mutually supportive role of such UN agencies became more visible and eventually more coherent when a series of conferences and task forces created a rough division of labor: UNICEF would concentrate on supply, WHO on health policy, UNCTAD on trade, and UNIDO on industrial development.

The emergence of generic pharmaceuticals

By the 1980s, the patents on many medicines developed in the two decades after World War II began to expire, opening the way for worldwide production and distribution. Southeast Asia, especially, had a growing number of new pharmaceutical firms with low overhead costs that began to manufacture generic versions of well-known medicines and sell them at a fraction of the original price. Because they were working in countries where foreign patents were not recognized, some of these manufacturers had long-term experience in copying pharmaceutical products; not all maintained high standards of quality, however. Nevertheless, public pharmaceutical supply systems found that they could obtain much better prices by procuring the new, low-cost generic versions of familiar medicines.

The movement accelerates

WHO’s Action Programme on Essential Drugs grew vigorously in the early 1980s. By 1984, large amounts of extra-budgetary funds from European donors were provided specifically to support projects in each region of the world

for strengthening medicine selection, procurement, and distribution. Issues of pharmaceutical financing were tackled, and standards were set for pharmaceutical information and training. In 1985, the WHO Conference of Experts in Nairobi broadened the approach with a new emphasis on the need to use medicines rationally. That same year, the *Essential Drugs Monitor*, an international newsletter advocating an essential medicines policy in all its forms, began publication. Such initiatives were heavily backed by voluntary efforts from the outside, notably by Health Action International (HAI), an international coalition of NGOs from some fifty countries with a special interest in pharmaceuticals.

The industry’s reaction

As they gained momentum, these dramatic developments provoked mixed reactions from the international pharmaceutical industry. Major multinational corporations had reaped substantial profits from selling their new products in the industrialized world. However, even given the fierce competition among multinational pharmaceutical firms, a low-cost solution to the problem of access to medicines in the developing world had not evolved. One explanation was that the industry had grown accustomed to serving affluent populations, where buyers generally accepted high prices in exchange for the newest products, which they assumed were the best. To cultivate that market, companies focused on marketing and promoting their new products. Selling a relatively small volume of pharmaceuticals to the most affluent part of the population was simpler and more profitable than trying to meet the needs of larger populations with limited ability to pay.

Despite the limited coverage of the people in the developing world by the multinational pharmaceutical industry, these countries constituted a potentially lucrative market, with promise for the future. As developed countries introduced stricter systems of pharmaceutical regulation and were forced by the economic recession of the 1970s to look critically at their own medicine costs, the largely unregulated countries of the rest of the world provided a new prospect for profitability. The fact that the UN and WHO were encouraging restrictive policies and beginning to formulate ethical criteria for pharmaceutical marketing in the developing world seemed to threaten the multinationals’ future prospects. Where the new generic manufacturers now saw an opportunity, the traditional multinationals saw a threat. One reaction of the producers of originator products was to demand better patent protection, which came to fruition with the World Trade Organization’s Agreement on Trade-Related Aspects of Intellectual Property Rights in 1994 (see [Chapter 3](#)).

The pharmaceutical industry’s direct reactions to essential medicines policies varied from hostile to mixed,

with representatives declaring on occasion that the concept was completely unacceptable. The Geneva-based International Federation of Pharmaceutical Manufacturers and Associations (IFPMA) suggested that the adoption of an essential medicines list “would result in substandard rather than improved medical care and might well reduce health standards already attained.” The federation was heavily backed in its protests by the U.S. Pharmaceutical Manufacturers Association, which by 1985 was arguing that the imposition of additional and arbitrary criteria involving “essentiality” or “medical interest” would clearly be contrary to the public interest. In retrospect, one major problem was probably the failure to communicate to the industry and practitioners what “essential medicines” really meant. As noted, the essential medicines concept was not a question of reducing access to medicines for those who already enjoyed it, but of providing access for those who had otherwise been without.

Subsequently, having accepted that for poorer countries the essential medicines approach might be “practical, even if regrettable,” the research-based segment of the pharmaceutical industry turned to limiting its application, insisting that the concept applied only in the public sectors of the least-developed countries. This segment of the industry simultaneously discouraged WHO’s other policy initiatives, notably those involving advertising standards, and continued to promote the view that generic medicines were likely to be substandard and even dangerous.

Since 1985, however, the research-based multinational industry and the trade as a whole have largely come around to the view that they can earn a fair profit by providing low-cost medicines—whether brand-name or generic—on a large scale to essential medicines programs, with high sales volume compensating for low profit margins. On some fronts, the IFPMA has collaborated with essential medicines programs, with WHO, and with donors. Tensions between pharmaceutical manufacturers and international organizations have shifted from the essential drug concept to other issues, such as intellectual property and parallel importing.

The campaign for rational use of medicines

After access to essential medicines is addressed, proper use remains a challenge, because waste by both prescribers and users is common. The notion that if one medicine is good, two are better (and three ideal) dies hard, and both prescribers and users are prone to overuse. The quantities of medicines prescribed for a given illness are often far more than what is reasonably needed. Medicines are often prescribed when none is needed at all, because patients expect or demand a pill or an injection, or because physicians or medical assistants are anxious to be seen as doing something. In some cases, half of medicines reaching the periphery are

wasted by irrational prescribing and by inappropriate use by patients, who fail to follow the instructions given by prescribers.

The notion that all pharmaceutical policies need to promote the “rational use of medicines” was only slowly accepted. Pharmaceutical policies had always centered on medicines, not on patients. Pharmaceutical policies had been the concern largely of administrators and pharmacists, whereas medicine use was largely in the hands of physicians and paramedical staff. The medical profession in particular resented any suggestion that it might be acting irrationally as a group or that it might be in need of guidance or control. Medical personnel often insisted on the “right” to prescribe the medicine of their choice.

The rational use of medicines concept developed momentum after WHO’s 1985 Nairobi Conference of Experts used it as its central theme. The conference emphasized the need for the public to understand and use medicines better, particularly in view of all that was known about nonadherence to treatment. In many cases, neither the prescriber nor the patient was to blame for irrational use; the fault often resulted from lack of proper information and training, compounded in some cases by fear, carelessness, or misleading persuasion from the seller or others. With much of a nation’s pharmaceutical supply potentially being wasted because of irrational use, the effort to promote proper use, although time-consuming, is vital to any effective health policy and any well-managed economy.

Basic data on how medicines are actually being used in a particular country and situation, why errors are made, and the types of intervention that may improve the situation are important aids in understanding and modifying medicine use. WHO’s Collaborating Centre on Drug Utilization Research developed methods—including some that can be applied simply and quickly—for studying these matters, and those methods have now been used in many parts of the world (see WHO 2003). In 1989, the International Network for the Rational Use of Drugs (INRUD) was formed to bring together developing-country teams composed of decision makers in ministries of health, researchers, health care professionals, social scientists, and support groups. INRUD continues to serve as a forum for joint country-level efforts to investigate medicine-use problems, test strategies to change providers’ and consumers’ behavior with regard to specific problems, implement large-scale behavior-change efforts, and share national experiences internationally with colleagues. The International Conferences on Improving Use of Medicines (www.icium.org) in 1997 and 2004 have played a large role in the evolution of paradigms for promoting rational use of medicines.

In 2001, WHO launched the Global Strategy for Containment of Antimicrobial Resistance, which recognizes antimicrobial resistance as a global problem that must be addressed in all countries (WHO 2001b). No country,

however effective it is at containing resistance within its borders, can protect itself from the importation of resistant pathogens through travel and trade. Poor prescribing practices and irrational use in any country now threaten to undermine the potency of vital antimicrobials around the world. In addition, the U.S. Agency for International Development has recognized the critical importance of the issue and supports a variety of programs that help contain the spread of antimicrobial resistance.

The evolution of malaria treatment is an example of how irrational use has created major problems with drug resistance. During the past century, antimalarial drugs were used on a large scale, generally as monotherapies, introduced in sequence, and were used continually, despite unacceptably high levels of resistance. In addition, many people have typically sought care for malaria through the private sector—antimalarial medications are often available at retail drug outlets. Private prescribers and dispensers, however, are less likely to follow standard treatment guidelines, and patients will generally pay for and take only the medications needed to feel better—not necessarily what constitutes the recommended dose; for example, anecdotal evidence suggests that some people prescribed artemisinin-based combination therapy (ACT) take only the artemisinin-based drug because it is the one that makes them feel better, a practice that negates the purpose of taking a combination of medicines to slow the spread of drug resistance.

As discussed in [Chapter 51](#), the lack of trained health professionals in many countries makes it difficult to adequately monitor rational medicine use, especially in the case of antiretrovirals (ARVs), which patients must take for the duration of their lives. This gap in human resources makes it that much more crucial to educate patients as well as the entire community about the importance of adherence and medicine use and to explore the effectiveness of community-based interventions (see [Chapters 31](#) and [33](#)).

2.4 Global focus on AIDS, tuberculosis, and malaria

The devastation caused by the HIV/AIDS pandemic helped draw attention to the plight of people living in resource-limited areas—especially sub-Saharan Africa. The WHO’s “3x5” initiative was the first to declare a global target to provide three million people living with HIV/AIDS in low- and middle-income countries with antiretroviral therapy (ART) by the end of 2005, with the ultimate goal of making treatment accessible to all people. An additional incentive for specific action has been the establishment of the UN Millennium Development Goals; Goal 6 targets the end of the spread of HIV by 2015 and universal treatment by 2010. By 2010, however, new infections were still outstripping gains made in treatment coverage (UN 2010).

The increased interest in health care and funding for treatment in developing countries has spawned a number of significant global initiatives to address inequities and increase access to health care and essential medicines in the most-affected countries.

Large-scale funding initiatives include the following—

- *The Global Fund to Fight AIDS, Tuberculosis and Malaria* is a large multilateral funding program that approved grants for over USD 3 billion in its first two years of existence. Of that money, more than 60 percent has been distributed in Africa and almost 50 percent has gone to procure medicines and commodities.
- *The U.S. President’s Emergency Plan for AIDS Relief (PEPFAR)*, announced in 2003, made a contribution of USD 19 billion to sixteen countries—including twelve in Africa. In 2009, PEPFAR became part of the Global Health Initiative, which responds to a broad range of global health needs. In response to the evolving global HIV/AIDS situation, PEPFAR now places more emphasis on overall health systems’ strengthening and sustainability rather than emergency action.
- *UNITAID*, whose funding comes from taxes on airline tickets in six countries and from country and foundation contributions, was established to support the health-related Millennium Development Goals. UNITAID’s model is based on long-term funding commitments and the purchase of high volumes of medicines and diagnostics used to leverage price reductions. It disburses funds to international partners working in health commodities procurement, such as the William J. Clinton Health Action Initiative and UNICEF.

Prominent partnerships and initiatives include the following—

- *The AIDS Medicines and Diagnostics Service* is a network to support increased access to good quality and effective treatments for HIV/AIDS by improving supply of ARVs and diagnostics in developing countries.
- *The Stop TB Partnership’s Global Drug Facility* helps TB programs get quality-assured TB medicines at the best prices, store them properly, distribute them in a timely manner, and use them rationally.
- *The Stop TB Partnership’s Green Light Committee* works to assure access to preferentially priced second-line medicines for multidrug-resistant TB.
- *The Roll Back Malaria Partnership*, established in 1998, has a goal of achieving the malaria-specific Millennium Development Goal, which is to halt and begin to reverse the incidence of malaria, by 2015, through a coordinated global approach toward prevention and treatment, including the establishment

of the Malaria Medicines and Supplies Service, which facilitates access to affordable antimalarial medicines and commodities such as insecticide-treated mosquito nets, rapid diagnostic tests, and insecticides. Also, the Global Fund's Affordable Medicines Facility–Malaria Initiative seeks to increase access to affordable ACTs subsidies. Instituting subsidies for ACTs will allow prices to be brought into line with those of cheap, yet ineffective medicines, such as sulfadoxine-pyrimethamine, eventually driving them out of the market.

The role of advocacy groups and community-based organizations

Increased advocacy from various groups, such as multi-lateral organizations, bilateral donors, nongovernmental organizations from all levels, and civil society organizations, has resulted in pressure to change policies and push pharmaceutical issues onto national and international health care agendas. Issues highlighted by these groups include the need for new health technologies and medicines for the three diseases, such as more sensitive TB diagnostics and pediatric formulations of ARVs. The response to HIV/AIDS, in particular, put into motion an advocacy movement that has profoundly influenced issues on a global scale.

The extreme impact of the AIDS pandemic fostered a unique alliance of activists and people living with the infection acting as advocates within the community. In 1983, an advocacy group in Brazil created a nongovernmental organization to fight AIDS, a year after the first case had been diagnosed there, and more groups followed. In addition to increasing prevention and treatment in poor and remote communities, Brazilian activists are credited with assuring adequate funding for ARVs and contributing to the country's successful pricing negotiations with pharmaceutical manufacturers (Homedes and Ugalde 2006). In 1987 in New York City, the AIDS Coalition to Unleash Power (ACT UP) was formed as an activist group dedicated to influencing AIDS-related policy. ACT UP was the most visible example of how involvement at the community level and from people living with HIV/AIDS could greatly affect public policy and issues such as ARV access and affordability, demonstrating an impact that ranged far beyond the group's New York roots. Since 1998, the Treatment Action Campaign and its allies in South Africa have led a lengthy and highly visible public campaign to improve access to ART through the public health sector.

Today, organizations around the world strive to mobilize community support and action not only to improve the lives of local families touched by HIV/AIDS, but to keep AIDS issues—especially access to ARVs—high on the public agenda. For example, the International HIV/AIDS Alliance (www.aidsalliance.org), which was founded in 1993, works

with community organizations in more than forty developing countries to strengthen the local response to HIV-related disease, including building community knowledge of and demand for ART. The HIV/AIDS Alliance produces a range of resources and tools to improve the effectiveness of the community effort.

Lack of systems to support access to medicines for HIV/AIDS, TB, and malaria

As the world has responded with increased financial assistance to provide affordable medicines for HIV/AIDS, TB, and malaria, there is a growing recognition that the effectiveness of these large initiatives is limited by the capacity of health and pharmaceutical supply systems at the national and local levels. Indeed, this challenge was borne out by the findings of a UN Millennium Project task force with a mandate to combat HIV/AIDS, malaria, TB, and other diseases and improve access to essential medicines. The task force concluded that attempting to address individual diseases through global programs cannot succeed without the allocation of more resources for strengthening entire health systems, noting that “existing approaches to combating AIDS, tuberculosis, and malaria, although imperfect, are adequate to greatly reduce the effect of these three diseases. However, the woeful state of health systems in most developing countries prevents these effective interventions from reaching those in greatest need, even where resources are available . . . Reliable provision of essential drugs is a strong indicator of the effectiveness of the health system” (Ruxin et al. 2005).

Although the additional financial commitment for medicines to treat these diseases is welcomed and necessary, funding is never the only constraint and is now, often, not the major constraint. Other constraints to improving access to medicines include inadequate infrastructure in facilities such as clinics, hospitals, pharmacies, and laboratories and a lack of trained staff and equipment for those facilities.

2.5 Current organizational roles in essential medicines

Organizations that are active in the essential medicines field may be useful points of contact. Numerous organizations in the public and private sectors offer a range of experience in advocacy, in public policy development, and in education and technical assistance. Several of these organizations are discussed briefly in the following sections. Organizations (such as the World Bank, the regional development banks, the Global Fund to Fight AIDS, Tuberculosis and Malaria, and aid agencies in Europe and the United States) that primarily finance development projects, including pharmaceutical programs, are discussed in [Chapter 14](#).

WHO and other UN agencies

WHO's Department of Essential Medicines and Pharmaceutical Policies has played a leading role in promoting the essential medicines concept. WHO publishes documents on practices and methods as well as the *Essential Medicines Monitor* newsletter on current developments around the world. It convenes expert committees, holds workshops and training sessions worldwide, and has supported some country-specific pharmaceutical management programs, largely with funds provided by interested donors.

WHO's Department of Essential Medicines and Pharmaceutical Policies is also responsible for promoting pharmaceutical quality, providing information on safety and efficacy, and convening an expert committee that revises the Model List of Essential Medicines every two to three years, and now another list specifically for children's medicines. It is responsible for the quality certification scheme and good manufacturing practices standards. In addition, its prequalification program plays a major role in promoting quality medicines through evaluation and inspection activities and by building national capacity for sustainable manufacturing and quality monitoring.

Other WHO programs dealing with specific health areas, such as diarrhea, immunizations, and HIV/AIDS, have interests in essential medicines. The WHO regional offices and individual country programs often have additional technical staff in advisory positions.

The Pan American Health Organization is WHO's regional office for the Americas. Its technical pharmaceutical management staff collaborates with ministries of health, social security agencies, and other governmental and nongovernmental institutions to strengthen national and local health systems. Other regional offices, in the Eastern Mediterranean, Africa, Europe, the Western Pacific, and South East Asia, contribute to supporting and managing essential medicines activities in their regions.

UNICEF is actively involved in program and project development internationally and at the country level. Headquarters activities include technical supervision, design, and support of country-level programs ranging from large-scale procurement (through its Supply Division, based in Copenhagen) to strategies for the purchase, distribution, and use of medical supplies. In some countries, UNICEF coordinates medicine procurement and distribution for public health programs receiving Global Fund grants.

The Interagency Pharmaceutical Coordination Group includes senior pharmaceutical advisers from WHO, the World Bank, the Joint UN Programme on HIV/AIDS (UNAIDS), the UN Population Fund (UNFPA), and UNICEF. The group, which meets every six months, coordinates the pharmaceutical policies underlying their

technical advice to partner countries and plans and coordinates the preparation of interagency statements and technical documents.

In 2002, the UN Secretary-General commissioned the UN's Millennium Project to develop an action plan for the world to achieve the Millennium Development Goals, which were established in 2000. The eight Millennium Development Goals, which have a target date of 2015, range from halving extreme poverty to promoting gender equality. The goals were agreed to by the world's countries and have formed the basis for a remarkable worldwide effort to improve the lives of those living in extreme poverty. Pharmaceutical management is a prominent component in achieving several of the goals, such as reducing child mortality, improving maternal health, and combating HIV/AIDS and other diseases.

Nongovernmental organizations

Health Action International is an association of NGOs founded in 1982 "working to increase access to essential medicines and improve their rational use." HAI and local and regional affiliates, such as Acción Internacional para la Salud, are focal points for campaigns on essential medicines action by governments and UN agencies and against industry products and practices that counter the concept.

Healthy Skepticism, previously known as the Medical Lobby for Appropriate Marketing, was formed in 1983 in Australia. The organization tracks inappropriate and misleading promotion of pharmaceutical products in developed and developing countries and encourages the use of accurate and consistent information about pharmaceuticals to improve health-related decision making. The organization's AdWatch program publicizes techniques used in pharmaceutical advertising. Healthy Skepticism has been a stimulus for other groups to monitor advertising and promotion of pharmaceuticals and other medical products. It has also influenced multinational corporations to modify their promotional practices.

The International Network for the Rational Use of Drugs works through national groups representing individuals from ministries of health, universities, NGOs, and private-sector institutions to understand local medicine-use problems and create reproducible activities that improve medicine use. INRUD's interdisciplinary focus links clinical and social sciences and emphasizes the behavioral aspects of medicine use, particularly as they concern providers and consumers, the promotion of well-designed research studies, and the sharing of experiences and technical expertise among participating individuals. INRUD also promotes cooperation among donors interested in funding activities that contribute to these objectives. The INRUD secretariat at Management Sciences for Health (MSH) is the coordinating body for the country core

groups and publishes an annual newsletter, *INRUD News* (www.inrud.org).

The International Society of Drug Bulletins (ISDB) is an association of independent and official medicine information bulletins that provides the medical community with the most current information on individual medicines free from funding and the influence of the pharmaceutical industry. ISDB helps countries develop independent, unbiased medicine information bulletins and facilitates cooperation among countries in promoting independent medicine information (see [Chapter 34](#)).

Through its Center for Pharmaceutical Management, the nonprofit organization MSH is involved in pharmaceutical sector assessments and analysis, research, technical assistance, training, and publications to improve health through the rational use of medicines. MSH staff members work with international agencies and other NGOs, as well as directly with the public and private sectors in many countries. MSH produces training materials, software for pharmaceutical management, and publications such as this manual and the widely recognized *International Drug Price Information Guide*.

The International Pharmaceutical Federation (FIP) is a global organization comprised of 122 national associations of pharmacists and pharmaceutical scientists and 4,000 individual members. FIP advocates globally on behalf of the role of the pharmacist in the health care system. FIP is active in promoting good pharmacy practice and pharmacy education and gathering and disseminating important data on the profession; a key resource is the *2009 FIP Global Pharmacy Workforce and Migration Report*.

The U.S. Pharmacopeia (USP) is the official public standards-setting authority for prescription and over-the-counter medicines manufactured or sold in the United States. USP sets standards for the quality, purity, strength, and consistency of these products, which are recognized and used in more than 130 countries. USP also works in developing countries to improve pharmaceutical quality and the information available on medicines.

Médecins Sans Frontières (MSF), the humanitarian medical organization, started its Campaign for Access to Essential Medicines in 1999 to advocate for better access and lower prices of essential medicines at the local, national, and international levels. An example of MSF's work is the annual update of *Untangling the Web of Price Reductions: A Pricing Guide for the Purchase of ARVs for Developing Countries*.

As noted in [Chapter 8](#), missions and other NGOs provide a substantial portion of health care and pharmaceutical supply services in many countries. The Ecumenical Pharmaceutical Network (EPN) works to strengthen the medicine-related activities of faith-based health care organizations in Africa. At the international level, the EPN acts as an advocate for access to medicines and a clearinghouse for information.

Regulatory bodies

The International Conference of Drug Regulatory Authorities is a biennial forum of officials from national regulatory authorities. Its principal concerns include mechanisms to guard against substandard, counterfeit, and dangerous products. It also supports WHO's certification scheme and guiding principles for small regulatory authorities.

The International Conference on Harmonization (ICH) of Technical Requirements for Registration of Pharmaceuticals for Human Use is a collaborative effort by the regulatory authorities of the European Union, the United States, and Japan to harmonize technical issues related to the registration of pharmaceuticals in these countries. The conference also makes recommendations on how to achieve greater harmonization around the world in the interpretation and application of related technical guidelines and requirements. The ICH norms do not always fully reflect the needs and capabilities of developing countries; however, WHO promotes developing-country interests by serving in an observer capacity, and the ICH Global Cooperation Group works with drug regulatory authorities in nonmember countries to facilitate the harmonization process in all countries.

Industry organizations

Most countries have individual national associations that represent manufacturers, distributors, and private pharmacies. These associations are intended primarily to protect members' interests, but they provide support to selected activities, such as training, local publications, and community medicine outlets in some countries. The IFPMA is an international advocacy group formed of many national and regional pharmaceutical manufacturers' associations and companies; it prepares position papers for the industry, testifies before international organizations, acts as a public-relations resource for the industry, and occasionally undertakes educational projects, such as quality-control training for developing-country staff. The International Federation of Pharmaceutical Wholesalers plays a similar role with respect to pharmaceutical distributors.

2.6 Clients, governments, producers, and beyond: changes in the pharmaceutical field

A review of the changes in the pharmaceutical field over the last forty years may suggest that a new symmetry among its players is on the horizon; however, a look at the future suggests a continuing process of evolution.

The evolving pharmaceutical industry

As noted previously, the multinational pharmaceutical industry has become less hostile toward some national and international pharmaceutical policy initiatives in recent decades, while focusing more on intellectual property issues. One reason for the shift in industry strategy has been the declining rate of pharmaceutical product innovation. Research-based companies are less confident that they can build their future on a regular flow of innovative new medicines; regulatory authorities have more difficulty approving new medicines to be marketed in their countries; and some medicines have been withdrawn from the market because of safety issues, such as the anti-inflammatory drug Vioxx (rofecoxib). For example, although the U.S. Food and Drug Administration (FDA) approved an average of eighty-three new medicines per year between 1998 and 2002, only one-third were new chemical entities. Over that same period, the FDA granted priority review to no more than seven medicines per year that represented a treatment advance, and the only real “breakthroughs” were usually “last-ditch treatments” for rare conditions not responding to other therapy (Angell 2004). Such medicines were likely to be used only occasionally and would not provide a significant income for the innovator company. As for safety issues, of thirteen new medicines that were removed from the U.S. market for safety reasons over a decade, not one left a significant therapeutic gap (Sigelman 2002). In the case of Vioxx, estimates are that it led to between 88,000 and 139,000 heart attacks in the United States that would not otherwise have occurred (Graham et al. 2005). With fewer new medicines emerging that carry the promise of major revenues, and with the occasional safety disaster, the industry today hesitates to rely on product innovation alone to assure a robust future as much as it once did. As a result, most major pharmaceutical developers are evaluating their research and development practices and are considering changing their current development paradigm (Kaitin 2010).

Another reason for a shift in industry policy is that developed countries have become increasingly critical of pharmaceutical prices and expenditure. Many countries have imposed rigid price controls on medicines or limits on the permitted cost of a course of treatment or instituted other interventions to control medicine prices (see [Chapter 9](#) on pharmaceutical pricing policies). Pharmaceutical companies now must not only persuade doctors to prescribe their products but also convince critical therapeutics committees and pharmacy benefit managers that their medicines are sufficiently cost-effective to merit a place in treatment manuals and reimbursement lists—examples of the principle of essential medicines in practice.

New industry attitudes have also come as a result of structural changes in the pharmaceutical industry itself. Seeking to develop new business models to compensate for

market obstacles in industrialized countries, many companies have entered once unfamiliar areas; for example, some research-based companies have started (or restarted) producing generic medicines, either by diversifying their own activities or by acquiring established generic manufacturers.

Intellectual property laws

The issue of access to medicines for HIV/AIDS, TB, and malaria has had an impact on international trade activities. Activists working to improve affordability of ARVs in developing countries first highlighted the negative implications of the World Trade Organization’s Agreement on Trade-Related Aspects of Intellectual Property Rights (TRIPS) for access to essential medicines in developing countries, resulting in the development of the Doha Declaration, which addresses the right of all countries to protect the health of their citizens (see [Chapter 3](#)).

The TRIPS agreement may make it difficult for resource-limited countries to get access to new medicines at affordable prices. Although certain flexibilities were included in the agreement to help countries circumvent the intellectual property restrictions and accommodate their public health needs, without the necessary technical expertise, countries have found it difficult to interpret the laws and implement the appropriate policy mechanisms; however, governments are addressing this issue. For example, the regional group representing countries of East, Central, and Southern Africa created a model national pharmaceutical policy that addresses ways for member countries to incorporate these flexibilities into their policies.

Public-private pharmaceutical initiatives

For a long time, the private and public pharmaceutical sectors worked in relative isolation from each another; contact was formal, critical, and sometimes hostile. In the final years of the twentieth century, however, a number of international public-private partnerships were developed to create positive and innovative collaboration in research, development, and distribution, especially in serving the needs of developing countries. Promising advances are emerging, particularly through initiatives under the auspices of the United Nations and its specialized agencies, such as WHO. Examples include the Global Alliance for TB Drug Development and the Medicines for Malaria Venture. More time is needed to determine the long-term value of these partnerships, but increasing evidence suggests that such public-private initiatives can be productive.

Globalization and the Internet

No more than fifty years ago, the world remained rigidly divided into nation-states, each with its own specific

approach to its own specific problems; however, the process of globalization has quickly broken down that compartmentalization. Many companies now operate worldwide, developing policies and conducting activities that can only partially be controlled by national governments; in fact, some corporations have greater financial resources than many of the governments with which they do business.

The Internet is an example of a worldwide activity that largely escapes national control. On the one hand, the Internet allows users to circumvent undesirable practices such as government censorship, but on the other hand, it facilitates activities that hurt society at large, for example, the dishonest advertising and sale of ineffective and dangerous medicines. Drug regulatory authorities and others have been working to address the issue of pharmaceuticals being sold through the Internet, as well as on ways to increase access to reliable information through the Internet (for example, see WHO/IMPACT 2009; WHO 2001a, 2002).

Ongoing policy changes

The changes in the political and economic environment discussed in this chapter mean that pharmaceutical management must also adapt to new opportunities and challenges.

Of the tools and concepts described throughout *MDS-3*, some originated in industrialized countries, others in the developing world, and others in the international community. Many have outgrown their origins, and the ideas and experiences are increasingly becoming common ground for solving important pharmaceutical management issues throughout the world while continuing to evolve as that world changes.

Although death and disability are always tragic, the rationale for national concern and action on essential medicines is driven by the large gap remaining between what we know and what we do. We know how medicines can help eliminate unnecessary and preventable deaths and disability, yet millions continue to die of TB, which is essentially curable with medical therapy. People living with HIV/AIDS can now extend their lives with ARV medicines, but more than half of those in need of treatment do not have access (UNAIDS 2009). Malaria, pneumonia, diarrhea, and hypertension are manageable with basic medicines, yet they continue to kill millions. Children are born unwanted and into poverty merely because low-cost family-planning supplies are unavailable.

The clear public health challenge is to continue to lead public policy makers and managers toward a consistent approach to essential medicines. The primary activity is to identify and attack the major problems that are amenable to solution with available resources. The strategies of many national pharmaceutical programs in less advantaged nations, and increasingly among decision makers in more-

advantaged settings, are converging: first, to ensure that the basic medicines that save lives and improve health are available to all; second, to ensure that they are used appropriately; and third, to logically deal with the many medicines that are not essential to public health, but may play a limited or specialized role in health care. ■

SUMMARY

In an era of increasingly globalized trade, pharmaceutical patents play a key role in the availability and affordability of medicines, as shown by the conflict over access to anti-retroviral medicines for people living with HIV/AIDS in resource-limited countries. Patent protection can also be a contentious issue in high-income countries, when high medicine prices impede access to effective treatment.

Governments grant intellectual property rights as an incentive to produce inventions that will benefit society as a whole. The varied extent of protection and enforcement of these around the world became a source of tension in international economic relations, leading to international negotiations within the World Trade Organization (WTO). These negotiations resulted in the Agreement on Trade-Related Aspects of Intellectual Property Rights (TRIPS), which is a set of trade rules meant to introduce a global system to monitor and enforce the protection of intellectual property rights among WTO members.

TRIPS covers five essential issues—

- How to apply basic principles of the trading system and other international intellectual property agreements
- How to give adequate protection to intellectual property rights
- How to enforce such rights adequately in a country's own territories
- How to settle disputes on intellectual property among members of the WTO
- What special transitional arrangements to apply during the period when the new system is being introduced

Developing countries expressed concerns regarding the possible effect of TRIPS, including the following—

- TRIPS treats medicines like any other commodity, but medicines are not ordinary consumer products.
- Prices will likely be higher for new medicines in countries with no previous patent protection.
- Generic competition will be delayed in countries with a previous patent term less than twenty years.
- The local pharmaceutical industry could be weakened, and dependence on developed countries may increase.
- TRIPS may not improve research and development (R&D) decisions regarding treatments for the diseases common in poor countries.

The minimum standards required by TRIPS resulted in developing countries losing some capacity to regulate pharmaceutical patents and control the cost of medicines; however, the agreement left some flexibility for them to take measures to protect public health. Because the provisions relating to patents and pharmaceutical regulation are confusing and contentious, regulators must acquire the relevant technical expertise to use these flexibilities within TRIPS to improve access to medicines.

The international rules regarding intellectual property are evolving quickly. Developing countries must actively participate in discussions of the future of the intellectual property system to ensure its appropriateness for countries at very different levels of development. As the rules evolve, their impact must be properly understood if policies are to be based on relevant evidence.

3.1 The global pharmaceutical market

The international trade in pharmaceuticals has expanded dramatically since 1980. During the 1990s, trade grew substantially faster than production. High-income industrialized countries used to dominate international trade in pharmaceuticals. In 1999, they accounted for 93 percent of global exports by value. Between 1980 and 1999, middle-income countries' share of world exports fell, while the export share of some low-income countries, such as India, Pakistan, and Indonesia, more than doubled, from 1.1 percent to 2.9 percent. High-income countries also dominated imports. During the same period, their shares increased, and the shares of both low- and middle-income countries in world imports dropped significantly (WHO 2004).

With the exception of Japan, the countries that contribute most to world trade are also the world's major producers: the United States, the United Kingdom, Germany, and France. Japan, the world's second-largest producer, continues to produce primarily for its domestic market.

Sales figures by value from 2005 indicate that North America, Japan, and Europe accounted for almost 90 percent of the world's pharmaceutical purchases (IMS Health 2006). So although sub-Saharan Africa, for example, represents a huge proportion of the disease burden relative to the rest of the world, its global pharmaceutical market share is only 1 to 2 percent (Scheffler and Pathania 2005; CIPIH 2006), which generally makes it an unattractive target market for manufacturers. However, the number of emerging pharmaceutical markets increased from seven in 2006

to seventeen in 2010, with China expected to become the third-largest market by 2011—up from eighth-largest in 2006 (Campbell and Chui 2010).

Categories of pharmaceuticals

The world pharmaceutical market consists of several categories, characterized by different degrees of market competition. Innovative pharmaceutical products that are patented (*original brands*) are protected from competition for the life of the patent in the countries that recognize the patent. Legal competition is limited to medicines that are *therapeutically equivalent* (used to treat the same clinical indication) but that have either a different composition or a different manufacturing process from the original brand. At the other end of the spectrum are pharmaceuticals known as *generics*. Generally, generic pharmaceutical products are the chemical equivalent of the original brand product that are usually manufactured without a license from the originator company. This large category includes pharmaceuticals whose patents or other exclusivity rights have expired, pharmaceuticals that have never been patented, and copies of patented pharmaceuticals in countries where the drug is not patented or where a compulsory license has been granted (see Section 3.2). The legality of copying patented products depends on the manufacturing country's patent legislation.

Generic medicines are usually sold under their generic names and may be manufactured and marketed by many companies. This market is highly price competitive because buyers can choose among several sources of chemically identical medicines. On the manufacturing side, the distinction between originator companies and generics manufacturers is often blurred. In some cases, major research-based international companies have generics manufacturing subsidiaries producing “branded generics.” For some medicines, these products account for a large share of the world's market in generics.

Another category comprises traditional or complementary medicine, which includes herbal medications. The use of herbal products has increased, especially in developed countries; however, regulation governing the quality, sale, and use of such medicines varies widely. Countries are recognizing the large role that traditional medicine plays in health care, and more countries are addressing the challenges of including traditional medicine in national health policy, including protecting indigenous knowledge and applying intellectual property rights. [Chapter 5](#) discusses traditional and complementary medicines.

Role of patents in the pharmaceutical sector

In an era of increasingly globalized trade, pharmaceutical product patents play a key role in the availability and affordability of medicines, as shown by the conflict over access to

antiretroviral medicines for people living with HIV/AIDS in resource-limited countries. Patent protection can also be a contentious issue in high-income countries, when high prices for branded medicines impede access to effective treatment.

A *patent* is an exclusive right that a government gives to an inventor, preventing others from making, using, offering to sell, selling, or importing an invention or inventive process for a defined period. The patent does not give an inventor the right to make, use, or sell the invention. The inventor may have to comply with other laws and regulations to make use of the claimed invention. For example, a pharmaceutical company may obtain a patent on a new medicine, but it will be unable to market the medicine in a country without the government's regulatory approval.

The patent gives the inventor the opportunity to recoup his or her investment in R&D in exchange for publicly disclosing the underlying information about the invention. The concept behind patenting medicines is that the exclusive marketing rights provided by a patent allow high prices during the patent term, which generate profits that fund the R&D necessary to create and bring new pharmaceutical products to the market. Therefore, patients who buy patented pharmaceuticals (or their employers, their insurers, or their governments) pay a premium that is in theory designed to support the research process. When a patent expires, generic products enter the market and force prices down through competition.

One of the functions of a patent is to serve as a financial incentive for creators of inventions that benefit society (CIPIH 2006). However, people living in developing countries and their governments have little purchasing power, which removes real incentive to the global private sector to invest in developing medicines that treat diseases endemic in developing countries—also known as tropical and neglected diseases. Section 3.5 discusses R&D issues.

Developing countries and nongovernmental organizations have argued that patents on pharmaceuticals in the developing world raise prices and thereby reduce access to lifesaving treatment. In contrast, the research-based pharmaceutical industry and many developed countries have argued that the larger problem in resource-limited countries is an insufficient health service infrastructure.

3.2 Globalization of intellectual property standards and access to medicines

Ideas and knowledge are increasingly important parts of trade. Most of the value of new medicines and other high-technology products lies in the amount of invention, innovation, research, design, and testing involved. Creators can be given the right to prevent others from using their inventions, designs, or other creations—and to use that right to

negotiate payment in return from others using such intellectual property rights. These intellectual property rights, which include not only patents but also copyrights and trademarks, reward the results of innovation and creativity in many areas, including music, science, and authorship.

Governments give creators intellectual property rights as incentive to produce inventions that will benefit society as a whole. The extent of protection and enforcement of these rights varied widely around the world, and as the focus on intellectual property in trade intensified, these differences became a source of tension in international economic relations. New, internationally agreed-upon trade rules for intellectual property rights were viewed as a way to introduce more order and predictability and to settle disputes more systematically.

History and evolution of intellectual property rights for pharmaceuticals

Intellectual property rights were important to chemical firms in nineteenth-century Europe and to U.S. and European pharmaceutical companies in the twentieth century. Because these companies particularly wanted patent protection, they began lobbying governments on the design of such protection. Large companies focused more

and more on the use of intellectual property rights as part of their business strategy, which gave them an increasingly greater incentive to influence how such rights evolved.

World Trade Organization agreements. In the 1980s, this context gave rise to collaboration among U.S., European, and Japanese companies, including pharmaceutical and chemical companies, in campaigning for the inclusion of an agreement on intellectual property rights in the WTO's Uruguay Round of Multilateral Trade Negotiations. (See [Box 3-1](#) for information on the WTO.) Those negotiations produced the Agreement on Trade-Related Aspects of Intellectual Property Rights and the Agreement on Technical Barriers to Trade. From its origin in 1989 until it was finalized in 1994, TRIPS evolved into a detailed international agreement containing industrialized-country standards of intellectual property protection, requiring multilateral trade negotiations among all WTO members. The Agreement on Technical Barriers to Trade seeks to ensure that technical standards, testing, and certification procedures do not create unnecessary obstacles to trade. This agreement can affect the development of production capabilities in developing countries by affecting their ability to export.

WTO agreements, including TRIPS, are treaties that create international obligations among the members. TRIPS

Box 3-1 World Trade Organization

The World Trade Organization (WTO) is the international organization that deals with the rules of trade between nations at a global or near-global level. At the center of the organization are the agreements that the members comprising the majority of the world's trading countries or customs unions (158 members as of July 2008) negotiate and sign. These agreements provide the legal ground rules for international commerce. WTO membership requires nations to adopt the terms of the twenty-six existing agreements and mandates that members' national laws conform to the global standards. The content of the WTO's twenty-six agreements covers many aspects of national law related to trade in goods, services, and intellectual property.

The majority of the WTO's current agreements come from the 1986–94 negotiations called the Uruguay Round and earlier negotiations under the General Agreement on Tariffs and Trade. Although difficult to achieve with so many diverging points of view, the WTO generally makes decisions based on member consensus. The highest decision-making authority within the WTO is the Ministerial Conference, composed of members'

ministers of trade, who meet at least once every two years to negotiate any matter under any of the multilateral trade agreements. Other meetings involving various committees, working groups, and special sessions occur between full meetings. The Council for Trade-Related Aspects of Intellectual Property Rights, which deals with TRIPS-related issues, reports directly to the WTO General Council. The World Health Organization (WHO) has an observer-status seat on the TRIPS council.

The WTO is unique as an international organization in that it has a dispute settlement body, the decisions of which are final and binding on members. This capacity gives the WTO the power to enforce trade rules.

Because many of the agreements have important implications for public health, WHO has established a new department called Trade, Foreign Policy, Diplomacy, and Health to promote greater policy coherence between trade and health policy, so that international trade and trade rules maximize health benefits and minimize health risks, especially for poor and vulnerable populations.

introduced intellectual property rules into the multilateral trading system for the first time and attempted to narrow the gaps in the way these rights are protected around the world and to bring them under common international rules. Consequently, TRIPS globalizes a set of intellectual property principles and harmonizes intellectual property regulation by establishing minimum levels of protection that each government has to give to the intellectual property of other WTO members. To the chemical and pharmaceutical companies that had been promoting it, TRIPS was a major step in the globalization of standards of protection for patents, copyrights, trade secrets, and trademarks.

Previously, patenting essential public goods such as medicines and food was considered contrary to the public interest. When the WTO launched the Uruguay Round of trade negotiations in 1986, more than fifty countries were not granting product patents on pharmaceuticals. After TRIPS, all WTO member countries had to reform their domestic intellectual property laws to conform to the new obligations of the agreement.

Many questions arose regarding the (mainly developing) countries that seemingly had little to gain by agreeing to these terms of trade. Lacking intellectual property experts in their WTO delegations, most developing states did not have a clear understanding of the ramifications of the TRIPS negotiations. Some countries were interested in agreeing to TRIPS in exchange for concessions that would expand their exports of agricultural or textile products. However, because TRIPS required countries to recognize patents on pharmaceutical products—often for the first time—it had implications for both the cost of patented medicines and the long-term outlook of the generics industries in those countries. In addition, TRIPS covers many more issues relevant to public health, including traditional medicines, biotechnology, genetic materials, medical devices, and technology transfer.

The Doha Declaration. Although one of TRIPS' stated goals was to reduce tensions arising from intellectual property protection, patent protection for pharmaceuticals and its effects on public health—and particularly access to medicines—has remained a highly controversial issue. Debate in developing countries reflected growing concerns about the implications of TRIPS regarding access to medicines, which were seen as signs of the conflict between the recognition of intellectual property rights and essential public health objectives.

Developing countries expressed concerns regarding TRIPS' possible effect that included the following—

- TRIPS treats medicines like any other commodity, but medicines are not ordinary consumer products.
- Prices will likely be higher for new medicines in countries with no previous patent protection.

- Generic competition will be delayed in countries with previous patent terms less than twenty years.
- The local pharmaceutical industry could be weakened, and dependence on developed countries may increase.
- TRIPS may not improve R&D decisions regarding treatments for the diseases common in poor countries.

The medicine access issue and related advocacy resulted in the Declaration on TRIPS and Public Health at the WTO Ministerial Conference in Doha in November 2001. The Doha Declaration, as it is known, affirms the right of developing countries to protect the health of their populations, declaring that TRIPS “can and should be interpreted and implemented in a manner supportive of WTO members' right to protect public health and, in particular, to promote access to medicines for all.” The right to health is embedded in international, regional, and national human rights instruments, including the constitution of WHO, the United Nations Universal Declaration of Human Rights, and various national constitutions.

Despite initial resistance by some developed countries, the Doha Declaration was adopted by consensus. It is one of the important benchmarks in trade history, because it is regarded as elevating public health above trade with respect to national intellectual property law. In addition, the Doha Declaration resulted from the success of civil society in focusing attention on these issues and from developing countries' solidarity in standing up collectively for their concerns about the intellectual property regime under TRIPS.

The Doha Declaration was not intended to amend TRIPS. Rather, it aims to clarify the relationship between TRIPS and public health policies of WTO member countries and to confirm the rights retained under the agreement, particularly by defining the flexibility allowed in certain key policy areas. The declaration can make it easier for developing countries to adopt measures necessary to ensure access to health care without the fear of legal consequences. However, the Doha Declaration is not self-executing, and countries therefore need to make the legal amendments necessary to implement it. Developing countries in particular should be encouraged (and provided the relevant technical assistance) to review their legislation to ensure that they incorporate into national laws any flexibilities allowed by TRIPS to address public health concerns.

Key concepts related to TRIPS

TRIPS covers five essential issues—

- How to apply basic principles of the trading system and other international intellectual property agreements
- How to give adequate protection to intellectual property rights

- How to enforce those rights adequately in a country's own territories
- How to settle disputes on intellectual property among members of the WTO
- What special transitional arrangements to apply during the period when the new system is being introduced

TRIPS includes an enforcement mechanism through economic sanctions for countries that fail to comply with the minimum standards for protecting intellectual property rights. When intellectual property disputes between countries arise because of differences in the interpretation of TRIPS, the WTO provides a dispute settlement process that includes negotiation, dispute settlement decision making, and an appeal process. Trade sanctions may be imposed only if the dispute settlement process has run its course and the losing country has failed to comply with the decision.

As mentioned, TRIPS introduced minimum standards for protecting and enforcing nearly all forms of intellectual property rights, including those for pharmaceuticals. As a minimum-standards agreement, however, TRIPS allows members to protect intellectual property more extensively if they choose. Members are free to determine how best to implement the provisions of the agreement within their own legal system and practice (see Correa 2000). The key concepts for pharmaceuticals are described in the following subsections.

Patent protection. Under TRIPS, member countries must provide patent protection for a minimum of twenty years from the filing date of a patent application for any pharmaceutical product or process that fulfills the criteria of novelty, inventiveness, and usefulness. National legislation and practices define what can be patented, and countries must establish their own criteria for what constitutes a “new” and “inventive” product.

Countries should recognize that patentability standards that are too broad can contribute to extending the patent life of a new medicine through designating new or inventive uses as described above or different dosages. This practice is called *evergreening*. To limit this extension of rights to original patent holders, national patent legislation needs to ensure that public health needs are taken into account. Similarly, incremental innovation, or “me-too” drugs, is within the same chemical class as one or more other pharmaceutical products already on the market; however, the pharmaceutical industry feels that me-too drugs advance safety and efficacy and support the development of novel products (Wertheimer and Santella 2009).

Transitional arrangements. TRIPS provides transitional periods during which countries must bring their national legislation and practices into conformity with its provisions. The compliance dates for WTO members were 1996 for developed countries; 2000 for developing countries;

2005 for developing countries that had not introduced patents for pharmaceuticals before joining the WTO, such as India; and 2016 (for medicines only) and July 2013 for least-developed countries (LDCs) in recognition of these countries' economic, financial, administrative, and technological constraints to conforming.

Generic medicines. After a patent expires (or a license is issued), copies of a medicine can legally be made. These are called multisource medicines—or generics—and should be chemically equivalent to the original brand medicine. Promoting generic medicines within a country requires appropriate legislation and regulations, reliable quality-assurance capacity, professional and public acceptance of generic medicines, and economic incentives and information for both prescribers and consumers.

Under the TRIPS regime, a different manufacturing process for a chemically equivalent pharmaceutical product would be blocked if the originator company still held a product patent on the chemical entity. Currently, a different chemical entity may pose therapeutic competition to an existing medicine, and a different company may hold such a patent. In some cases, however, an originator company will place a patent not only on the chemical entities in the ingredients, but also on the resulting metabolite that produces the desirable therapeutic effect (Correa 2000). Such metabolite patents may block pharmaceuticals in the same therapeutic category if they share a common metabolic pathway.

Trade liberalization can increase competition and reduce prices for generic medicines that are already on the market. But inappropriately implementing TRIPS-compliant national legislation can delay new generic products, which can result in large economic costs. The prompt introduction of generic medicines can be facilitated by drafting appropriate legislation and regulations on patentability, such as using exceptions to permit early testing and approval of generics and compulsory licensing (see following subsections).

As an alternative to promoting generics, some brand-name pharmaceutical manufacturers have volunteered to lower their prices in certain markets (for example, selling certain medicines in developing countries at greatly reduced prices compared to prices in major markets); however, such programs usually feature multiple restrictions. Some companies have gone further by donating medicines for particular programs (see [Chapter 15](#)).

Compulsory licensing (TRIPS Article 31). As a provision of TRIPS, compulsory licensing occurs when a government authorizes the production of a patented product or the use of a patented process without the patent holder's consent as long as certain conditions are met, such as the license being used predominantly (that is, 51 percent) for the domestic market. The patent holder, however, retains intellectual property rights and “shall be paid adequate

remuneration” according to the circumstances. In other words, compulsory licensing allows local manufacturers in resource-limited countries to make close-to-marginal-cost versions of patented medicines to address public health needs, if they give a royalty payment to the patent holder. Generally, the grant of a compulsory license requires prior negotiation with the patent holder. However, grounds for governments to grant compulsory licenses without any previous negotiation may include public interest, national emergencies such as epidemics, public noncommercial use, or remedying anticompetitive practices.

In the pharmaceutical sector, compulsory licenses have been used to stimulate price-lowering competition and to ensure the availability of needed medicines. For example, if a new product introduced to the market were to play an important role in public health, such as a vaccine against HIV/AIDS or malaria, a country’s national law could grant a compulsory license under Article 31 of TRIPS. Compulsory licensing, however, is not always a solution for resource-limited countries. For instance, when prior authorization from the patent owner is required, as is the normal case, negotiations can be lengthy and complicated, and a country may not have the necessary legal expertise. In addition, the manufacturing process for a pharmaceutical product may be protected under a separate patent or as a trade secret. Finally, countries may lack the technical expertise or facilities necessary to copy and manufacture the product or to attain the economies of scale that make such a decision feasible (see [Chapter 7](#) on production policy).

Despite the constraints, a country’s comprehensive patent legislation should adequately provide for granting compulsory licenses to strengthen its position, even if the country rarely uses the provision. Now, most developed countries and many developing countries include compulsory licensing in their national legislation; for example, in 2010, Colombia successfully used the threat of compulsory licensing to reduce by two-thirds the price of Kaletra, an antiretroviral, while the United States has used the threat to mitigate anticompetitive situations.

[Figure 3-1](#) shows the exact text from a compulsory license granted in Zambia in 2004.

Voluntary licensing (TRIPS Article 40). A voluntary license is an agreement negotiated between the patent holder and another company for manufacturing and marketing. TRIPS Article 40 authorizes the regulation of anticompetitive features of voluntary licenses. Regulation could favor export and regional production, nonexclusivity, technology-transfer requirements, access to confidential test data, and disclosure of reasonable royalty rates. Usually, efforts must first be made to obtain a voluntary license on reasonable terms and conditions before a party obtains a compulsory license (see [Country Study 3-1](#)).

Parallel importation (TRIPS Article 6). Parallel importation occurs when a third party, without the consent of the

patent holder, imports a medicine that has already been put on the market abroad more cheaply by the patent holder or a licensee. The practice is based on the principle that the patent holder has been compensated through the first sale of the product and that further control over the resale of the product would unreasonably restrain trade and competition. In other words, having been paid, the patent holders are said to have “exhausted” their rights. If the importing country’s patent system provides that the patent holder’s right has been exhausted when the patented product has been placed on the market in another country, the patent holder cannot prevent parallel importation into the importing country. TRIPS permits WTO members to determine their own rules regarding exhaustion—international exhaustion permits parallel trade and may permit importation of a medicine produced under compulsory license in another country.

Because most pharmaceutical companies set prices for the same products at different levels in different countries, parallel importation promotes competition for the patented product by allowing the importation of equivalent patented products marketed at lower prices in other countries. However, companies have been pressuring governments not to import medicines from countries that produce generic versions, claiming that the practice is a breach of the TRIPS agreement. Article 6 of TRIPS explicitly states that practices relating to parallel importation cannot be challenged under the WTO dispute settlement system, provided that no discrimination exists on the basis of the nationality of the persons involved; however, preexisting or new “TRIPS-plus” legislation (see below) often specifies national exhaustion. Here, the patent holder has exclusive marketing rights, and resale is permitted only within the country after first sale. Preferential pricing offers are frequently linked to the prevention of parallel importation between developing and developed markets.

Exceptions to rights conferred (including Bolar exception) (TRIPS Article 30). TRIPS specifies the rights given to a patent owner but allows limited exceptions, subject to specified conditions in Article 30. Of particular interest regarding access to medicines is the so-called Bolar exception to patent rights that allows a country to complete all of the procedures and tests that are necessary to register a generic product before the patent expires on the original medicine. Allowing generics manufacturers to conduct the tests needed to prepare their applications for regulatory approval during the term of the patent enables them either to market their products immediately upon expiration of the patent or, for example, to apply for a compulsory license during the term of the patent.

Protection of undisclosed test data (TRIPS Article 39.3). In many countries, national regulatory agencies require originator pharmaceutical companies to submit extensive data showing the safety and efficacy of a new product before it is approved for the market. These data

Figure 3-1 Compulsory license granted in Zambia

Republic of Zambia
MINISTRY OF COMMERCE, TRADE AND INDUSTRY

The Government of Zambia, conscious that the HIV/AIDS pandemic constituted a serious handicap in the national struggle against hunger, illness, under development and misery;

and taking into consideration that high rates of morbidity and mortality have put Zambia among the ten countries in Africa most hit by this disease. Current estimates are that, at the end of 2003, over **917,718** Zambians were infected by HIV of whom an unestimated number are suffering from full-blown AIDS. The AIDS death toll is so far in excess of **835,904** and about **750,504** children have been orphaned by this pandemic, creating a situation where 75% of households in Zambia are caring for at least one orphan and that children aged below 14 years headed more than 130,000 poverty stricken households out of a total of 1,905,000, and that;

in spite of the multiplicity and diversity of vigorous prevention campaigns, the spread of the virus is still on an upward trend as shown by the high number of infections;

Taking into account the gravity of the situation being faced by most African Countries, including Zambia, the need to ensure access to drugs at affordable prices, while respecting the protection of intellectual property, is well recognised. For this reason;

On 14 November, 2001 the World Trade Organisation, while recognising Members' commitment to the TRIPS Agreement, declared the right of each Member State to take measures aimed at protecting public health and in particular to promote access to medicines for all, by utilising to the full, the flexibilities in the TRIPS Agreement relating to among others, the granting of compulsory licences, in cases which constitute a national emergency or other circumstances of extreme urgency and of public health crisis including those relating to HIV/AIDS, tuberculosis, malaria or other epidemics which can represent a national emergency or other circumstances of extreme urgency.

Considering further that;

A triple compound of Lamivudine, Stavudine and Nevirapine has proved, in the last few years to be one of the most effective and economical anti-retroviral treatment, but that the three different international owners of such single drugs failed to reach an agreement to produce this combination, and therefore;

The Ministry of Commerce, Trade and Industry of the Republic of Zambia making use of the provisions of Section forty of the Patent Act, Chapter 400 of the Laws of Zambia, and Statutory Instrument No 83 of 2004 titled "The Patents (Manufacture of Patented Antiretroviral Drugs) (Authorisation) Regulations, 2004" Regulation 3, has decided to grant a Compulsory Licence No. CL 01/2004 to PHARCO LTD, a company incorporated in Zambia, which has already presented a project proposal for the local manufacture of the mentioned triple compound under the names of Normavir 30 and Normavir 40.

It is further understood that the use or vending of the above mentioned drugs is subject to Regulation 4 of Statutory Instrument No 83 of 2004, titled "The Patents (Manufacture of Patented Antiretroviral Drugs) (Authorisation) Regulations, 2004" and therefore cannot be exported to any place outside Zambia.

Communication of this decision will be given to the applicant and to the patent right holders.

In consideration that the mentioned product, a triple combination of drugs, is not marketed in Zambia by the International Patent owners and that it is in the national interest to keep the final price as low as possible, the total amount of royalties due to the patent right owners shall not exceed 2.5% of the total turnover of the mentioned products at the end of each financial year of PHARCO LTD.

The Ministry of Commerce, Trade and Industry shall in accordance with Section forty one of the Patent Act notify the concerned parties of the expiration of the present Compulsory Licence as soon as conditions of national emergency and extreme urgency created by the HIV/AIDS pandemic will come to an end, or upon expiry of the period of emergency stipulated in Statutory Instrument No 83 of 2004 titled "The Patents (Manufacture of Patented Antiretroviral Drugs) (Authorisation) Regulations 2004."

The Government of the Republic of Zambia reserves the right to review the Compulsory Licence should the conditions and circumstances under which it is granted change.

Country Study 3-1**Using voluntary licenses in sub-Saharan Africa to produce antiretroviral medicines**

A number of companies in Africa have obtained voluntary licenses from originator pharmaceutical producers (in some cases through advocacy efforts) to locally manufacture antiretroviral medicines for HIV/AIDS. South Africa led the way with several generics pharmaceutical companies receiving voluntary licenses from patent holders of antiretroviral medicines. Aspen Pharmacare, which is South Africa's largest pharmaceutical manufacturer, and Cipla Medpro are two of the companies that secured the rights to distribute generic HIV/AIDS medicines to other countries in sub-Saharan Africa. Voluntary licenses from several different patent holders allow the generics companies to produce medications that combine multiple products into one tablet (fixed-dose combination), which helps patients adhere to treatment. In addition, the U.S. Food and

Drug Administration qualified Aspen Pharmacare, which allowed U.S.-government-funded organizations in Africa to purchase generic antiretrovirals for the first time.

In Kenya, Cosmos Limited was the first producer to receive voluntary licenses from GlaxoSmithKline and Boehringer Ingelheim to produce generic versions of lamivudine, zidovudine, and nevirapine. One of the benefits of producing the products locally is that the packaging will include instructions printed in both English and Kiswahili, but more important, the supply and availability should become more reliable, and prices are expected to fall. As part of the voluntary licensing agreements, Cosmos will be able to sell the generic medicines to five other sub-Saharan countries.

are the result of many years of research and are sometimes very expensive for the originator company to produce. Sometimes, such as in the case of the cancer medicine paclitaxel, a government has underwritten much of the product's R&D. In addition, a multinational company may simply acquire the innovation from an academic institution or biotechnology company.

TRIPS Article 39.3 obliges member countries to protect this confidential test data from "unfair commercial use" including disclosure, except where necessary to protect the public. Countries vary in how they implement the requirements of Article 39.3. Whereas some countries permit pharmaceutical regulatory authorities to rely on the original test data to register generic equivalents, others, such as the United States and European Union countries, grant the originator company a time-limited period that excludes regulatory authorities from using existing test data to register generic products without consent. These laws are known as data exclusivity laws.

The originator company is unlikely to consent to its data being used to register a generic equivalent to its product, and although generic competitors could replicate clinical trials at considerable cost, another significant barrier relates to the ethics of conducting redundant trials on patients. Therefore, data exclusivity laws provide a form of market protection for the originator company.

Consequently, controversy exists about how Article 39.3 should be implemented to ensure the protection of public health. The disagreement centers on whether the phrase "unfair commercial use" means that regulatory agencies can use original data to assess generic product applications,

as long as they do not disclose the data to the competitor. This interpretation would imply that Article 39.3 does not require data exclusivity. On the contrary, the research-based pharmaceutical industry and some trade representatives have argued for the alternative interpretation that Article 39.3 does require data exclusivity.

Exclusive marketing rights (TRIPS Article 70.9). As noted, when TRIPS was launched in 1996, many countries did not offer patents for pharmaceutical products. These countries were given a transition period to phase in patent protection for pharmaceuticals. However, TRIPS Article 70.9 says these countries have to accept patent applications for pharmaceuticals, even though they are not obligated to examine the applications or grant any patents until the end of the transition period.

In cases where the country takes advantage of the transition period, Article 70.9 requires that when a patent application has been filed for a product in that country, the WTO member must grant exclusive marketing rights to the patent applicant for a period of five years after obtaining marketing approval, as long as the product has been patented and received marketing approval in another WTO member country. The rights can expire before the end of the five years if either a patent is granted (in which case the patent holder would rely on the patent instead of the exclusive marketing rights) or the patent application is rejected. Exclusive marketing rights, therefore, are considered a mechanism for the patent applicant to obtain payment for use of the product until the patent is granted.

Least-developed countries have been granted a waiver to Article 70.9—extending the transition period until 2016.

Decision on the implementation of paragraph 6 of the Doha Declaration. Although developing countries have the right to exercise the flexibilities under TRIPS, they often find using these flexibilities in public health policy a challenge. For example, paragraph 6 of the Doha Declaration recognized that while developing countries can issue compulsory licenses, TRIPS did not take into account the difficulties they faced because of a lack of manufacturing capacity. Many developing countries and LDCs cannot produce either active ingredients or formulations because of lack of technology, equipment, human resources, or other domestic production capacity. Although these countries may issue compulsory licenses to import generic versions of patent-protected medicines, TRIPS rules constrain the ability of countries that do have the capacity to manufacture generics, such as India, to export such products. Manufacture must be primarily for the domestic market. Therefore, countries without sufficient manufacturing capacity in pharmaceuticals could issue a compulsory license for the importation of products they cannot manufacture, but they may not be able to find sources for importing affordable new medicines.

Consequently, after the adoption of the Doha Declaration, WTO members spent almost two years in negotiations that culminated in the Decision on Implementation of Paragraph 6. That decision is intended to permit all LDCs (as designated by the United Nations) and developing countries with insufficient or no manufacturing capacity to import a particular medicine to make effective use of compulsory licensing. The Paragraph 6 Decision allows nonproducing countries to issue a compulsory license to import medicines in accordance with a special compulsory license for export issued in the exporting country. However, making use of this flexibility is a complex process, and both importing and exporting countries will need to pass the legislation to make it possible.

The terms of the Doha decision were made a permanent feature of TRIPS through an amendment including a new article, 31*bis*. Essentially, the Paragraph 6 Decision and the amendment eliminate the requirement that pharmaceutical products manufactured under a compulsory license be “predominantly for the supply of the domestic market.” In addition, to prevent duplicating payment to the patent holder, the amendment eliminates the need to remunerate the patent holder in the importing country if the patent holder in the exporting country has already been remunerated.

A publication from WHO gives more information on how countries can implement the Paragraph 6 Decision (Correa 2004).

Decision on the implementation of paragraph 7 of the Doha Declaration. Paragraph 7 permits LDCs to extend the transition period for pharmaceutical patents beyond what is defined in TRIPS to the year 2016. Part of the moti-

vation for paragraph 7 concerns the rights of LDCs to promote technology transfer by giving them additional time to build a technological base for their pharmaceutical sectors. In addition, Article 66.2 seeks to provide benefits specific to LDCs by requiring developed countries to offer incentives to private companies and other institutions in their territories to engage in technology-transfer activities.

Practically, however, the only LDCs that can take advantage of the extension in paragraph 7 are those that do not grant patents for pharmaceuticals. For example, Angola and Eritrea are the only countries of thirty African LDCs that do not grant patents for pharmaceuticals (Correa 2002). To take advantage of the benefit, other LDCs that already grant pharmaceutical patents must amend their legislation and not grant product patents until 2016.

Another consequence of paragraph 7’s transition extension concerns the requirement to grant exclusive marketing rights (TRIPS Article 70.9). After the Doha Declaration, ambiguity existed regarding whether a transition extension for pharmaceuticals applied to exclusive marketing rights as well as to patents. To clarify the situation, WTO members approved a waiver that exempts LDCs from having to provide exclusive marketing rights for any new medicines during the period without patent protection.

3.3 Constraints to establishing health-sensitive intellectual property laws

Although the adoption of the TRIPS minimum standards resulted in developing countries losing some policy flexibilities in regulating pharmaceutical patents and controlling the cost of medicines, the agreement left some room for countries to take measures to protect public health. Furthermore, at Doha, WTO members reaffirmed the right of each member to fully use the provisions of the agreement that provide flexibility for protecting public health; however, the provisions relating to patents and pharmaceutical regulation are confusing even to specialists in the field of intellectual property law and medicine regulation. Therefore, countries with little capacity for interpreting and acting on international trade agreements are most at risk in terms of losing access to medicines. Regulators and legislators must acquire the relevant technical expertise to use the flexibilities, such as compulsory licensing and parallel importation, to improve access to medicines in their countries.

Substantial legal and administrative obstacles exist to introducing and implementing these complex provisions. Several constraints that developing countries face at the national level in their efforts to use TRIPS flexibilities are mentioned below, but countries can address many of these constraints by adopting complementary policy and legal measures.

Country Study 3-2 Countries in Asia, Latin America and the Caribbean, and Africa that are using TRIPS flexibilities

Although TRIPS establishes minimum standards that WTO members must follow related to intellectual property rights, certain flexibilities in the agreement allow exemptions to developing countries, especially regarding pharmaceutical patents. However, taking advantage of these flexibilities requires that the eligible countries amend their national intellectual property rights legislation.

An analysis of forty-nine countries in Asia, Latin America and the Caribbean, and Africa looked at the extent to which countries have incorporated the TRIPS flexibilities affecting pharmaceuticals and public health. Updated use of flexibilities in selected African countries is also available (Munyuki and Machedmedze 2010; UNAIDS, WHO, and UNDP 2011).

Countries implementing selected TRIPS flexibilities

National law provisions	Asia (n = 13)	Latin America/ Caribbean (n = 19)	Africa (n = 17)
Pharmaceutical products are patentable	10 (77%)	18 (95%)	11 (65%)
Data protection	6 (46%)	16 (84%)	6 (35%)
Government or noncommercial use allowed	7 (54%)	9 (47%)	17 (100%)
Exhaustion of rights			
• National exhaustion	2 (15%)	4 (21%)	6 (35%)
• International exhaustion (allowing parallel importation)	6 (46%)	13 (68%)	7 (41%)
• No exhaustion	3 (23%)	1 (5%)	1 (6%)
Early working exception	4 (31%)	6 (32%)	5 (29%)
Compulsory licensing grounds			
• Failure to work/exploit	10 (77%)	14 (74%)	15 (88%)
• Anticompetitive practice	5 (38%)	14 (74%)	5 (29%)
• Dependent patents	7 (54%)	10 (53%)	10 (59%)
• Demand not met on reasonable terms	3 (23%)	5 (32%)	13 (76%)
• Public interest	10 (77%)	15 (79%)	8 (47%)
• National emergency	5 (38%)	11 (58%)	6 (35%)
• No provision	2 (15%)	0 (1 unknown)	0

Lack of technical expertise to incorporate TRIPS flexibilities into national law

Countries can use the flexibilities offered by TRIPS only if they incorporate them into their legislation; however, many developing countries have not done so for various reasons, including a lack of technical expertise and information on best practices. Resource-limited countries are generally not aware of the measures undertaken by their counterparts around the world. As a result, countries within a region with similar access problems may adopt different strategies, with varying degrees of success. [Country Study 3-2](#) summarizes the extent to which TRIPS flexibilities are being used in forty-nine different countries. For example, while 100 percent of the countries surveyed in Africa provided for government or noncommercial use in their laws, less than half the countries in Asia or Latin America/Caribbean had done so.

Insufficient domestic research and manufacturing capacities

Most developing countries have limited pharmaceutical research and manufacturing capacities. The challenge for these countries is how to enlarge their capacity for research through increased investment in basic sciences, R&D, and technological innovation. As technology evolves and becomes an important tool for development, it also becomes more of a means of gaining competitive advantage.

Developing countries face significant barriers that may block their own R&D efforts or opportunities for collaboration with other countries, such as insufficient numbers of trained researchers and inadequate research support at local universities or institutions. In addition, an individual country's interest in bolstering indigenous, national manufacturing capacity may limit regional, multicountry collaboration

Country Study 3-3 Differences between bilateral trade agreements and TRIPS

Many countries that trade with the United States are members of the WTO and therefore are obligated to abide by the TRIPS provisions. However, they may enter into bilateral trade agreements that commit them to more stringent intellectual property rules than TRIPS (TRIPS-plus) in exchange for concessions in other areas of trade—often access to the U.S. market for agricultural or manufactured goods. Evaluating the implications of bilateral trade agreements on public health can be difficult. The benefits and costs associated with protecting pharmaceutical patents vary by country, and these agreements will take many years to take full hold. The public health community has raised concerns regarding these bilateral agreements and their possible effect on access to medicines, especially how they may limit the availability of generic medicines in developing countries.

The following are key differences in intellectual property provisions between bilateral trade agreements and TRIPS:

Use of compulsory licenses. Under TRIPS, governments may issue a compulsory license to obtain generic medicines by temporarily overriding a patent. Compulsory licensing is an important tool for governments to protect the public interest or to remedy anticompetitive behavior. Four bilateral agreements now limit the use of compulsory licensing to emergencies, antitrust remedies, and cases of public noncommercial use.

Test data protection. Getting approval to market medicines requires a company to submit test data to regulatory authorities to prove a medicine's safety and efficacy. The protection of such data differs from country to country. TRIPS requires only that test data be protected against "unfair commercial use." However, most bilateral

agreements require governments to guarantee exclusive use of test data for pharmaceutical products for five years, which is the U.S. standard. Furthermore, some free-trade agreements require an additional data exclusivity period for new uses of already approved medicines, and some go even further by prohibiting generic manufacturers from using test data submitted to a regulatory authority in another territory—even outside the trade agreement territory. These new test data provisions may be an obstacle for governments using compulsory licensing.

Patent terms. Bilateral agreements mandate the extension of patent protection beyond the current twenty-year limit mandated in TRIPS to compensate for procedural delays in granting patents or in securing marketing approval for pharmaceuticals.

Use of parallel imports. Parallel importation allows a government to import pharmaceuticals that have been placed on the market more cheaply in foreign markets, which can help reduce medicine prices. TRIPS allows WTO members to establish their own national policies regarding whether to permit parallel importation of patented medicines. By contrast, many bilateral agreements allow patent holders to prevent parallel importation.

Bolar exception. TRIPS does not limit generics companies from starting the process of entering a new market before a patent has expired. Generics producers often take this action so they can be ready to sell their product immediately after the patent expires. Most bilateral agreements prevent marketing approval of a generic medicine during the patent term without the consent of the patent holder, which could make compulsory licenses an ineffective way to allow competition from generics manufacturers.

to produce medicines unless the benefits of investment in R&D and procurement of locally manufactured products can be shared across the region.

Insufficient capacity for medicine registration and regulation

Pharmaceutical registration is the process by which a country's regulatory authority assesses the safety, quality, and efficacy of medicines to approve their use. Countries normally require that all medicines offered for sale in their territories be registered locally. Although the ultimate role of medicine

regulation is to protect public health, national regulatory authorities in developing countries often lack the facilities and expertise needed to review medicines destined for their national markets.

Regulatory authorities handle applications for new chemical entities, generic medicines, new fixed-dose combination products, and even herbal medicines. Innovative new products, including important antimalarials and antiretroviral medicines for HIV/AIDS, require more complex assessment than their generic equivalents; therefore, most countries carry out a fast-track review based on prior approval by U.S. or EU regulatory agencies. Where a comparable product is

already on the market, the assessment of generic medicines tends to take place at the national level (see [Chapter 6](#)).

When a country's pharmaceutical regulatory process is unwieldy, that can delay the entry of needed medicines in a particular market and act as a barrier to access as well as to growth of the local pharmaceutical industry. Many developing countries have no reliable fast-track procedure for registering new essential medicines, such as antiretroviral medicines. The requirement for local clinical trials can also deter and delay registration. With growing demand for rapid registration of new and more complex medicines, pharmaceutical regulatory capacity needs to develop in a way that also protects public health.

Procurement is also affected. A country's procurement agency must determine whether a medicine is locally under patent before it can import a generic version of the medicine; however, finding this information can be complicated and difficult (Tayler 2004). The procurement agency can ask the national patent office to help, but staff may not have the capacity to undertake such a request. Professional firms will search for patents, but the fees may be prohibitive. Médecins Sans Frontières has published the patent landscapes for HIV/AIDS medicines in developing countries, although it notes that it cannot promise complete accuracy. WHO's AIDS Medicines and Diagnostics Service maintains a drug regulatory database and additional information related to HIV/AIDS products (http://www.who.int/hiv/amds/patents_registration/en/index.html). Other organizations have called for the creation of a global patent database, including the World Health Assembly in its *Global Strategy and Plan of Action on Public Health, Innovation and Intellectual Property* (WHO 2008).

TRIPS-plus provisions

"TRIPS-plus" refers to the incorporation into national legislation of intellectual property rights that are stricter than those mandated by TRIPS. This includes efforts to extend patent life beyond the twenty-year TRIPS minimum, limit compulsory licensing in ways not required by TRIPS, limit exceptions that facilitate the prompt introduction of generics, and extend the period of data exclusivity. Because the public health effect of TRIPS requirements has yet to be fully assessed, WHO recommends that developing countries be cautious about enacting legislation that is more stringent than the TRIPS requirements. From a public health perspective, countries that are not bound by TRIPS should evaluate TRIPS requirements and incorporate into national legislation and trade-related practices those elements that clearly benefit national public health interests.

Existing intellectual property protection in many resource-limited countries is often stronger than the mini-

um required by TRIPS; so in countries such as Kenya and Malawi, the existing legislation is already considered TRIPS-plus (DFID 2004). These countries will not be able to use TRIPS-compliant flexibilities unless they amend their national legislation. Moreover, almost all developing countries will need to change their legislation to take advantage of the import/export mechanisms in the Paragraph 6 Decision.

Free-trade agreements. One form of TRIPS-plus is bilateral and regional free-trade agreements that have intellectual property components. Most developing-country members face difficulties in trade negotiations, where they are asked to accept obligations in the public health sector in exchange for concessions in areas such as market access for agricultural products, which may be important to their economies (see [Country Study 3-3](#)). For example, both Vietnam and Cambodia entered into bilateral trade agreements with the United States that contain intellectual property requirements, including compliance with TRIPS standards, when these countries were not members of the WTO.

International patent law harmonization. An indirect influence on the evolution of TRIPS-plus provisions is the World Intellectual Property Organization (WIPO) Patent Agenda initiative. WIPO is a specialized agency of the United Nations whose primary objective is the promotion of creative intellectual activity and the facilitation of the transfer of technology to developing countries. The WIPO Patent Agenda initiative comprises a set of interrelated activities designed to harmonize the international patent system by building a legal framework that would create something comparable to a global patent. Such a system would, in essence, reduce the need for countries to have national patent offices, but more important, it would eliminate the flexibilities permitted by the TRIPS agreement that allow developing countries exceptions to rules on patents—essentially creating TRIPS-plus standards for everyone. A WIPO forum in 2006 allowed stakeholders to present their arguments both for and against the harmonization efforts and how such efforts might affect public health (WIPO 2006). Opinions on the benefits of harmonization have been sharply divided, and as of 2011, the WIPO standing committee was still trying to finalize recommendations for an international patent system.

3.4 Access to medicines in the TRIPS era

The globalized intellectual property system is one factor among many that affects access to pharmaceuticals in developing countries. Sometimes, countries may adopt policies that adversely influence access, such as applying tariffs or taxing medicines. Other restraints include a lack of human and financial resources, reliance on the public sector, and absence of an adequate infrastructure to supply and admin-

ister medicines effectively. For example, in sub-Saharan Africa, medicines for HIV/AIDS treatment are increasingly available from multiple sources: Indian-manufactured copies of patented antiretrovirals, generic purchases, brand-name purchases, and donations from pharmaceutical companies; bilateral and multilateral programs provide funding for procurement. Still, less than half the patients who need treatment are getting it, in part because of weak pharmaceutical management infrastructures and too few trained health professionals.

As intellectual property rights are strengthened globally, the cost of medicines in developing countries is likely to increase unless effective steps are taken to facilitate their availability at lower costs. Moreover, countries need to adopt a range of policies to improve access to medicines. Additional resources to improve services, supply mechanisms, and infrastructure are critical. Countries need to ensure that their intellectual property protection legislation does not run counter to public health policies and that other economic policies are in harmony with health policy objectives.

Box 3-2 includes a list of issues for country-level policy makers to keep in mind regarding intellectual property rights and access to medicines.

Using available resources to develop expertise

A lack of clarity often exists about the options available on the patent status of medicines and importing generic medicines from foreign producers. Within developing-country governments, experience in implementing TRIPS and its flexibilities is limited, and the political will to act is often low. Making changes to a country's intellectual property regime requires effective cooperation between different government departments, including health, trade, and industry, which may have limited experience in developing common policy.

The international rules regarding intellectual property are developing quickly. Active participation by developing countries in discussions of the future of the global intellectual property system is essential to ensure both

Box 3-2

Issues on intellectual property and pharmaceuticals for policy makers

Governments should—

- Avoid provisions in bilateral trade agreements that could reduce access to medicines in developing countries
- Increase funding for research projects run by public-private partnerships and by developing countries, and make that funding more sustainable
- Develop advance-purchase schemes for vaccines, medicines, and diagnostics
- Incorporate digital libraries of traditional medical knowledge into their patent offices' data to ensure that data contained in them are considered when patent applications are processed
- Make available reliable information on the patents they have granted
- Amend their laws to allow compulsory licensing for export consistent with TRIPS
- Eliminate tariffs and taxes on health care products

Governments of developing countries should—

- Identify a trade and pharmaceuticals focal point within the ministry of health
- Establish contacts, perhaps a working group, with trade and other key ministries
- Obtain reliable specialized legal advice
- Develop a mechanism to monitor the health effect of new trade agreements

- Promote health research that is in line with public health needs
- Promote the use of research exemptions as part of their patent law
- Invest appropriately in health-delivery infrastructure
- Improve financing of the purchase of medicines and vaccines
- Make use of compulsory licensing provisions where they will promote innovation or access to medicines

National patent and related legislation should—

- Promote standards of patentability that take health into account
- Establish process and product patents for twenty years
- Incorporate exceptions, trademark provisions, data exclusivity, and other measures to support generic competition
- Permit compulsory licensing, parallel importation, and other measures to promote availability and ensure fair competition
- Permit requests for extension of the transitional period for TRIPS implementation, if needed and if eligible
- Carefully consider national public health interests before instituting TRIPS-plus provisions

the legitimacy of standard setting and its appropriateness to countries at very different levels of development. As the rules evolve, their impact must be properly understood if policies are to be based on relevant evidence.

[Box 3-3](#) contains a list of organizations and resources that provide information on intellectual property rights and public health.

Regional collaboration

The constraints on national efforts to implement TRIPS flexibilities to improve public health show that developing countries need significant additional resources and technical assistance. One way to provide such support is through regional mechanisms that can complement national efforts. A regional approach to using the TRIPS flexibilities creates better policy conditions for addressing the challenges of implementing TRIPS flexibilities, which can be daunting for each individual country. Politically, a collective regional position on matters of public health and access to medicines can provide bargaining advantage for developing countries in their negotiations within WTO and with developed-country trading partners.

A regional approach to the use of TRIPS flexibilities could enable similarly situated countries to address their constraints jointly by drawing on each other's expertise and experience and by pooling and sharing resources and information. Policies that are likely to benefit significantly from regional collaboration in implementing TRIPS flexibilities include those related to production of pharmaceuticals, regulatory approval of medicines, market surveillance and maintenance of quality standards, and import rules and competition issues (Musungu, Villanueva, and Blasetti 2004).

3.5 Intellectual property and R&D for new medicines

Patent protection is an incentive for R&D for new medicines. The patent-holding company has exclusive rights over the product for a defined period, protecting it from competition in the country where the patent is recognized. Patent protection allows the manufacturer to set prices according to what the market will bear, which is likely to be well above production cost for medicines that treat widespread and severe illnesses in high-income markets. The temporary monopolies that patents create reward firms for taking expensive risks in developing new medicines.

Trends in new medicine innovation

Following years of rapid innovation from 1980 to the mid-1990s, evidence suggests an overall decline in the output

of global R&D into new medicines. Although R&D spending tripled between 1990 and 2000, the annual number of new medicines approved fell from its peak of more than fifty in 1996 to thirty-two in 2000, the lowest output in more than twenty years (WHO 2004). The increasing costs of R&D and the decrease in productivity have been factors in encouraging mergers between pharmaceutical companies. Rising R&D costs are also prompting manufacturers to develop strategic alliances with small research companies, particularly biotechnology companies, reflecting the emerging commercial potential of genomics-based discoveries.

In general, patents are most effective at attracting investment in products that have commercial prospects, leaving important gaps where R&D is the most commercially risky. The diseases and conditions that affect people in the world's major markets largely determine where the pharmaceutical industry's investments go. Of the 1,393 new chemical entities developed between 1975 and 1999, only 16 were for the treatment of tropical diseases and tuberculosis (Trouiller et al. 2002). The Global Forum for Health Research highlights the fact that only 10 percent of R&D spending is directed to the health problems that account for 90 percent of the global disease burden—the so-called 10/90 gap (see <http://www.globalforumhealth.org>). For example, no new class of anti-tuberculosis medicine had been developed in almost twenty years, despite the high global burden of this disease. Therefore, the debate centers around how to reach a balance between meeting the high costs of pharmaceutical R&D and creating incentives to stimulate access to those medicines in poor and developing countries.

Encouraging R&D in neglected diseases

Various initiatives are being used to encourage R&D into medicines for neglected diseases. Public-sector or donor funds or research mandates often address gaps in research that are not adequately provided for by intellectual property rights incentives. Some “push” mechanisms work by reducing costs and risks, including tax credits, grants, and support for clinical trials. “Orphan” medicine laws are examples of this type of mechanism. Another mechanism, called a “pull” initiative, creates a market for medicines or increases their profitability; for example, when a company develops a medicine for a neglected disease and in return gets the right to extend the patent on one of its more profitable products. Another type of proposal to tackle the problem of R&D for these forgotten medicines is the creation of public-private partnerships that mobilize expertise, capacity, and funding from both the public and private sectors (see [Box 3-4](#)). In fact, recent research has shown that two-thirds of projects developing medicines for neglected diseases involve these sorts of public-private collaborations (Moran 2005).

Science and Development Network. This Internet-based network, also known as SciDev.Net, provides up-to-date information on science- and technology-related issues that affect developing countries, including news, policy briefs, key documents, and feature articles. It includes a section devoted to intellectual property. <http://scidev.net>

South Centre. South Centre is an intergovernmental organization that promotes the interests of developing countries by analyzing development problems and experience and providing intellectual and policy support on global issues including trade, development, and intellectual property rights. <http://www.southcentre.org>

World Health Organization (WHO). In 2006, WHO member states established an Intergovernmental Working Group (IGWG) on Public Health, Innovation and Intellectual Property. The working group's mandate was to prepare a global strategy and plan of action on public health, innovation and intellectual property to address conditions disproportionately affecting developing countries. Documents related to IGWG activities can be found on its website <http://www.who.int/phi/documents/en/>. In addition, the website of WHO's unit on Trade, Foreign Policy, Diplomacy and Health includes an updated list of related publications and links to other WHO sites related to globalization. <http://www.who.int/trade/en>

World Intellectual Property Organization (WIPO). This specialized agency of the United Nations administers twenty-three international treaties dealing with different aspects of intellectual property protection. It also provides technical assistance to member countries needing help with developing national systems for intellectual property. <http://www.wipo.org>

World Trade Organization (WTO). This international organization deals with the rules of trade between nations at a global or near-global level. See [Box 3-1](#) for a detailed discussion. <http://www.wto.org>

Box 3-4**Using public-private partnerships to develop medicines for neglected diseases**

Some partnerships act like pharmaceutical companies that develop their own medicines, whereas others act more like funding agencies. An example of the former type of partnership is the Drugs for Neglected Diseases Initiative, started by Médecins Sans Frontières, with the support of several ministries of health, research institutes, and pharmaceutical manufacturers—including partnerships with southern research centers. Initially focused on treatment for sleeping sickness, leishmaniasis, and Chagas disease, this nonprofit research organization develops or adapts medicines for patients suffering from several different diseases with little profit-making potential. The initiative's first commercial development, in collaboration with Sanofi-Aventis SA, is a new anti-malarial medicine. This inexpensive, fixed-dose combination of artesunate and amodiaquine was launched in 2007 and by 2011, more than 80 million treatments had been distributed.

The Medicines for Malaria Venture, founded in 1999, is a public-private partnership concerned with the discovery, development, and registration of new medicines for the treatment and prevention of malaria; similarly, the Global Alliance for TB Drug Development is committed to delivering new anti-tuberculosis medicines; it has three medicine candidates in clinical trials, including moxifloxacin, which is the nearest to approval. Moxifloxacin should

shorten the treatment duration for drug-sensitive, adult tuberculosis cases. The business model of the nonprofit pharmaceutical company Institute for One World Health is to take promising leads on new medicines that lack a profitable market and complete the development process. The company then collaborates with other companies and nonprofit hospitals and organizations in the developing world to conduct medical research and to manufacture and distribute the newly approved therapies.

In the vaccines area, the International AIDS Vaccine Initiative researches and develops HIV vaccine candidates by directing and financing partnerships with private companies and academic and government agencies, including those in developing countries; the Malaria Vaccine Initiative operates in a similar fashion for malaria vaccine projects. Further downstream in the R&D process, the Global Alliance for Vaccines and Immunization works to enhance the commercial attractiveness of vaccines by stimulating demand in developing country markets, strengthening infrastructure, and guaranteeing some product purchase. The idea is that a strong advance commitment to purchasing safe and effective vaccines will reduce the financial risks faced by private-sector manufacturers and help redirect research toward the vaccines that are a priority for resource-limited countries.

These mechanisms fill some important gaps between the opportunities that face commercial medicine manufacturers, on the one hand, and the global burden of disease, on the other. Strong public-sector involvement is needed to ensure that new medicines are created to address priority health problems in developing countries. To help address such issues, WHO created an intergovernmental working group to develop a framework that identifies and prioritizes needs-based research for diseases that disproportionately affect developing countries. As a result of the group's work, in 2008 the sixty-first World Health Assembly adopted Resolution WHA 61.21: Global Strategy and Plan of Action on Public Health, Innovation and Intellectual Property. In 2009, the World Health Assembly adopted Resolution WHA 62.16: Final Agreement on Stakeholders in the Plan of Action on Public Health, Innovation, and Intellectual Property. The global strategy and plan of action comprises eight elements, which are designed to promote innovation, build capacity, improve access, and mobilize resources. Additional information and materials are available at

WHO's website: http://www.who.int/phi/implementation/phi_globstat_action/en/index.html.

Technology transfer

Technology transfers involve knowledge sharing between developed and developing countries. TRIPS recognizes that “the protection and enforcement of intellectual property rights should contribute to the promotion of technological innovation and to the transfer and dissemination of technology” and suggests that developed-country members introduce incentives to encourage technology transfer by private companies.

As encouraged by TRIPS, the transfer of technology is potentially an important source of growth in developing countries. One of the reasons that developing countries do not use the compulsory licensing mechanism in TRIPS is because of a lack of mechanisms for technology transfer. Although compulsory licensing permits an invention to be used without the consent of the patent holder, it does not guarantee that the country will have

the appropriate technology available, including facilities for manufacturing.

Increasingly, technology transfer is a component in non-profit initiatives and public-private partnerships that involve developing-country governments and the private sector. For example, several R&D companies are linking with industry partners in India, China, and elsewhere to increase the supply of patented medicines. In the cases of South Africa and Kenya, advocacy efforts on the part of governments and civil society resulted in patent holders granting voluntary licenses to local manufacturers. WHO, international philanthropic groups, and nongovernmental organizations are brokering collaborations between R&D and generics companies.

In all of these partnerships, both the research-based company and the developing country stand to benefit. For example, a company benefits from being seen as committed to corporate social responsibility, and developing-country partners get increased access to scientific technology and skills, new products for new markets, and experience in working with international standards.

Alternative paradigms in R&D of pharmaceuticals

In addition to public-private partnerships, a different R&D paradigm for pharmaceuticals is the use of an open collaborative model, such as the Human Genome Project's successful international effort to sequence the human genome,

which used a nonproprietary system sanctioned by the governments of six major countries. One of the innovative aspects of this model is the publicly available results, which has been a growing trend in biomedical research (see additional discussion in [Chapter 34](#)). The collaborative and transparent nature of this kind of openly accessible research is appealing, but its application to pharmaceutical R&D is still unclear.

Others have suggested creating a global decision-making process to name targets for R&D funding, with each individual country deciding how it will meet those targets (Hubbard and Love 2004). The theory is that to meet the R&D targets, some countries will choose public-sector management of investments, while others will rely on a more private (profit or nonprofit) approach. Most will choose mixed approaches. Another idea is to set up a global fund to pay for research into medicines for neglected diseases; such medicines would then be supplied free or at greatly discounted prices to resource-limited countries. One R&D paradigm or another is unlikely to be chosen explicitly. [Box 3-5](#) illustrates how some developing countries are approaching R&D for new medicines.

UNITAID is working to establish an international patent pool that would, in theory, increase access to patents and promote the development of more affordable medicines in developing countries. The concept of the pool is for patent holders to give up their patents and allow their intellectual

Box 3-5 How developing countries are approaching R&D

Only 4 percent of the entire global spending on health research is by low- or middle-income countries, and the majority is public-sector funded. Researchers in all but the most technologically advanced countries find developing new and innovative pharmaceutical products difficult without adequate infrastructure or equipment, and few countries have the regulatory framework to oversee the process of ensuring pharmaceutical quality, efficacy, and safety. However, developing and transitional countries such as India, Indonesia, South Africa, and Brazil have created successful industries specializing in the manufacture of generic medicines, while a few countries have even developed new medicines.

For example, in the 1970s, Pliva, a small Croatian company, developed a new antibiotic called azythromycin, which looked promising in animal trials. Pliva did not have the resources necessary to mass produce and market the new medicine in the world market. It patented the product globally, which led to a licensing agreement with the U.S. pharmaceutical giant Pfizer to market the medi-

cine worldwide, while Pliva retained marketing rights in Eastern Europe. Zithromax became one of Pfizer's top antibiotic products.

Although this kind of R&D success may not be realistic for every small company, other ways exist to make progress. For instance, the generic pharmaceutical industry in India was the first to create a fixed-dose combination of antiretroviral medicines for HIV/AIDS, which is less expensive, and by simplifying the dosage improves patients' ability to adhere to their treatment. Scientists in other countries, such as South Africa and China, are focusing their R&D efforts on taking centuries-old herbal preparations used in traditional medicine and creating modern medicines. Some of these R&D efforts are advancing with the help of public-private partnerships, with large pharmaceutical companies providing the technology and expertise, and some are using a combination of state and private financing or nonprofit foundation funding to develop their pharmaceutical sectors.

Source: Fleck 2005.

property rights to be managed by the pool under certain conditions. By giving up a period of exclusive marketing rights, patent holders receive royalties from the pool in exchange for a license to produce the medicine in a developing country (UNAIDS 2009). WHO's Expert Working Group on Research and Development Financing rated the patent pool model high for operational efficiency, feasibility, and impact on health in developing countries. As it is based on the voluntary donation of intellectual property, however, questions remain about the quantity and quality of intellectual property that patent holders would choose to donate, particularly outside the area of HIV/AIDS. For the pool to work well, a minimum critical mass is needed, and it is not clear whether this would be achieved voluntarily for many diseases (WHO 2010). ■

Glossary

- Bioequivalence:** Two pharmaceutical products are bioequivalent if they are pharmaceutically equivalent and the rate and extent of bioavailability are similar to such a degree that their effects can be expected to be essentially the same.
- Bolar (early working) exception:** An exception to patent rights allowing a third party to undertake, without the authorization of the patentee, acts in respect of a patented product necessary

for the purpose of obtaining marketing approval for the sale of a product.

- Compulsory license:** A license to exploit a patented invention granted by the state upon request of a third party.
- Data exclusivity:** A legal provision that data collected (for example, the results of clinical trials) for obtaining marketing approval may not be used for a specified period by the regulatory authorities to grant approval to a generic equivalent.
- Data protection:** An obligation imposed on third parties to protect test data, such as the results of clinical trials, that are usually collected to comply with government regulations on the safety, efficacy, and quality of a broad range of products (for example, drugs, pesticides, medical devices). For example, TRIPS provides for the protection of such data against unfair commercial use.
- Differential pricing:** The practice of setting different prices for different markets, typically higher prices in richer markets and lower prices in poorer markets.
- Doha Declaration:** The Declaration on the TRIPS Agreement and Public Health agreed upon at the Doha WTO Ministerial Meeting in 2001.
- Downstream research:** Applied research usually directed at the development of a product or process with a potential commercial application.
- Evergreening:** A term popularly used to describe patenting strategies that are intended to extend the patent term on the same compound.
- Exhaustion of rights:** Principle whereby the right holder's intellectual property rights in respect of a product are considered exhausted (that is, he or she can no longer exercise any rights) when that product has been put on the market by the right holder or by an authorized party.
- Incremental innovation:** Innovation that builds incrementally on previous innovation, as compared with “breakthrough” innovation, which is a completely novel means to prevent, treat, or cure a particular disease.
- Intellectual property rights:** Rights awarded by society to individuals or organizations over inventions, literary and artistic works, symbols, names, images, and designs used in commerce. They give the titleholder the right to prevent others from making unauthorized use of their property for a limited period.
- Interchangeability:** A pharmaceutical product that is therapeutically equivalent to a comparator (reference) product.
- Parallel imports:** The purchase of a patented medicine from a lawful source in an exporting country and its importation without seeking the consent of the “parallel” patent holder in the importing country.
- Patent:** An exclusive right awarded to an inventor to prevent others from making, selling, distributing, importing, or using the invention, without license or authorization, for a fixed period of time. In return, the patentee discloses the invention to the public. Three requirements usually exist for patentability: novelty; inventive step or nonobviousness (knowledge not obvious to one skilled in the field); and industrial applicability or utility.
- Patent pools:** An agreement between two or more patent owners to license one or more of their patents to one another or third parties.

SUMMARY

A national medicine policy (NMP) is a political commitment and a guide for action that shows how the government will ensure that efficacious and safe medicines of good quality are affordable, accessible, and rationally used. The NMP provides a framework for coordinating the activities of all the parties involved, such as the public and private sectors, nongovernmental organizations (NGOs), donors, and other interested stakeholders; it also defines the role that the public itself should play.

The medicine policy of one country may be similar in many ways to the medicine policies of other countries, but because their starting situations will vary, the policies will likely differ in what they emphasize and in how problems can best be tackled. A national government will be the principal agency responsible for creating the overall NMP and putting it into practice; however, collaboration will be needed with prescribers, dispensers, consumers, and those who make, market, distribute, and sell medicines. Sometimes, disagreements among the parties will be unavoidable because their interests differ, but ideally a wide partnership will develop, because an effective medicine policy is ultimately in the best interests of all.

This chapter examines the components of an NMP. Countries must choose the elements most relevant to their situation and most realistic, given their available human and financial resources. At the outset, governments will need to give priority to solving current problems, such as a lack of relevant laws and regulations and

difficulty in implementing and enforcing laws and regulations that already exist; issues of finance, supply, cost, and pricing; and rational use of medicines. Less pressing matters may be addressed later.

This chapter reviews the main steps in formulating an NMP including—

- Organizing the process
- Identifying and analyzing problems
- Setting goals and objectives
- Drafting the policy
- Seeking wide agreement on the policy
- Obtaining formal endorsement of the policy
- Launching the policy

Formulating a policy is one thing; putting it into effect is another. No single, best way to implement an NMP exists, but this chapter shares the approaches that some countries have taken.

Experience shows that the essential medicines concept is central to a successful national medicine policy. The core of the concept is using an established list of essential medicines based on standard treatment guidelines, leading to a better supply of medicines, more rational prescribing, and lower costs. Finally, the success of an NMP will depend heavily on political commitment by the government and support from all stakeholders in the pharmaceutical sector.

4.1 Introduction

For many decades, pharmaceutical policies were developed in a piecemeal fashion, where they existed at all. At one moment, a country may have developed a regulation on pharmaceutical advertising—at another moment, a decree on the places where medicines can be sold. One country might concentrate on sound manufacturing practice—another country on the problem of providing very poor populations with access to medicines. Only gradually did people come to realize that the issue of medicines and their proper place in society needed to be looked at as a whole. If a policy covered only select issues in the pharmaceutical sector, problems could soon arise with other issues; in fact, a one-sided approach might actually make a situation worse.

In the 1970s, for example, efforts were made in certain countries to solve problems involving pharmaceutical procurement and distribution without examining the ways in

which medicines were being prescribed or used by patients. The result in some instances was that access to medicines improved, but people did not know how to use them rationally. Similarly, essential medicines policies developed for the public sector only were ineffectual because they did not address how the private and public sectors could complement each other. More recently, some East African countries' difficulties in collecting direct taxes have led to a heavier reliance on import duties and manufacturing taxes, including those from medicines. This policy makes imported pharmaceuticals more expensive and discourages local production, resulting in the availability of fewer low-cost medicines in the marketplace.

These experiences suggested that pharmaceutical problems might be better tackled within a common framework created through the development of a comprehensive national medicine policy. The overall goal of an NMP should be to promote equity and sustainability of the pharmaceutical sector (WHO 2003). Its general objectives can be simply

Figure 4-1 Structure of a complete national medicine policy

This figure shows how many different elements are linked in the construction of a national medicine policy. No individual country's policy is likely to be structured in exactly the same way, and many national medicine policies are simpler. The chart can, however, be useful in analyzing the situation and looking for solutions. For example, the area of rational prescribing can be analyzed by examining the linkages illustrated. The figure shows that the prescriber is likely to receive information, advice, and persuasion from various sources: the institution where he or she was educated, the drug regulatory agency, formularies, industry representatives, and others. Can the quality of influencing sources be improved? Do they reinforce or contradict one another? Is some better form of guidance needed if the prescriber is to improve rational prescribing practices?

stated: a national medicine policy should ensure that *effective* and *safe* medicines of *good quality* are *accessible* and *affordable* to the entire population and that they are *rationally used*.

The 1980s saw the idea of an NMP emerging as a positive concept, and the World Health Organization (WHO) and World Bank became active in developing the idea further. Now the idea that every country should try to achieve optimal availability, quality, and use of medicines for patients and consumers is widely accepted. By 2007, more than 130 countries had formulated NMPs, about 60 percent of which had an updated implementation plan in place (WHO 2010).

4.2 What is a national medicine policy?

An NMP is a political commitment to a goal and a guide for action. It is a written document specifying the medium- to long-term goals set by the government for the pharmaceutical sector, their relative importance, and the main strategies for attaining them. Moreover, it provides a framework for coordinating activities of the pharmaceutical sector: the public and private sectors, NGOs, donors, and other interested parties. (Figure 4-1 illustrates the structure of a national medicine policy.) The NMP should be incorporated into the national health system to ensure that NMP goals and objectives are addressed in broad national health plans,

including disease-specific programs, and that resources are allocated efficiently. An NMP should also express the government's commitment to promoting good governance practices, including increased transparency and accountability.

In the developed world, most countries do not have written NMPs, yet many are successful in pursuing pharmaceutical sector goals. However, even in those countries, some experts advocate drawing up a document that clearly outlines the objectives of an NMP; for example, Australia launched an official NMP in 1999. In countries where resources are severely limited, an integrated approach to solving problems helps make the best use of limited resources.

What should a medicine policy accomplish?

The overall purpose of an NMP is usually expressed in general terms, without necessarily touching on every aspect of the policy. The purpose stresses the most important objectives in the simplest way. In Nigeria, the medicine policy states that the goal is “to make available at all times to the Nigerian populace adequate supplies of drugs that are effective, affordable, safe and of good quality; to ensure the rational use of such drugs; and to stimulate increased local production of essential drugs” (Federal Ministry of Health, Nigeria/WHO 2005). In Ghana, the overall goal of the policy is “to improve and sustain the health of the population of Ghana by ensuring the rational use and access to safe, effective, good quality and affordable pharmaceutical products” (Ministry of Health, Ghana, 2004).

Although specific objectives differ according to the priorities recognized by the government, the most common follow the essential medicines concept and are directly *health related*—

- To make essential medicines available and affordable to those who need them
- To ensure the safety, efficacy, and quality of all medicines provided to the public
- To improve prescribing and dispensing practices and to promote ethical practices among health professionals and the correct use of medicines by health workers and consumers

The core of the essential medicines concept is that the use of a limited number of medicines that have been carefully selected based on agreed standard treatment guidelines leads to a better supply of medicines and more rational prescribing, as well as to lower medicine costs.

The national medicine policy may also include economic goals (for example, to reduce the use of foreign exchange for pharmaceutical imports, or to provide jobs in areas such as dispensing, prepackaging, or production of pharma-

ceuticals) and national development goals (for example, to improve internal transportation and communication systems, develop national pharmaceutical production, or to take a stand on intellectual property rights in this particular field). Regardless of a country's specific circumstances, a comprehensive NMP should clearly specify the roles of both the public and the private sectors.

In addition, the policy should be concerned with *efficiency* (delivery of the maximum level of services given a certain level of resources); *equity* (fairness in access); *sustainability* (the ability to provide continued benefits into the future without relying on external support); and *transparency*, with clear lines of accountability. Finally, the NMP should address the issue of access to essential medicines as part of the government's obligation to fulfill its citizens' right to health (see Section 4.4).

What approaches should be used?

In addition to indicating the broad political choices that the government has made regarding the pharmaceutical sector, a general medicine policy should define some specific objectives—outcomes to achieve within a given time frame. Each objective must be linked to some clear ideas about how it will be obtained. For instance, the supply of essential medicines can be improved in the public sector by increasing the pharmaceutical budget, introducing cost-sharing mechanisms, or allocating more resources to underserved populations. Pharmaceutical supply can also be increased through the private sector by introducing economic incentives for pharmaceutical manufacturing and distribution. Some of these strategies can be introduced in the national policy document, whereas others may need to be worked out separately, after additional research and consultation. Including too much detail in the national policy may make it difficult to read and understand. The optimal solution is likely to involve applying different approaches in the private and public sectors. This combination of different approaches and strategies forms the core of an NMP.

Why do medicine policies differ by country?

Objectives and strategies may differ from country to country for various reasons. Differences may exist in the structure of the health care system, the number of trained pharmacists and physicians, the capacity of the drug regulatory authority, the way in which pharmaceuticals are distributed, or the level of funding available for pharmaceuticals. The biggest differences in the scope of medicine policies lie between industrialized countries and least developed countries.

In most industrialized countries, health care coverage is broad, and access to medicines per se is not a prominent

issue (although cost is likely to be a concern). The annual public and private expenditure on medicines is high, perhaps 500 U.S. dollars (USD) per person or more (WHO 2004b). The role of the government here is to set up rules for the operations of the private sector without becoming directly involved in medicine provision or in the pharmaceutical industry. This model requires the existence of an active private sector that is capable of developing, manufacturing, marketing, and distributing medicines to the entire population. Therefore, in these settings, pharmaceutical policies are oriented heavily toward containing costs while ensuring rational use in the interests of both public health and the economy, and the regulations should focus on the quality assurance of pharmaceutical products and services as well as on cost containment.

Although many middle-income countries have experienced improvements in indicators that measure pharmaceutical access, WHO estimates that almost one-quarter of the population in middle-income countries still lacks access to essential medicines (WHO 2004b). Whereas least developed countries are afforded equity pricing for some medicines, such as those for HIV/AIDS, middle-income countries that are ineligible for such discounts pay higher prices; however, in 2009, only one-third of these countries were instituting economic policies that could help make medicines more affordable (Stevens and Linfield 2010).

In the least developed countries, total spending on pharmaceuticals is less than USD 5 per person per year (WHO 2004b). The private sector has traditionally failed to supply affordable, high-quality medicines to the majority of the population. Consequently, governments have attempted to supply and distribute essential medicines through the public sector, often with donor support. In addition, policies often focus on such matters as ensuring the proper use of a basic range of essential medicines and encouraging the private sector to play a more constructive role in supplying those medicines.

Who are the main participants in developing and implementing a national medicine policy?

The national government is the essential driving force in designing and implementing medicine policies. Through its medicine policy, the state seeks to guarantee the availability and accessibility of effective, high-quality essential medicines for the population and to ensure that they are properly used. This goal holds true whether the government is directly involved in procurement and distribution of medicines, empowers parastatal or private institutions to carry out this function, or acts mainly as a regulatory authority for a largely private pharmaceutical market.

The government is not, however, the only actor involved with the NMP. A partnership is required, involving government ministries of health, finance, and industry; health

professionals, including doctors and other prescribers and pharmacists; public and private wholesalers and retailers; academia; NGOs and consumer groups; and the pharmaceutical industry (national and multinational). Consulting with provincial and district personnel and traditional medicine practitioners is important. In addition, governmental agencies, such as the drug regulatory authority and government-sponsored health care and insurance schemes, must be involved. The involvement of such diverse groups and conflicting interests means that development and implementation of a sustainable NMP is not easy. Reaching full agreement with all the parties on every matter is ideal but not always possible. With patience and goodwill, however, an environment conducive to success can be created.

The ministry of health should establish a specific office that is responsible for coordinating the NMP review and implementation process. The office should arrange regular NMP stakeholder committee meetings to assess implementation and policies. Working groups may be needed to analyze the effect of the NMP on specific areas. In addition, the NMP office should be given the capacity to monitor and evaluate the implementation process and coordinate necessary action plans with stakeholders.

The consultations and national discussions that lead to the production of the medicine policy document are very important because they create a mechanism to bring all parties together and achieve a sense of collective ownership of the final policy. This “buy-in” is crucial in view of the national effort that will later be necessary to implement the policy. The policy *process* is just as important as the policy *document* (WHO 2001). (Box 4-1 lists all of the stakeholders involved with the most recent revision of Ghana’s National Medicine Policy.)

The development and implementation of an NMP is a highly political process, requiring careful analysis to understand who the advocates are, who the opponents are, and what each group’s strategies are. Mobilizing alliances and coalitions and creating constituents inside and outside the government are necessary to mobilize political will during the process.

4.3 Components of a national medicine policy

The areas of pharmaceutical policy unavoidably overlap, but the main components include legislation and regulation, choice of medicines, supply and financing policies, and a means of encouraging rational medicine use. Some countries also have a tradition of local production (or they have ambitions in this area), and that factor can also be a key issue in a national medicine policy. These components form the basic framework, with other components added according

to local conditions. Each component is essential but not sufficient in itself to ensure access. [Box 4-2](#) summarizes these basic components of a national medicine policy, which are discussed further in the following sections.

Legislative and regulatory framework

The formulation of a medicine policy should be followed by the enactment of appropriate legislation and the introduction of regulations to provide a legal basis for the policy and make it enforceable. An NMP is usually a declaration of intent rather than a law, so the strategies set out in the policy may need to be supported by appropriate laws and regulations. In the Philippines, for example, one policy objective was to extend the use of generic medicines, and many activities related to that objective were reinforced by a new law on generics.

Legislation should provide the basis for ensuring that pharmaceutical products are of acceptable quality, safety, and efficacy and specify an agency to be responsible for this. Regulations, which are more flexible than legislation, should define the actors in the system and their responsibilities: regulations should state who can produce or import pharmaceuticals, who can prescribe them, and which medicines can be sold without the need for a prescription. Regulations should also state who can store and sell pharmaceuticals, and which institution is responsible for monitoring and enforcing regulations. Several legislative models and struc-

tures have been devised for the regulation of medicines, as discussed in [Chapter 6](#).

As noted, making a policy, or even a law or regulation, provides no guarantee that it will be implemented. Too often, laws and regulations are not enforced, and the penalties and sanctions that the law provides are not imposed. Sometimes this failure results from lack of resources or lack of political will; sometimes an element of corruption exists. Although a commitment to good governance and the need to fight corruption should be included as a cross-cutting item throughout the NMP, some countries may also have a separate component that specifically defines how a good governance program will be implemented (Anello 2006). Another reason for failure may be that the government's rules are impractical or difficult to enforce. In this case, a careful review of the main regulations applying to the pharmaceutical sector may lead to proposals to amend them so that they are better adapted to local realities and can be better enforced.

Appropriate legislation and regulation should be accompanied by a functioning quality assurance system; pharmaceuticals of low quality, either imported or locally produced, should never reach the patient. Quality assurance calls for a transparent pharmaceutical registration system and a well-organized and -trained inspection administration that is independent of commercial pressures and a system of quality control backed by one or more laboratories (see [Chapter 19](#)).

Box 4-2 Components of a national medicine policy

Legislative and regulatory framework

- Legislation and regulations
- Drug regulatory authority
- Medicine registration and licensing
- Pharmaceutical quality assurance, including inspection and enforcement
- Pharmacovigilance
- Regulation of prescription and distribution
- Infrastructure for good governance in medicines

Choice of essential medicines

- Principles of essential medicine selection
- Selection process (market approval and selection based on national morbidity patterns)
- Selection criteria (sound and adequate evidence, cost-effectiveness)
- Use of essential medicines lists
- Traditional and herbal medicines

Supply

- Local production
- Supply system strategies and alternatives, including mix of public and private sectors
- Procurement mechanisms
- Inventory control, including prevention of theft and waste
- Distribution and storage
- Disposal of unwanted or expired medicines

Rational use of medicines

- Multidisciplinary national body to coordinate medicine use policies
- Standard treatment guidelines as the basis for selecting essential medicines and training health professionals
- Independent medicine information
- Rational medicine use training for health personnel
- Education about rational use of medicines for consumers
- Promotional activities

Affordability

- Taxes or tariffs on essential medicines
- Distribution margins and pricing

- Measures to encourage competition through generics and price information and negotiation
- Trade-related intellectual property mechanisms

Financial strategies for medicines

- Role of government in the pharmaceutical market
- Pharmaceutical financing mechanisms (public financing, user charges, health insurance, donor assistance)
- Measures to improve efficiency and cost-effectiveness

Human resources development

- Role of health professions
- Role of government in planning and overseeing training and development of human resources for the pharmaceutical sector
- Human resources management and development plan
- Education, training, and courses, including minimum requirements for each cadre of professional staff
- National and international collaborating networks
- Motivation and continuing education
- Ethical framework and code of conduct

Monitoring and evaluation

- Responsibilities and commitment
- Baseline survey of the whole country
- Indicators for monitoring
- Periodic monitoring
- Independent external evaluation every two to three years

Research

- Operational research
- Pharmaceutical development and clinical research

Technical cooperation among countries

- Information sharing
- Harmonization

Sources: Adapted from WHO 1995 and WHO 2003.

Choice of essential medicines

The selection of essential medicines to meet the health needs of the population and the registration of safe, high-quality, and effective medicines are important features of an NMP. Adoption of and political commitment to the essential medicines concept should guide selection and reimbursement decisions. Essential medicines are those considered most vital for saving lives and alleviating serious and common diseases in the majority of the population. WHO created the first Model List of Essential Drugs in 1977 and encouraged countries to use it as an example for making their own lists. Such national essential medicines lists have, in many countries, become the basis of public pharmaceutical supply systems. Hospital and outpatient practice formularies commonly guide prescribing in both the private and the public sectors. The principles, criteria, and process of medicine selection are described in [Chapter 16](#).

In a wealthy country, any medicine that meets standards of quality, safety, and efficacy can be sold, and several thousand registered pharmaceutical products may be available on the market. Where resources are limited, however, an essential medicines list can limit the number of unnecessary or inappropriate purchases. For example, more than a hundred medicines are available to treat rheumatism and arthritis, but many are similar and some are unnecessarily expensive; three or four such medicines that are proven efficacious and affordable may be all that are needed to adequately treat patients. This selective approach is likely to save money and enable a resource-limited pharmaceutical management system to concentrate on essential medicines.

Medicines may also be selected using other criteria. For example, some countries have been hesitant to add fixed-dose combination products to lists that already include the individual components. Sometimes, a drug regulatory authority may be willing to accept a product only if its price is competitive with that of similar medicines already on the market. Some countries have accepted only medicines for which they believe a “medical need” exists—for example, where the medicines have special advantages over other products. This criterion is unpopular with manufacturers, and it is difficult to apply, but many insurance schemes now use the principle to determine for which medicines they are willing to make reimbursements. The NMP can define procedures to periodically update the national essential medicines list and address the selection of traditional and herbal medications.

Supply

In many developing countries, availability of essential medicines is the most pressing concern of the NMP. To ensure that high-quality medicines are available to all, govern-

ments not only need to select their priority medicines but also to define policies in production, procurement, and distribution, as well as to provide a mechanism for financing, which can be a key limitation. Such policies should take into account what is feasible in the short term and what is necessary for sustainable systems in the long term and under special circumstances, such as when transport is likely to be impeded during the rainy season.

In most countries, the private sector operates in the pharmaceutical supply system to some degree, including commercially based producers, importers, wholesalers, pharmacies, and other retail drug sellers. Private-sector products are often relatively expensive, with the costs covered either from the patient’s pocket or refunded from a private or public insurance system. In less affluent countries, however, a public pharmaceutical supply system procures and distributes medicines and makes them available to consumers at either low or no cost. These public systems were set up in part because private-sector activities were concentrated in urban areas, prices put products out of reach of the poor, and no universal health insurance systems existed. The rationale for many of these state-supported systems persists, but they often require improvements in organization, management, and financing to carry out their mandate.

Another type of supply system is operated by NGOs, such as Christian or Islamic missions. Their goal is largely to supply the needs that are not met by the commercial private sector or the public sector, especially among the poor and in rural areas. Often their role is explicitly recognized by government and incorporated into the NMP and public health strategies.

Both government and NGO health services can be supplied through a variety of alternative arrangements that incorporate components of private-sector flexibility and efficiency (see [Chapter 8](#)).

Pharmaceutical production policy (see [Chapter 7](#)) is an important aspect of pharmaceutical supply. For many years, countries have been interested in developing their own local manufacturing capacity and a degree of national self-sufficiency. Unfortunately, the difficulties of local production have frequently been underestimated. Local production in developing countries is not necessarily a low-cost venture; although wages and some other costs are likely to be lower than in industrialized countries, pharmaceutical constituents and even packaging materials have to be imported, and maintenance of machinery is costly. Many factors influence the feasibility of local production, and a range of policy options exists. When formulating an NMP, the most important objective should be to get good-quality, therapeutically useful medicines to the people who need them, at prices they can afford—policies related to industrial production should not interfere with policies related to health care.

Affordability

Affordable prices are necessary to ensure access to medicines in both the public and private sectors. Newer medicines, such as those to treat HIV/AIDS and the newer artemisinin-based combination therapies for malaria, are very expensive. Possible mechanisms to increase affordability to essential medicines in all sectors include selecting cost-effective treatments, comparing price information, promoting price competition through generic substitution, regulating producer prices and retail margins (see [Chapter 9](#), on pharmaceutical pricing policy), limiting tariffs on pharmaceuticals, and taking advantage of trade-related intellectual property measures such as compulsory licensing and parallel imports (see [Chapter 3](#), on intellectual property and access to medicines).

Financing strategies

Ensuring stable and adequate financing for medicines is a major challenge. Public financing of medicines for government health services to increase access to medicines is accepted as a legitimate policy in most countries and by most institutions, and indeed, funding initiatives such as the Global Fund to Fight AIDS, Tuberculosis and Malaria have dramatically altered the pharmaceutical financing context in many developing countries. In addition, financing mechanisms such as user fees are used in the least developed countries to increase financial resources, but they are difficult to manage in a way that protects the poorest members of the population. Public and private health insurance schemes are becoming more common, and including reimbursement for medicines should be promoted. Financing policies should be designed to maximize resources for pharmaceuticals while keeping prices as low as possible. These issues are discussed in [Chapter 11](#).

Rational medicine use

Medicines should be used appropriately, safely, and only when needed. Irrational medicine use includes overuse, underuse, and inappropriate use, caused by such factors as lack of adequate regulatory systems; shortages of essential medicines and availability of nonessential medicines; lack of sound, objective medicine information; and the considerable influence of medicine promotion on both prescribers and consumers.

An NMP should specify major activities and responsibilities for promoting rational prescribing, dispensing, and patient medicine use. A wide variety of approaches has been developed in an effort to promote rational prescribing and dispensing ([Chapters 29](#) and [30](#)). Medicine prescribing and use have been improved in certain institutional settings. Although not yet widely implemented, programs focused on

rational medicine use can help improve medicine use in the public and private sectors. Pre- and in-service training can also promote rational medicine use.

Inadequate training of health professionals, lack of control of medicine promotion, and dispensing of medicines by untrained persons all promote irrational use of medicines. Strategies for public medication education should provide individuals and communities with the information, skills, and confidence necessary to use medicines in an appropriate, safe, and judicious way (see [Chapter 33](#)).

Human resources, monitoring, evaluation, and research

Implementing an NMP depends on people; they must be trained, motivated, and retained through competitive salaries and other incentives. Human resources management is therefore an important element of the policy. The roles of different health professions should be clear. The policy should lead to a human resources management plan that identifies education, training, continuing education requirements, and other elements necessary to develop and sustain an adequate supply of skilled professionals who are motivated to perform at a high level ([Chapter 51](#)).

The implementation of an NMP should be routinely monitored, and its effect should be evaluated at regular intervals. Provisions for monitoring and evaluation need to be included in the policy itself, and adequate staff and budget need to be allocated. Appropriate use of indicators helps quantify progress and needed improvements ([Chapter 36](#)).

Research is essential for health service and health care improvements. NMPs are particularly concerned with operational research aimed at constantly improving and adapting the selection, procurement, distribution, and use of existing medicines. The Lao People's Democratic Republic (P.D.R.) incorporated operational research into the monitoring and evaluation plan of its NMP (see [Country Study 4-1](#)). NMPs may also include specific provisions for clinical research and the development of new medicines, especially using local resources, such as indigenous plants.

Finally, many NMPs address technical cooperation among countries. Cooperation among countries within the same region and the same economic area has become increasingly common. There are examples of cooperation in virtually every aspect of pharmaceutical policy and management.

4.4 Setting priorities

When the basic components of a policy have been identified, choices must be made about the most appropriate strategies and activities to achieve policy objectives at each

Country Study 4-1**Using operations research to develop and implement the Lao P.D.R. National Drug Policy**

The Food and Drug Department of the Ministry of Health in the Lao People's Democratic Republic introduced a National Drug Policy (NDP) in 1993 with the goal of ensuring the availability and rational use of high-quality medicines at a low cost, with a focus on vulnerable populations in remote areas. Over the initial ten years, the Food and Drug Department implemented the policy in three phases—

- Phase I (1993–95): Develop a draft NDP, train inspectors, and create an information, education, and communication strategy on the rational use of medicines
- Phase II (1996–2000): Implement the NDP in five pilot provinces, including building individual and institutional capacity, developing related laws and standard treatment guidelines (STGs), and initiating and evaluating operations research projects
- Phase III (2001–2003): Consolidate NDP achievements and revise the policy, roll out policy implementation to the rest of the country, further strengthen pharmaceutical management capacity, and continue operations research

The success of the Lao P.D.R.'s NDP implementation is due in part to the emphasis placed on health systems research, which began during Phase II. Operations research was built into the pilot program design to improve implementation by bridging the gap between policy and practice and to provide evidence for policy making. The six operations research areas included—

- Use of public health messages to reduce irrational use of antibiotics
- Use of traditional medicine in Champassack province
- Knowledge, attitudes, and perceptions about quality of drugs among customers and health care providers (including drug sellers)
- Effectiveness of “feedback” for improving treatment based on STGs
- Methods used to effectively implement the NDP

- Regulation of private pharmacies in Savannakhet province

When results of a mid-program evaluation in 2000 showed the success of the NDP pilot program, policy makers revised the NDP to broaden its scope to include three new components: health systems research, human resources development, and overall management and coordination. In addition, recommendations were made to adapt the Lao NDP model for use elsewhere in the region.

Building research into the design of the Lao P.D.R.'s NDP yielded two strategic benefits. First, the results of this research guided the revision of the NDP in 2001 and showed policy makers how to more efficiently scale up the NDP nationwide. Second, building a research component into the NDP framework made monitoring and evaluation possible; the choice to pilot the implementation in only five districts made evaluating the NDP's effect by comparing pilot districts to control districts easier. In fact, research results showed that the pilot provinces performed significantly better in several aspects of quality and rational use of medicines. Research on the effectiveness of communications that promoted the rational use of medicines found that consumers still self-medicated with antibiotics, even after hearing medicines information on the radio and receiving advice from the doctor. This finding indicated that policy makers needed to adjust the information, education, and communication strategy regarding rational use of medicines.

Seeing the value of this research-based evaluation, policy makers made operations research a permanent component in the 2001 NDP. However, a solid operations research component alone is not enough to ensure a NDP's successful implementation. Research must be coupled with effective communication and dissemination of results, strong political will, and technical competence in the pharmaceutical sector.

Sources: Tomson et al. 2005; Lao P.D.R. Food and Drug Department 2003; Paphassarang et al. 2002.

level of the system. For example, to improve the supply system for essential medicines, many possible solutions exist: developing the central medical stores (CMS) further or transforming the CMS into a parastatal organization (as in Tanzania), decentralizing pharmaceutical procurement (as in Cameroon), or developing incentives for the private sector to manage supply and distribution. Activities

can then be undertaken to implement the approaches selected—for example, using restrictive or competitive tenders, buying only from the essential medicines list, negotiating contracts with the private sector, and so forth. A series of interventions can be undertaken to increase rational prescribing and use of essential medicines, but depending on the country, some of these strategies will

NATIONAL MEDICINE POLICY—A TREE THAT BEARS FRUIT

be more cost-effective than others. Options may involve training medical students, providing independent medication information to all prescribers, or using programs for the ongoing review of medicine use to identify opportunities for improvement.

The range of strategies and activities that can be successfully implemented depends on the pharmaceutical situation and the socioeconomic conditions of the country. If resources are insufficient without external input, a set of

priority activities should be identified that can be executed within existing means.

Initially, considering the following questions may be helpful—

- Is this approach based on scientific evidence, and has it proved to be effective in other countries?
- Is this approach or activity really needed to improve the situation in a particular area?

- Does it address the greatest needs?
- Are other approaches or activities available that might be more effective?

Policy elements may have to be set aside that—however successful they may have been in another country—would be no more than expensive luxuries in the local context, or would not work because too few technical and financial resources exist.

The combination of pharmaceutical policies that can be successfully implemented in a particular country over the short to medium term is closely linked to the structure of the pharmaceutical distribution systems, pharmaceutical spending levels, the presence or absence of health insurance schemes, the number of trained people available, and the capacity of the drug regulatory authority.

4.5 Formulating a national medicine policy

Formulating and implementing a national medicine policy are highly political processes. A policy should promote equity of access to health care by making the pharmaceutical sector more efficient, cost-effective, and responsive to health needs. Such responsiveness may involve the redistribution of goods and power, leading to increased competition among the groups affected by reform.

As mentioned, given the diverse interests and the economic importance of the issues involved, designing or revising an NMP requires complex negotiations with all stakeholders: the national and international pharmaceutical industry, the medical profession, retail drug sellers, NGOs, the government bureaucracy, and international donors. The challenge is to identify the main elements of an appropriate pharmaceutical policy and then construct a process that will bring the diverse groups together.

The pharmaceutical sector represents many varied interests that do not always run parallel; opposition to a new policy and sometimes even legal confrontations must be expected. Therefore, identifying political allies and maintaining their support throughout the process is important. Strategies to identify and deal with opponents should be developed, ways of working with them must be identified, and steps must be taken to resolve disputes. Differences may be resolved through effective communications, a collaborative approach, and careful monitoring of the policy formulation process. Decisions and priorities touching on the interests of various stakeholders must be balanced by estimating gains and losses. Nothing can be left to chance, particularly if the proposed policy seeks to change in an important way structures, historical practices, or the behavior of people. The more significant the proposed changes, the more the process of policy formulation should involve all stakeholders, taking account of their needs and fears and

encouraging them to take an active part in the new policy. No simple formula exists, but political will and leadership, and effective communication and collaboration are the main components for success.

Step 1. Organize the policy process

The ministry of health (MOH) is usually the most appropriate agency to take the lead in developing an NMP. The first step is to decide how formulation of the policy will be achieved, who will be involved at the various stages, and how the necessary finances will be obtained. A plan outlining the process and the final output can be drawn up by the pharmaceutical department in the ministry, with the support of a small committee. The more changes the policy seeks to produce, the more different stakeholders will need to be involved. This factor should be considered from the beginning, because it helps to determine the resources needed. The need for external assistance from WHO or other countries with experience in developing an NMP should also be assessed at this stage.

Step 2. Identify and analyze problems

The second task when formulating a policy is performing a thorough analysis of the main problems so that attainable objectives can be set (see [Chapter 36](#)). The best way to begin is to bring together a small team of experts, including some who have performed similar studies in other countries. The national experts should not come only from the MOH; they may be from the health professions, from trade and industry, and from other agencies of government (particularly the treasury). The group's function is to examine the situation systematically, identify problems and root causes, recommend what must and can be done, and suggest approaches that might be taken. Recommendations can be formulated and discussed in a multidisciplinary workshop to prepare advice for the government. Ghana followed a similar process, which led to the drafting of an NMP in 2004 by a team of experts representing diverse interests, including consumer rights, law, traditional medicine, trade, and manufacturing.

However ambitious it may seem in the early stages of medicine policy development, the situation in the country as a whole needs to be systematically reviewed so as to identify viable reforms. This objective may be best achieved through a detailed situational analysis. For example, in countries where a poor national economic situation is a major factor leading to unsatisfactory pharmaceutical supply, basing reforms on demands for more government money makes no sense because such funds are not available. The ultimate solution must take these structural constraints into account. Not everything can be done at once, and for some urgently needed changes, reliance on donor

help may be necessary while a longer-term national solution is developed.

Step 3. Set goals and objectives

After high-priority problems and related goals have been defined, primary objectives can be identified. (See [Box 4-3](#) for a list of the objectives of Malawi's NMP.) For instance, if one of the priority problems is the availability of poor-quality medicines, one of the primary objectives should be to ensure that they are replaced by products of good quality. The selection of the strategies or approaches is more complex and should come from the situational analysis in step 2 or perhaps in a workshop with key people asking some key questions: Where do these poor-quality medicines come from and why are they here? Would good-quality medicines necessarily be more expensive? What incentives would encourage improvements? After objectives and strategies are outlined, key participants can work out a strategy for improvement, which can then be discussed in a larger workshop to reach consensus among all the main participants.

However, not all the parties are likely to agree immediately on the strategy. Representatives of the pharmaceutical industry may be suspicious, fearing loss of profit; doctors and pharmacists may have different points of view and may worry about losing freedom; any party that feels secure in the status quo may feel threatened by change. Not uncommonly, one government agency will disagree with another on objectives, approaches, or timetables. To move forward, it is important to establish as much trust as possible, identify matters on which consensus and compromise are possible, and use those matters as the basis on which to proceed.

Step 4. Draft the policy

After a thorough analysis of the situation and an outline of the main goals, objectives, and approaches have been completed, a draft of the NMP should be written. It should state the general goal of the policy; in most countries, the goal will be to ensure that high-quality medicines are accessible and affordable to the entire population and that they are used rationally. Then the NMP should describe specific objectives and the strategy or strategies to be adopted for meeting each. For example, to ensure that essential medicines are available in health facilities (objective), the policy might propose the creation of an autonomous procurement unit and the strengthening of pharmaceutical management in health facilities (strategies).

This drafting of the policy can be done by the small committee of experts set up in step 2, with the support of the people who performed the situational analysis. The group should remain small, because a big group is difficult to manage and will have problems drafting a coherent text. The group may find that examples of NMP documents from other countries are helpful.

The draft policy should be assessed for its approach to human rights issues. Human rights concern the relationship between the state and the individual, generating individual rights and state obligations. [Box 4-4](#) includes a list of questions to ask when assessing health programs for their attention to the right to health.

Step 5. Circulate and revise the policy

To get full support from all sectors, the document should be widely circulated for comments, first within the MOH

Box 4-3

Objectives of Malawi's 2009 National Medicine Policy

Broad objective of the NMP

To develop within the available resources the potential that medicines have to control common diseases and alleviate suffering.

Specific objectives of the NMP

- To ensure ready and constant availability (universal access) of essential medicines and medical supplies to the community
- To rationalize use of these essential medicines through the provision of improved medicine utilization information
- To educate the public on appropriate medicine use and storage

- To improve supply management, prescribing, dispensing practices, and patient adherence
- To ensure continuing education and professional development for pharmaceutical and other relevant health workers
- To institute a sustainable financing mechanism to ensure continuous availability of adequate quantities of the required essential medicines
- To ensure effective regulation of pharmaceuticals
- To strengthen partnership at the national, regional, and international levels in ensuring the full implementation of NMP through utilization of available resources, knowledge, and expertise

Box 4-4**Access to essential medicines as part of the fulfillment of the right to health**

The basic principles of what is called the “rights-based approach” include participation, accountability, non-discrimination, attention to vulnerable groups, and explicit linkage to human rights instruments. Five simple questions are presented here to assess the medicines policy in a specific country or program.

1. Which essential medicines are covered by the right to health? Although WHO provides guidance on essential medicine lists, exactly which medicines are regarded as essential remains a national responsibility and, therefore, the national list of essential medicines should be used to define the minimum needs. If no such national list exists, the first step is to develop one. For situations outside the scope of national governments, such as ships and refugee camps, specific lists of essential medicines have been developed by WHO and relevant stakeholders.

2. Have all beneficiaries of the medicine program been consulted? True participation means that the beneficiaries of national medicines policies and programs are consulted in decisions that affect them. Besides the usual stakeholders, such as the government, universities, and professional associations, other important beneficiaries to be consulted are rural communities, nongovernmental organizations, patients and consumer groups, and representatives of the vulnerable groups listed in item 4.

3. Do mechanisms exist for transparency and accountability? The objectives of the medicines policy and program should be clear and include government obligations to respect, protect, and fulfill the right to health in line with any applicable international treaties. The policy should identify indicators and targets

to monitor progress toward universal access to essential medicines. The national medicines policy should specify the roles and responsibilities of all stakeholders, with mechanisms in place to hold each of them accountable.

4. Do all vulnerable groups have equal access to essential medicines? How do you know? The main vulnerable groups to be considered are children (especially girls), women, people living in poverty, rural communities, indigenous populations, national (ethnic, religious, linguistic) minorities, internally displaced persons, the elderly, those with disabilities, and prisoners. Ensuring equality starts with collecting disaggregated access statistics for each of these groups. Such statistics are essential to create awareness among policy makers, to identify vulnerable groups that need special attention, and to monitor progress toward universal access. The minimum effort should consist of gender-disaggregated statistics and surveys specifically aimed at vulnerable groups.

5. Are safeguards and redress mechanisms in place in case human rights are violated? Access to essential medicines is best ensured by the development and implementation of rights-based medicines policies and programs; however, when progress is unjustifiably slow, mechanisms for redress and appeal are needed as a last resort. A WHO study has shown that targeted litigation is an additional means to encourage governments to fulfill their constitutional and international treaty obligations regarding the right to health and access to essential medicines.

Sources: Hogerzeil et al. 2006; Hogerzeil 2006.

and then in other government departments and agencies. Endorsement by ministries or departments, such as planning, finance, education, and commerce, is of particular importance, because the success of decisions regarding registration, foreign exchange allocations, and human resources development depends on the support of government officials outside the health sector. After this wide consultation is completed, the document can be finalized. Although the formulation of the policy should reflect broad participation by the community, health workers, the pharmaceutical industry, and universities, ultimate responsibility for producing the policy remains with the MOH and the government.

Step 6. Obtain formal endorsement for the policy

In some countries, the document can then go to the cabinet or parliament for formal endorsement. In others, it can be an administrative document that serves as a basis for the implementation plans and for changes in pharmaceutical laws, which are often needed. In certain cases the NMP document becomes a law—for example, in Uganda, where it was called the National Drug Policy and Authority Statute; however, the MOH found that arrangement made the implementation and revision of the NMP unwieldy, so the revised NMP was separated from the statute in 2002. Although creating a law can demonstrate strong com-

mitment on the part of the government, it is not always advantageous, because legislation is difficult to pass and difficult to change once enacted. Incorporating select components of the NMP into a law, such as was done with the Generics Act in the Philippines, may be more useful. When a national medicine policy was drafted in 2000 in newly independent East Timor, the policy was written as a simple text that could be printed in the media and posted on health facility walls for all to read, so that it became the property of the people as a nation.

Step 7. Launch the policy

Launching an NMP is a political task rather than merely a technical one. It requires as much attention as any other political campaign. Promotion should be based on good information, top-level political support, mobilization of highly qualified people, and securing of international support. The policy should be promoted through a clear and well-designed campaign that disseminates information through a variety of channels to reach different target groups. The policy needs to be explained in a way that allows the media and the public to become involved in discussions.

4.6 Implementing a national medicine policy

Policy implementation—the execution of approaches included in the policy through specific plans and programs—is a critical step; the policy itself is worthless if it is not implemented. Each NMP requires an overall implementation plan or master plan. Given the multisectoral nature of pharmaceutical issues, the MOH should develop, as early as possible, a consensus with other government agencies on action plans dealing with specific issues of economics and finance (including foreign exchange), commerce, industry, and education. The implementation plan roughly outlines for each component of the policy what needs to be done and who is responsible, estimates the budget requirement, and proposes an estimated time frame. The implementation plan allows coordination of donor input and assists in monitoring the policy implementation and intervening where necessary to keep the process moving.

The master plan should then be broken down into annual workplans, which should be carefully developed with the various agencies involved in implementation. The workplans should outline the specific approaches and activities for each component, specifying in detail who is responsible, listing the major tasks, and describing the target output, the detailed time frame, and the exact budget. (See [Chapter 38](#) for more information on developing plans.)

Countries take different approaches to implementation (see [Country Study 4-2](#) for Australia's approach). In all cases,

if the policy is to succeed, government officials must be proactive and committed. A number of strategies are summarized below.

Use appropriate timing, and a combination of approaches and methods of implementation. Not everything can be done at the same time. In the Philippines, the rules for generic labeling and promotion had to be put in place before generic prescribing and dispensing could be implemented. In practice, a one-year interval was necessary between the issuance of the rules on generic labeling and the issuance of those on dispensing. In this way, by the time doctors and pharmacists were required to switch to generics, the products in the pharmacies had already been generically labeled.

Start implementation in relatively easy-to-change areas to ensure initial high-visibility success. Perception of success is an important consideration; if the policy is perceived to have yielded significant positive results, it is likely to continue to receive support from important sectors.

Adopt a flexible policy. In certain cases, an activity may have to be postponed because the timing is not right. If, for example, the policy proposes imposing strict rules on pricing, waiting until pharmacists have received an explanation about why the rules will be to everyone's advantage may be better than imposing the rules immediately and being met with resistance. Consensus building should always be balanced against compromising too much on key points. If the initial planning process has been carried out properly, valid objections should already have been addressed, and there should be no need to compromise later.

Use experts to vouch for the policy's technical soundness. It is important that the most qualified people in the medical and pharmaceutical fields support the policy (for example, clinical pharmacologists or specialists in the main hospitals and universities). Those who have been involved in developing the policy are likely to be its strongest advocates and its most useful allies as it is introduced and implemented.

Mobilize consumers, the media, or other key groups.

Although such mobilization has been successful in the Philippines and Australia, this approach has not been common in Africa, because of the lack of a well-organized consumers' movement.

Create constituencies that support the policy both inside and outside the government. After suspicions have been allayed, such constituencies may be found in any sector. Even within the private sector, support will develop when people realize that a healthy public sector will complement rather than undermine the private sector. Having constituencies in all sectors is critical to the success of the implementation and the long-term sustainability of the policy.

Country Study 4-2**Innovative approaches in formulating and implementing a national medicine policy in Australia**

In 1985, WHO called the Conference of Experts on the Rational Use of Drugs, which resulted in a document known as the *Revised Drug Strategy*. The 39th World Health Assembly, held in 1986, adopted this strategy, which calls on governments to implement a national medicinal drug policy. Australia, as a participant at this assembly, contributed to the development of this strategy. The need for a national medicine policy was further illustrated in the *Health for All Australians* document issued jointly by all Australian state and territorial health ministers in 1988.

Initially, in 1991, the government formed two advisory groups. The Australian Pharmaceutical Advisory Council (APAC) was a council of representatives from the major organizations involved, which would raise issues and make recommendations across the gamut of medicine policy. APAC represented an opportunity for all interested parties to contribute positively on a multilateral and consensus basis to the development and conduct of the policy.

The second group was the Pharmaceutical Health and Rational Use of Medicines (PHARM) working party, which advised the ministry on a policy for the use of medicines and a strategy for its implementation. PHARM drew on the best available knowledge and relevant concepts to establish a coherent framework for tackling the complex set of problems involved in the way medicines are used. The group also drew on research in behavioral change and health education; espoused principles of community ownership, participation, and consultation; and acknowledged the importance of media advocacy.

In 1992, this collaborative approach led to adoption of a draft national medicine policy. The approach was to—

- Use consumer and professional education as a primary tool
- Stimulate partnerships among the major players
- Identify—
 - What will empower consumers to use drugs well and encourage health professionals to help them do this?
 - What constitutes effective education?
 - What combination of information, skills, and motivation will be effective for different groups?
 - What will work in practice?
 - What standards should apply, and who should set them?

After policies were developed and implemented over several years, the government conducted a major review

during 1999. What had evolved were four good but separate programs for improving the availability, quality, and quality use of medicines and the viability of the national pharmaceutical industry. In late 1999, the revised policy bringing these four programs together into one document was launched with government-wide support.

The 2000 National Medicines Policy has four objectives based on active partnerships, taking into account elements of social and economic policy—

- *Timely access to the medicines that Australians need, at a cost individuals and the community can afford.* The Commonwealth Government's Pharmaceutical Benefits Scheme helps improve the health of all Australian residents by ensuring they have timely access to necessary and lifesaving medicines at an affordable price.
- *Medicines meeting appropriate standards of quality, safety, and efficacy.* The Therapeutic Goods Administration provides a national framework for regulating therapeutic goods in Australia. It also ensures their quality, safety and efficacy.
- *Quality use of medicines.* Australia's National Strategy for Quality Use of Medicines (QUM) is central to the National Medicines Policy. The National Strategy for QUM is intended to assist the QUM partners, health care consumers, health practitioners and educators, health care facilities, the medicines industries, the media, health care funders and purchasers, and governments in becoming more aware of the QUM framework and approach.
- *Maintaining a responsible and viable medicines industry.* The chairs of the National Medicines Policy groups—the Pharmaceutical Health and Rational Use of Medicines Committee; the Australian Pharmaceutical Advisory Council; the Pharmaceutical Benefits Advisory Committee; and the National Prescribing Services—meet regularly to discuss issues of importance to the National Medicines Policy.

Each partner shares responsibility to various degrees for achieving each of these objectives, and all partners consider these central objectives in any relevant initiatives. The policy also recognizes the fundamental role consumers have in reaching these objectives, and all partners have committed to consult with consumer representatives. As of 2010, the policy still served as the framework for Australia's pharmaceutical sector.

Sources: Hodge 1993; Australian Government 1999.

There is no single, perfect way to implement an NMP. In most countries, the implementation process is launched and maintained directly through the pharmacy department of the MOH, as in Guinea, Tanzania, and Zimbabwe. Such a department is generally supported by committees that continue to deal with different aspects of the policy. The problem with this approach is the policy's lack of visibility; often, the limited human and financial resources of these departments prevent them from being proactive and coordinating all the actors, and physicians may not accept the promotion of rational medicine use if it comes from the MOH pharmacy department. In addition, the department may focus too much on pharmacological issues rather than on the broad public health aspects that should inform the NMP. The policy's central leadership needs to smooth out these differences and facilitate implementation; for example, by having the rational use component of the policy come from the medical department or an NGO. [Country Study 4-3](#) illustrates how implementation can go wrong.

Regional cooperation can be useful in implementing medicine policies. Countries, institutions, and organizations can share information, expertise, skills, and facilities. Exchanging experiences helps ensure that best practices are promoted, that mistakes are not repeated, and that limited resources are used effectively. The East, Central, and Southern Africa Health Community of fourteen member countries has developed a template for a national pharmaceutical policy that its members can use as a resource for creating or revising their own national policies. The WHO Regional Office for Africa has a website with country profiles that include documents related to national medicine

policy in African countries (<http://www.afro.who.int/en/clusters-a-programmes/hss/essential-medicines/edm-country-profiles.html>). These various documents can be used as resources and bases for comparison for any country developing or implementing an NMP.

4.7 Monitoring and evaluating a national medicine policy

Monitoring is a form of continuous review that allows senior managers to assess the progress toward achieving defined targets in each policy area and adjust strategies accordingly. It can be carried out using a combination of methods, including supervisory visits and both routine and sentinel reporting.

Evaluation is a way of analyzing progress toward meeting objectives and goals. It should build on and use monitoring systems. At the start of a program, evaluation is used to provide a clear assessment of needs. A midterm evaluation can provide valuable information about how well the program is working. Final evaluation allows a complete review of program achievements from which lessons can be drawn for the future.

A system for monitoring and evaluation serves as a management tool that enables continuous assessment of progress and helps officials make management decisions in response to problems identified. The findings, results, and recommendations of the monitoring and evaluation team should be discussed with national stakeholders and should serve as the basis for identifying problems, finding solutions, and improving performance. A monitoring and evaluation sys-

Country Study 4-3

When things go wrong with national medicine policies: The case of Yemen

From 1995 to 2002, the Republic of Yemen received technical help in developing a national medicine policy. An important element included the creation of an effective public pharmaceutical supply system to serve the 30 percent of the population unable to afford private-sector medicines.

Initially funded by donors, the system was intended to rely partly on government funding and partly on patient contributions. By late 2005, the system had virtually collapsed, and in an attempt to improve the situation, the government “nationalized” the system and declared that all medicines would be supplied free of charge from then on; however, no evident improvement occurred. By early 2006, donors were helping the government determine

why the system had failed while instituting an emergency supply program.

The situational analysis showed that the revolving fund proposal had never been adequately implemented through a detailed plan of action, that expectations of patient contributions had been too optimistic in view of widespread poverty, that successive governments had shown too little commitment to funding, and that corruption had played a major role.

In such situations, bringing together the original players and seeking their views on the failure and on a recovery plan are vital. In Yemen, a small-scale emergency scheme was set up to restore faith in the system, to be followed by a longer-term (five-year) recovery plan.

tem also provides transparency and accountability and creates a standard by which comparisons can be made between countries and areas and over time. All this information may produce the necessary evidence that progress is being made (or not) to support the policy in discussions with interested parties and policy makers.

Indicators for monitoring national medicine policies have been developed by WHO and are discussed in [Chapters 36 and 48](#). Indicators may need to be developed, adapted, or deleted to match particular national contexts. For example, countries may have additional objectives beyond those included in the WHO manual, such as development of national medicine production. In any case, a formal monitoring system is needed; ideally, this system would be integrated with the health information system. A lack of understanding about the value of monitoring and feedback can be a limitation that results in the inadequate allocation of human and budgetary resources. Therefore, this institution-building process requires the commitment of senior policy makers, but effective monitoring can be carried out even in countries with limited resources.

4.8 Constraints and facilitating factors

Formulating and implementing an NMP should be manageable, yet few countries have succeeded in implementing all aspects of their planned policies. Why? Some of the main reasons are clear—

Lack of political will: Many governments hesitate to create policies that might antagonize industry and other groups, particularly if opposition is known to exist. Building support even in potentially hostile sectors is important at the start of the process and as implementation progresses.

Lack of resources: Often, understanding or documentation of the problems, their causes, and solutions in the pharmaceutical sector is not sufficient to persuade national governments to devote scarce resources to building and implementing NMPs. The MOH will need to be persuasive in its communication with other ministries and departments to avoid these problems; the essential message is that a national medicine policy contributes to improving people's health and therefore to strengthening the economy and the nation.

Opposition: Frank opposition to medicine policies often comes from those who benefit from a laissez-faire approach. Doctors fear interference with their freedom to prescribe. Importers and manufacturers are commonly earning large profits on precisely the medicines or pharmaceutical practices that they fear would be threatened by policy changes, such as price controls or better procurement procedures. Retail pharmacists may

oppose policy initiatives that would threaten their earnings.

Corruption: Corruption can be an issue in the pharmaceutical sector, where a great deal of money flows and where demand, as a rule, greatly exceeds supply. No easy solution exists; corrupt practices in a country usually extend well beyond the pharmaceutical sector. However, as the pharmaceutical sector balances the roles of public and private services, corruption is likely to decrease.

None of these impediments is easily overcome, but a number of factors can facilitate the policy process—

Support of domestic and international interest groups:

Some of the domestic groups whose support is needed include political parties, industry groups, physicians and other health care professionals, consumers, and consumer activist groups. International interest groups include foreign governments, multilateral organizations, multinational corporations, and international lending agencies. Their support is required for successful policy formulation, even if it is sometimes necessary to enter into bargains and trade-offs to win such support. The consequences of each trade-off in the formulation and implementation of pharmaceutical policies should be carefully considered.

Shared values: The extent to which a congruence of interests exists among groups is another important predictor of the success of an NMP. The interests of a politically weak group (for example, poor consumers) can often be protected if its goals coincide, at least partially, with those of more powerful interest groups (for example, retail pharmacists who want to sell more medicines and are willing to handle generic products because the higher volume of sales can compensate for lower unit earnings).

The macroeconomic situation: Improvements in the efficiency of the pharmaceutical system may help countries cope with the consequences of macroeconomic shocks. For instance, the devaluation of the franc in West Africa pushed countries in the region to strengthen their essential medicines policies in the public sector and to introduce mechanisms to promote the sale of medicines under generic names in the private sector alongside more expensive branded products.

Technical expertise: The existence of technical expertise and capabilities within ministries of health, as well as access to data on patent-related issues and pharmacological, legal, and economic policy (including the policies of other countries), are key to the formulation of a sound and workable policy. WHO has a cadre of medicine advisers located in its country offices who can provide technical expertise (<http://www.who.int/medicines/areas/coordination/medicinesadvisers/en/index.html>). Donors and international organizations can also sup-

ASSESSMENT GUIDE

National medicine policy development and content

- Does an official NMP document exist? Has it been updated in the past ten years?
- Does the document contain objectives and strategies based on priority problems?
- Does it cover issues such as legislation, essential medicines list, registration of pharmaceuticals, supply of essential medicines, financing and pricing policies, and rational use of medicines?
- If no official NMP document exists, do any unofficial documents set objectives and strategies for the pharmaceutical sector?
- Do laws exist that specify the government's responsibility in ensuring equitable access to essential medicines?
- Does the national constitution or any other national law recognize the right of everyone to the enjoyment of the highest attainable standard of health?
- Were patients' organizations and rural communities consulted when the NMP and program were developed?

NMP implementation

- Is the NMP used as a guide for action by policy makers and senior management officers in the ministry of health?
- Does the NMP describe the obligations of the various stakeholders?
- Does the pharmaceutical legislation provide a legal basis for enforcement of the NMP?
- Does an implementation plan exist to put the policy into practice?
- Is the policy monitored regularly? If so, how is it monitored? Are baseline and target data available on access to essential medicines against which progress can be measured?
- Does any evaluation take place of the performance and outcome of the NMP in terms of attaining its objectives?
- Are legal mechanisms available to file complaints about lack of access to essential medicines? If so, have they been used?
- Is the NMP highly visible in the ministry of health and the government?

port the emergence and revision of medicine policies in developing countries through planning and technical assistance.

The presence of committed people in the MOH: In the United Kingdom in 1968, Bangladesh in 1982, the Philippines in 1986, Guinea in 1992, and Uganda in 1993, the development of these countries' first medicine policies was sustained by individuals and institutions that were persuaded of the need for it and worked toward its realization.

Each country must shape its own NMP in accordance with its needs and resources. The goals outlined at the beginning of this chapter provide a policy focus. Experiences in countries show that success in terms of public health is linked to the essential medicines concept, with an emphasis on a list of essential medicines. Strategies vary among countries, and in the end, the impact of a country's NMP depends on political commitment from the government and the support of doctors and other health professionals. ■

SUMMARY

For thousands of years, traditional medicine (TM) has been an important source of health care for much of the world, and many populations use and value TM not only as the source of their primary health care but also as part of their spiritual and cultural belief systems. Meanwhile, people in Europe, Australia, and North America have increasingly embraced TM, also referred to as complementary and alternative medicine (CAM), by using herbal medications to complement their standard health care.

Attractive features of TM practices include greater accessibility in many parts of the world, cultural acceptance in low- and middle-income countries, comparatively low cost and, often, a lesser need for modern technology. In developed countries, CAM is used for preventing disease and maintaining wellness, in addition to complementing conventional care for chronic and acute health conditions.

Although TM/CAM has a great influence on health care practices, there is wide variation from country to country in policies, laws, and regulations governing the safety, quality, and efficacy of TM/CAM therapies. Many consumers use herbal products to treat themselves—often without a health practitioner’s knowledge or advice.

Consumers and practitioners may not be adequately informed about potential adverse effects, drug interactions, and how to use herbal medicines safely. Lack of regulations on quality standards and evaluation for safety and efficacy of these products may cause problems, resulting in the marketing of unsafe or ineffective TM/CAM products.

Countries that already have a strong pharmaceutical regulatory structure in place should adapt their existing systems to include herbal medications, and countries that lack regulatory standards should work toward setting up a national system that encompasses both pharmaceuticals and herbal medicines. All countries should have some framework in place to review and monitor herbal medicines, including a regulatory agency, a national advisory committee, and a system to monitor adverse reactions from herbal medicines.

Expanding the credibility and integration of TM/CAM will require developing an evidence base for safety and efficacy, which means consolidating data from existing national and international studies and supporting new research to fill evidence gaps.

5.1 The changing role of traditional and complementary medicine in health care

For thousands of years, traditional medicine has been an important source of health care for much of the world, and many populations use TM not only as the source of their primary health care but also as part of their spiritual and cultural belief systems. Meanwhile, people in Europe, Australia, and North America have increasingly embraced alternative and complementary practices, such as the use of herbal medications, to supplement their standard health care.

The growing attention focused on TM has introduced a number of public health issues in developing and developed countries alike, including policy, safety and quality, efficacy, access, and appropriate use. Regulations that ensure the quality and safety of TM products and procedures are often lacking, and because herbal medicines are now marketed across regions and internationally, these issues have evolved from being local in scale and are now of global concern.

Definitions of traditional and complementary medicine

The World Health Organization (WHO) defines *traditional medicine* as—

Diverse health practices, approaches, knowledge and beliefs incorporating plant, animal, and/or mineral based medicines, spiritual therapies, manual techniques and exercises applied singularly or in combination to maintain well-being, as well as to treat, diagnose or prevent illness (WHO 2002, 7).

Traditional medicine is a comprehensive term that refers to forms of medicine long-established in a country, whether developed or developing. Health care practices that are not part of a country’s own tradition and that are not well established within the country’s conventional health care system are often referred to as *complementary* and *alternative* medicine. Sometimes, the terms *complementary medicine* or *alternative medicine* are used interchangeably with *traditional medicine*, but CAM may include more recently developed technologies, unlike TM.

TM/CAM therapies are considered medication based if they use herbal medicines, animal parts, minerals, or homeopathic remedies. Herbal medicines include herbs, herbal materials, herbal preparations, and finished herbal products that contain therapeutically active ingredients that are plant based. Therapeutic interventions that are not based primarily on medications are procedure based. These therapies may include acupuncture; manual therapies, such as

massage and chiropractic, heat, or exercises; and qigong, tai chi, yoga, meditation, or spiritual practices. Box 5-1 includes a list of definitions developed by WHO related to TM/CAM and herbal medications.

Increasing popularity of traditional and complementary medicine

Traditional medicine has been used continuously in developing countries for centuries, but more recently, alternatives to conventional medicine have become increasingly popular

in developed countries. TM and CAM have also attracted more attention within the context of the globalization of the health care sector, health sector reform, and health care provision. The popularity of TM/CAM is reflected in its worldwide economic importance: the global market for herbal medicines is estimated to be over 60 billion U.S. dollars (USD) and growing 10 to 20 percent a year (UNCTD 2000).

Traditional and complementary medicine usage is widespread. For example, according to WHO, up to 80 percent of people in Africa and Asia use TM as part of their primary health care; in China, traditional herbs make up 30

Box 5-1 WHO definitions related to traditional medicines

Traditional medicine. *Traditional medicine* is the sum total of the knowledge, skills, and practices based on the theories, beliefs, and experiences indigenous to different cultures, whether explicable or not, used in the maintenance of health as well as in the prevention, diagnosis, improvement, or treatment of physical and mental illness.

Complementary/alternative medicine. The terms *complementary medicine* and *alternative medicine* are used interchangeably with *traditional medicine* in some countries. They refer to a broad set of health care practices that are not part of that country's own tradition and are not integrated into the dominant health care system.

Herbal medicines. *Herbal medicines* are defined as plant-derived material or preparations with therapeutic or other human health benefits, which contain either raw or processed ingredients from one or more plants. In some traditions, material of inorganic or animal origin may also be present. Specific elements of herbal medicines are defined as discussed here.

- *Herbs*, including crude plant material such as leaves, flowers, fruit, seed, stems, wood, bark, roots, rhizomes, or other plant parts, which may be entire, fragmented, or powdered.
- *Herbal materials*, including, in addition to herbs, fresh juices, gums, fixed oils, essential oils, resins, and dry powders of herbs. In some countries, these materials may be processed by various local procedures, such as steaming, roasting, or stir-baking with honey, alcoholic beverages, or other materials.
- *Herbal preparations* are the basis for finished herbal products and may include comminuted or powdered herbal materials, or extracts, tinctures, and fatty oils of herbal materials. They are produced by extraction, fractionation, purification, concentration, or other

physical or biological processes. They also include preparations made by steeping or heating herbal materials in alcoholic beverages and/or honey, or in other materials.

- *Finished herbal products*, consisting of herbal preparations made from one or more herbs. If more than one herb is used, the term *mixture herbal product* can also be used. Finished herbal products and mixture herbal products may contain excipients in addition to the active ingredients. However, finished products or mixture products to which chemically defined active substances have been added, including synthetic compounds and/or isolated constituents from herbal materials, are not considered to be herbal.

Traditional use of herbal medicines. This refers to the long historical use of these medicines. Their use is well established and widely acknowledged to be safe and effective, and may be accepted by national authorities.

Therapeutic activity. This refers to the successful prevention, diagnosis, and treatment of physical and mental illnesses; improvement of symptoms of illnesses; as well as beneficial alteration or regulation of the physical and mental status of the body.

Active ingredients. These are ingredients of herbal medicines with therapeutic activity. In herbal medicines where the active ingredients have been identified, the preparation of these medicines should be standardized to contain a defined amount of the active ingredients, if adequate analytical methods are available. In cases where it is not possible to identify the active ingredients, the whole herbal medicine may be considered as one active ingredient.

Sources: Adapted from WHO 2002, 2000.

to 50 percent of total medicine consumption; and 90 percent of Germans, 70 percent of Canadians, and 50 percent of Swedes have used a natural remedy at some time (WHO 2008b; Hanssen et al. 2005).

Even with the long history of TM use in most countries, however, and a sharp increase in TM/CAM in developed countries, a schism remains between traditional and conventional medical practice. Typically, both traditional and conventional practitioners are unaware or even suspicious of what the other can offer in terms of health care and services. In addition, patients can be reluctant to admit to health care providers that they are using both types of treatment, creating what could be a potentially alarming risk—especially for those patients taking certain herbal medications in combination with pharmaceuticals.

But barriers to addressing issues related to TM/CAM appear to be weakening in some areas, such as government recognition. More countries are considering ways to integrate TM/CAM into their national health care system, as some Asian countries, including China and South Korea, already do (Holliday 2003). For example, a recent report notes that increasing numbers of U.S. hospitals and physicians are offering CAM therapies; more insurers are covering alternative treatments; and integrative medicine centers now exist, many of which have ties to medical schools and teaching hospitals (IOM 2005). Developing countries, too, are acting on the need to officially recognize TM; for example, the government of Uganda has begun to integrate TM into its health system, and South Africa now legally recognizes traditional healers as health care professionals (Bianchi 2004).

5.2 Why people use traditional and complementary medicines

Positive features that attract people to TM/CAM include diversity, flexibility, greater accessibility in many parts of the world, extensive acceptance in developing countries, comparatively low cost, and a lesser need for modern technological capability.

Accessibility

Traditional medicine therapies are commonly used in developing countries because they are often more widely available and more affordable than conventional therapies. In addition, because TM practices are, often, woven into everyday life and belief systems, and because traditional healers are trusted members of the community, TM is often the first source of health care at the community level. Conventional health care may be a last resort, especially if the nearest primary health care facility is some distance from the community.

In resource-limited countries, especially in rural areas, there are usually fewer conventional health care practitioners than TM practitioners. In India, TM is the only available source of health care for a large part of the rural population (WHO 2002). This situation has been aggravated as large numbers of trained and licensed conventional health care workers leave their native countries for better opportunities elsewhere (the “brain drain” phenomenon); sub-Saharan Africa has been particularly hard hit (see [Chapter 51](#)).

In developed countries, patients have become more informed about their health and use print media, television, and the Internet to get information on which to base their health decisions. As a result, alternative therapies are appealing because they are perceived as more natural and therefore safer compared to “manufactured” pharmaceutical products (WHO 2004a). A perceptual difference between cultures may be that people in developing countries are more likely to view TM as their primary source of medical care, whereas people in developed countries generally view alternative treatments as complementary to, rather than competitive with, conventional medicine.

Affordability

Most poor people in developing countries buy their medicines out of pocket; even if the public health sector offers medicines at no charge, essential medicines may not be reliably stocked, or health facilities may be too far away. The rural poor often cannot afford the transportation costs to get to a public health facility. Herbal medicines in developing countries are often cheap, and the TM practitioner may accept a trade in-kind or offer a sliding payment scale. In addition, many herbal medications are available for purchase in stores, so patients may buy and take medication without ever incurring the cost of seeing a practitioner. A cost comparison of malaria treatments in Ghana showed that clinic treatment cost USD 1.60, self-treatment with medicines bought from a private drug shop (both chloroquine and herbal) was USD 0.35, and self-treatment with herbs cost USD 0.10 (Ahorlu et al. 1997). Recent evidence also suggests that the rising cost of conventional medicine in some developed countries is contributing to increased use of alternative medicines (Pagan and Pauly 2005).

Perceived safety

TM/CAM therapies are also popular because of the lower rate of adverse effects compared with some pharmaceutical-based therapies. For example, St. John’s wort taken to treat mild depression generally causes fewer side effects than antidepressive pharmaceuticals; capsaicin cream, derived from hot *Capsicum* peppers and used to treat osteoarthritis, does not cause the gastrointestinal effects that nonsteroidal anti-inflammatory medications do. Evidence suggests that

some patients may choose an herbal medication over a conventional medication specifically to avoid adverse effects (Fraenkel et al. 2004). Although consumers may perceive herbal products as natural and therefore less likely to cause problems, these products are not without risk and are not necessarily safer than conventional pharmaceuticals.

Potential for treating disease

People also use TM/CAM because of its perceived efficacy, both in general (Sydara et al. 2005) and in particular for treatment of chronic, debilitating diseases that defy conventional pharmaceuticals. Indeed, plant extracts have been proved to have pharmacological effects on many conditions, both acute and chronic. Moreover, analysis from U.S. National Cancer Institute researchers showed that more than two-thirds of all drugs discovered in the previous quarter-century were derived from natural products, such as plants (Newman and Cragg 2007); for example, aspirin (salicylic acid) uses a compound derived from the white willow tree, and paclitaxel, a chemotherapy agent, is made using a substance found in the Pacific yew tree. As long-time treatments for the most severe form of malaria have become ineffective because of antimicrobial resistance, artemisinin compounds from *Artemisia annua*, an herb native to Asia, are now the first-line treatment for malaria in most countries.

Although research projects have investigated the effectiveness of herbal medicines to treat HIV/AIDS, thus far no equivalent to artemisinin for malaria has been found for HIV/AIDS. However, traditional healers have been targeted as essential partners in efforts to educate their communities and provide support for people living with HIV/AIDS (see [Country Study 5-1](#)), and many Africans use traditional herbal medications to treat AIDS symptoms and manage opportunistic infections (UNAIDS 2000, 2002). TM/CAM is also important to HIV/AIDS patients in developed countries; more than eighty percent of a sample of people living with HIV/AIDS in the United States reported regular use of alternative medicine therapies (Sparber et al. 2000).

5.3 Risks associated with herbal medications

Many people believe that, because herbal medications are “natural,” or have been used in some parts of the world for generations, they must be safe. But, like modern pharmaceuticals, herbal medications can cause adverse effects (Farah et al. 2000). The causes of such adverse reactions are diverse: the use of inherently toxic herbal medicines or an overdose of herbs, conventional drug–herbal medicine interactions, and idiosyncratic reactions such as allergies. Most countries have no adverse drug reaction surveillance (pharmacovigi-

lance) system for medicines at all, or the existing system may exclude herbal medicines.

Poor quality

A lack of strict standards for the production and manufacture of herbal medications can cause quality problems, such as adulteration, misidentification of ingredients, substitution of one herb with another, inclusion of pharmaceuticals without identification on the labels, contamination, and variability in the amount of active ingredient. For example, an analysis of different red yeast rice products on the market showed levels varying by 100-fold across ten products, and four were contaminated with a mycotoxin (ConsumerLab 2009). Heavy metals, fumigation agents, microbial toxins, and pharmaceutical substances have all been found in toxic concentrations in TM/CAM medications (Ernst 2001; Huang et al. 1997; Ko 1998). In 2009, a manufacturer recalled its herbal weight-loss product, which was found to actually contain the unlabeled prescription drug sibutramine, which can substantially increase blood pressure, and phenolphthalein, a suspected cancer-causing chemical that is not approved for marketing in the United States (FDA 2009).

Incorrect usage

Incorrect usage of herbal medication therapies can have fatal outcomes. The inappropriate long-term use of kava kava (*Piper methysticum*), for example, has been associated with serious cases of liver damage (Stevinson et al. 2002), and *Ginkgo biloba*, which stimulates circulation, may cause excessive bleeding during surgery (Ang-Lee et al. 2001). The U.S. Food and Drug Administration recalled all botanical products, marketed for a variety of ailments, that contained aristolochic acid, from the plant *Aristolochia*, after reports of adverse events showed a relationship with kidney failure. Problems also occur, when TM therapies are marketed and used in different cultures, with potentially hazardous changes in indicated uses and doses. *Ma huang* (*Ephedra sinica*), which contains ephedrine, has long been used in traditional Chinese medicine for respiratory symptoms, but its marketing at higher doses in the United States as a weight-loss product led to a number of severe effects and deaths (Ang-Lee et al. 2001).

Lack of information

Many consumers in both developed and developing countries use herbal products to treat themselves without a health practitioner’s advice because of the availability and relatively inexpensive cost of such products. Consumers who treat themselves, however, may be uninformed about potential adverse effects and the safe use of herbal medicines.

Country Study 5-1**Using traditional practitioners in HIV/AIDS activities in sub-Saharan Africa****Kenya**

Women Fighting AIDS in Kenya (WOFAK) is a non-profit support organization started in 1994 by ten women affected by HIV/AIDS. WOFAK has incorporated traditional medical practices into its program because of a concern that conventional medicine is too expensive for WOFAK clients. WOFAK works to sustain and promote various forms of traditional medicine and beneficial cultural practices throughout the country, and it supports the exploration of traditional therapies for HIV and associated opportunistic infections.

To further its objectives, WOFAK established a collaboration with the Kenya Forestry Research Institute (KEFRI) to grow, process, and conduct safety assessments and analyses of medicinal herbs. Although collaboration between conventional and traditional practitioners in Kenya is rare, WOFAK encourages such partnerships to improve the quality of health services to people living with HIV/AIDS. For example, a KEFRI herbalist worked part-time at the WOFAK drop-in center treating clients with herbal medicine. The center has two clinic rooms—one for traditional medicine and one for conventional medicine—and the center employs one community nurse, one traditional healer, one part-time doctor, and two herbal nurses. Cross-referrals occur between the conventional health practitioners and the traditional medicine practitioners, according to the condition, the medicine available, or the patient's preference. Conventional screening methods are used to determine the problem before treatment begins. In addition, WOFAK conducts training sessions for traditional healers in HIV/AIDS issues, including patient counseling, the role of traditional healers in AIDS control, and the identification of herbs for treatment of opportunistic infections.

Tanzania

The Tanga AIDS Working Group (TAWG) was begun in 1990 after a traditional healer successfully used herbal medicines to treat a patient in a government hospital in the Tanga region of Tanzania. The doctors were so impressed that they initiated collaboration with healers to better provide services for their patients with HIV/AIDS. One of the first TAWG activities was to work with local healers to develop three herbal remedies to treat a variety of HIV/AIDS-related conditions. From that activity evolved a home-care service for patients and their families, a type of service that patients often pre-

fer because it is more confidential than hospital-based services. These home visits are used to monitor general health, administer traditional therapies, and provide counseling services. Many hospital staff members refer patients to TAWG for HIV testing because they know that TAWG staff members have been trained as counselors on how HIV/AIDS is contracted, spread, and prevented.

In addition to home-based counseling, HIV testing services are provided at TAWG facilities. For patients who are hospitalized, TAWG prescribes herbal medicines collected by a healer and distributed by the hospitals, a process that allows patients to be monitored by conventional health care providers. TAWG's success is due to the trusting and collaborative relationship between clients, staff members, traditional healers, and conventional health practitioners.

Uganda

In the early 1990s, when the prevalence of HIV/AIDS in Uganda was among the highest in the world, the National AIDS Control Program, the Uganda AIDS Commission, and two nongovernmental organizations launched Traditional and Modern Health Practitioners Together Against AIDS and Other Diseases (THETA). THETA's first project was a collaborative clinical study to evaluate traditional herbal medicines for their effectiveness against HIV/AIDS-related symptoms, and its second project aimed to determine whether traditional healers could be trained as effective counselors on sexually transmitted infections and HIV/AIDS.

THETA's clinical studies showed that local herbal medications were just as efficacious in treating herpes zoster, which is especially problematic for people living with HIV/AIDS, as the conventional drug acyclovir. To increase access to these local products, THETA started an herbal processing-and-packaging demonstration laboratory, and grows medicinal herbs in a garden in Kampala. THETA also developed a Resource Center for Traditional Medicine and AIDS, which includes a library and a speakers bureau. To facilitate the exchange of information, the center has published booklets, training kits, educational videos, and a newsletter.

In addition, THETA's training program for traditional healers has been so successful that it has expanded to several districts. Healers who have gone through the intensive, two-year training and certification program serve as HIV/AIDS trainers for other traditional healers and

fill a gap in providing counseling services in geographic areas where counseling would not otherwise be available. Healers have been recognized for their unique education methods, which include song, dance, storytelling, and drama. Part of the training process includes workshops with conventional health practitioners to promote collaboration between traditional healers and health care providers.

I work together with fellow healers to educate the communities. When there are many of us, we can handle all the questions.

—Trained healer from Kiboga

South Africa

In South Africa, an estimated 80 percent of people regularly see *sangomas*, or traditional healers. The Nelson R. Mandela School of Medicine at the University of KwaZulu-Natal (KZN) in Durban has developed the Biomedical and Traditional Healing Collaboration Against HIV/AIDS to improve collaboration with traditional healers caring for people with HIV/AIDS. In 2003, a memorandum of understanding was signed between the school and the KZN Traditional Healers' Council (including the Ethekewini Traditional Healers' Council), as well as two other traditional healers' organizations, Mwelela Kweliphesheya and the Umgogodla Wesizwe Trust. The provincial health department helps run the project.

The project has trained hundreds of traditional healers on HIV/AIDS awareness, voluntary counseling and testing, home-based care, and antiretroviral therapy awareness. Membership in one of the councils is required for participation in the program. Traditional healers are recognized as effective counselors, and the project is

developing strategies that use *sangomas* to deliver HIV prevention messages and behavioral counseling.

Sangomas are already treating many patients with HIV/AIDS while they are on the waiting list for antiretroviral therapy. They not only treat people's opportunistic infections, but also encourage patients' behavioral changes and advise them on good nutrition and healthy living. The project is working to improve two-way communication and referral between *sangomas* and conventional health practitioners. The *sangomas* already refer patients to health care facilities, but they feel that they do not receive reciprocal referrals because of hostility on the part of the conventional practitioners. The project is working with all parties to clarify patient confidentiality issues, which should help improve communication and information exchange.

In addition, the project supplies the traditional healers, who do not have the resources to buy supplies such as rubber gloves, with home-based care kits and helps them incorporate record keeping into their practices, which, although advocated by the healer councils, is challenging because of low literacy. Record keeping is seen as an important element of successful collaboration between the traditional and conventional health systems.

Biomedical and Traditional Healing Collaboration Against HIV/AIDS recognizes that the integration of traditional healers into care for patients with HIV/AIDS will help reduce workload, improve patient care, and give the HIV/AIDS treatment program partners within patients' communities.

Sources: Kenya, Tanzania, Uganda: UNAIDS 2002; South Africa: Smart 2005; IRIN PlusNews 2010.

Often, the labeling of herbal preparations contains inadequate or unclear information about usage or possible adverse effects, leading to improper use by consumers. In a fatal example, the label on a bottle of Chinese wintergreen oil indicated that it was primarily for external use but could be taken orally for enhanced efficacy, even though ingesting as little as 4 mL can be fatal. An elderly consumer seeking relief from arthritis drank the entire contents of the 60 mL bottle that she purchased in a grocery, resulting in her death (Hofman et al. 1998).

Another problem is that most people do not communicate with their health care providers about other medications they are taking. Studies show that up to 70 percent of people use TM/CAM therapies simultaneously with conventional medicine without telling their health care providers (Eisenberg et al. 2001). This lack of com-

munication puts consumers at risk of suffering serious adverse effects caused by the interaction between herbal medicines and conventional medicines (Ernst 2001; Fugh-Berman 2000). Problems with herbal medicine-conventional medicine interactions can be prevented through improved communication between patients and health care providers and, in the case of self-treatment, better consumer information.

Clearly, issues related to herbal safety, herb-drug interactions, and health care provider and consumer education and communication are increasingly important for national and international authorities to address, given the growing popularity of herbal products in both developed and developing countries. WHO has published guidelines on developing consumer information for TM and CAM that discuss many of these issues (WHO 2004a).

5.4 Meeting the challenges of traditional medicine

Although TM has a great influence on health care practices worldwide, little reliable information exists regarding the safety, quality, and efficacy of TM/CAM medications, in part because most country governments do not regulate or officially recognize TM/CAM therapies. In the countries that do recognize TM, the scope of regulations varies considerably because of differences in history, culture, and product use. Some countries classify herbal products as medicines and some as food, and regulate accordingly. Generally, countries do not register herbal and other TM products the same way as conventional medicines, and evidence of quality, efficacy, and safety may not be required before marketing. Governments will continue to take different approaches in recognizing and classifying TM/CAM preparations unless an international framework is established for evaluating and regulating these products (Bast et al. 2002).

TM therapies have the potential to contribute to a better health care system in many places; however, a number of challenges must be met to avoid the emergence of more costly and less safe and effective health care (see [Box 5-2](#)). WHO has developed strategies to address these challenges through recent resolutions and through the publication of the *WHO Traditional Medicine Strategy: 2002–2005*. This overarching strategy includes four major objectives: (1) framing government policy; (2) ensuring safety, efficacy,

and quality; (3) enhancing access; and (4) promoting proper use of TM/CAM, including herbal medicines (WHO 2002).

To share experiences and support the adoption of TM/CAM strategies, more than 1,500 representatives from member states and interested stakeholders attended the first WHO Congress on Traditional Medicine in 2008 in Beijing. Attendees shared national experiences and information on national TM/CAM policy, regulation of traditional and herbal medicines and TM/CAM practice, TM in primary health care, and research. The resulting Beijing Declaration calls on WHO member states and other stakeholders to take steps to integrate TM/CAM into national health systems (WHO 2008a).

Government policy on traditional medicine

TM is used widely to prevent, diagnose, treat, and manage disease, but considering TM's popularity, the development of regulation and legislation of the herbal medicines market has generally been inadequate. Public policies on TM differ significantly because countries and regions have diverse priorities; for example, the Chinese and Indian governments want to use TM to strengthen primary health care in remote areas; in Africa, many countries are looking for the best ways to use local TM resources and make TM an integrated part of minimal health care packages; and in Europe, licensing providers and creating standards of training and priorities for research have become crucial issues.

Box 5-2

Traditional, complementary, and alternative medicine challenges

National policy and regulatory frameworks

- Lack of official recognition of TM/CAM and TM/CAM providers
- TM/CAM not integrated into national health care systems
- Lack of regulatory and legal mechanisms
- Equitable distribution of benefits of indigenous TM knowledge and products
- Inadequate allocation of resources for TM/CAM development and capacity building

Safety, efficacy, and quality

- Lack of research methodology
- Inadequate evidence base for TM/CAM therapies and products
- Lack of adequate regulation and registration of herbal medicines
- Lack of registration of TM/CAM providers
- Inadequate support for research

Access

- Lack of data measuring access levels and affordability
- Need to identify safe and effective therapies and products
- Lack of official recognition of role of TM/CAM providers
- Lack of cooperation between TM/CAM providers and conventional practitioners
- Unsustainable use of medicinal plant resources

Rational use

- Lack of training for TM/CAM providers as well as for conventional practitioners on TM/CAM
- Lack of communication between TM/CAM and conventional practitioners, and between conventional practitioners and consumers
- Lack of information for public on appropriate use of TM/CAM

Source: WHO 2002.

Countries create policies that help characterize the role of TM in the national health care system and ensure that regulatory and legal mechanisms promote good practice, equitable access, and assurance of quality, safety, and efficacy. Unfortunately, a 2003 WHO survey found that only forty-five countries reported having enacted a national TM policy (WHO 2005). Fifty-one additional countries, however, reported having such policies in development. Without relevant policies, TM/CAM is practiced with little government oversight and without patient or consumer protection. Therefore, national policies should encompass legislation and regulation of practice and products; education, training, and licensing of providers; and research and development.

Before a country develops a national TM policy, it should assess TM use and practices and evaluate how TM can be used to improve the existing health care system. A national policy on TM/CAM must ensure the safety, efficacy, and quality of TM/CAM products and practices; at the same time, such a policy is not useful if it unduly hinders patient treatment options or leads to higher health care costs.

Although national TM policies have been, initially, slow to take shape, countries are increasingly aware of the importance of ensuring the safety and efficacy of TM, and those with some sort of regulations on herbal medicines increased from fourteen in 1988 to fifty-three in 2003 (WHO 2005). Another survey showed that eleven of twenty-six drug regulatory authorities in sub-Saharan Africa actually registered TMs (WHO 2010a). But, again, because national priorities differ, government approaches to legislation and regulations lack consistency (see [Country Study 5-2](#)).

Integration into national health care systems

The integration of TM within the national health care system generally follows four approaches (Bodeker 2001; WHO 2008a).

A *tolerant* health system is based on conventional Western medicine, but allows some TM/CAM practitioners to practice in some capacity. In the United Kingdom, only the practice of osteopathy and chiropractic are protected by statute; Canada's provinces individually regulate CAM practitioners, resulting in some CAM practitioners being regulated in some provinces but not others; in the United States, provider training, credentialing, and licensure requirements vary from state to state. Few national credentialing and licensing bodies are available to determine qualifications for a particular practice.

An *inclusive* system recognizes TM practices but does not fully integrate them into health care delivery, education, or regulation. Nigeria and Mali are examples of inclusive systems, where the governments have a national TM policy, but there is otherwise little regulation of products or practices. In some countries, such as Norway, Zimbabwe, and

South Africa, authorities are giving substantial recognition to TM/CAM providers through national efforts designed to increase the integration of TM/CAM and conventional medical systems.

A *parallel* health care system has both conventional and TM as separate components of the national health system. For example, the government of India officially recognized the Ayurvedic and Unani medical systems through the Indian Medicine Central Council Act of 1970. More than 700,000 registered traditional medical practitioners are active in India and almost 500 colleges of Ayurvedic and other traditional medicine education exist (Joshi 2008).

An *integrated* system integrates conventional and TM systems at the level of medical education and practice. Integrative measures include government regulation and registration to control the safety, efficacy, and quality of herbal medicine products; registration of traditional healers and herbalists; and establishment of specialized hospitals, colleges, and universities. Worldwide, only China, the Democratic People's Republic of Korea, the Republic of Korea, and Vietnam are considered to have fully integrated systems (WHO 2002). The Association of Southeast Asian Nations recently committed to promoting the integration of TM/CAM into its members' national health care services, including drafting an Action Plan and Declaration on Traditional Medicine (ASEAN 2009).

Ensuring quality, safety, and efficacy

Many developing countries have a weak regulatory infrastructure for conventional pharmaceuticals, and most countries have no national regulations governing the quality, safety, and efficacy of herbal medications. To be registered as medicines, herbal products must undergo scientific study to assure their safety and efficacy, composition, dosage form, and claimed indications. However, in some countries, such as the United States, herbal products are regulated as foods rather than as medicines; manufacturers are not required to conduct safety or efficacy tests on their products and thus have little incentive to invest in research. Under U.S. law, the onus is on the Food and Drug Administration to prove toxicity in order to remove a product from the market.

Countries that do have a strong pharmaceutical regulatory structure in place should adapt their existing systems to include herbal medications, and countries that lack regulatory standards should work toward setting up a national system. All countries should have some framework in place to review and monitor herbal medicines, including a coordination agency, a national advisory committee, and a pharmacovigilance system for herbal medicines. WHO and its Regional Office for the Western Pacific have published a number of references and guidelines on assessing traditional therapies, and specifically herbal medicines, for use by government authorities and researchers. They are available

Country Study 5-2 The regulatory status of traditional medicine in eight countries

The creation of a national TM policy helps define the role of traditional medicine in a national health care system by putting mechanisms in place for ensuring availability, accessibility, safety, quality, efficacy, and appropriate use. Although more countries are recognizing and addressing the legal and policy issues surrounding TM and CAM, their efforts vary considerably in scope and approach. The following table summarizes the status of regulations, training, and insurance coverage in eight countries as of 2005 or before.

Country	Regulations and laws	Official training and education
Bolivia	<ul style="list-style-type: none"> Regulation of herbal medicines was instituted in 1982; they are regulated in their own category as over-the-counter medications. There are 52 registered herbal medicines. A postmarketing surveillance system is planned. Practice of TM was legally recognized in 1985. TM practitioners must have a government license, although no registry exists. No official program exists to integrate TM and conventional medicine. 	<ul style="list-style-type: none"> Ministry of Health established a training program for TM practitioners at conventional medical schools in 1982. KUSKA, a research organization, runs two TM schools. Formal courses, workshops, and seminars in TM are available through the government health sector.
Ethiopia	<ul style="list-style-type: none"> Health, Drug, Science and Technology Policy of 1999 covers TM national policy. Ethiopia does not regulate herbal medicine, and no regulatory status exists for herbal medicine. There are no restrictions on the sale of herbal medicines. Ethiopian Traditional Healers Association reviews practitioner qualifications in the absence of regulations. 	None
Gambia	<ul style="list-style-type: none"> No laws or regulations regarding TM exist, but a national policy is under development. There are no restrictions on the sale of herbal medicines. There is a licensing process for TM practitioners. Some TM practitioners are involved in the primary health program. 	<ul style="list-style-type: none"> There is a training program for TM for health workers.
Kenya	<ul style="list-style-type: none"> TM was incorporated into national health policy in the 1970s. Herbal medicines are not regulated, and there are no restrictions on their sale. TM practitioners must be registered. Patent law was revised in 1999 to include protection for TM. In 2004, Kenya announced that it would develop a national action plan on regulating and promoting TM. A postmarketing surveillance plan is under development. 	<ul style="list-style-type: none"> Some training is available for traditional birth attendants.
Netherlands	<ul style="list-style-type: none"> There is no national policy on TM/CAM. Herbal medicines are regulated under the same laws as conventional pharmaceuticals. There is no registration system for herbal medicines. They are sold in pharmacies and other outlets as over-the-counter products. As of 1997, CAM practitioners can legally practice medicine, except for specific medical acts reserved for conventional physicians. Legal registers exist for various categories of nonconventional practitioners who have satisfied specific requirements. Registration gives them the right to practice under a protected title, to ensure they are qualified in a specific field of health care. 	<ul style="list-style-type: none"> CAM institutions have organized training courses, developed standards of training and professionalism, and established national registration systems. Most members of CAM organizations are trained as conventional physicians or nurses. Courses on CAM are offered at conventional medical schools. Three-year programs are offered in homeopathy, separate from conventional medical school curricula.
Philippines	<ul style="list-style-type: none"> National policy on TM was established in 1997. There is a TM division within the Department of Health. Herbal medicines are regulated as over-the-counter medications, separate from conventional pharmaceuticals; medical claims may be made for herbals with supporting scientific proof. The postmarketing surveillance system includes conventional and herbal medicines. Traditional and Alternative Medicine Act signed in 1997 seeks to integrate TM into the national health care delivery system. Philippines Institute of Traditional and Complementary/Alternative Health Care was created to promote research and integration of TM. 	<ul style="list-style-type: none"> Training in TM for conventional practitioners is a government priority.

Country	Regulations and laws	Official training and education
United Kingdom	<ul style="list-style-type: none"> Herbal medicines can be licensed or unlicensed; if licensed, they must meet the same manufacturing and safety requirements as conventional medicines. Unlicensed herbal products are not required to meet any specific quality or safety standards, but that may change in accordance with new EU directives. The postmarketing surveillance system was expanded to include herbals in 1996. CAM practitioners without a conventional medical degree are tolerated by law but not officially recognized. No restrictions exist on registered physicians who also practice CAM if they have the required skills and/or qualifications. 	<ul style="list-style-type: none"> The British Medical Association recommends incorporating CAM into the undergraduate curriculum of medical schools and making accredited postgraduate training available. Many professional CAM associations offer training in their specialties. The Institute of Complementary/Alternative Medicines is working to establish national standards of training.
Vietnam	<ul style="list-style-type: none"> A national TM/CAM policy is under development. Laws and regulations on herbal medicines were established in 1989. They are regulated as prescription and over-the-counter medicines. More than 1,500 herbal medicines are registered. Safety requirements for herbal medicines include traditional use without demonstrated harmful effects and reference to documented scientific research on similar products. The postmarketing surveillance system integrates conventional and herbal medicines. Vietnam's constitution, as well as various laws and regulations, outlines the integration of conventional and traditional health care. Promotion of these objectives is a shared responsibility of the Ministry of Health, Vietnamese Traditional Medicine Association, and the Viet Nam General Union of Medicine and Pharmacy. Regulations from 1991 specify qualifications for TM practitioners as well as procedures they are permitted to use. The government entrusts an assessing committee with issuing licenses to TM practitioners. 	<ul style="list-style-type: none"> Government programs train community health workers to use TM methods to treat common diseases. No college or university of traditional medicine exists, although the government plans to create one. Hanoi Medical University has a department of traditional medicine. Two secondary schools are the main seats of learning in TM.

Sources: WHO: 2001, 2005.

online at <http://www.who.int/medicines/areas/traditional/en/index.html>.

Expanding the credibility of TM will depend on developing an evidence base for safety and efficacy, which means consolidating existing national and international studies and supporting new research to fill evidence gaps. The increasing number of national TM/CAM research institutes in developed and developing countries is an encouraging sign that more research and collaboration is under way. Examples are found in China, Germany, Ghana, India, Indonesia, Mali, Nigeria, Norway, Thailand, the United States, and Vietnam.

Evaluating quality. Correct botanical identity is a critical step in ensuring the quality of herbal medicine. Formal procedures are needed, including retaining botanical voucher specimens for each raw material batch and using simple organoleptic tests. Increasingly, thin-layer chromatography and qualitative and quantitative high-performance liquid chromatography methods are being used to confirm the identity and quality of raw materials. Other strategies that help ensure the quality of herbal products include developing standard operating procedures for cultivation and manufacturing, quality standards, and assays for determining the pharmacological activity of the product.

Evaluating or even establishing quality standards for herbal medications is difficult because the properties of plants vary drastically according to the plants' genetic makeup and variability; where they are grown, climatic conditions, and time of harvest or collection; and post-harvesting treatment. Some products share more properties with food products, whereas others are potent medicines, and each plant may have hundreds of natural constituents that contribute to its therapeutic qualities.

Without any sort of manufacturing standard, herbal products range in composition from products that are virtually unprocessed, to extracts, to mixtures that include other chemicals. Given their natural complexity and the differences in formulation, isolating and identifying key active ingredient(s), establishing dosage levels, determining mechanisms of action, and weighing risks against benefits often prove difficult. Overall, the general lack of regulations governing quality-control standards and consistency among herbal products hinders the ability of health professionals to guide patients on product selection and use, as well as the ability of researchers to conduct studies that could further clarify product efficacy and appropriate uses.

To ensure that herbal products marketed to consumers are of adequate and consistent quality, national drug regulatory authorities must establish guidance on all elements

of quality assurance, including standard operating procedures, such as Good Agricultural and Collection Practices (GACPs), Good Manufacturing Practices (GMPs), and Good Laboratory Practices (GLPs). Guidelines have been published related to these standards, such as WHO's *Quality Control Methods for Medicinal Plant Materials*. These guidelines not only facilitate the technical work of drug regulatory authorities but also encourage countries to establish quality-control procedures for herbal medicines.

Evaluating clinical efficacy. A report from the U.S. Institute of Medicine (IOM 2005) stated that conventional and complementary medical treatments should be held to the same standards for demonstrating clinical effectiveness and that investigators should use common methods, measures, and criteria to generate and interpret the evidence necessary for making decisions about the use of complementary medicines. Because TM/CAM practices have developed within different cultural and regional contexts, there have been only limited efforts at parallel development of standards and methods—either national or international—for undertaking the type of evaluation that exists for conventional pharmaceuticals. Importantly, scientific research has increased on the chemistry and pharmacology of raw herbal materials and constituent phytochemicals. Despite this increase, however, many natural products on the global market lack clinical proof of safety and efficacy. [Table 5-1](#) lists some herbal medicines that have been evaluated for clinical efficacy.

Additionally, TM/CAM practitioners often focus on the overall condition of the individual patient, rather than on the particular ailment or disease from which the patient is suffering. This more holistic approach to health care makes TM attractive to many people; to be evaluated, however, it requires an evidence base that uses innovative scientific approaches to include the many patient health factors, both specific and nonspecific, considered by TM practitioners. Therefore, the debate continues concerning the appropriateness of applying and combining accepted research methodologies to evaluations of TM/CAM.

Pharmacovigilance. Insufficient safety and efficacy research has hindered the development of national surveillance systems for monitoring and evaluating adverse reactions from herbal medicines. Pharmacovigilance needs to incorporate instruments to identify adverse reactions experienced by patients, studies to determine adverse reactions in specific settings, and a postmarketing quality surveillance system for herbal medicines.

Any adverse reaction reporting must document the product's specific batch number, identify the botanical ingredients present, and include other relevant information, when available. For example, an adverse reaction recorded for a product labeled "ginseng" could be incorrectly assumed to be caused by *Panax quinquefolius* (American or Western ginseng), whereas the product

may actually be made from *Pfaffia paniculata*, which is sold as Brazilian ginseng. Monitoring adverse drug reactions requires some technical sophistication to differentiate crude-milled herbal material in tablet or capsule form from concentrated extracts; the latter may contain solvent residue that may be the cause of an adverse reaction, rather than the plant. Similarly, simultaneous conventional pharmaceutical and illicit drug use should be documented to help clarify causality.

In cases where a national pharmacovigilance system for conventional pharmaceuticals exists, it should be enhanced and broadened in ways that will include surveillance of herbal medicines. Knowledgeable researchers and practitioners of TM should be consulted during the development of such systems. WHO has published guidelines on how to include herbal medicine monitoring in pharmacovigilance systems (2004b). [Chapter 35](#) provides more information on pharmacovigilance monitoring.

Enhancing access

Poor countries are the most in need of inexpensive, effective treatments for diseases and access to essential medicines. In these regions, some form of TM is often the most widely available and affordable source of health care. Creating linkages between traditional and conventional medicine through collaboration and communication may help improve health care access and services for all people, and especially for those in resource-limited, rural areas. Such linkages may also promote the acceptance of TM as part of the overall health care system.

Other access issues relate to the protection of TM knowledge and intellectual property rights and the sustainable use of natural resources. Many methods can be used to protect TM knowledge, such as creating a national policy on protecting indigenous knowledge and formalizing the record of information on medicinal plants.

Promoting acceptance of TM in the health care system. One strategy is to develop local professional organizations of TM/CAM practitioners that can form the basis of future national organizations. A strong organization of TM/CAM practitioners will help create better mechanisms for self-regulation and contribute to enhanced professional standards and increased consumer trust and safety. Establishing such professional organizations also facilitates outreach and communication within the health care community.

Countries in Asia that have better-integrated health care systems experience more professional information exchange and cooperation between the TM and conventional health sectors, partly through links in their educational systems (Holliday 2003). Recognizing the effect that TM has on the lives of most Africans, Uganda has added traditional healing studies to its university curriculum to

Table 5-1 Select examples of clinical effectiveness based on meta-analyses of clinical TM/CAM therapy research

Therapy	Medical condition	Conclusion
Artemether	Severe malaria	Equally effective as quinine, but more effective in quinine-resistant areas
<i>Ginkgo biloba</i>	Peripheral arterial disease	More effective than placebo
St. John's wort	Mild depression	More effective than placebo, as effective as (and safer than) synthetic antidepressants
Kava kava	Anxiety	More effective than placebo
Saw palmetto	Prostate hyperplasia	Effective in relief of symptoms
Horse chestnut (<i>Aesculus hippocastanum L</i>) seed extract	Chronic venous insufficiency	Effective in short term at reducing leg pain and swelling
Glucosamine sulfate	Osteoarthritis	Decreased pain and increased function

Sources: Ernst 2001; Pittler and Ernst 2008, 1999; Schneider 1992; Towheed et al. 2008.

show that TM has a role in the health care system. In some countries, more informal links are being made between TM practitioners and primary health care providers—especially through efforts to increase access to HIV/AIDS treatment and counseling (Kaboru et al. 2006). But in many other countries, the two types of health care providers work in isolation from each other. Creating opportunities to improve cooperation between TM practitioners and conventional medicine practitioners may allow patients to use both TM and conventional therapies to best meet their needs while improving patient safety. WHO has published the results of a workshop on how to help traditional health practitioners become more involved in primary health care (WHO 2009a).

Protecting medicinal plants. A key to guaranteeing access to traditional medicines is the protection and sustainable use of medicinal plant resources. Raw materials for herbal medicines are often collected from wild plant populations, and overharvesting for local use or to meet export demand is a growing problem. For example, when countries affected by chloroquine-resistant malaria began turning to artemisinin-based antimalarials, China, which exports raw material and extracts of the source plant, *Artemisia annua*, could not fulfill the need. Fortunately, *Artemisia annua* can readily be grown from seed as an annual crop, and many countries, including Kenya, Nigeria, and Tanzania, are establishing commercial plantations.

To help protect its resources, Kenya has banned the export of an endangered tree, *Prunus africana*, that has medicinal properties. The Republic of Kiribati is promoting resource management, conducting agricultural research on medicinal plants to help improve crops and yield, as well as offering registered traditional healers seeds and advice on growing conditions (B. Snell, *E-drug*, Feb. 7, 2005). As part of national TM strategies, other countries are compiling national inventories of medicinal plants to help focus efforts on natural resource management and sustainability.

Protecting indigenous knowledge and intellectual property. Use of herbal medicines requires access not only

to biological resources, but also to community knowledge about plants' therapeutic properties. However, rights to indigenous knowledge and resources have, for the most part, been overlooked by Western intellectual property systems, where the components of TM have been treated as part of the public domain and available to anyone. Although research into TM is essential to ensuring access to safe and effective treatments, the knowledge of TM practices and products can be a source of substantial economic benefit to companies and research institutes.

Currently, TM knowledge is being appropriated, adapted, and patented by scientists and industry, with little or no compensation to its original creators or holders, and without their informed consent. Because of such appropriation and because of the focus on intellectual property rights and pharmaceuticals in general, growing attention is being paid to the issue of protecting TM knowledge and products. But, because intellectual property rights are usually given to individuals or organizations, whereas indigenous knowledge is community based, determining what can and should be protected may be difficult.

Country Study 5-3 describes a unique collaboration between the University of California, Berkeley, and Samoa that is designed to protect indigenous knowledge while exploiting modern research and development capabilities.

WHO encourages countries to adopt systems that compile a national inventory of medicinal plants and create records to preserve TM knowledge and enable its correct and continuous use over generations. For example, the Ministry of Health in Côte d'Ivoire has conducted a knowledge survey among traditional practitioners and recorded more than 2,000 traditionally used plants (WHO 2002); traditional healers, lawyers, and scientists are some of the stakeholders in Zambia working to create a national policy specifically to protect and document knowledge and biological resources (Ngandwe 2005); and India has developed a digital library of knowledge and formulations used in Ayurveda that is organized to help international patent offices to avoid granting inappropriate patents. Other countries, such as China, are

Country Study 5-3**Innovative indigenous knowledge research agreement: Samoa and the University of California, Berkeley**

In the 1980s, an ethnobotanist from the United States was searching for a cure for breast cancer among the flora in Samoa. As part of the project, he interviewed two *taulasea* (traditional healers) who had used the bark of the indigenous mamala tree (*Homalanthus nutans*) as a treatment for hepatitis. Later tests of mamala showed that it contained prostratin, a previously known substance that showed powerful effects against HIV in the laboratory. The hope is that prostratin will become an effective treatment for HIV/AIDS. However, the supply of prostratin is limited to mamala tree bark, found wild in Samoa and a few other South Pacific islands. To make prostratin more widely available without endangering its source in the rain forest, researchers at the University of California, Berkeley (UC Berkeley), are using genetic engineering to clone the tree's genes and insert them into microbes to mass-produce the substance.

This research is conducted under an innovative agreement between the university and the nation of Samoa, which asserts national sovereignty over the gene

sequence. The intellectual property agreement was made after scientists visited tribal chiefs to give a presentation on genetic engineering. The contract gives Samoa and UC Berkeley equal shares of any royalties that the university might ultimately derive from the use of the genes. Samoa's portion will be allocated to the government, villages, and the families of the *taulasea* who first showed the American ethnobotanist how to use the plant. In addition, if the research results in a marketable product, UC Berkeley and Samoa will establish a distribution process that will allow access to developing countries at a cost including no or minimal profit.

A separate agreement was established in 2001 between the Samoan government and the AIDS Research Alliance (ARA), allowing clinical research on prostratin, with 20 percent of the ARA's profits to be returned to the Samoan people. ARA planned to finish its preclinical trials in 2010, paving the way to begin human clinical trials.

using the Indian database as a template for developing their own knowledge libraries (Hepeng 2005). The information generated by these inventories should be used by national patent offices worldwide to evaluate the novelty and innovation of patent applications. In South Africa, the Patents Amendment Act of 2005 requires that every patent application state whether the invention is based on or derived from traditional knowledge.

Promoting rational use

As with the rational medicine use concept promoted for conventional pharmaceuticals (Chapter 27), appropriate use of TM and herbal medicines is dependent on qualified practitioners, proper prescribing and use of high-quality products, and reliable information and guidance for practitioners and patients. The degree to which traditional or alternative medicine is integrated into the conventional health care system will affect the type of information about TM/CAM needed in the community. In many countries, additional work is needed to raise awareness of safe and appropriate use of TM, but unfortunately there is a shortage of organized networks of traditional practitioners to help promote safe TM practices.

Reliable information based on results from high-quality scientific studies is crucial in guiding TM/CAM practitioners, conventional health care providers, and the public

in the most appropriate use of herbal medicines. The *WHO Monographs on Selected Medicinal Plants* is an important reference for national health authorities, scientists, and pharmaceutical companies, providing technical information on the safety, efficacy, and quality control of widely used medicinal plants (WHO 1999, 2004, 2007, 2009).

Proper use by providers. Training for TM practitioners should ensure that their knowledge and qualifications are adequate in their area of expertise. Without appropriate training or accompanying qualification and licensing schemes, it is difficult for national authorities and consumers alike to identify qualified TM providers. In the few countries that integrate TM and conventional medicine into one health care system, TM practitioners benefit from university education, which should include study of both TM and conventional medicine. Subsequently, these practitioners can become part of staff at hospitals of conventional medicine, promoting the use of TM in combination with conventional medicine practices. In the absence of formal education, TM practitioners or healers who receive basic training in primary health care can help disseminate important health information, especially in areas where people rely predominantly on TM.

Also, because TM/CAM use is becoming more widespread, all doctors, nurses, pharmacists, and other conventional health care providers should receive education about TM treatments during their professional education. Parallel

ASSESSMENT GUIDE

TM/CAM national policy, laws, and regulations

- Is there a national policy on TM/CAM?
- Are there any laws or regulations relating to TM/CAM? How are the laws enforced?
- Do any laws or regulations pertain specifically to herbal medicines?
- If so, are herbal medicines regulated separately from conventional medicines? Are they classified as prescription or over-the-counter, or are they given another status, such as food?
- Is there a national program or expert advisory group that has responsibility for TM/CAM issues?

Evaluating the quality, safety, and efficacy of herbal medicines

- What regulatory requirements apply to the manufacturing of herbal medicines?
- What are the regulatory requirements for the safety assessment of herbal medicines?
- What type and level of evidence, if any, is required to prove the efficacy of herbal medicines?
- Is there a registration system for herbal medicines?
- Is there a postmarketing surveillance system for herbal medicines? Does it include reporting for adverse reactions?

TM/CAM research

- Is there a national research institute devoted to TM/CAM?

- Are there any policies in place to compile an inventory and/or protect traditional medicine resources, such as endangered plants? Is there any system to document indigenous knowledge and resources?

Integration of TM/CAM into the conventional health system

- Is TM/CAM officially recognized by the government as part of the health care system? Is there any integration with the national health care system? Are there any herbal medicines on the national essential medicines list?
- Is the practice of TM/CAM regulated both for health care providers and TM/CAM providers?
- Are there any training programs for TM/CAM practices?

Use of TM/CAM

- How do consumers typically use herbal medicines? Where do they buy herbal medicines? From pharmacies or other medicine outlets? From licensed or unlicensed practitioners?
- How are consumers informed about the benefits and risks of herbal medicines? Are there any regulations related to medical or health claims or labeling?

education helps TM providers and conventional health care professionals understand how their roles can complement each other for the benefit of the patient.

Proper use by consumers. Because many consumers use herbal medicines without consulting a health care professional, they must have access to reliable information and product labeling to make informed decisions on the safe use of herbal medicines. Without knowledge of the potential for adverse reactions, patients may fail to inform their doctors about the TM/CAM products they are using, and doctors may fail to ask.

Public information about TM/CAM helps spread knowledge about the health benefits as well as the possible risks, but the information must be reliable and adapted to the specific local context. An information campaign on herbal medicines should consider the local social, cultural, religious, and spiritual contexts, because medical concepts and understanding can vary significantly. Consequently, efforts to ensure that consumers use TM/CAM properly

must involve a range of stakeholders, including government representatives, health authorities, professional and consumer organizations, and TM/CAM researchers. An important resource related to consumer education is *Guidelines on Developing Consumer Information on Proper Use of Traditional, Complementary and Alternative Medicine* (WHO 2004a).

Currently, few standards exist to control the labeling and advertising of herbal medicines. The regulatory framework for TM/CAM products should include guidelines on how to educate the public, including restrictions on information and advertisements. Such regulations can be issued either by national authorities, in the form of enforceable controls, or by local organizations, such as professional groups, in the form of voluntary controls. These kinds of regulations help secure the trustworthiness of the information, prevent false health claims and misleading advertisements, and ensure the appropriate labeling of TM/CAM products.

Consumers also need to be reminded that information on the Internet is not easily controlled or regulated and that special attention is needed when evaluating online information (see Chapter 34). Some countries have special regulations to control the publication of health information on the Internet, but product marketing and advertising are mostly unrestricted. ■

SUMMARY

Realistic and effective laws and regulations are needed for the pharmaceutical sector because—

- Pharmaceuticals concern the whole population
- Many parties are involved: patients, health providers, manufacturers, and salespeople
- Serious consequences, including injury and death, can result from the lack or misuse of medications
- The consumer has no way to determine product quality
- Informal controls are insufficient

Countries may choose to develop new legislation or to revise existing laws. When starting afresh, it is useful to prepare a general law. Models exist, and expert assistance is readily available. After the law is passed, regulations made under it can bring its various provisions into operation, one by one, as the necessary resources and experience are acquired.

In drafting or revising legislation, a country should—

- Inventory the laws and regulations already in force
- Determine what type of legislative instrument is required
- Involve both legal and health experts
- Keep all interested parties informed

National drug legislation generally includes provisions relating to the manufacturing, importing, distribution, marketing, prescribing, labeling (including language), dispensing, and sometimes pricing of pharmaceutical products, as well as the licensing, inspection, and control of personnel and facilities. A regulatory authority is usually established for administrative control. Medicine registration is often a major element in legislation, to ensure that individual products meet the criteria of efficacy, safety, and quality.

Countries that need to introduce comprehensive legislation can seek guidance from the experiences of others and from WHO (2001a) guidelines.

6.1 The role of pharmaceutical legislation and regulation

The role of pharmaceuticals has become more prominent on international agendas as health indicators have been increasingly linked with a country's successful development. In addition, the legal and economic issues that surround pharmaceuticals have become more complex and politicized because of the increase in global trade.

Why pharmaceutical laws and regulations are necessary

The use of ineffective, poor-quality, or harmful medicines can result in therapeutic failure, exacerbation of disease, resistance to medicines, and sometimes death. It also undermines confidence in health systems, health professionals, pharmaceutical manufacturers, and distributors. To protect public health, governments need to approve comprehensive laws and regulations and to establish effective national regulatory authorities to ensure that the manufacture, trade, and use of medicines are regulated appropriately and that the public has access to accurate information on medicines.

Differences between pharmaceutical laws, regulations, and guidelines

Laws today are usually written in fairly general terms to meet present and possibly future needs. Laws usually have

language that enables the government to issue regulations based on the law. Passing new laws may require a lengthy process, with the country's legislative branch giving final approval. Regulations can be passed more rapidly and simply than laws, sometimes requiring, for example, only the approval of a single government minister on the advice of experts. They can also be altered more easily. After approval, a regulation has the same power as the law itself. Guidelines, which do not carry the force of law, can be more easily modified and updated and offer informal information on what the government's thinking is regarding the best way to implement regulations. Following guidelines will help avoid misinterpretation of and facilitate compliance with laws and regulations.

Pharmaceuticals involve many parties, including patients, doctors, other health workers, salespeople, and manufacturers. The field also involves important risks: people can suffer or die not only from a lack of medicines, but also from drugs that are impure, wrongly prescribed, or used incorrectly. Thus, it is easy to see why laws and regulations are needed. However, some argue that medicines—like many other commodities—should be subject only to the control of the ultimate user. But medicines are indeed different, as discussed in [Chapter 1](#).

Additionally, informal controls are insufficient: charlatanism or quackery (that is, the deliberate sale of remedies known to be worthless) is centuries old, and firm action may be needed to put a stop to it; however, as discussed later in the chapter, the Internet presents new challenges in

controlling deceitful drug promotion. Counterfeiting, also, has been on the rise in developed and developing countries. U.S. customs officials, for example, report that pharmaceuticals are one of the fastest-growing categories of counterfeit goods coming into the country illegally. Pharmaceuticals accounted for 10 percent of total seizures in 2008 to become the third-largest category, compared to 6 percent in 2007 (Mui 2009).

The approach to pharmaceutical regulation should not be simply punitive: rules creating a positive situation tend to be more effective. Finally, laws and regulations are effective only to the extent that they meet society's needs.

Evolution of policy and law

There may be a long preparatory period before the sort of consensus develops that can form the basis for a law. It is sometimes preferable to work for a while with informal agreements among parties or with government guidelines, so that generally accepted rules of behavior can develop in practice; the law then serves to confirm and formalize them (see [Country Study 6-1](#)).

Whether or not a national drug policy exists, countries need effective, enforceable legislation and regulation. These legislative acts may take the form of a single national drug law that deals with all the issues or a series of complementary laws, each introduced when the time is right. In some countries, certain aspects of the pharmaceutical sector are governed by national laws, and other aspects, such as pharmacy and medical practice, are governed by state or provincial laws. This chapter focuses on a single, comprehensive drug law at the national level. Most of the issues discussed are also applicable in situations where legal responsibility is divided between national and state or provincial governments.

A law on medicines must, first and foremost, clearly define what all the parties—manufacturers, doctors, pharmacists—are required to do, so that no serious misunderstanding is possible. Medicine registration laws and regulations, for example, make clear what a manufacturer needs to do to obtain a license to sell a product. They define how a registration agency should assess both the manufacturer and the product to determine if they meet society's needs.

A good law also creates administrative bodies to put rules into practice—for example, a national drug regulatory authority with broad competence, or separate organs to deal with the various aspects of pharmaceutical regulation such as practice of pharmacy, inspection of factories, and advertising of medicines.

Trying to achieve too much, too quickly, can be tempting. It took more than a hundred years for pharmaceutical policies and laws to evolve to current levels in the industrialized world. Sensible questions to ask are—

- What are the most important goals to achieve within five, ten, and fifteen years?
- What means are available to achieve them?
- In which order can they best be tackled?
- What help is available?

The answers to these questions provide a good starting point in developing both policies and the laws needed to support them.

Laws and regulations are intended to be used together to achieve their objective. It is appropriate to begin with passing a broad law, emphasizing the requirement that pharmaceutical products be safe and effective. The various provisions of the law are then brought into operation through regulation, step by step, addressing the most important things first. For instance, in resource-constrained countries, setting up a new pharmaceutical distribution system may be urgently necessary, but pharmaceutical registration can wait for several years, while procuring essential medicines in the meantime through reputable channels where product quality is controlled.

Globalization and harmonization

Laws and regulations evolve within countries over time, but in recent years, the trend has been toward the globalization of pharmaceutical issues, which affects national legislation. This globalization, exemplified through changes in international trade, patent protection, and pricing, has resulted in a number of initiatives that must be considered by countries developing pharmaceutical regulations. Some examples of these initiatives follow.

TRIPS Agreement. The TRIPS Agreement (Agreement on Trade-Related Aspects of Intellectual Property Rights) of the World Trade Organization (WTO) has greatly affected international pharmaceutical regulation. TRIPS is an attempt to reduce gaps in the way intellectual property rights are protected around the world and to bring them under common international rules; however, the implications of the agreement's provision on patents caused concerns in developing countries. In response to those concerns, at the Doha Conference in 2001, WTO members adopted a special affirmation—known as the Doha Declaration—on issues related to TRIPS and public health. The declaration affirms that the TRIPS Agreement should be implemented in ways that protect public health and promote access to medicines. [Chapter 3](#) on intellectual property and access to medicines goes into more detail on these issues.

Driven by the increase of global trade in pharmaceutical products and the subsequent complexity of technical regulations related to medicine safety and quality, several initiatives have been established to promote the harmonization of international pharmaceutical guidelines and regulations

by intergovernmental organizations at regional and inter-regional levels.

International Conference on Drug Regulatory Authorities. Organized by WHO, the International Conference on Drug Regulatory Authorities (ICDRA) provides officials from the drug regulatory authorities from all WHO member states with a forum to work on strengthening cooperation and collaboration. Held since 1980, the annual conferences promote the exchange of information

and provide a platform to develop international consensus on pharmaceutical regulation. The conferences are a unique forum that assemble all drug regulatory authorities, regardless of their organizations' stage of development. The ICDRA has been instrumental in guiding regulatory authorities on how the harmonization of regulation can improve the safety, efficacy, and quality of medicines.

International Conference on Harmonisation. The International Conference on Harmonisation of Technical

Country Study 6-1 The evolution of pharmaceutical legislation

Venezuela's first medicine-related law was issued in 1883 as the Ordinance of the Council of Physicians on Secret Medicines and Patents. Pharmaceutical laws have been revised regularly; a significant number of pharmaceutical laws were adopted over the course of the twentieth century. The law that established the medicine registration system—the Law on the Exercise of the Pharmacy—was passed in 1928, before the Ministry of Health was set up in 1936. The National Institute of Hygiene was established in 1938 to serve as the nation's national regulatory agency. Over the years, new rules and organizations have been created to expand the scope of regulation and to add capacity for executing the laws. The section on pharmacological advice, the Laboratory for Pharmacological Analysis, and the Center for Pharmacological Surveillance were established in 1944, 1946, and 1962, respectively. Rules for good manufacturing practices (GMP) were drawn up in 1990. A pharmaceutical law was approved in 2000 that addressed certain concepts for the first time, such as generic and essential medicines.

Tunisia first introduced pharmaceutical regulation in 1942, in the form of a decree on medical and pharmaceutical promotion and medicine control. All finished pharmaceutical products, whether manufactured in Tunisia or imported, must undergo a technical committee review and obtain a certificate of approval from the Ministry of Health before they may be placed on the market. Registration is also required for homeopathic drugs, and some herbal medicines are registered with the status of allopathic medicines. Key legislation includes the 1961 Law on Inspection of Pharmacies and Manufacturers, the 1969 Poisonous Drug Law, and the 1985 Law on Production of Drugs for Human Use. Between 1985 and 1991, several legal texts were promulgated concerning GMP, clinical trials, medical and scientific information, procedures to obtain licensing of manufacturing and registration. New organizations

were also created by law, for example the Pharmacy and Medicines Directorate in 1981, the National Pharmacovigilance Center in 1984, and the National Medicines Control Laboratory in 1990.

In the **Netherlands**, the legal basis for licensing of pharmaceutical manufacturing and distribution was established in 1956. The Medicines Act of 1958 thereafter regulated the admission of medicines to the Dutch market through the Medicines Evaluation Board. But the board started to operate only after 1963, triggered by the thalidomide disaster of 1961. European pharmaceutical regulation is now playing a growing role. In 1995, the European Medicines Evaluation Agency was founded to coordinate the tasks of the drug regulatory authorities of European Union member states. Certain aspects of the Netherlands' pharmaceutical regulation now follow European Union rules. For example, GMP inspection is based on the 1983 European Union guidelines for GMP. Since January 1, 1995, a European procedure for registration has operated in the Netherlands. Now two types of trade licenses exist: a European license and a national license. Products with a European license may be sold throughout the European Union, while the national licenses are valid only for the country in which the license was issued by means of the national registration procedure.

Estonia's drug regulatory framework began to take shape only over the two decades since the country gained independence. However, the pace of regulatory development has been rapid. The Licensing Board of Pharmaceutical Activities and the Center of Medicines were both created in 1991. Registration and licensing were introduced that year. In 1993, the State Agency of Medicines was created to become the Drug Regulatory Authority. The main legislation—the Medicinal Products Act—came into force in 1996.

Requirements for Registration of Pharmaceuticals for Human Use (ICH) is a project that brings together the regulatory authorities and experts from the pharmaceutical industry of Europe, the United States, and Japan to discuss scientific and technical aspects of product registration. The purpose is to promote harmonization in the application of technical guidelines and requirements for new product registration in order to reduce the duplication of and facilitate the evaluation of testing carried out during the research and development of new medicines. Harmonization conserves resources and increases the availability of new

medicines, while maintaining regulatory obligations to safeguard the products. Although intended for new products, ICH guidelines are also being used to register existing products. The guidelines, formally produced by and for ICH member countries, reflect the technical capabilities of their well-developed regulatory agencies and pharmaceutical industries. Thus, other countries should consider their local situations before trying to apply ICH guidelines. However, the ICH guidelines do end up affecting all countries, particularly as they relate to the quality specifications of medicinal products, including generic medicines, the

Country Study 6-2 Harmonization efforts in the Americas

Although subregional harmonization activities have been under way in a number of countries in the Americas (for example, Mercosur, the Andean Community, NAFTA), no overarching mechanism existed for exchanging information and promoting harmonization in the Americas.

In 1999, a hemispheric forum was established, with the Pan American Health Organization (PAHO) as its secretariat, to communicate about pharmaceutical regulation among the different subregions. The resulting organization, known as the Pan American Network for Drug Regulatory Harmonization (PANDRH), has a steering committee that represents the drug regulators of subregional groups active in the pharmaceutical regulatory harmonization process and formulates recommendations on how to promote coordination among the countries. PANDRH includes all representatives involved in addressing the problems connected with pharmaceuticals: regulatory authorities, industry (domestic and multinational), consumers, and professional associations.

In addition, PANDRH has formed a number of working groups to address issues of importance to pharmaceutical regulations including good manufacturing practices, bioequivalence, good clinical practices, drug counterfeiting, pharmacopoeias, and external quality control. Examples of working group activities include harmonizing good manufacturing practices guidelines for inspectors and making the guidelines easily available on the PANDRH website (http://new.paho.org/hq/index.php?option=com_content&task=view&id=1054&Itemid=513); developing specific criteria to prioritize necessary bioequivalence studies; and developing inspection guidelines for audits on good clinical practices, including establishing legal penalties for noncompliance.

The PANDRH steering committee adopted statutes in 2009, which are available on the website.

As PANDRH secretariat, PAHO supports the member countries with—

- Information on pharmaceutical legislation
- Collection and dissemination of documents, experiences, and procedures on drug regulatory harmonization in each country and subregion
- Research to document compliance with existing harmonization agreements
- Definition of the analytical methodology for addressing common problems
- Exchange of information among the harmonization efforts of the different integration processes

Subregional and technical meetings are held often, and PAHO convenes periodic conferences that bring together all the groups to share information and advance harmonization efforts. The Pan American Conference is a meeting open to all interested stakeholders, including consumers, industry representatives, and nongovernmental organizations. Providing an open forum helps ensure the successful adoption and implementation of harmonized outcomes.

One of the major issues of concern to PANDRH members is the recognition that serious limitations exist in some subregions, such as Central America, where no legal framework exists to authorize and operationalize the commitments made by technical groups; therefore, PANDRH takes the particular needs of each subregional bloc and the different degrees of development of their constituent countries into account to implement the subregional agreements. This specificity means that the agreements must be implemented gradually.

requirements for which vary considerably across countries (Gray 2004). WHO, with its observer status on the ICH steering committee, is expected to act as a link between ICH and non-ICH countries (through the ICDRA) and to disseminate information to non-ICH countries. The ICH has also established a Global Cooperation Group that promotes ICH guidelines by acting as an information resource for nonmembers.

Country Study 6-2 discusses regulatory harmonization efforts in the Americas.

Pharmacopoeias. Pharmacopoeias are documents that outline technical information, manufacturing and testing procedures, and standards for active pharmaceutical substances and products. Some countries, such as Germany and Thailand, also have pharmacopoeias specifically for herbal products. A pharmacopoeia is usually recognized as part of a country's national pharmaceutical laws; therefore, the standards and procedures are legally enforceable. WHO has also developed an international pharmacopoeia that, unlike other pharmacopoeias, has no legal status, but is meant as a reference for member countries that may adapt it and incorporate it into their national legislation. Because of the extensive resources required to produce and maintain these complex documents, most countries do not have national pharmacopoeias and rely on one or more internationally recognized pharmacopoeias, such as those from the United States, the European Union, Japan, or WHO. The organizations that publish pharmacopoeias, pressured by the need to facilitate international trade, are actively working to harmonize their requirements.

Drafting and revising pharmaceutical legislation and regulations

Regulatory authorities are continually faced with new issues—such as globalization and extension of free trade—while increased responsibilities from market expansion and the sophistication and new categories of products place heavy demands on regulatory systems. The development of cutting-edge technologies and health care techniques and the extensive use of the Internet as a source of information and commerce impose further complex challenges.

As a first step before drafting any new law, it is important to inventory the laws and regulations already in force. Even if no general drug law exists, pieces of legislation are likely to touch on the field—for example, laws on narcotics and the licensing and responsibilities of pharmacists. An out-of-date general drug law may exist that should be replaced rather than merely amended. Determining the extent to which existing laws and regulations contribute to attaining the national policy objectives is essential. Because concepts of pharmaceutical policy are modern, legislation more than twenty years old may not be relevant; starting over may be simpler.

The second step is for drafters and experts to meet to decide what type of legislative instrument is required. The most straightforward model is likely to be a comprehensive law that deals in outline with all the relevant issues, each main section taking up a particular matter. Sections can then be implemented one at a time, through the passage of regulations.

In countries with a long history of regulation, laws on pharmacists and the registration of medicines as well as regulations on prices and costs are likely to be separate, because they came into being at different times. In starting afresh, however, and particularly if the laws on these matters are outdated or incomplete, it may be easier to pull together all relevant elements into a single law.

Ideally, the task of writing or revising the law should be entrusted to a group of legal and health experts who are familiar with all the issues, but not all countries can assemble such a group. Rather than solving the problem by copying laws from abroad, countries with limited expertise can obtain assistance from international and bilateral agencies to draft new pharmaceutical legislation that meets the country's own needs. International and regional meetings of drug regulatory authorities (for example, ICDRA) also provide opportunities for learning how to approach the problem and identifying expert colleagues who can be called on for advice. In addition, WHO has a number of publications that can assist countries in developing national medicine policies (available at http://apps.who.int/medicinedocs/en/cl/CL1.1.1.1.2/clmd,50.html#hlCL1_1_1_2).

At all stages of the process, it is important to discuss early drafts of the law with all interested parties, including the health professions, trade and industry groups, other concerned government departments (such as those handling commerce and education), and consumer groups. The greater the consensus, the greater is the chance that a law will be passed and will work in practice. Sometimes, countries react to a crisis by rushing through the enactment of a new law without putting it through a consensual process or carefully evaluating its effect on other sectors. However, this attempt to respond quickly may backfire if the law is not carefully thought through.

When the law is approved, regulations are developed to guide the implementation of the law. Regulations can be modified more easily than laws as the local situation evolves. When a regulation is revised, it is important to research and take into account what other laws will be affected by the revision. Declaring that a revision nullifies all previous laws and regulations in conflict, without making sure what those previous laws cover, can result in confusion. It is easier to track revisions when a country's laws are well codified, such as in the *U.S. Code of Federal Regulations*. Following the adoption of regulations, guidance documents may be developed to provide more flexible and detailed information on how to comply with regulations.

Box 6-1 Elements of a comprehensive drug law

A. General provisions

1. Title*
2. Purposes*
3. Territorial extent
4. Application of other laws
5. Definitions*

B. Control of availability and marketing

1. Drug registration*
2. National essential medicines list/national formulary
3. Scheduling prescription, and dispensing authority*
4. Labeling*
5. Generic labeling, manufacturing, and substitution
6. Pharmacovigilance
7. Information and advertising*
8. Public education
9. Imposition of fees
10. Price control
11. Special products (herbal medicines, medicines for clinical trials, orphan drugs)

C. Control of supply mechanisms

1. Importation of medicines*
2. Exportation of medicines*

3. Controls, incentives, disincentives for local manufacture
4. Control of distribution, supply, storage, and sale*

D. Drug control administration

1. Organization and function*
2. Appeals against decisions of the drug control authority*

E. Powers of enforcement

1. Prohibition of specified activities*
2. Penalties for each offense based on magnitude and occurrence*
3. Legal procedures for offenses*

F. Powers to make rules and regulations

1. Who has authority*
2. Under which circumstances*

G. Repeals and transitional provisions

1. Repeal of sections of existing laws in conflict with the act
2. Transitional period to implementation*

H. Exemptions from provisions of the law*

* Elements for which model legislation has been developed by WHO.

6.2 Basic elements of national pharmaceutical legislation

A well-defined set of elements constitutes the initial requirements for a strong and comprehensive national pharmaceutical law. These elements, though basic, are sufficiently wide and varied in their scope to meet most of the objectives of a national pharmaceutical policy. [Box 6-1](#) presents a model for national pharmaceutical legislation, showing the various key elements. This model can be adapted to support the efforts of small national drug regulatory authorities in countries where only one or two professionals are available to deal with pharmaceuticals and related products.

6.3 Key provisions of national pharmaceutical legislation

Because a consumer cannot independently assess the safety, efficacy, or quality of pharmaceuticals, these products are

universally recognized as being different from ordinary items of commerce, such as clothing or household appliances, and therefore in need of handling by specially trained health professionals. These requirements make pharmaceuticals subject to numerous controls at all levels, and legal authority is granted to regulate their manufacture, distribution, marketing, prescribing, labeling, dispensing, and related activities, such as pricing.

An effective national pharmaceutical law is a primary means of ensuring that pharmaceutical policy goals are achieved while the unique character of pharmaceutical products, personnel, and facilities is preserved. The law may specify what products can legally be imported—for example, those included on the national medicines list and possessing a WHO-type certificate of quality—and which individuals are legally qualified to prescribe and dispense them, thus promoting certain national pharmaceutical policies.

Likewise, control of the manufacture, storage, distribution, and sale of pharmaceutical products enables a government

to better ensure compliance with a national policy of having essential medicines of appropriate quality, safety, and efficacy available for their intended purposes. The processes of licensing and registration can grant authorization only to those personnel, products, and facilities that conform to the national pharmaceutical law. For example, counterfeit or dangerous medicines can be taken off the market, and sanctions can be taken against those responsible for introducing them illegally.

In addition, countries that host clinical trials to test new medicines should incorporate regulations on how the studies should be conducted, including an application process that explains the purpose and protocol of the intended research and the creation of an ethics committee to approve and monitor any study protocol that includes human participants. For countries needing assistance in this area, WHO publishes guidelines on good clinical practices (WHO 2005b).

The promulgation of regulations, the collection of licensing and registration fees, and the enforcement of the national law and its regulations are legally delegated to an agency—usually called the national drug regulatory authority—headed by a commissioner or director who is responsible to a cabinet-level person, such as the minister of health. For example, in the United States, the basic national pharmaceutical law is called the Federal Food, Drug, and Cosmetic Act, which is enforced by the Food and Drug Administration. For controlled substances, additional restrictions are imposed by the Drug Enforcement Administration. In the United States, wholesale distributors, pharmacy practice, and medical practice are regulated by individual states.

Defining the roles of various parties

Because so many parties are involved with medicines, the laws need to clearly state the roles, responsibilities, and rights of each, ranging from practitioners, auxiliaries, nurses, and pharmacists to importers, manufacturers, and distributors. Countries approach prescribing and dispensing differently, depending on their circumstances; for example, in Canada, a physician must be the medicine prescriber, but in areas where physicians are scarce, legal authority may be granted to nurses or other health practitioners to prescribe essential medicines. The legislation should establish the qualifications required for those handling medicines, or it must state who has the authority to set these standards by passing appropriate regulations (for example, a government minister).

Licensing, inspection, and quality control

The law should create mechanisms to ensure that relevant parties are licensed and inspected so the community can have confidence in them. Doctors and nurses may be covered by other laws, but the medicine law needs to ensure that

the people who import, distribute, and sell medicines are properly qualified, approved, registered, and inspected.

Pharmaceuticals themselves require a special form of inspection. An inspector visiting a pharmacy or warehouse may have reason to suspect that medicines are not of sufficient quality or in good condition: they may be damp, dirty, or disintegrating. More often, samples need to be obtained for testing in the quality-control laboratory, an essential part of the inspection system.

Some countries have their own quality-control laboratories, either specifically for medicines or shared with other commodities (such as foods). A number of countries use regional laboratories, such as the ones serving sub-Saharan Africa or the Caribbean. Whatever the structure, the pharmaceutical law needs to designate a quality-control laboratory that has the capacity and equipment to do the job.

Countries that have pharmaceutical manufacturing operations should enforce good manufacturing practices (GMP), which is a system to ensure that products are consistently produced and controlled according to quality standards. GMP covers all aspects of production from the starting materials, premises, equipment, and quality testing to the training and personal hygiene of staff. WHO has established detailed guidelines for good manufacturing practice, and many countries have formulated their own requirements based on WHO's GMP. Other regions, such as the Association of Southeast Asian Nations and the European Union, have harmonized their GMP requirements.

Although important, GMP monitoring sometimes receives more resources than the inspection of distribution channels; however, the consumer's interest is not served by manufacturing a product under GMP but then storing and distributing it under adverse conditions. Inspection of distribution channels, including the importation of pharmaceuticals, should also be emphasized, particularly in countries where the distribution system has several intermediate levels or the climate is unfavorable. WHO has produced guidelines relating to good storage practices for pharmaceuticals (WHO 2003a).

[Chapter 19](#) has more information on quality-control and inspection procedures.

Pharmacovigilance

The law should also provide a basis for a pharmacovigilance (that is, postmarketing surveillance) system to report problems with adverse reactions and product quality. *Pharmacovigilance* is defined by WHO (2002a) as “the science and activities relating to the detection, assessment, understanding and prevention of adverse effects or any other drug-related problems.”

Pharmacovigilance is an overarching concept that encompasses any system used to monitor medicine safety, use,

and efficacy. For example, adverse drug reaction monitoring as part of a product's postmarketing surveillance contributes to the assessment of benefit, effectiveness, and risk of medicines. A pharmacovigilance system is difficult—if not impossible—to implement in an unregulated market that allows the importation and sale of pharmaceuticals

through informal channels or the sale of powerful medicines without prescription. Drug regulatory agencies should have access to information from the WHO Programme for International Drug Monitoring (http://www.who.int/medicines/areas/quality_safety/safety_efficacy/Joining_WHOProgrammeForInternationalDrugMonitoring.pdf),

Box 6-2 Adverse drug reaction monitoring

An adverse drug reaction (ADR) is a harmful and unexpected reaction to a drug taken at a normal dosage. The research done on medicines before they are allowed on the market is incomplete; generally fewer than 5,000 people have been exposed to the medicine in premarket tests, an insufficient number to detect less common ADRs. In addition, information on chronic toxicity and reactions in special groups, such as pregnant women and children, is often unavailable from this premarket research, because these groups are usually not included as subjects in clinical trials. Postmarketing surveillance, therefore, allows for the detection of rarer, but possibly critical ADRs. In addition, postmarketing monitoring may detect counterfeit or substandard products. Often, a country's national drug regulatory authority is responsible for ADR monitoring and reporting.

To facilitate information gathering, the drug regulatory authority should provide case report forms to health providers on adverse drug reactions. The completed case report form is then sent to the national or regional ADR center or to the manufacturer of the product. These forms vary by locale, but should include the following minimum information.

Patient information—

- Patient identifier
- Age at time of event or date of birth
- Gender
- Weight

Adverse event or product problem—

- Description of event or problem
- Date of event
- Date of report
- Relevant tests/laboratory data
- Other relevant patient information/history
- Outcomes attributed to adverse event

Suspected medication(s)—

- Name (international nonproprietary name and brand name)

- Dose, frequency, and route
- Therapy date
- Diagnosis for use
- Event abated after use stopped or dose reduced
- Batch number
- Expiration date
- Event reappeared after reintroduction of the treatment
- Concomitant medical products and therapy dates

Reporter—

- Name, address, telephone number
- Specialty and occupation

It can take years or even decades before adverse events are linked to the use of particular medicines. For example, several years passed before certain birth defects were associated with thalidomide use by pregnant women; decades passed before aspirin was linked to gastrointestinal problems. In some cases, medicines are withdrawn from the market, as was the case with bromfenac, terfenadine, and encainide after they were connected to serious health outcomes. In other cases, labeling is changed to include the new information on effects, contraindications, or dosage as a result of information received through postmarketing surveillance.

Clearly, the usefulness of a postmarketing surveillance program depends on cooperation from health professionals. All health care providers, including physicians, pharmacists, nurses, dentists, and others, should report ADRs as part of their professional responsibility. Even when some doubt exists about the relationship between the product and the ADR, all suspected ADRs, especially related to new medicines, should be reported as soon as possible. Many countries provide an easy system for reporting ADRs to their drug regulatory authorities, such as a dedicated phone line as provided in Ghana and a special reporting website as in Brazil.

Source: WHO 2002c.

which provides a clearinghouse for the millions of adverse drug reaction reports received from almost 100 countries. International pharmacovigilance activities have had a notable effect on international drug regulation. [Box 6-2](#) describes the elements that comprise an adverse drug reaction program, and [Chapter 35](#) has more information on implementing a pharmacovigilance program.

Advertising and promotion

Although many countries have rules to ensure that advertising is not misleading, these rules are generally not sufficient to cover pharmaceuticals. With consumer products, a certain degree of exaggeration is often tolerated as the normal practice of the marketplace. But for medicines that have the capacity to kill or cure, and with claims that people cannot easily verify, it is important that advertising to health professionals and to consumers be objective and reliable; misleading and extravagant pharmaceutical advertising claims may pose significant risks to the public.

For these reasons, most laws on pharmaceuticals now include a clause empowering regulation on advertising. In many countries, it is illegal to advertise to consumers medicines intended to be prescribed by health professionals. However, direct promotion of pharmaceutical products through the Internet is practically impossible to control; therefore, the national regulatory agency should educate consumers on identifying reliable sources of information, preferably in collaboration with national consumer and professional organizations. All advertising and labeling must be consistent with the information verified when the pharmaceutical product was registered or approved for marketing, with modifications required by the regulatory authority on the basis of postmarketing experience.

Useful guides to the principles that should underlie honest pharmaceutical promotion have been issued by WHO and separately by manufacturers (WHO 1988, 1999b).

Sanctions

Because constant vigilance is needed if the public is to be protected, pharmaceutical laws must be properly enforced with appropriate penalties for violators. There is no use establishing that medicine quality is poor, a warehouse is rat infested or damp upon inspection, or an advertisement is untruthful unless something is done about it. The drug regulatory agency must use its authority to impose appropriate penalties when necessary: sanctions may be penal (fines, imprisonment, or both) or simply corrective (banning the drug, closing down the warehouse). Sometimes a party has contravened the law so seriously that the appropriate sanction is determined to be loss of license to prescribe, manufacture, import, or distribute. On occasion, all of the penalties may be imposed.

To be effective, the drug regulatory authority must be able to apply sanctions on a timely basis, so it must have either the legal staff to ensure compliance or the necessary links with the relevant government department charged with enforcement. Therefore, the law governing pharmaceutical products must give legal authority to the appropriate personnel to carry out any necessary enforcement activities.

In addition, because the pharmaceutical sector is vulnerable to corruption, a country should not only include an anticorruption mechanism in its regulatory framework, but also have sanctions in place for bribery, fraud, collusion, and other dishonest acts (WHO/PSM 2006). Many countries have specific laws that address corruption in the public sector or provisions in their procurement regulations to ensure transparency and provide sanctions against, for example, bribery.

6.4 Medicine registration, licensing, and marketing authorization

The licensing and inspection of manufacturers and importers, although important, do not provide assurance about the products. Many countries have evolved systems of drug registration to ensure that individual products approved for sale meet the following criteria—

Efficacy: The medicine should be shown to be effective for the indications claimed. However, note that no product is ever 100 percent effective for all users. In practice, efficacy means that in a majority of cases the product meets its therapeutic claim.

Safety: The medicine should not present risks that are disproportionate to its benefits. Some patients may suffer severe reactions even to medicines shown to be safe in clinical studies. However, in the great majority of cases, adverse effects are minor or very infrequent.

Quality: The medicine should be well made, as specified in the official pharmacopoeia chosen as a standard. If not listed in an official pharmacopoeia, the product's manufacturing should comply with the quality documentation submitted by the applicant that demonstrates its safety and efficacy.

Clinical use information: All the clinical information needed to use the medicine properly, including indications, doses, precautions, and adverse effects, should be provided as part of the packaging, in language understandable to the health professional or patient, as appropriate.

Medicine registration, also referred to as licensing or marketing authorization, is often a major element in national pharmaceutical law. In its fully developed form, however, it is costly and labor intensive. Establishing a drug registration system is generally not justified until a country has a

Box 6-3
Stages in the evolution of a medicine registration system

Stage 1: Notification procedure. Standard information is obtained on all pharmaceutical products currently marketed in the country and entered into a register. No judgment is made at this time regarding the appropriateness of the drugs for sale in the country.

Stage 2: Basic authorization procedure. Products listed in the register are provisionally authorized to remain on sale. All other drugs that are to be sold require a license, which is issued after an appropriate assessment of the efficacy, safety, and quality and a review of truth and completeness of packaging and labeling information.

Stage 3: Full registration or licensing procedure. Full evaluation of individual products is conducted by examining detailed data submitted by the manufacturer and obtained from the literature to assess their quality, safety, and efficacy.

Stage 4: Reevaluation of older drugs. All older pharmaceutical products on the market are systematically reassessed for compliance with the standards.

significant volume of private-sector pharmaceutical sales. The primary concern of many resource-limited countries is ensuring a reliable flow of essential generic drugs from reputable suppliers into the public health system.

As a country's economic development proceeds and more resources become available, priorities may change. The private sector may become more active, and local and multinational firms may begin actively promoting their new products to prescribers and even to the public. At this point the need for a medicine registration system arises.

As proposed in the WHO (1999c) guidelines for small drug regulatory authorities, a medicine registration system can best be developed in stages, starting with an inventory of all pharmaceutical products on the market, followed by a provisional authorization that allows products to continue to be sold until they complete the full registration procedure as shown in [Box 6-3](#). [Country Study 6-3](#) shows how Namibia maximized its resources by streamlining its medicine registration system.

In stage 1, the information requested initially may be simply the international nonproprietary name; product trade name, if any; name of the manufacturer; and country of origin. Later, this can be expanded to include composition, including inactive ingredients; pharmacological action; therapeutic classification; and claims made in the package

insert. Having a complete register of what is on sale in the marketplace allows the regulatory agency to evaluate information from other countries or from WHO about problems with a particular medicine (for example, toxicity, contamination, evidence of inactivity), to determine whether the product is on sale in their country, and what actions might be taken.

Stage 2 requires assessment for new pharmaceutical products. Because this procedure is costly and time-consuming, countries can rely on decisions made in other countries with well-developed regulatory agencies, such as those that are members of the ICH. Is the drug approved for sale in its home country? If so, what claims have been made for it? Does it carry a WHO-type certificate indicating that it is manufactured under satisfactory conditions? The firm wishing to import the product must provide documented answers to these questions. Regulatory authorities may consult other countries directly before deciding to accept or reject a product. WHO and other bodies hold international and regional meetings of regulatory authorities from different countries, which helps create trust across borders and facilitates informal work sharing. Approval of locally manufactured pharmaceuticals requires inspection of the manufacturing premises and staff.

The task of full registration described in stage 3 should never be taken up lightly—even a large regulatory agency can be overwhelmed by the vast amount of material that needs to be examined. Some groups of countries handle assessment jointly; others look at where else in the world the medicine is licensed, and under what conditions. Countries that have the resources to handle registration and licensing independently can often obtain technical advice and practical help from WHO and support from other countries with well-developed regulatory agencies.

Stage 4, the reevaluation of older products on the market, is the final stage in the development of a registration system and is very ambitious. Few industrialized countries have yet managed to complete it.

If a medicine is intended to be generically equivalent to another already on the market, regulations must stipulate the evidence needed to support their equivalence (see [Box 6-4](#)). WHO has a resource for countries without a fully functioning system for premarket evaluation and market authorization that wish to assess and authorize multi-source (generic) pharmaceutical products (WHO 1998b). WHO also makes available findings from assessment reports generated as part of its program to prequalify medicines for HIV/AIDS, tuberculosis, and malaria, including information based on product data showing compliance with international standards for quality, safety, and efficacy, bioequivalence (for generic products), and findings resulting from inspections of production sites according to GMP standards (see <http://mednet3.who.int/prequal/>). The WHO prequalification process should be useful to

Country Study 6-3 Revising registration procedures in Namibia

In its first fifteen years of independence, Namibia developed very comprehensive pharmaceutical regulatory procedures, considering its small population and limited resources. Unfortunately, human resources capacity did not keep pace with administrative requirements, and the number of medicine registration applications quickly created a huge backlog of about 1,000 medicines awaiting marketing approval, including antiretroviral (ARV) medicines. At that time, forty-nine ARVs were on the market, but the backlog prevented access to valuable fixed-dose combinations and pediatric products. One estimate showed that at the current capacity, it would take eighteen years to review all outstanding applications.

The Rational Pharmaceutical Management (RPM) Plus Program worked with the government on interventions to streamline the registration process. Key was a policy change allowing the Medicines Control Council (MCC) to give priority to ARVs for registration and create a proxy evaluation process to quickly accept prod-

ucts already registered in International Conference on Harmonisation countries or South Africa; for example, the new policy permits the MCC to accept certain quality requirements that have already been approved by recognized authorities, such as through WHO's prequalification program. Other interventions included training nonprofessional staff to take on some application processing responsibilities and creating a drug registration database.

Within a year after RPM Plus's intervention began, 1,392 applications for new medicines were evaluated. Of those, fourteen ARVs and twenty-four generic ARVs were reviewed and approved (which increased the number of ARVs on the market by 75 percent). The fourteen approvals included much-needed pediatric dosage forms and fixed-dose combinations; the addition of generic products helps reduce prices.

Box 6-4 Interchangeability

New multisource (generic) pharmaceutical products must be of good quality and at least as safe and efficacious as existing products. The need for interchangeability arises when a patient changes from one brand to another, for example, when—

- Physicians prescribe by generic name
- Generic substitution is permitted by national legislation
- The same brand is not always available, for example, in remote areas of the country
- Patients in hospitals are given whatever brand the hospital has in stock, and sometimes different brands on different occasions
- Patients receive a different brand after discharge from the hospital

A number of features are important to interchangeability, although the science behind demonstrating interchangeability is still evolving: compliance with appropriate

quality standards and at least compliance with relevant pharmacopoeial standards; stability; possible differences in sensitizing potential caused by the use of different excipients; therapeutic equivalence in terms of, as appropriate, bioequivalence, pharmacodynamic studies, clinical studies, or in vitro dissolution rate; and product information and labeling.

By their nature, different brands of modified (sustained-, continuous-, prolonged-, slow-) release products are more likely not to be equivalent than are different brands of immediate, conventional-release products. Some drug regulatory agencies take the view that such products should never be considered interchangeable, while others define a series of studies that should be conducted, including in some circumstances comparative clinical trials. For delayed-release products, such as enteric-coated tablets, interchangeability is more easily demonstrated.

developing-country regulatory authorities that do not have sufficient capacity to fully assess products and determine their acceptability before licensing.

The registration systems of many African countries are still lagging. For example, in twenty-six countries surveyed, the technical standard of evaluations, if they existed, were not in line with WHO standards; only 11 percent had adequate standard operating procedures for assessment, 85 percent did not have enough space to store data securely, and only one-quarter of the countries had functioning computerized registration systems (WHO 2010b) (see Figure 6-1).

Classifying pharmaceuticals for dispensing

As part of the marketing authorization process, the national drug regulatory agency is also responsible for classifying each pharmaceutical product in terms of how it is dispensed and sold. For example, prescription-only medicines require a directive from an authorized health practitioner; pharmacist-only medicines are available without prescription, but only under a pharmacist's supervision; and over-the-counter medicines are available without a prescription in retail outlets besides the pharmacy, such as a grocery or licensed drug seller. This classification affects the product's availability and appropriate use. Factors to consider in the classification include—

- The safety of the active ingredient
- The need for professional counsel before use
- The nature of the ailment or symptoms the medicine is intended to treat
- The risk/benefit ratio (TGA 2003)

Consideration should also be given to the restrictions for prescribing and dispensing controlled drugs as provided in the international drug control treaties, namely the 1961 Single Convention on Narcotic Drugs and the 1971 Convention on Psychotropic Substances. The list of narcotic

and psychotropic drugs is available from the International Narcotics Control Board (<http://www.incb.org>).

Regulating traditional and herbal medicines

As discussed in Chapter 5, countries are increasingly recognizing the large role that traditional and complementary medicine plays in their health care systems. An important challenge is the evaluation and assurance of the quality, safety, and efficacy of herbal and traditional medicines. Since the earliest days of humankind, herbal medicines have been applied in health care throughout the world. Many are still widely used and have become important in international trade. Significant quantities of herbal products are now imported by countries in the European Union, North America, and Asia. However, the use and production of herbal products remains largely unregulated, and their safety and therapeutic value cannot always be guaranteed.

Recognition of the clinical, pharmaceutical, and economic value of herbal medicines is growing, although the level of official recognition through legislation varies widely among countries. WHO published a reference on the national experiences of fifty-two countries in formulating policies on traditional and herbal medicinal products and in introducing measures for their registration and regulation (WHO 1998c). WHO also published a summary of the legal status of traditional and complementary medicines in 141 countries (WHO 2005c) and guidelines on how to develop national policies on the safety, efficacy, and quality of herbal medicines (WHO 1998a).

6.5 Controlling alternative and informal distribution channels

In some countries, unregulated, informal, or even illegal distribution (including sales in marketplaces and on streets) and smuggling of medicines are widespread. Another major

problem is that medicines may be traded through several intermediaries and free-trade zones and are sometimes repackaged and relabeled to hide their true source or identity, leading to the circulation of substandard and counterfeit medicines.

As the volume of expensive medicines such as for HIV/AIDS and malaria increases in formal distribution channels, there will be an increase in leakage of these medicines to informal channels. A WHO study of regulations in ten countries (Ratanawijitrasin and Wondemagegnehu 2002) showed that pharmaceuticals distributed through the informal sector received little regulatory attention from governments compared with those distributed through the formal sector. Products of substandard quality and incorrect information—especially exaggeration about efficacy—are often found in the informal sector.

It is important for countries to assess the influence of alternative and informal distribution channels on their health care systems. If citizens purchase most of their medicines from informal dealers, they may be getting substandard-quality products, which may adversely affect public health. Medicine regulation can be used to promote quality criteria for medicines and health commodities by establishing and enforcing standards for all distribution channels and encouraging the public to be careful about where they buy pharmaceutical products. [Chapter 32](#) discusses how initiatives can improve the quality of products and services from private-sector drug sellers. [Country Study 6-4](#) describes how

the government in the Lao People's Democratic Republic (P.D.R.) has instituted regulations to improve the quality of private pharmacies.

Another challenge to drug regulators that has emerged in recent years is the widespread use of the Internet to sell uncontrolled pharmaceuticals across national borders (WHO 2003b). Regulation and enforcement can deter illegal practices, although it requires cooperation among national agencies such as those handling drug regulations, customs, and the postal service. Because of the transnational nature of e-commerce, international cooperation in its control is also needed.

6.6 Substandard and counterfeit medicines

Substandard medicines are products whose composition and ingredients do not meet the correct scientific specifications and consequently may be ineffective, dangerous to the patient, or both. Substandard products may occur as a result of negligence, human error, insufficient human and financial resources, or counterfeiting.

Counterfeit medicines are considered a subset of substandard medicines, but the difference is that they are deliberately and fraudulently mislabeled regarding their identity or source. Counterfeiting can apply to both branded and generic products, and counterfeit medicines may include products with the correct ingredients but fake packaging,

Country Study 6-4 Regulatory interventions in Lao P.D.R.

In Lao P.D.R., private pharmacies make up the majority of the retail market for medicines. However, little or no control of private pharmacies existed until 1996, when such regulation was incorporated into the National Drug Policy. District pharmacists became responsible for inspecting and monitoring private pharmacies, and a special unit was created at the provincial level to oversee the regulations. Inspectors made sure that the pharmacies had up-to-date regulatory documents. In addition, the central drug regulatory authority instituted a number of policies to improve the quality assurance system in the country. These included the development of a good manufacturing practices regulation with associated training, improvements in the medicine registration system, and the institution of fines and sanctions to enforce the new regulations.

In 1997, a baseline assessment was conducted in 115 of 214 licensed private pharmacies in Savannakhet province before the new regulations had fully taken hold.

A follow-up study in 1999 used the same indicators to assess the effect of the new policies and activities on private pharmacy services. The results showed significant improvement in almost all indicator values, including the organization in the pharmacy; availability of essential medicines and essential materials for dispensing, such as a hygienic counter; and information given to the customers. Analysis of samples from the 115 pharmacies showed a decrease in the proportion of substandard medicines—from 46 percent in 1997 to 22 percent in 1999—still high, but substantially better.

Before the regulatory interventions, the quality of pharmaceutical service was low in Savannakhet province. The development of a regulatory framework with regular inspections and enforcement through sanctions was not only possible to initiate in a resource-limited country, but also appeared to be an important catalyst for better quality medicines and pharmacy practices.

Figure 6-2 Reports of counterfeit medicines by therapeutic class received in 2007

Total number of cases: 1,513. One case reflects at least one production lot (e.g., thousands of tablets, capsules, or other forms).

Data from the Pharmaceutical Security Institute (<http://www.psi-inc.org>).

with the wrong ingredients, without active ingredients, or with insufficient active ingredients.

In wealthier countries, the most frequently counterfeited medicines are new, expensive lifestyle medicines. In developing countries, the most counterfeited medicines are those used to treat life-threatening conditions such as malaria, tuberculosis, and HIV/AIDS. Figure 6-2 gives the number of reports of counterfeit medicines, by therapeutic class, submitted in 2007 and shows that the highest percentage reported concerned genito-urinary medicines.

Trade in these medicines is more prevalent in countries with weak pharmaceutical regulatory control and enforcement, scarce or erratic supply of basic medicines, unregulated markets, and unaffordable prices. Governments need to develop strategies and put appropriate legislation and sanctions into place to reduce corruption and criminal activity. As in the case of e-commerce, enforcement of these laws requires cooperation among regulatory authorities, police, customs services, and the judiciary to control more effectively the pharmaceutical market.

6.7 Establishing effective administrative control

In many countries, medicine legislation and regulation are not regularly updated or are imported from other countries and do not reflect national realities. Countries can draw

guidance from the experiences of others, but problems have arisen when overly complex provisions were adopted. Legislation and administrative practices must be attuned to available resources, and every opportunity must be taken to understand and use the information provided by regulatory authorities in other countries (WHO 1990). The example of approving microbicides to control HIV infection shows the regulatory difficulties faced by resource-constrained countries (Box 6-5).

Required resources

To perform effectively, national regulatory authorities must have the necessary political support, legal power, human and financial resources, and independence in decision making. They also must have strong public support and proper management. Where national regulatory authorities have a high profile within the government, they are organized as a commission, board, statutory authority, or department, with the legal power from government to acquire and use resources, including hiring qualified full-time staff at a salary scale that discourages corruption and conflicts of interest.

Ideally, one central, autonomous agency should be accountable for the overall effectiveness of pharmaceutical regulation. In countries whose regulatory functions are split among two or more agencies, the fragmentation can lead to duplication of effort, lapses in implementation, inconsistent regulation, and wasted resources. In recent years, several countries (for example, Argentina and Brazil) have successfully established such centralized agencies to regulate food, medicines, and consumer products. However, a survey of twenty-six countries in sub-Saharan Africa showed that most countries' regulatory systems were uneven—with gaps and overlaps in responsibilities spread over several bodies other than the drug regulatory authority, including the ministries of trade and health, pharmaceutical councils, and regional authorities, especially for licensing and inspection (WHO 2010b).

Table 6-1 details the resources required to achieve effective administrative control; at a minimum, these needs include a drug regulatory authority with staff, a team of inspectors to visit warehouses and retailers, and access to a laboratory capable of performing quality-control testing.

Personnel are the key resource for making effective pharmaceutical regulation possible. Because of the technical nature of their work, the law often prescribes that inspectors be pharmacists or have other relevant education and training. Others can be trained to undertake licensing, registration, and enforcement duties. Depending on the size of the country and the degree of pharmaceutical development, the entire staff may consist of only a few individuals. Sometimes contracting out specific duties may be appropriate; however, it is important for the contractor not to have any conflicts of

Box 6-5**Regulatory hurdles in the development of microbicides for HIV/AIDS**

More women than men account for new HIV infections in many parts of the world. In certain places, women's lack of power means they cannot insist on condom use to protect themselves, and even if they have a single partner or husband, they are still at risk. This situation has resulted in much interest in the development of microbicides—a topical medicine used vaginally to prevent HIV transmission—that gives women control of usage.

A major obstacle to the approval of an effective microbicide is the fact that those now in clinical testing are new medicines that have not been on the market yet. Many developing countries do not have the resources or regulatory framework available to perform the testing and review of new medicines themselves, so they rely on product reviews from the United States or Europe to determine acceptability for their countries. However, because microbicides will be marketed primarily in developing countries, developed countries have no incentive to review and license them for their own markets.

To help fill the gaps, the European Parliament approved an initiative for the European Medicines Agency (formerly known as the European Medical Evaluation Agency) to scientifically assess products such as microbicides that are proposed for use primarily in developing countries. The drug regulatory agencies in developing countries would then use the scientific assessments to make decisions about licensing. Other steps that could help overcome these regulatory hurdles would be collaboration between regulatory authorities in developing and industrialized countries to jointly review product profiles and to help resource-limited countries develop the capacity to make drug registration decisions autonomously.

Although results of clinical trials of microbicides for HIV have been mixed, research continues, and the European assessment mechanism is one that could be used with other similar products.

Sources: Coplan, Mitchnick, and Rosenberg 2004; Davis 2009; Fox, Beasley, and Kelland 2010.

interest, such as an ongoing consultancy with a pharmaceutical company that could specifically benefit from the contracting arrangement.

Computer software now greatly simplifies many of the administrative tasks of the regulatory agency. Personnel should have access to the latest scientific and technical information to facilitate their work.

Financing

The law must provide a realistic mechanism for funding regulatory functions. Funds may be provided from general tax income and from charges levied on the manufacturers, importers, and distributors to cover the bulk of the costs of the pharmaceutical control system. The level of charges may be set from year to year, but the nature of the charges can be defined in the law. For example, the law may set lower fees for essential medicines; importers can be required to pay a fee when they submit a new medicine application to the regulatory authority for consideration, a supplementary fee when the license is issued, and an annual fee for as long as the medicine remains on sale; and manufacturers might be required to relicense their products periodically (for example, every five years).

Fees and charges substantially fund the cost of operating the national regulatory agencies in most developed and some developing countries. In Canada, the United Kingdom, and the United States, the agencies recover 70

percent, 100 percent, and about 50 percent, respectively, of their regulation costs (WHO 2003b). Because of their large markets, developed countries tend to charge higher fees than developing countries. In addition, in developing countries, fee revenues are often added to the general treasury rather than being assigned specifically to the drug regulatory agency, which makes it hard to adequately finance regulation. However, regulatory agencies should not be completely dependent on fees to fund all of their activities; they should receive some financial support from their governments to help ensure their independence and ability to carry out basic responsibilities. Most of the twenty-six drug regulatory authorities surveyed in Africa get their funding from more than one source (e.g., fees, government, donors); however, none had sufficient or sustainable operating funds (WHO 2010b).

Guiding principles for small national drug regulatory authorities

Regulation is not the only component of pharmaceutical policy, and sometimes in resource-limited settings, it is not even the most pressing one. Nonetheless, the existence of a well-functioning national drug regulatory authority to help ensure medicine quality, safety, and efficacy is the best guarantee that the public is getting the medicines it deserves. A national regulatory authority needs a clear mission statement including goals and objectives to direct its work. Goals

Table 6-1 Resources required for effective administrative control

Resources required	Specific function or purpose
Personnel	<ul style="list-style-type: none"> • Regulatory activities (licensing, registration, and so forth) • Monitoring, inspection, and surveillance • Enforcement
Physical and infrastructure	<ul style="list-style-type: none"> • Office space for regulatory and enforcement personnel • Access to appropriate analytical laboratory resources • Computers, software, sampling equipment, and office equipment • Vehicles for distribution, inspection, and enforcement activities
Technical	<ul style="list-style-type: none"> • Preservice and in-service training • Knowledge of pharmaceutical manufacturing processes, packaging, and so forth • Collation of data • Dissemination of information • Reference library (books, journals, bulletins)
Financial	<ul style="list-style-type: none"> • Capital and recurrent expenditures • Technical programs • Payments for patents and royalties • Payments for consultants • Payments for quality-control samples • Publications (forms, licenses, pharmacopoeia) • Travel for inspection and enforcement activities

usually include protecting public health by ensuring the safety, efficacy, and quality of medicines and their appropriate use. Plainly outlined objectives provide a measure to evaluate how well the agency is functioning.

Primary pharmaceutical regulation activities should not be compromised by other nonregulatory tasks with which the national regulatory authority may be charged. If the authority responsible for pharmaceutical regulation has nonregulatory functions, such as manufacturing, procurement, or service delivery, conflicts of interest may occur regarding mandates and resource allocation.

When a country is ready to introduce pharmaceutical regulation, work by WHO (1990) provides useful guidance for authorities with limited human, financial, scientific, and technological resources. To be effective, a small drug regulatory authority needs to operate within the national pharmaceutical laws and policies that have been established and must relate to other interested bodies, including organizations responsible for pharmaceutical procurement in the public sector and the national formulary committee. As mentioned, effectively enforcing pharmaceutical legislation requires national regulatory authorities and other government enforcement agencies, such as customs, police, and prosecutors, to work together. National regulatory agencies should also seek the cooperation of health professionals, pharmaceutical and consumer associations, and other interested parties through stakeholder workshops, meetings addressing specific issues, or other venues open to the public.

A drug regulatory authority's objectives can be accomplished effectively only if a mandatory system of licensing

products, manufacturers, importing agents, and distributors is in place. A small authority has limited capacity to undertake these tasks. For imported pharmaceutical substances, a small authority is dependent on information generated in the exporting country. The WHO certification scheme on the quality of pharmaceutical products moving in international commerce (WHO 2000) was designed to provide this information, although recommendations have been made on how to update the scheme (WHO 2008). As discussed in [Chapter 19](#), this scheme must be supplemented by direct contacts with international agencies and other regulatory agencies to obtain necessary information; however, the certification scheme is only as good as the certifying authority. WHO's prequalification program provides information on approved sources for products related to HIV/AIDS, malaria, tuberculosis, and reproductive health.

Many national regulatory authorities do not make publicly available their regulatory policies, administrative procedures, guidelines, and criteria for decisions. Lack of transparency means that communication is probably lacking on medicine regulation between national regulatory authorities and their stakeholders. Moreover, transparency is required to make the agency accountable for its actions and to limit the influence of political pressures and personal favors in the decision-making process. Transparency will also contribute to the credibility and authority of communications between the agency and those affected by its actions: manufacturers, importers, distributors, health professionals, and consumers. An assessment tool is available to measure transparency in the pharmaceutical sectors (WHO 2009a) and a report describes the assessment of four

countries' pharmaceutical registration, selection, and procurement systems: Lao P.D.R., Malaysia, Philippines, and Thailand (WHO 2006a).

To increase the amount of information and communication, WHO is helping drug regulatory authorities develop websites with information on—

- Lists of approved medicines
- National pharmaceutical regulations
- Methods to ensure safe, efficacious, and rational use of specific medicines
- Lists of approved companies and their authorized activities
- Details of persons and institutions with responsibility for pharmaceutical regulation

WHO resources available for drug regulatory authorities include—

- A model website for drug regulatory authorities that aims to enhance communication and transparent dialogue among national drug regulatory authorities, industry, consumers, and health professionals (http://www.who.int/medicines/areas/quality_safety/regulation_legislation/model_site/en)
- A list of recognized drug regulatory authorities' websites (http://www.who.int/entity/medicines/areas/quality_safety/regulation_legislation/ListMRAWbsites.pdf)
- A tool to assess regulatory authorities (http://www.who.int/medicines/areas/quality_safety/regulation_legislation/assesment/en/index.html)
- Practical guidance for conducting a review (based on the WHO Data Collection Tool for the Review of Drug Regulatory Systems) (http://www.who.int/medicines/areas/quality_safety/regulation_legislation/GuideAssessRegSys.pdf)
- A drug regulatory status database (http://www.who.int/hiv/amds/patents_registration/en/index.html)

In summary, the regulatory authority should be vested with legal powers to—

- Issue, vary, and revoke licenses for pharmaceutical products on grounds of quality, safety, and efficacy
- Ensure the safe and effective use of each product by controlling, through the terms of the license, the content of all labeling (including package inserts, associated prescribing information, and advertising) and the channels through which the product may legitimately be supplied
- Inspect and license all manufacturing premises, importing agents, wholesalers, distributors, hospital dispensaries, independent pharmacies, and other retail

outlets to ensure that they comply with prevailing regulations and guidelines

To implement these responsibilities, the authority must have the power to order that certain things be done and to prosecute those who disregard the law. To retain public confidence and respect, the authority must be seen as operating in an independent, authoritative, and impartial manner. It should be concerned exclusively with the determination of standards and the implementation of controls. Although it needs to work closely with the body responsible for public pharmaceutical procurement, it should not be responsible for procurement and should remain independent in its operations and decisions.

6.8 Evaluating the effectiveness of pharmaceutical legislation

Evaluating the effectiveness of pharmaceutical legislation and accompanying regulations is not always easy. The process of evaluation depends on the types of performance indicators and criteria used and on the availability of adequate data. The questions in the Assessment Guide at the end of this chapter provide a framework.

The most important factor in the effectiveness of pharmaceutical laws and regulations is the extent to which the legislative framework is in tune with national policy and the existing situation in the pharmaceutical sector. Changes in policy need to be reflected in the legislation and in its implementation.

Measuring the effectiveness of a law on pharmaceuticals is easier for certain elements than for others. For instance, the registration process can be evaluated in relation to quantitative targets and time schedules to see whether the agency is on schedule.

The degree of noncompliance with a law or regulation may suggest not only the need to take action against those responsible but also the desirability of identifying the causes of noncompliance: it may be related to technical defects in the law or in its wording, or to operational problems of implementation, such as lack of transparency or poor communication, which can be resolved. Enforcement personnel should periodically report on their perception of how the law functions and the types of problems encountered to facilitate any necessary revisions. Many legislative and regulatory provisions can be improved and updated when the legislation is sufficiently flexible to allow for modifications by the regulatory agency.

Responsibility for evaluating the effectiveness of a drug law often falls on the regulatory authority established by law for policy making, implementation, or both. The level of accountability and transparency under which the drug regulatory authority operates can be evaluated by examining

reporting requirements, external reviews of performance, processes involved with lodging complaints, and appeals procedures. Periodic self-evaluation to identify weaknesses in policy making and implementation activities is important. The body must devise its own systems to judge whether it receives sufficient feedback and whether its operational effectiveness can be improved. ■

ASSESSMENT GUIDE

Policy, legislation, and regulation

- Is there a national medicine policy approved by the government? Is the policy suitable to regulate the market? When was it last updated?
- Is there a comprehensive medicine law? Is it appropriate? Is it a new law or a revision of an existing law? When was it last updated?
- Is the legislation flexible in allowing for the passage and revision of regulations in response to new scientific information and market changes?
- Is there a drug regulatory authority responsible for the promulgation of regulations and for enforcement? Does the necessary political will and funding exist to support it?
- Are regulatory policies, procedures, and criteria for decisions available to all stakeholders?

Medicine selection and registration

- Is there a system for medicine registration? Is this a notification procedure? A basic authorization procedure? A full registration procedure? Is periodic renewal required?
- Is medicine registration based on an assessment of a medicine's efficacy, safety, quality and truth of packaging information? Are pharmacological or therapeutic standards used?
- Are there different registration procedures for essential medicines, generic products, multisource drugs, or imported products from selected countries?
- Is the WHO certification scheme on the quality of pharmaceutical products moving in international commerce used systematically for the registration of imported medicines?
- Are relevant medicines procured from suppliers prequalified by WHO?
- Is there a system for the collection of data regarding the efficacy and safety (adverse effects) of marketed medicines?

Licensing, inspection, and control

- Do mechanisms exist for the licensing, inspection, and control of pharmaceutical personnel and for

manufacturing, distribution, and dispensing facilities?

- Do inspectors use a checklist for inspecting different types of pharmaceutical establishments?
- How many inspections were made during each of the last three years for the different types of pharmaceutical establishments?
- Is there an audit system to evaluate the inspection system?

Advertising and promotion

- Is there any specific regulation regarding therapeutic claims in drug labeling and promotion?
- Is there any legal provision for the compulsory use of generic names in medicine labeling and promotion?
- Are there controls on pharmaceutical promotion, and are these consistent with the WHO ethical criteria for medicinal drug promotion?

Compliance and enforcement

- What measures exist for enforcement of pharmaceutical laws and regulations? Are they enforceable administratively or through court actions? Are statistics available about compliance and enforcement?
- During the last three years, how many pharmaceutical products were eliminated from the register? How many batches of pharmaceutical products were recalled from the market?
- Is there a system for reporting pharmaceutical product problems? What types of and how many complaints were registered in the past three years, and what corrective measures were taken?
- How many violations have occurred with regard to pharmaceutical advertising and promotion in the past three years? What corrective measures were taken?
- Are there any statistics about the reaction of the industry and consumers to regulatory actions?

SUMMARY

Policy makers must be concerned about pharmaceutical production for the same reasons that underlie other policy and legal decisions: pharmaceuticals can be dangerous as well as lifesaving. Health professionals and patients have no ready way of making judgments about medicines without public surveillance as a guide.

The potential for national or local production of quality-assured, low-cost pharmaceuticals to meet national needs is an issue that has been debated and discussed for several decades. The justifications for local production have included the problems of lack of access, high prices for imported pharmaceuticals, and poor pharmaceutical quality. These challenges prompted public and political interest in considering local production to promote self-sufficiency, achieve independence from international suppliers, develop local industrial capacity, and create jobs. The changing landscape in the global pharmaceutical market, however, has made local production of pharmaceuticals in many countries unlikely as a viable option, except under certain circumstances, such as the existence of a large national market or a need to address specific requirements within a local market. Furthermore, self-sufficiency in pharmaceutical supply has proved to be a myth; because most active pharmaceutical ingredients are now sourced globally, even the most developed countries cannot be considered wholly self-sufficient in pharmaceutical production.

The globalization of the pharmaceutical sector and the advent of worldwide public health funding initiatives have led to a more competitive market for generic pharmaceuticals, resulting in significant decreases in the prices of some essential medicines. Domestic production operations have had difficulty achieving the high quality expected in the market at prices that compete with those of large-scale international producers, and many countries have limited capacity to monitor and regulate pharmaceutical production activities. Decisions regarding producing or importing pharmaceuticals are complex and involve health policy, industrial policy, a country's national development strategy, and related political pressures. Despite the argument that actual production decisions should be left to private-sector and market forces, policy makers must sometimes respond to pressures to become more involved in decisions about pharmaceuti-

cal production. The principal policy question now is often not whether to make or buy pharmaceuticals, but rather what pharmaceuticals to buy and where to buy them.

Three important points related to decision making about local pharmaceutical production guide this chapter—

- Pharmaceuticals are potentially lifesaving and life-threatening. Pharmaceutical production requires precise standards, quality control, a highly skilled labor base, capital, national regulatory capacity, and management. Modern pharmaceutical production often uses raw materials that are most economical in the international market, which means that high-quality, low-cost medicines are not likely to be produced from the raw materials stage in countries that do not have the required market size and resources in terms of skilled people, technology, and quality control.
- Section 7.1 describes several types of pharmaceutical manufacturers that operate in low- and middle-income countries, ranging from subsidiaries of multinational firms to small, hospital-based operations that repackage medicines into course-of-therapy packs. Policy makers must assess the feasibility for the range of production options, from the primary manufacture of raw materials to the packaging of finished products.
- Because consumers are unable to judge medicine quality on their own, policy makers must be concerned about regulating the production quality of medicines from either international or domestic sources. Regulatory policy should focus on assuring that manufacturers who supply products to the national market follow good manufacturing practices. Whether policy makers take an active or a passive role, they must recognize that the regulations and incentives existing in a country always affect pharmaceutical production. The most constructive stance is to shape policies and regulations that promote the goal of reliable access to effective, safe, and inexpensive medicines rather than to focus on where the production takes place. If preferences are given to locally produced medicines, the sick may pay directly or indirectly for these preferences through higher prices or poorer quality.

7.1 Levels and types of local production

Most countries are part of the global pharmaceutical market, but few try to be entirely self-sufficient. Raw materials, which form the backbone of the industry, are produced and traded as commodities worldwide. Almost all countries, even the largest ones, actively acquire at least some raw materials, machinery, and packaging goods abroad—at the most economical prices and at different stages of production—and then complete the process at home. It is a matter of competitive advantage, not imaginary independence, in an increasingly globalized economy.

Production standards known as good manufacturing practices (GMPs) are quality requirements that have been adopted as guidelines by the industry and the World Health Organization (WHO). The GMP system ensures that products are consistently produced according to quality standards appropriate to their intended use and as required by the product specification. Some countries require more-exacting standards to further ensure quality, and any hope for an export market increasingly requires compliance with international GMP standards.

The three different levels of production are primary, secondary, and tertiary.

Primary production

Primary production is the processing of raw materials to create active pharmaceutical ingredients (APIs) and ancillary substances used in pharmaceutical formulations. The final API, which is the biologically active compound in the pharmaceutical that produces the therapeutic effect, should meet pharmacopoeial or similar requirements. Primary manufacturing may involve either chemical or biological processes requiring different types of production facilities, technologies, skills, and knowledge. The manufacture of active ingredients is the most expensive aspect of pharmaceutical production because of the necessary investment in capital equipment, process development, and quality assurance systems.

The more modern or sophisticated the products, the more skills and greater capability are needed to develop and maintain the production processes. Few middle- to low-income countries will have all the infrastructure needed, including a pool of skilled workers (scientists and engineers), industrial technology, a research and development base, quality-control experience, capital, and reliable utilities—as well as the potential market size—to make primary production an initial goal. Rather, because these basic commodities are most efficiently produced in large volumes—much greater than the markets could absorb in many countries—they tend to be traded and bought as are other international commodities, such as steel, some foods, and other chemicals.

Secondary production

Secondary production is the large-scale processing of finished dosage forms, such as tablets, capsules, or injections, from raw materials or intermediate products, often from both local and imported sources. Production of sterile preparations (such as injections, antibiotics, and intravenous fluids) and nonsterile preparations (oral solids, liquids, and topical preparations) can be carried out with either locally produced or imported packing materials. Although less technically demanding than primary production, this stage must be completed to precise specifications. It requires modern, high-speed, precision equipment to produce pills, capsules, and liquids, often in large quantities and at very low unit costs, which are targets that small facilities find difficult to achieve, especially while also meeting international GMP standards.

Tertiary production

Tertiary production includes packaging and labeling finished products from primary and secondary sources into bulk packs, smaller dispensing packets, bottles, or course-of-therapy units for individual use. The initial quality of the pharmaceutical product established in the earlier phases of production must be maintained in the tertiary and final step, so ensuring high quality standards through rigorous operational procedures is important. This type of production can be developed first in many countries as a positive contribution that also builds industrial skill and experience. Tertiary production also addresses specific local needs for certain formulations, labeling, and packaging.

7.2 Trends in local production

During the 1970s and 1980s, some international organizations and governments were promoting the idea of creating or strengthening the pharmaceutical manufacturing capacity of developing countries under the assumptions that such initiatives would—

- Increase countries' self-sufficiency in pharmaceutical supply
- Improve medicine quality
- Produce foreign exchange through exports of domestically manufactured medicines
- Create new jobs

However, even with the enthusiasm about the potential role of pharmaceutical production in the developing world, a 1986 World Bank report (Lashman 1986) concluded that the economies of scale and technological requirements for manufacturing medicines made local production an unrealistic

option for most countries. The exceptions were countries with large local markets and the capacity to produce APIs, including Argentina, Brazil, China, Egypt, India, Mexico, and Thailand.

At that time, the pharmaceutical industry in most developing countries depended on production by multinational affiliates and the licensed production of generic products; very few developing countries were able to initiate any systematic pharmaceutical export (Balance, Pogany, and Forstner 1992). In addition, the increased market for generic medicines plus greater price competition led to significant decreases in the prices of many essential medicines. This market shift worked against domestic manufacturers, who were largely unable to produce medicines at prices that were competitive with those of large-scale international pharmaceutical producers. These factors led to a trend away from the promotion of local pharmaceutical production and toward more emphasis on quality-control and procurement issues (Kaplan and Laing 2005).

In a 2004 report, the World Health Organization estimated the worldwide pharmaceutical production capacity of 188 countries, which had changed little from the 1992 statistics—

- Ten countries had a sophisticated pharmaceutical industry and a significant research base (eight Western European countries, plus Japan and the United States). These countries—led by the United States and Japan—were responsible for 84 to 88 percent of the world's pharmaceutical production value.
- Sixteen countries had innovative capabilities: a sound production capacity and at least one new molecular entity marketed between 1961 and 1990 (including several European countries, Argentina, Australia, Canada, China, India, Israel, Mexico, and the Republic of Korea). India and China had seen huge growth in their pharmaceutical production over the preceding decade. India, in fact, had developed highly specialized manufacturing capabilities and had become one of the largest exporters of API raw materials for the production of generics (World Bank 2005).
- Thirteen countries produced both active ingredients and finished products (including Brazil, Egypt, Indonesia, Norway, and Turkey).
- Eighty-four countries from virtually every continent only produced finished products from imported ingredients.
- Forty-two countries and areas had no pharmaceutical industry (primarily low-income African and Asian countries).

Moving from one category to the next requires substantial technical and financial resources, and still, no country is completely self-sufficient in pharmaceutical production.

Even countries that export more pharmaceuticals than they import still rely on imports of some finished products, APIs, or other materials.

Currently, several types of pharmaceutical manufacturers, with different business models, operate manufacturing facilities in low- and middle-income countries (World Bank 2005)—

- *Subsidiaries of large multinational companies* that manufacture patent-protected, branded products for local and regional markets.
- *Global manufacturers of generics* that focus on developed markets in the United States, Europe, and large middle-income markets such as India and China. Some have manufacturing operations in smaller developing countries or joint ventures with local manufacturers.
- *Generics companies with predominantly national operations* that focus on the domestic market with occasional exports into neighboring countries. Their ability to comply with good manufacturing practices varies.
- *Small-scale local manufacturers* that usually make a limited number of products, including traditional medicines, to serve local or regional markets. Most are not able to meet GMP standards.

In addition, most hospitals repackage medications in smaller, unit-dose containers and may compound specialty items, such as creams with special formulations, for their own patients and for satellite facilities. The type of small-scale production of pharmaceuticals in a hospital pharmacy could include secondary production from existing raw materials that are usually imported and the packaging or repackaging of finished goods into smaller dispensing packs and course-of-therapy packages (see [Chapter 45](#)).

National manufacturers vary widely in the scope of their operations. Some in larger markets may have substantial capabilities in primary and secondary manufacturing activities and extensive pharmaceutical distribution networks. Smaller countries may be limited to a few major companies that do basic manufacturing or formulation and packaging. Many developing countries may have only one or two local importing distributors who represent all the international manufacturers. Multinational manufacturers of proprietary medicines have used this pathway to globalize their operations, and as multinational generic producers grow, they will likely follow the same expansion model (Guimier, Lee, and Grupper 2004). [Country Study 7-1](#) profiles three types of manufacturers operating in West Africa.

Finally, one of the most important global trends has been the rapid growth of active-ingredient manufacturing companies in India and China. India, especially, led the way in developing highly specialized manufacturing capabilities

that cover a large range of medicines, from antibiotics to antiretrovirals. Leading companies have invested in manufacturing facilities that meet the highest international standards for GMPs. Technical advances in China have caught up as it has entered into joint ventures with pharmaceutical manufacturers in developed countries as a way of acquiring technological expertise. China and India will probably maintain a competitive production advantage because of their skilled labor forces, low resource costs, and large, high-volume domestic markets, which will help them keep their pharmaceutical prices low (Attridge and Preker 2005).

7.3 The effect of globalization on local production

The creation of high-profile international initiatives, such as the Global Fund to Fight AIDS, Tuberculosis and Malaria, and increased funding for public health treatment programs

are part of the growing momentum to increase access to medicines in developing countries (see Chapter 2). In addition, initiatives to reduce pharmaceutical prices, such as the Clinton Foundation's negotiations with multinational producers and global procurement mechanisms, such as the Global Fund's voluntary pooled procurement system, are expanding the number of procurement options for these countries. As a result, the market is growing for pharmaceuticals that treat diseases that disproportionately affect poor countries. In addition, the scale-up of public health treatment programs, such as antiretroviral therapy, is creating a large demand for pharmaceuticals in the public sector. Countries that are tempted to add to or expand their production of pharmaceuticals to fulfill the needs of such targeted public health programs must carefully evaluate the cost-effectiveness of global production compared with that of their procurement options. Global funding mechanisms require that products either be prequalified by WHO or approved by a stringent regulatory authority. So far, mainly

Country Study 7-1

Profiles of three pharmaceutical facilities operating in West Africa

A 2004 study looked at the pharmaceutical production capacity in West Africa using data available from interviews with key stakeholders and field visits to Ghana and Côte d'Ivoire. The following profiles illustrate the similarities and differences of three different types of pharmaceutical production operations.

The first firm is an owner-operated company that started small and grew into an operation employing more than 300 people, with production lines for tablets, liquids, capsules, syrups, and powders. The company sells most of its products to private-sector customers, but some sales go to the public sector. The firm does not export its products but has developed a large sales and distribution network covering the entire country. The company funded its expansion using sales profits that were supplemented by loans from commercial banks. Because the company already had significant domestic market share, it was looking for new markets and new products, including medicines to treat HIV/AIDS and malaria. Although the company's owner-operated status has probably helped keep costs manageable, strict control by the owners could discourage the recruitment of talented workers from outside the firm whose expertise could help the firm expand into a large-scale, international player.

Large European multinational pharmaceutical companies own the majority of the second firm, and it operates under licensing agreements with them and other international partners. The company's structure allows

it to benefit from both the financial support and technical expertise of these experienced partners. However, because the firm buys most of its APIs through its parent companies, costs are higher than what the firm could achieve by procuring through open international tenders. Consequently, the prices of imported medicines from Asia are generally lower. The company is not planning on producing any new medicines to treat HIV/AIDS, tuberculosis, or malaria.

The third company is privately owned but run by professional expatriate managers brought in by the principal investors, who are based outside the country. On one hand, the company benefits from easier access to international financing and management expertise, but on the other hand, the expatriate management team is costly. The company is looking to expand its reach to export markets throughout West Africa and is planning to add an artemisinin-based combination therapy (ACT) product to its production portfolio.

The structure of each of these firms offers advantages and disadvantages to operating pharmaceutical production facilities in West Africa. The first and third companies, however, which plan on adding antiretrovirals and ACTs to their production, may have a difficult time meeting WHO prequalification requirements.

Source: Guimier, Lee, and Grupper 2004.

large, well-established companies have been able to achieve prequalification standards.

An additional factor affecting the globalization of the pharmaceutical sector is the World Trade Organization's Agreement on Trade-Related Aspects of Intellectual Property Rights (TRIPS). TRIPS allows countries affected by a public health crisis such as HIV/AIDS to bypass patent laws and issue a voluntary or compulsory license to a company to manufacture or import a particular medicine to ease the crisis. However, the consensus is that many smaller middle- and low-income countries lack the necessary infrastructure to take advantage of this mechanism by investing in and successfully operating pharmaceutical plants (although they may issue compulsory licenses to import such products). This situation may be changing, however. In 2010, WHO founded Quality Chemical Industries, Ltd., of Kampala, to be the first manufacturer in a least-developed country in compliance with GMPs—moving a step closer to achieving prequalification status in the WHO system.

7.4 Issues that affect local production decisions

In some countries, national pharmaceutical policies promote local pharmaceutical production as a way of improving access to medicines and achieving national self-sufficiency. But decisions regarding which pharmaceuticals and how many should be imported or locally produced are complex and involve health policy, industrial policy, and a country's national development strategy. Sometimes, a health policy with the goal of increasing access to affordable and quality-assured medicines is pitted against an industrial policy with the goal of promoting a local industry whose products may be more expensive than those on the international market (see [Country Study 7-2](#)). Countries should consider their economic conditions and health services infrastructure when deciding on investments in the local pharmaceutical industry.

The greatest challenge for policy makers is often not the creation of a comprehensive policy on local production, but rather the creation of policy elements that function as constructive next steps and build on existing conditions and local institutional capacities. Many countries are limited in their capacity to monitor, supervise, and regulate pharmaceutical production. Policies need to take into account a country's capacity to implement and enforce appropriate regulations.

The Assessment Guide for this chapter lists many of the factors and policy issues that affect production decisions. Each issue contains elements that may favor or hinder the production decision or leave it unaffected. In general, policy makers should concentrate on promoting guidelines that

Country Study 7-2 Health policy versus industrial policy: Rifampicin in India

The international market for rifampicin, an essential antituberculosis medicine, presented an example of rivalry between the pharmaceutical production sectors in China and India. In India, the cost of imported rifampicin from China, at 40 U.S. dollars (USD) per kilogram, was lower than the cost of Indian manufacturers, at USD 70 per kilogram. However, Indian manufacturers questioned the quality of the Chinese medicine and demanded that their government place restrictions on these imports. India already had an overcapacity for rifampicin manufacturing; therefore, this situation illustrates a typical schism between health policy goals and industrial policy goals. Because India was estimated to have 25 percent of the world's tuberculosis cases, the government had to decide which was more important: getting the cheapest rifampicin from China, which would presumably make the medicine more affordable for patients, or sustaining and developing national rifampicin manufacturers.

Source: Attridge and Preker 2005.

support the essential medicines concept: improving the prospects of access to low-cost, quality-assured, effective medicines. Producers can make their own decisions about what and how much to make, and essential medicines program managers can concentrate on choosing to buy from the best sources, whether they are domestic or international.

Human and physical infrastructure

A primary issue in many countries, especially low-income countries, is the ability to find experienced and skilled staff, particularly scientists and engineers. Managing the issues of quality assurance, including regulatory compliance and meeting GMP standards, is key to ensuring high quality. In the current market, technical expertise to produce complex formulations, such as fixed-dose combinations, is critical. In the short term, human resources can be supplemented from external sources, but production decisions are long-term investments that require sustainable, local staffing.

In addition to human resources, the reliability of water, power, and environmental controls are central to the production decision. If materials, equipment, and spare parts are not available, items will have to be imported from countries with established pharmaceutical industries.

Market factors

Population size and distribution combine with per-capita income to determine how many potential customers in the national market will be able to buy medicines. Although aspirations for health are high, difficult economic times can lead to falling real personal incomes and low government capacity to provide health services, both of which limit actual market size in many countries. The national markets of most developing countries are too small to absorb all the outputs of domestic production if done at scale; therefore, a manufacturer producing essential medicines at a scale adequate to lower unit production costs to competitive levels will often have to consider exporting its products, which requires a more sophisticated distribution network and the ability to ensure that its products meet international quality standards.

Other local competitors and importers also need to be taken into account, along with the possibility of a preference in the public-sector market for local production. Barriers to importation of finished products may help local producers initially, but they will increase local prices paid by consumers (and public health organizations) and make the national producers uncompetitive internationally.

Regulatory and legal provisions

As discussed in [Chapter 6](#), pharmaceutical registration requirements are rules that prohibit dangerous, unproven, or useless items and promote the availability of quality-assured and effective medicines. However, a cumbersome or corrupt registration process can limit a producer's incentives to offer a product. From the producer's viewpoint, the important issues related to registration are the transparency, speed, fairness, and expense of the process.

With the globalization of the pharmaceutical sector, an increasing movement exists to establish and enforce GMPs as common high standards for quality. The enforcement of these standards is through regular inspection of manufacturing facilities by authorities. Therefore, a strong regulatory agency in the home country facilitates an export business, because it provides a credible proof of quality.

A manufacturer's adherence to GMPs can add significantly to investment and operating costs. If the national drug regulatory authority is not strong enough to enforce GMPs, facilities may be tempted to relax their practices. Given the shift toward globalized quality standards in pharmaceutical production, however, the rationale for local production at some lower quality standard has shrunk, and such second-tier products will be exposed in the world market. Currently, developing countries vary greatly in their capacity to monitor GMPs, and pharmaceutical manufacturing should be encouraged only in countries that have an effective regulatory agency to enforce them.

Economic incentives and disincentives

Pharmaceutical production involves a worldwide marketplace, and the raw materials that constitute about half of production costs are traded widely as competitive commodities. Reliable, rapid access to foreign exchange is essential. The pharmaceutical industry is commonly one of the most price-controlled industries, which can help as well as distort a local production decision; price controls, by definition, distort the marketplace. (See [Chapter 9](#) for more information on pharmaceutical pricing policies).

Tax treatment and local development incentives can affect the cost of production start-ups through direct subsidies, assisted capitalization schemes, training support, or tax abatement. However, evidence suggests that legislated incentives to promote exports from local production do not affect developing-country production: by 1999, less than 5 percent of low-income country pharmaceuticals were exported on average, a figure that had been on the decline for two decades (WHO 2004).

Duties and import controls

Differential taxation of pharmaceutical materials, both imported and local, can significantly affect the production decision. If the public-policy goal is to create a level playing field for producer decisions on what and where to produce, there should be no difference in the tax treatment of raw materials, both active and inactive ingredients, and finished

Table 7-1 Distribution by country groups of tariff rates for finished pharmaceutical products, 2009

Tariff rate (%)	Number of countries (n = 136)	Low-income countries	Low-middle-income countries	Upper-middle-income countries	High-income countries
0	62	16	13	12	21
0–5.0	32	9	14	6	3
5.1–10.0	28	5	9	12	2
10.1–20.0	13	3	5	2	3
> 20.0	1	0	1	0	0

Source: Stevens and Linfield 2010.

products. Heavy taxation of packaging materials and production will deter local industrial development.

The Organisation for Economic Co-operation and Development (OECD) countries have an agreement to impose zero tariffs on specified lists of active ingredients for medicines, which has facilitated internal OECD pharmaceutical trading. Average tariff rates have been decreasing; however, in a 2009 analysis, 54 percent of countries were applying import tariffs, down from 61 percent in 2005 (Stevens and Linfield 2010). As [Table 7-1](#) shows, for many middle-income and low-income countries, substantial tariff barriers remain.

Many pharmaceuticals are classified as chemicals, with tariffs that have been levied to protect and promote a national chemical industry. Many countries, including India, use nontariff barriers to protect national industries from cheaper pharmaceutical-related imports, which may decrease their consumers' and health systems' access to inexpensive products. Such barriers include antidumping regulations, onerous systems of certification of origin and quality, and legislation requiring local pharmaceutical manufacture (see, for example, Olcay and Laing 2005).

To increase pharmaceutical access, countries may be better off focusing on reducing or eliminating their tariffs and taxes on pharmaceuticals. Markups added throughout the pharmaceutical distribution system may be far greater than import tariffs; additionally, such internal distribution tariffs could outweigh any price benefits achieved through local production. [Chapter 9](#) discusses the effects of taxes and tariffs within the pharmaceutical distribution system.

Collaboration and public-private partnerships

The use of public-private partnerships in the research and development of pharmaceuticals has been growing. Efforts such as the Drugs for Neglected Diseases Initiative are described in [Chapter 3](#). In addition, public-private partnerships and joint ventures can be mechanisms for developing countries to gain some of the benefits of local production, such as the acquisition of technical expertise, without taking on business risk. In fact, partnering with international companies is often the most common form of local production support, with joint ventures and majority or minority ownership shares depending on the strength of the local economy and the political and market potential. The potential for profit repatriation by the external partners is critical.

As pharmaceutical markets become more globalized on many levels, suppliers may be more likely to form alliances and partnerships that increase their capability to compete in the world market. Likewise, multinational pharmaceutical producers have developed a better awareness of the need to consider the social implications of their business practices, and as a result, to be more open to entering into collabora-

Figure 7-1 Preinvestment, investment, and operating phases of the project cycle

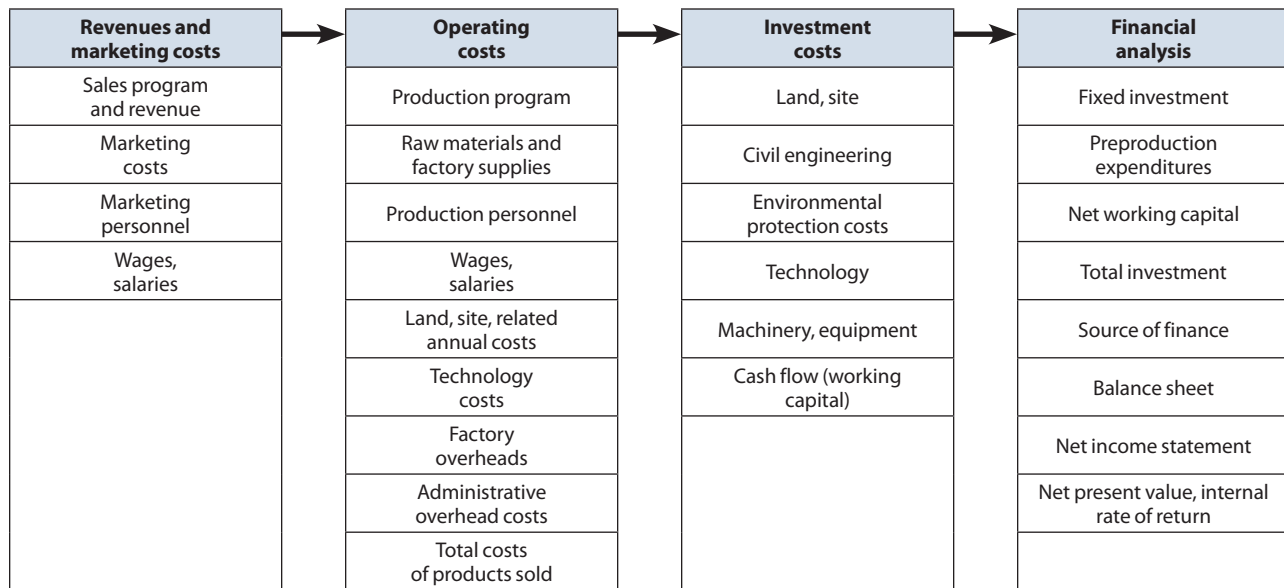

tive arrangements that promote technology transfer in low-income countries ([Chapter 3](#)).

In addition to benefiting from collaboration between large multinational companies and smaller enterprises, small country markets can coordinate or join together to create economies of scale. Some African governments have adopted policies that favor local industrial development and investment and have created trading blocs in an effort to harmonize tariffs, currency, and medicine registration processes (Guimier, Lee, and Grupper 2004).

7.5 Assessing the feasibility of local production

Despite the argument that production decisions should be left to private-sector and market forces, policy makers must sometimes respond to pressures to become more involved in decisions about pharmaceutical production. A feasibility study may serve either to warn against a hasty decision to consider manufacturing locally or, if the decision is made to go forward, to establish an appropriate framework, timetable, and resource plan for analysis. [Figures 7-1](#) and [7-2](#) illustrate the project investment cycle and the complexity of the analysis process *only* for the feasibility stage. The issues to be considered in a careful investigation include marketing analysis, raw materials and supplies, location, engineering and technology, organization and overhead costs, human resources, implementation planning and budgeting, financial analysis, and investment appraisal.

Figure 7-2 Information flow for an industrial feasibility study

Source: Behrens and Hawranek 1991.

When a project feasibility analysis is carried out in the public sector, many different government agencies (ministries of treasury, industry, and commerce, as well as the ministry of health) must be involved to appraise the forces and issues that will determine the outcome of the analysis. The complexity of these negotiations means substantial time commitments from senior analysts and policy makers. Nevertheless, the vast majority of worldwide production is done by private companies that have learned from experience how to manage the process efficiently. *Country Study 7-3* illustrates the difficulties encountered by some public-sector production programs.

A feasibility assessment of how well sub-Saharan African countries could use local production to increase access to medicines concluded that a few countries appeared to meet the criteria for developing a successful pharmaceutical production industry; however, long-term financial viability was unknown because of major factors out of the companies' control, such as the price they would have to pay to import APIs and the stability of their market share (Guimier, Lee, and Grupper 2004).

As mentioned, new global public health initiatives have greatly influenced the pharmaceutical marketplace. Countries' desire to increase access to antiretrovirals, artemisinin-based combination therapies for malaria, and other essential medicines have renewed their interest in assessing the feasibility of local production, based on the assumption that domestically manufactured medicines would be cheaper than those bought from a foreign manufacturer. The World Bank (2005) points out that local manufacturing has the potential to strengthen political support for public

health treatment programs and institute pride in a national industry. Under the challenging conditions for developing and maintaining a successful domestic production enterprise, however, national stakeholders will have to consider whether scarce resources should support local pharmaceutical production or be used to improve the health system infrastructure or other areas of pharmaceutical management, such as the distribution system and the pharmaceutical regulatory system. Investments in local medicine production will be cost-effective only if domestic pharmaceuticals can be produced more cheaply than they can be imported on the open market (Guimier, Lee, and Grupper 2004). For example, the institutions and governments that buy recommended medicines to treat HIV/AIDS, tuberculosis, and malaria must follow the procurement guidelines of their major donors. Therefore, domestic producers must meet international quality standards, such as WHO's prequalification standards, as well as be price competitive with large international competitors. If the cost of developing local production capacity is too high or the quality of the products is doubtful, local production must be viewed as probably not justifiable.

WHO, the United Nations Conference on Trade and Development, and the International Centre for Trade and Sustainable Development are collaborating on a project to promote local production of medical supplies and related technology transfer in developing countries. Started in 2009, the project is working to identify the challenges and obstacles of local production and make evidence-based recommendations on their feasibility and sustainability (WHO n.d.). ■

Country Study 7-3 Local public-sector production problems

- The Social Security Agency (CSS) laboratory in Panama had produced a number of pharmaceutical products for decades. The government gave the laboratory a permit to operate, but it did not require registry of the laboratory's products, which would entail instituting some quality-control measures. In 2006–2007, more than 120 people died after taking cough syrup contaminated with diethylene glycol, an industrial solvent, and the CSS treated more than 50,000 patients exposed to the contaminated medicines. The director of CSS explained that analyses are performed on the medications to guarantee quality, “but unfortunately in this case they did not detect the toxic substance.” The laboratory was closed. Investigation showed that adulterated glycerin (which contained over 20 percent diethylene glycol) that a local firm sold the laboratory had come from China via Spain. More than a dozen people in Spain and Panama (but not China) were charged with crimes related to the incident.
- One Latin American ministry created an “in-house” pharmaceutical factory to produce essential medicines for its own system. Production had little connection with the ministry market, however, and the product line drifted into over-the-counter preparations and beauty aids, largely missing its original purpose.
- In another semi-autonomous government laboratory, production of essential medicines is usually two to three years behind schedule, throwing ministry purchasing into turmoil and resulting in higher prices because of emergency purchases.
- A parastatal company in East Africa faced multiple problems in producing pharmaceuticals at competitive prices. Inadequate capitalization and inadequate foreign-exchange allocation left the firm unable to purchase enough raw materials to operate at the break-even level of 60 percent capacity. For the pharmaceuticals that were produced, containers of inadequate quality—metal tins without aluminum coating—were all the local suppliers had, and these had to be lined with polyethylene bags, adding to production costs. Plastic containers were tried, but the lids fit poorly because a proper mold could not be obtained locally at reasonable cost. The cardboard used for boxes to pack intravenous fluids collapsed when stacked, and the containers broke when transported over rough roads. When the government attempted to purchase pharmaceuticals on tender from the company, it could not meet the competitive prices on the market, and as a result of a structural adjustment program, the company was put up for sale.
- For political reasons, a Latin American government was obligated to purchase a nonfunctional private facility as a means of expanding its production capacity. Originally constructed to produce small quantities of a large number of sterile injectable products, it had never functioned because of an inadequate water supply, which rendered it useless as a production facility. In addition, the plant lacked the production capacity, types of equipment, and storage capacity to produce the priority items required by the ministry.

ASSESSMENT GUIDE

Human and physical resources

- Are technical specialists available?
- Are skilled production staff available?
- Is there an educational system that can supply trained workers?
- What are the cost and reliability of water, power, construction, equipment, and other resources?
- Are there financial resources available to retain skilled workers and to support the maintenance of infrastructure?

Market factors

- What are the population size, geographic distribution, and income levels in the country?
- Is there existing local production capacity (competition)?
- What are the barriers to imported products (degree of protection)?
- Can the size, reliability, and preference of the public-sector market ensure economies of scale?
- Is there predictable demand for medicines?

Regulatory environment

- What is the status of laws on pharmaceutical registration?
- What is the status of product and process patent protection?
- Does the regulatory agency have systems and capacity to assure product quality through GMPs and enforcement of standards?

- Are there generic labeling, prescribing, and dispensing laws and practices?

Investment and industrial development environment

- How strong is the country's financial sector (banking and nonbanking activities)?
- Is there sufficient access to capital?
- Are tax or other investment incentives available?
- Are industrial development funds available (access to start-up capital)?
- What are the ownership requirements (limits on foreign ownerships, requirements of local ownership)?
- Are there restrictions on repatriation of profits (foreign investors)?

Economic incentives

- Does the government enforce price controls?
- Is there access to foreign exchange?
- Are there export incentives?

Duties and import controls

Are there duties or import controls on—

- Active pharmaceutical ingredients (versus finished products)?
- Inactive pharmaceutical ingredients and other raw materials?
- Packaging materials?
- Specialized pharmaceutical equipment?
- Nonspecialized equipment?

SUMMARY

The basic goals of national medicine policies and public-sector pharmaceutical supply systems are to provide access to needed medicines and supplies, promote the rational use of medicines, and ensure the quality, safety, and efficacy of medicines. Various strategies exist to achieve these goals through different combinations of public and private involvement in the pharmaceutical management cycle. National systems vary with respect to public and private roles in financing, distribution, and dispensing of pharmaceuticals, ranging from fully public to fully private systems.

At least five alternatives have traditionally existed for supplying medicines and supplies to governmental and nongovernmental health services—

- *Central medical stores (CMS)*: Traditional public-sector pharmaceutical supply system, in which medicines are procured and distributed by a centralized government unit.
- *Autonomous supply agency*: An alternative to the CMS system, managed by an autonomous or semi-autonomous pharmaceutical supply agency.
- *Direct delivery system*: A decentralized, non-CMS approach in which medicines are delivered directly by suppliers to districts and major facilities. The government pharmaceutical procurement office selects the supplier and establishes the price for each item, but the government does not store and distribute medicines.
- *Primary distributor (or prime vendor) system*: Another non-CMS system in which the government pharmaceutical procurement office establishes a contract with one or more primary distributors as well as separate contracts with pharmaceutical suppliers. The contracted primary distributor receives medicines from the suppliers and then stores and distributes them to districts and major facilities.
- *Primarily private supply*: An approach used in some countries that allows private pharmacies in or near government health facilities to provide medicines for public-sector patients. With such an approach, measures are required to ensure equity of access for the poor, medically needy, and other target populations.

These systems vary considerably with respect to the role of the government, the role of the private sector, and incentives for efficiency. Mixed systems in which different categories of pharmaceuticals are supplied through different mechanisms are frequently seen, and countries

that take advantage of the capacities in both the public and private sectors usually have systems that are more effective; they also tend to be more resistant to shock from disaster events.

In many countries, missions, charities, and other not-for-profit, nongovernmental organizations (NGOs) provide an important share of health care. NGOs in some countries have established not-for-profit essential medicines supply agencies to provide high-quality, low-cost pharmaceuticals for their health facilities. Some of these have been very successful, but the model has not worked in all countries.

In most countries, the commercial sector is able to provide a range of services that can enhance public access to essential medicines. In general, this sector would potentially respond well to new opportunities for providing supply services; however, the private commercial sector is not always sufficiently well developed or motivated to provide critical supply services to the public sector and should not be seen as a cure-all remedy for solving problems with existing systems.

The commercial sector also plays a vital role in providing access to many people, especially in rural and underserved urban areas where retail drug outlets are the first stop to treat common illnesses. Because these outlets operate in a relatively uncontrolled environment, improving and monitoring the quality of products and services is challenging, and drug sellers generally lack qualifications or training in pharmaceutical management. Much work remains to be done to solve these problems, although strategies that engage the interests of shop owners, dispensers, the government, and the public have recently been developed and tested with some success. [Chapter 32](#) covers drug seller initiatives.

In many countries—especially in countries that have been rolling out large-scale HIV/AIDS programs—the relative roles of the public and private sectors in pharmaceutical supply management are undergoing change in both the pharmaceutical sector and the overall health sector. Changes in public and private roles need to be designed to account for the planned magnitude of scale-up and to promote accessibility to medicines and rational medicine use.

Perspectives on the role of government in health care vary from a solidarity, or social welfare, approach (which holds that the state should provide all health and other social services except when it is unable to do so) to a self-

help, or market-economy, approach (which holds that the private market should provide most health services). This chapter does not argue for or against either approach but advocates that, for most countries, the best strategy is a balanced approach drawing on the strengths and capabilities of both public and private sectors.

This chapter provides an overview of systems and strategies for organizing pharmaceutical supply for public health services and issues related to health-sector reform, including the decentralization of pharmaceutical

management functions. Issues and options related to meeting public health needs through the private pharmaceutical sector are also considered, including the potential contribution of private nonprofit essential medicines services. In the context of rapidly growing programs to treat critical diseases, such as HIV/AIDS, the chapter outlines approaches for addressing supply problems. Finally, the chapter summarizes different government roles, including periods of transition from one model of service delivery to another.

8.1 Systems for pharmaceutical financing and distribution

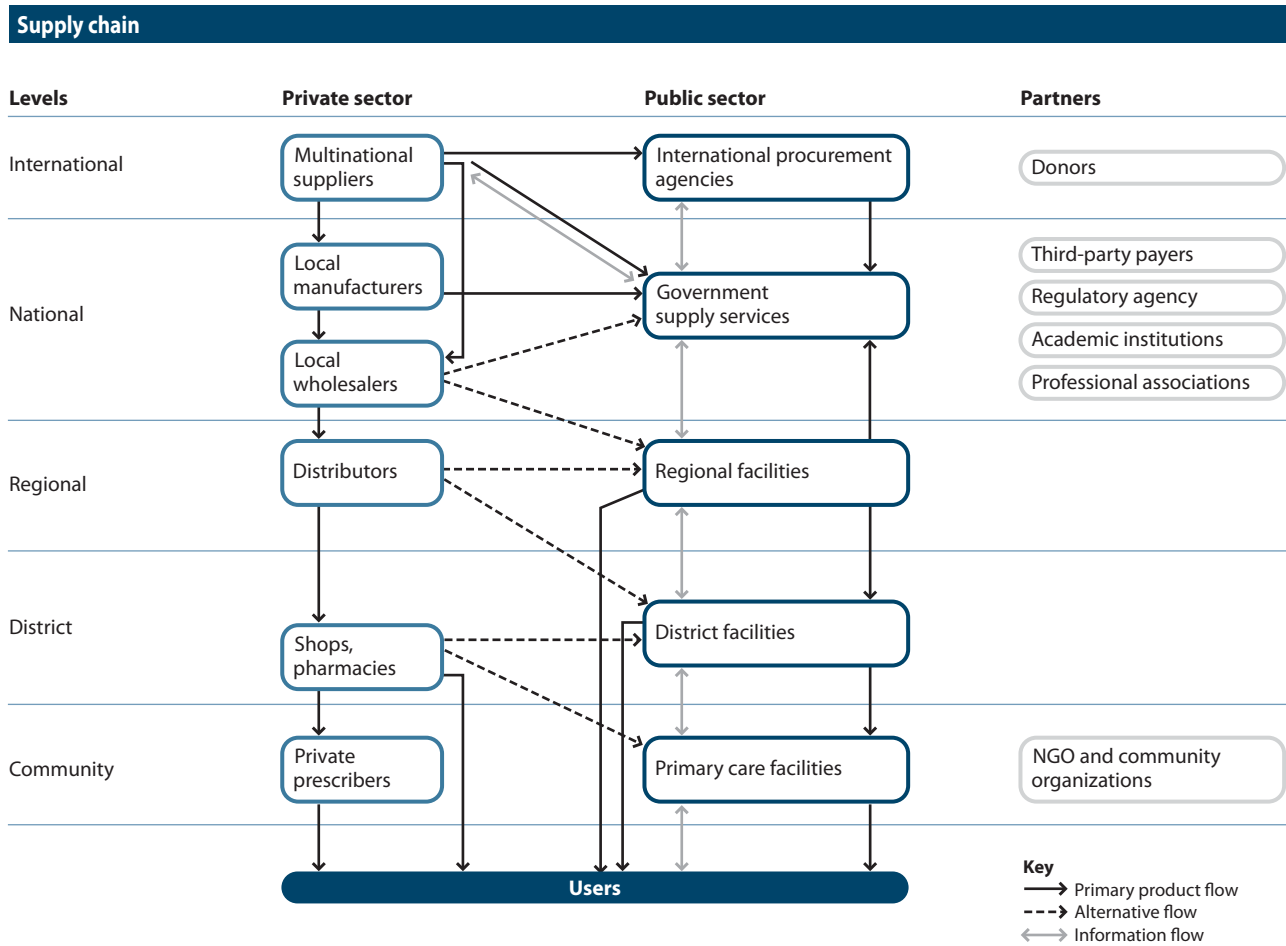

Approaches to pharmaceutical supply can be described in terms of public and private roles in financing, wholesale distribution, and retail distribution. The six main approaches range from fully public to fully private, as summarized in Table 8-1.

1. *Fully public*: The classic public system follows a CMS approach, in which a centralized government unit finances, procures, and distributes medicines. The state is the owner, funder, and manager of the entire supply system. Many countries in Africa, Asia, Europe, and Latin America have made this their standard strategy.
2. *Private supply to government health services*: Through direct delivery or prime distributor contracts (described later in this chapter), private channels are used to provide publicly funded medicines to government-operated health facilities. Although most common in North America, where it is known as a prime vendor system, this approach can also be found in Africa, Asia, and Latin America.
3. *Social health insurance systems*: Public funding from central budgets and social health insurance premiums can be used to reimburse pharmacies or patients themselves for medicines that are provided through private pharmacies. Australia, many countries in Western Europe, and North America have followed this approach in recent years.
4. *Private financing and public supply*: Government medical stores or state-owned wholesalers may supply medicines that are dispensed by government health facilities but paid for (in whole or in part) by patient fees. Many former socialist economies followed this approach. In the 1990s, it was being used by China and by government health services in Asia, Africa, and Latin America that implemented user fees for pharmaceuticals but continued to operate government medical stores. China specifically has shifted its health financing scheme from a socialized system to a market-oriented one. Some countries, such as Uganda, have eliminated user fees and increased public spending, whereas others are working toward instituting social health insurance systems in place of user fees (WHO 2003; WHO/WPRO n.d.).
5. *State wholesale monopoly*: At least through the 1980s, in parts of Europe and Africa, pharmaceuticals were imported and distributed by a state monopoly that supplied private pharmacies as well as government

Table 8-1 Systems for financing and distributing medicines

Financing	Distribution

Figure 8–1 Supply chain management framework

Source: CPM/MSH 2011.

health services in some cases. Although this model has historical significance, it is rarely seen now.

6. *Fully private*: Patients pay the entire cost of medicines and purchase them from private retail pharmacies and drug sellers, which now exist in nearly every country in the world and account in some cases for a large percentage of pharmaceutical distribution. Outside the market economies that have high levels of social and private health insurance, this approach is also the major source of prescription medicines in many countries, including many of those that nominally provide free pharmaceutical services.

The context of financing public health in resource-limited countries has changed because of global funding initiatives to combat specific diseases—primarily HIV/AIDS and malaria. The Global Fund to Fight AIDS, Tuberculosis and Malaria; the Global Drug Facility; the U.S. President’s Emergency Plan for AIDS Relief; and others are dramatically changing the public health financing paradigm for

these programs, with a particular emphasis on pharmaceuticals. More information on these donor initiatives can be found in [Chapters 2 and 14](#).

Public financing includes government budgets (central, regional, and local) and compulsory social health insurance programs. Private financing includes out-of-pocket payments by individuals and households, private health insurance, community medicine schemes, cooperatives, employers, and financing through other nongovernmental entities. [Chapter 11](#) includes more information on financing, and [Chapter 12](#) covers pharmaceutical benefits in insurance.

Public distribution includes wholesale distribution and retail dispensing by government-managed pharmaceutical supply and health services as well as distribution through state-owned enterprises (state corporations). Private distribution includes private for-profit wholesalers, retailers, and nonprofit essential medicines supply services. [Figure 8–1](#) illustrates a pharmaceutical supply chain framework featuring the public and private sectors and possible partners.

8.2 Perspectives on the role of the state in health care

Different perspectives on the role of the state in providing health care result in differences in assigning the responsibility for pharmaceutical supply. The debate over the proper role of government is as old as government itself. This debate has been heightened, on the one hand, by the failure of centrally planned economies to ensure economic security for their populations and, on the other hand, by the inability of some market economies to ensure access to basic social services such as health care. Two views of the role of government can be identified—

- *Social welfare perspective*: the government should provide all health and other social services, except in specific instances when it is unable to do so.
- *Market economy perspective*: the private market should be left to provide all health and other social services, except when the private market fails to do so and the state can be expected to achieve better outcomes.

Such totally divergent views may exist in theory, but in practice, neither approach sufficiently provides adequate access to health services for all population groups. Increasingly, countries recognize that they must strike a balance between public and private control to create the most efficient service delivery system, and each country's context for making these decisions differs.

Governments everywhere, regardless of level of economic development, are subject to a common set of constraints. These include—

- Inefficiency in service delivery, which may result from lack of individual incentives for good performance, bureaucratic inflexibility, and overemployment
- Interest-group pressures from political supporters, business partners, members of one's local community, or concerned parties, which may lead to inefficient or inequitable use of public resources

- Lack of good governance, which may manifest itself in self-interested manipulation of the medicine selection process, corruption in the award of tenders, nepotism in the appointment of key staff, or theft of pharmaceutical products by health staff

Although government effectiveness has its limits, leaving the supply of pharmaceuticals entirely to the market economy may also fail to achieve public health objectives. Issues that must be considered include—

Equity: Because of the relatively high cost of medicines compared with incomes, without government involvement, the poor and medically needy may be denied access to necessary and often lifesaving medicines.

Information failure: Patients and some health professionals do not have full information about the quality, safety, efficacy, value for money, and appropriateness of individual medications.

Competition failure: Patents and brand names may establish a virtual monopoly for some products, and cumbersome or obstructive registration procedures, combined with the high initial investment required to build manufacturing facilities and develop new medicines, may limit the number of new competitors.

Externalities: Health services such as vaccination and treatment of contagious tuberculosis or sexually transmitted infections benefit people besides those who receive the services.

Chapter 10 has more information on pharmacoeconomic issues.

The remaining sections of this chapter discuss major areas of public involvement in pharmaceutical supply: organizing pharmaceutical supply for government and NGO health services, decentralization and pharmaceutical management, and use of private channels to meet needs for essential medicines and health commodities.

Government action in each of these areas should be informed by a realistic assessment of the appropriate role

Table 8-2 Comparison of basic pharmaceutical supply systems

Model	Responsibilities			Advantages	Disadvantages
	Contracting suppliers	Storage and delivery	Monitoring medicine quality		
Central medical stores Conventional supply system; medicines procured and distributed by centralized government unit	CMS	CMS	CMS, DRA	<ul style="list-style-type: none"> • Maintains government control over entire system • Is easy to monitor 	<ul style="list-style-type: none"> • High capital cost for offices, storage, and transport facilities • Recurrent cost of staff, transport, other operating costs • Limited incentive for efficiency • Open to political and other interference
Autonomous supply agency Bulk procurement, storage, and distribution managed by autonomous or semi-autonomous agency	Autonomous agency	Autonomous agency	PPO and autonomous agency, DRA	<ul style="list-style-type: none"> • Maintains advantages of centralized system • Flexibility in personnel and management systems may improve efficiency • Is less open to interference • Separate finances facilitate revolving drug funds 	<ul style="list-style-type: none"> • Cost and effort of establishing supply agency • May retain some constraints of CMS • Limited competitive pressure for efficiency if operated as monopoly

of the state, given the country's circumstances. Whatever a society's expectations or a government's promises, constraints exist to government involvement, and dangers arise in an unregulated market approach to pharmaceutical supply. Government supervision of the private pharmaceutical market involves complex and often contentious issues. Public health objectives may conflict with short-term commercial interests. Ideological or political considerations not directly related to either public health or commercial perspectives may further cloud discussions.

8.3 Basic pharmaceutical supply systems

Of all the decisions policy makers and managers face, the most complex and costly often concern the financing and supply of medicines for government health services. In some countries, public-sector pharmaceutical supply is well financed and administratively efficient. In other countries, the pharmaceutical supply system is unreliable and shortages are common; such systems suffer from inadequate funding, outdated procedures, interference of various sorts, and a variety of other problems.

The pharmaceutical management framework—including all aspects of procurement and distribution—is the subject of Part II of this book. Before confronting the particulars of the pharmaceutical management framework, however, the basic structure of the supply system must be established, and pharmaceutical and supply chain management practices should be applied to achieve maximum efficiency.

Although many variations exist, five basic approaches are used for organizing pharmaceutical supply for public health services (see [Table 8-2](#))—

- Central medical stores
- Autonomous supply agency
- Direct delivery system
- Primary distributor system (also known as prime vendor system)
- Primarily private system

A mixed system is frequently seen in practice, where different approaches are used for different levels of health facilities or different categories of products. Sometimes, separate supply systems for disease-specific programs operate parallel to the primary supply system; these *vertical supply systems* are discussed in Section 8.6.

This discussion speaks primarily from a government perspective. However, the mechanisms described here are equally relevant to faith-based and other nonprofit health services, private hospital purchasing groups, for-profit health systems, and other institutional health services. This is particularly true for the autonomous agency, direct delivery, and primary distributor approaches.

Central medical stores

The traditional approach to public-sector pharmaceutical supply is the CMS, in which medicines are financed, procured, and distributed by the government, which is the owner, funder, and manager of the entire supply system. The government handles selection, procurement, and distribution—usually through a unit within the ministry of health. Financing is usually from central treasury allocations and donors, although this model can be adapted to a revolving drug fund (see [Chapter 13](#)). In countries that have decentralized budgeting and procurement, lower-level units, such as districts, may have the authority to purchase directly from the CMS.

With the CMS approach, problems with financial management, quantification of requirements, management of tenders, warehouse management, transport, and security of pharmaceuticals are common. These problems often arise from political or administrative interference; civil service constraints on discipline or dismissal of poorly performing or dishonest staff; overall inadequacy of financial resources; procurement constraints arising from the treasury payment cycle, erratic release of ministry of health funds, or slow payment from districts; and transport difficulties resulting from the need to maintain a large vehicle fleet. In Malawi, for example, regulations force the CMS to continue shipping medicines to districts that have not paid, which provides a disincentive for districts and creates decapitalization in the CMS.

One way to address some of these constraints is to contract out (or outsource) specific aspects of the supply system (see Section 8.4). Outside contractors that specialize in certain services may be able to provide them at lower cost and higher quality. Port clearing, warehouse management, and transport are among the services that are sometimes contracted out to the private sector.

Autonomous supply agency

Problems with CMS systems have led some governments to establish systems that place the responsibility for bulk procurement, quality assurance, storage, distribution, and financial management in the hands of an autonomous or semi-autonomous supply agency. This model has been tried in several countries, particularly in Africa and Latin America ([Country Study 8-1](#)).

Autonomous supply agencies are often established as parastatals, either under the ministry of health or as independent organizations with a board of directors with representatives from several government ministries and sometimes from the private and nonprofit sectors. These supply agencies operate like the nonprofit essential medicines supply services described in Section 8.7, except that their primary client is the government's health services. The

Country Study 8-1**An autonomous medical supply service: Medical Stores Department in Tanzania**

Before 1994, Tanzania functioned with a traditional CMS model for procurement, storage, and distribution. Throughout the 1980s, CMS management became increasingly ineffective, and operational and financial sustainability were major issues. Recognizing the seriousness of the situation, the Ministry of Health made reforming the CMS a cornerstone of its 1992 Pharmaceutical Master Plan. The reforms resulted in the development of an autonomous Medical Stores Department (MSD) to procure, store, distribute, and sell health commodities to the public sector and authorized private organizations. The department had a mandate to make available essential medicines and supplies on a nationwide basis, to be financially self-sustaining, and to base decision making on “sound commercial principles.” Although MSD is still a government-owned institution, it has autonomous status and makes its own rules, regulations, and procedures.

Now MSD is the predominant single distributor of pharmaceuticals and medical supplies in Tanzania. It operates a self-sustaining revolving drug fund with eight zonal stores. MSD serves national referral hospitals, regional health facilities, district health facilities, health centers and dispensaries, faith-based health facilities, and approved NGOs.

MSD improved the supply of essential medicines and health commodities to the public sector compared with the CMS, but major increases in workload in recent years have stretched MSD’s physical and managerial capacity. At one time, MSD had a virtual monopoly on distributing pharmaceuticals and supplies to all public-sector and mission or faith-based health facilities. Now, however, because of decentralization, districts and hospitals have control over their own budgets and can procure medicines and supplies from sources other than MSD. A 2007 survey showed that only 33 percent of health facilities procured exclusively from MSD, whereas most also procured medicines and supplies from private pharmaceutical wholesalers and private pharmacies. The government provides no guidelines to health facilities on when they should procure from private sources. Between 2000 and 2007, the number of private wholesalers had doubled to almost 200. Although facilities may not use MSD as their exclusive supplier, MSD sales turnover has been steadily increasing (see table).

MSD Total sales and percentage markups: 2004–2006

	2004	2005	2006
Sales in U.S. dollars	38,417,481	52,000,000	86,980,000
Percent markup of total sale	17.0	17.0	15.5

Storage space and general stock availability from MSD have been problematic. In a 2001 assessment, on average, MSD was able to supply less than 80 percent of items requested, with some zonal stores achieving less than 70 percent. A spot assessment in 2003 showed that the MSD facilities had an average of 49 percent of vital medicine items available, although its target is to have 100 percent availability for these medicines. In 2007, however, the availability of tracer items in the MSD zonal stores was only about 50 percent when measurement included buffer stock; not surprisingly, primary health facilities received only 67 percent of their orders from MSD. MSD and its zonal stores reported product delivery delays and insufficient forecasting as the main problems resulting in stockouts; product rationing at different levels of the supply chain distorts the perception of demand. The assessment did find good practices in place for storage and stock management operations at the central and regional stores. At every MSD warehouse visited, stocks were secure, protected from light, in properly ventilated areas, and well organized. The information technology stock management system was functioning.

A major concern in 2007 was the effect of vertical program supply systems, which, because of their large value relative to the essential medicines supply system, distort health priorities. The assessment concluded that government-funded essential medicines were being “crowded out” by the disproportionate funding and attention given to vertical programs. In addition, the report noted that vertical systems caused duplication and overburdened staff, who have to manage parallel information and funding flows. Evidence also suggests that MSD receives only a fraction of what it is owed for distributing vertical program goods.

successful transition from a CMS system to an autonomous supply system requires substantial time and resources to upgrade and develop infrastructure, such as a pharmaceutical information system. Moreover, political commitment is needed to support the wide-ranging changes in government regulations and laws that are often required to ensure the necessary autonomy for the new system.

For example, Zambia's pharmaceutical distribution agency is a parastatal called Medical Stores Limited (MSL). MSL is publicly financed but is an independent entity with its own management and board. Because it has management and operational flexibility, MSL has instituted practices that are more often seen in the private sector, such as creating performance incentive schemes for its staff and workers and investing in technologically advanced systems for warehouse management and fleet tracking. MSL also outsources its senior operational management to Crown Agents, Ltd., under a fixed-term contract, which requires Crown Agents to build local management capacity using global best practices in warehousing, inventory management, and distribution (Dalberg Global Development Advisors/MIT-Zaragoza International Logistics Program 2008).

Autonomous supply services are established to achieve the efficiency and flexibility associated with private management while maintaining sufficient public-sector supervision to ensure that the services provide essential medicines, at reasonable prices, with adequate quality control. The basic concept is that, under the right conditions, a well-constituted management board or board of directors will appoint qualified senior managers, who will ensure an efficient, accountable supply service. In practice, however, finding and retaining qualified senior management staff are often difficult, which can result in poorly managed autonomous agencies. In addition, success relies on sufficient human and financial resources to create and maintain the needed infrastructure and management systems.

Pharmaceutical supply agencies may be established in the context of a public-sector revolving drug fund or in a system in which government institutions purchase medicines with centrally allocated treasury funds. In either system, funds are best used to purchase medicines on a cash-and-carry basis; not extending credit is a key to sustainability.

Experience to date, though limited, suggests that the following features are necessary to establish a successful autonomous supply agency (see [Figure 8-2](#))—

Figure 8-2 Checklist for evaluating an autonomous essential medicines supply agency

--	--

- Sufficient autonomy to allow efficient operations that are free from political interference
- Oversight by an independent management board
- Professional pharmaceutical supply managers with substantive decision-making powers
- Good personnel management and adequate salaries for staff
- Adequate financing
- Public accountability and sound financial management
- Continued focus on essential medicines (rather than “profitable” alternatives)
- Focus on quality assurance of both products and services
- High-quality storage, distribution, and information technology infrastructure

An autonomous supply agency may achieve value for money and improved pharmaceutical availability through more efficient management. The two important questions are: Does the agency have the flexibility to be efficient? Does the agency have the incentive to be efficient? Such agencies are likely to improve pharmaceutical supply only if they are structured to overcome the constraints of the CMS approach. Competitive pressure encourages efficiency.

Difficulties can be anticipated if any of the following occur—

- Senior managers are political appointees rather than professional managers appointed by an independent management board.
- The government retains the authority to require distribution of medicines without charge or on a credit basis (without ensuring payment).
- Special interests outside the agency influence medicine procurement.
- The agency is required to retain staff members regardless of their ability or performance.
- A well-functioning agency is expected to handle additional responsibilities beyond its capacity.
- The agency acts as a monopoly, with no pressure to maintain low prices, reliable service, and high quality.

Professional managers should have full authority to make decisions regarding hiring and firing, set terms and conditions of employment, and create or revise in-house policies and regulations. Finally, countries considering an autonomous supply agency should recognize that this approach will not solve problems related to overall lack of funding for medicines.

Direct delivery system

CMS and autonomous supply services involve bulk procurement and distribution from a central warehouse. The

costs and logistical problems associated with central storage and distribution are substantial. An alternative may be a direct delivery system in situations where suppliers have that capacity.

In this non-CMS model, a government procurement office tenders to establish prices and suppliers for each essential medicine, but the suppliers deliver the medicines directly to individual regional stores, district stores, or major health facilities. Variations of direct delivery contracts have been implemented in many countries.

Besides its general use for supply of essential medicines and commodities, direct delivery can be used successfully in very specific situations, such as the supply of nonstandard equipment (for example, X-ray machines), where a central procurement office contracts with a supplier that delivers, installs, and commissions expensive capital equipment.

Direct delivery contracts may specify fixed quantities with scheduled deliveries or estimated quantity tenders with orders placed by the local warehouses or health facilities as needed. Financing arrangements can be tricky. Debts can quickly accumulate if pharmaceutical supplies are not balanced against available funds. Separate accounts must be maintained for each supply point (if funding is from central allocations) or all supplies must be paid for at the time of delivery. Like most procurement systems, direct delivery contracts require a sole-source commitment—that is, for the tender medicines, the local warehouses and facilities order from the supplier that holds the tender contract. The local purchasers are free to order medicines that are not on the tender from any supplier. (See [Chapters 21](#) and [39](#) for details related to preparing and tendering direct delivery contracts.)

Direct delivery supply agreements depend on and encourage further development of private-sector distribution systems. In principle, they reduce storage and transport requirements for the government by specifying in procurement contracts that medicines are to be delivered directly to district stores and major health facilities. The government only has to store medicines at the district level and deliver them to health centers and peripheral health units.

Direct delivery contracts can preserve the benefits of centralized selection (the essential medicines list), bulk procurement (suppliers offer favorable prices to get all the business for the products they are awarded), and centralized quality control. Hospitals and districts benefit from being able to manage their own funds and determine the exact quantities needed. Finally, the problems of security, central storage, and transport are shifted from the ministry to the private suppliers.

With a direct delivery system, however, district-level and facility-level pharmaceutical management responsibilities are much greater, because they can include ordering, receiving, and paying for medicines. Success depends on adequate financing and management systems and the ability and willingness of staff to undertake the increased responsibilities.

Primary distributor system

The primary distributor system (also known as the prime vendor system) often involves the public procurement agency tendering for two types of contracts. First, the public procurement agency contracts with any number of suppliers to establish the source and price for each medicine, but the medicines are not delivered by the suppliers directly; instead, a separate contract is negotiated (through tender, if feasible) with one or more private-sector distributors, the primary distributors. In some cases, a single primary distributor serves the whole health system. In larger systems,

different primary distributors may serve different regions or different levels of the health system. Another variation is to contract with private or NGO systems to supply only a particular geographic area or a specific group of health facilities, thus easing the burden of the public-sector system ([Country Study 8-2](#)).

The suppliers deliver tender medicines to the primary distributors, which are responsible for maintaining sufficient stock to fill orders from regional warehouses, district stores, or health facilities. The local warehouses and health facilities order medicines from the designated primary distributor, and the primary distributor fills the orders from medicines

Country Study 8-2

Developing a prime vendor pharmaceutical supply system for the Tanzanian mission sector

Church-owned hospitals, health centers, and pharmaceutical dispensaries in Tanzania are principally located in rural areas, where 70 percent of the population resides. Historically, they had no central pharmaceutical procurement body and relied mostly on the Medical Stores Department, international donations, and private-sector pharmacies for medicines and supplies. However, church hospitals reported dissatisfaction with services provided by the MSD, such as unacceptable out-of-stock rates. The Mission for Essential Medical Supplies (MEMS), a not-for-profit organization established by the Evangelical Lutheran Churches in Tanzania, had a history of providing laboratory services and supplies to health facilities. These facilities asked MEMS to expand its supply list to include pharmaceuticals and medical supplies.

The Strategies for Enhancing Access to Medicines (SEAM) Program agreed to help MEMS develop and implement a private-sector prime vendor pharmaceutical supply system that would improve medicine quality, supply, availability, and affordability for participating not-for-profit hospitals. The system would use pooled procurement to purchase from a single supplier and offer participating health facilities supplementary services from MEMS, such as purchase requisition review, a strategy for pharmaceutical quality assurance, training in rational use and pharmaceutical management, and medicine information services. The contractual requirements were for the prime vendor to stock and supply more than 500 items, initially to twelve rural hospitals and expanding to forty hospitals as the project progressed. The contracted delivery time was either ten or twenty-one days, depending on the goods. The prices of the goods were fixed for twelve months, starting in November 2004.

From November 2004 until April 2005, fourteen hospital orders were received electronically from ten health facilities.

The prime vendor made twenty-nine deliveries, with an average of two deliveries per order (and a range of one to six). Despite considerable procurement experience, however, the contracted prime vendor (Diocare/Crown Agents) had difficulty meeting the terms of the contract, mainly because it underestimated the complexity and costs of the program: substantial variations occurred in stock demand from the health facilities, warehouse systems were overstretched, and contract expectations were unclear. Although the prime vendor worked to resolve its own infrastructure and inventory deficiencies and worked with MEMS to address supply chain management issues extending from the distributor to the end user, the negatives—out-of-stock situations, partial shipments, and poor service—outweighed the positives, and the parties agreed to discontinue the contract in late 2005.

Even with the failure of the original prime vendor relationship, MEMS continued with much of the original strategy developed during the SEAM Program, including quantifying requirements for pharmaceuticals and medical supplies for church hospitals, pooling procurement requirements, and using a prime vendor as its principal supplier (a local wholesaler, Pyramid Pharma, in collaboration with an international supplier, the International Dispensary Association). The network of hospitals grew; as of August 2008, MEMS coordinated routine pharmaceutical and medical supply procurement for thirty faith-based hospitals serving over 4 million rural Tanzanians. In addition, through the palliative care project of Evangelical Lutheran Churches in Tanzania, Interchurch Medical Assistance, and Catholic Relief Services, MEMS extended its services of procurement coordination to thirty-seven other hospitals, including public hospitals.

□ Potential intervention areas with private sector.

in stock. Primary distributors may maintain their own vehicle fleets or subcontract with other firms for transportation.

In some cases, a group of providers, such as hospitals, pool their resources to benefit from bulk purchasing, but instead of taking on the responsibility for selection, price negotiation, and quality assurance, the group contracts with a primary distributor that takes over these additional tasks, leaving the group to merely administer the contract.

Like other private-sector contracts, this system depends on sole-source commitment for the medicines under tender contract, although districts and health facilities may be allowed to purchase nontender medicines from any source. The system also requires the availability of good information, and performance monitoring and compliance by both health system staff and the contracted distributors.

The primary distributor is paid a fee for storage and delivery services. In some industrialized countries, this fee is typically less than 2 percent. Primary distributors are able to achieve such low margins by distributing very large volumes of goods and by generating revenue through the “float” in money markets or bank interest. This income is generated through a difference in payment terms: the primary distributor pays the supplier after thirty to sixty days but requires health facilities to pay within fifteen days, thus giving the primary distributor access to the equivalent of fifteen to forty-five days’ cash turnover.

The primary distributor system may appear to add an extra intermediary and extra costs, but experience has shown that the cost of a primary distributor can be more than offset in some situations by savings from increased efficiency. Competitive awards of primary distributor contracts and enforcing contract terms are important to achieve this efficiency.

Primarily private system

National policy, insufficient financing, or management problems have led some countries to avoid taking on the responsibility for providing hospitals and health centers

with even essential medicines. In some systems, commercial pharmacies are established within ministry facilities; such pharmacies may be part of a parastatal pharmaceutical enterprise, or they may be independent enterprises. In other cases, the government may contract with commercial pharmacies to provide medicines to public-sector patients. Pharmacies established in government health facilities may operate on a nonprofit or for-profit basis, depending on the arrangement with the government. Often, such pharmacies are limited to the sale of essential medicines. In some cases, private pharmacies operate in parallel with government pharmacies in the same institution.

In countries where pharmaceutical procurement has been decentralized to the regional, district, or even health facility level, procurement officers may be quick to fill their supply orders through a private wholesaler if they perceive that the public-sector supplier is undependable or slow. Not only is this practice more expensive, but also the quality of products in the private-sector supply chain is generally not monitored as closely, if at all. In addition, unreliable orders cripple the public-sector supplier by rendering forecasts useless, resulting in overstocks and expiries. Moreover, without the purchasers to make the public sector’s revolving funds revolve, decapitalization results. An added complication occurs when legislation forces the public supplier to continue to ship orders to districts that do not pay or when districts allow debts to build up and then quit placing orders with the CMS rather than pay off accumulated debt, as was the case in Ghana (Seiter and Gyansa-Lutterodt 2009).

In many countries, the relative roles of the public and private sectors in public health and pharmaceutical supply are undergoing change. Changes in public and private roles must be designed to promote accessibility to medicines and rational medicine use (Figure 8-3). As with revolving drug funds operated by the government, the greatest concern with a mainly private supply system is equity of access for the poor, children, patients with communicable diseases, and other target groups.

8.4 Contracting for pharmaceutical supply services

The direct delivery system, the primary distributor system, and in some instances, the autonomous supply agency system involve management or service contracts (see [Chapter 39](#)). Important differences exist between contracting for pharmaceutical products and contracting for services. Contract terms are different, and a different approach is needed for monitoring.

Contracting out or outsourcing in health care has most commonly been used for nonclinical services such as equipment maintenance, laundry, and food services. Contracting out services is common in the private sector. Often, companies find that outside contractors who specialize in specific services such as managing cafeterias or repairing computers can provide those services at lower cost and higher quality than companies can provide in-house.

In pharmaceutical supply, primary distributor systems, transport contracts, port-clearing services, and other private-sector involvement require contracting for services in contrast to contracting for products (for example, medicines). However, contracting out activities requires the skills of writing, negotiating, and monitoring contracts. The contract must include specific performance indicators with a time frame for when those indicators will be met. Even experienced companies can run into problems by underestimating the necessary financial and human resources to fulfill the contract requirements. In the case of pharmaceutical supply, for example, a lack of reliable data from health facilities on medicine use and demand makes estimating order quantities difficult, resulting in overages or stockouts. All parties to the contract need to have a clear understanding of any limitations that may affect performance.

The outsourcing process functions most effectively where potential competition exists, as with any tendering process. Contracting out also demands a commitment to pay the contractors according to the terms of the contract. Government officials must develop special skills to prepare and monitor such contracts.

8.5 Comparison of basic supply systems

The five basic supply systems are compared in [Table 8-2](#). The models vary with respect to the role of the state and the degree of private-sector involvement. The CMS approach demands the most of the central government in terms of human and physical resources, because it operates virtually the entire distribution system. With an autonomous supply agency, direct delivery system, or primary distributor system, the role of the government changes from direct operations to a combination of direct operations and contract management coordination and monitoring. Some direct

delivery or primary distributor systems do not require a large central government distribution infrastructure, but depending on where the responsibility for procurement lies, such systems may require a pharmaceutical procurement office or an equivalent department with oversight responsibility to manage contracts and monitor performance effectively. A CMS or autonomous supply agency approach may be required when the local private sector is not sufficiently developed to support the efficient operation of a direct delivery or primary distributor system.

Ghana and Zambia provide examples of different types of systems in terms of the role of the private sector. In Ghana, private-sector wholesalers provide a substantial portion of sales and delivery of medicines to public regional medical stores, hospitals, and NGO facilities. In Zambia, however, almost all of the public and NGO facilities receive medicines through international suppliers and procurement agents; medicines are then distributed through the public-sector supply chain (Dalberg Global Development Advisors/MIT-Zaragoza International Logistics Program 2008).

Pharmaceutical supply systems need to achieve three main objectives: (a) high service level, as measured by low rates of shortages and stockouts; (b) efficiency, as measured by having low total costs for a given level of service; and (c) the ability to cope with disaster situations (see [Chapter 15](#) for examples of pharmaceutical supply management issues in emergencies). Autonomous supply agencies, direct delivery contracts, and primary distributor systems offer different approaches to create the flexibility, competition, and clear performance targets that help achieve these objectives.

Historically, options for handling public supply have been presented as a choice between various stand-alone alternatives (for example, CMS, autonomous store, or primary distributor). However, with growing demand for products and services, individual organizations and companies, whether public or private, will undoubtedly struggle to satisfy all needs. Against this background, a multifaceted approach using the full range of resources, including a combination of public- and private-sector strategies that spread the burden and risk, will increasingly be required.

Some countries may choose to join forces with others in their region to increase efficiency in their pharmaceutical sectors. These regional partnerships could range from sharing information on pricing and suppliers to formal pooled procurement schemes, where one central body procures medicines and commodities for a regional group of countries (see [Chapter 18](#) on procurement). Some countries may consider setting up similar alliances for storage and distribution or contracting with a private company to provide regionwide services to multiple countries. Some regional organizations are exploring options for collaborating in pharmaceutical supply, and experiences from the eastern Caribbean and the Gulf states demonstrate the potential savings and sustainability of such arrangements (Kanavos

et al. 2010); however, strong political commitment and a shared cultural outlook and language appear to be required for success.

8.6 Vertical supply systems

Public health programs that focus on targeted interventions, such as family planning or tuberculosis control, may operate vertical pharmaceutical supply systems that are set up outside a country's regular health and pharmaceutical supply system. With the dramatic increase in global health initiatives, multiple vertical supply systems have become the norm in many countries. For donors, particularly, vertical programs can be appealing because they show quick results and they are easier to manage than inclusive, horizontal programs. However, many government and donor policy makers in developing countries see vertical programs as diverting human and financial resources from already resource-constrained health systems and as undermining sustainability of the pharmaceutical sector in general. An analysis of the effect of global health initiatives on country health systems found that, in some places, the resulting vertical supply systems duplicated or displaced the countries' existing systems and that lack of coordination between vertical and essential medicines systems caused stock excesses and deficits (WHO Maximizing Positive Synergies Collaborative Group 2009).

International vertical supply programs include the Global TB Drug Facility, which works to provide inexpensive, quality-assured tuberculosis medicines for DOTS programs worldwide. The World Health Organization (WHO) created a similar program for HIV/AIDS-related medicines and commodities; however, unlike the Global TB Drug Facility, the AIDS Medicines and Diagnostic Service does not procure medicines directly but rather provides resources and assistance to countries in procuring quality medicines at the best prices and managing the distribution of those medicines. Other large vertical programs include the President's Malaria Initiative; the U.S. President's Emergency Plan for AIDS Relief and its supply mechanism, the Supply Chain Management System project; and the Global Fund to Fight AIDS, Tuberculosis and Malaria's procurement mechanism. Some large-scale vertical supply programs are based on donated medicines, such as the ivermectin distribution program for onchocerciasis.

Efforts are being made in some countries, such as Uganda, to integrate supply systems for vertical programs into essential medicines programs. Resource-intensive functions such as procurement, quality assurance, storage, and physical distribution may be integrated under the essential medicines program, whereas financing, quantification, and monitoring may stay under the control of the vertical program. Integration can provide savings and benefits but is reliant on strong government commitment to the process.

The initial experiences with integrating vertical program supply systems may not be a reliable guide to the potential for incorporating mature HIV/AIDS programs into broader public health supply systems—even ones that are efficient and well managed. Integrating HIV/AIDS programs into a country's general essential medicines program may be very difficult because of the sheer difference in scale compared with previously integrated programs, such as those for family planning. Typically, integrating a vertical program involves the absorption of a smaller supply system into a larger one, which can be reasonably achieved when the larger system functions well and has sufficient spare capacity. However, a supply system for a country's HIV/AIDS program may be as large as or larger than its essential medicines supply program; under such circumstances, integration of the two systems would require a strategic redesign and restructuring of the entire pharmaceutical supply system.

8.7 Meeting health needs through private channels

As mentioned, changes in national policy, declining government financial resources, or other trends may lead to an increased role for the private sector, including for-profit and not-for-profit entities, in providing access to medicines. Governments' inability to provide regular medicines and supplies may push more health facilities to purchase medicines from private wholesalers, and patients to purchase medicines from retail drug sellers.

Not-for-profit pharmaceutical services

Nonprofit health care providers, including faith-based and charitable health services and other NGOs, play an important role in the financing and provision of health services in many countries. The share of health services provided through the private nonprofit health sector varies considerably among countries, but in low-income countries it can be large, especially in rural areas; for example, the Christian Health Association of Malawi provides up to 40 percent of services in the country overall, with 90 percent of its facilities located in rural areas (UN 2007). NGOs can play an important role in promoting the concept of essential medicines and in supplying essential medicines.

To the extent that NGOs target their services to rural populations, mothers and children, the urban poor, and other underserved groups, encouraging the growth and development of such organizations can be in the government's interest. Government incentives and subsidies for NGOs may include annual lump-sum grants, temporary assignment of ministry health personnel, payment of NGO staff, permission to purchase pharmaceuticals from government stores, exemption from import duties (sometimes

limited to products on the national essential medicines list), and payment of retirement benefits. Providing access to government medical stores and exemption from import duties are particularly important in encouraging NGOs to supply essential medicines for their patients. Some countries have allowed specific NGOs to purchase medicines from government medical stores—in some cases, at subsidized prices.

Beginning in the late 1970s, coincident with WHO's introduction of the essential medicines concept, mission or other nonprofit health associations in some countries began to create their own agencies to procure and distribute essential medicines. These NGOs generally develop their own essential medicines list, often based on the WHO model. NGOs obtain pharmaceutical products from the national parastatal (where one exists), local manufacturers, international nonprofit suppliers, or other foreign suppliers. Financing usually comes from a combination of external donations, local donations, and fees. Ghana, India, Kenya, Nepal, Nigeria, and Uganda are among the countries in which NGOs operate essential medicines supply services. [Country Study 8-3](#) describes the origin and operation of Kenya's Mission for Essential Drugs (MEDS) and Uganda's Joint Medical Stores (JMS). Despite financial and organizational difficulties, some NGO essential medicines services have been very successful. Furthermore, in some countries where public-sector systems have experienced problems, demands on NGO services have increased as they try to fill service gaps.

For NGOs that lack the capital or organizational capacity required to establish their own central store, the direct delivery or primary distributor system offers a means to obtain more favorable prices on a limited range of locally procured essential medicines.

For-profit pharmaceutical services: retail pharmacies and drug sellers

On the consumer side, when public facilities are not located where people can easily access them, or if their supply of medicines is unreliable, people will turn to retail drug outlets as their first source of health care. Such outlets often offer questionable product and service quality at higher prices. In these examples, patients are left to buy virtually all medicines on their own from the private sector. This situation usually results from lack of funds within the government rather than any official pharmaceutical management plan. Private pharmacies and other private drug outlets exist in virtually every country in the world. In addition, doctors, other clinicians in private practice, and practitioners in the informal health sector commonly dispense pharmaceuticals, often deriving more income from pharmaceuticals than from consulting fees.

The percentage of total pharmaceutical expenditures that pass through the private sector varies from under 10 percent in some small, relatively isolated countries to over 90 percent in countries with a well-developed private sector and limited public-sector pharmaceutical supply. By retail value,

Country Study 8-3 NGO essential medicines services in East Africa

Two mission-run pharmaceutical supply services that are generally considered success stories are Kenya's Mission for Essential Drugs and Uganda's Joint Medical Stores. A WHO-commissioned report presented the findings of an analysis of key factors for success and obstacles faced in running NGO pharmaceutical supply systems. Both systems are now largely self-sustaining, but they required—and continue to require to some degree—an enormous amount of multidonor support. Although operating in similar environments, MEDS, established in 1986, and JMS, established in 1979, differ in where they source their products, either locally or internationally, and what clients they serve, but both have efficient systems, producing 90 percent availability rates and competitive prices. Kawasaki and Patten (2002) said in their analysis, “The most important point is that both organizations maintain high staff motivation levels, and provide a reliable pharmaceutical supply

system for their customers. Both organizations voice a strong commitment to serving the poor in their respective countries, and achieve this goal through efficiency and maintaining their purpose. Both organizations are beginning to supply significant amounts of products to organizations in neighboring countries.”

Although MEDS and JMS are clearly effective in contributing to increased access to medicines in their respective countries, this success evolved from and depended on decades of sustained commitment—financial, technical, and political—from supportive donors. However, as it has for other essential medicine supply services in the region, the increase in demand for products has pushed MEDS and JMS to the limit of their current capacities, which will test their ability to maintain quality services.

Source: Kawasaki and Patten 2002.

the majority of pharmaceuticals in many developing countries flow through the private sector (including the private nonprofit or faith-based sector).

For many common medical problems, such as malaria and diarrhea, a variety of factors encourage people to diagnose themselves or their children, then purchase medications from retail drug sellers before visiting a government health facility. These factors include distance to the health facility; perceived seriousness of the illness; medicine availability in the public facility; cash availability; and perceptions of privacy and quality of the health care providers, health facilities, and medicines.

Because pharmacies are mainly located in urban areas, whereas many people live in rural and peri-urban communities, these informal shops are often the most convenient retail outlet from which to buy medicines. Moreover, when public primary health care facilities have unreliable supplies of medicines, patients will turn to private shops to obtain pharmaceuticals prescribed by the government health worker.

Given the absence of pharmacy services in rural areas and the shortage in poor urban areas, retail drug outlets play an important role in providing access to essential medicines for a significant proportion of the population in many developing countries; however, experience (CPM 2003) shows that access through retail drug outlets can be characterized by a number of problems including—

- Authorization to sell only a limited list of medicines, not including basic essential prescription medicines
- Illegal availability of prescription medicines that are prohibited for sale in drug shops
- Quality of medicines that cannot be assured
- Difficulty in finding reliable and legal sources of medicines and other health care commodities
- Lack of adequate facilities for storing medicines properly
- Dispensing staff who lack basic qualifications and training
- High prices charged to consumers
- Inadequate regulation and supervision

Because informal retail drug outlets generally operate in an uncontrolled environment, improving and monitoring the quality of products and services is a challenge; however, groundbreaking initiatives aimed at the informal private sector have been introduced successfully. [Chapter 32](#) describes programs that have created accreditation and franchising schemes to provide incentives to drug shop owners to maintain standards of quality medicines and services. Such initiatives are innovative approaches to improving products and services in the commercial sector, but they are complex, costly, and time-consuming undertakings that require extensive commitment and resources.

Other, less complex approaches aimed at improving dispensing by private-sector providers include interventions such as vendor-to-vendor education programs (Tavrow et al. 2003), face-to-face drug seller training (Ross-Degnan et al. 1996), and combined drug retailer and community education programs (Marsh et al. 2004) that often focus on one condition, such as diagnosing and treating childhood malaria. Knowledgeable dispensers are more likely to ask questions and give instructions and advice to customers rather than simply sell the medicine that the customer requests (Brieger et al. 2004).

8.8 Health systems strengthening, decentralization, and pharmaceutical supply management

The various mechanisms for buying and distributing pharmaceuticals must be couched in the context of ongoing efforts to strengthen health systems, which is a unifying theme for many global health organizations and initiatives, including WHO, the Global Fund to Fight AIDS, Tuberculosis and Malaria, and the U.S. President's Emergency Plan for AIDS Relief. Changes to strengthen the supply system may include incorporation of competitive mechanisms within the public sector, decentralization of health service provision, contracting out specific services, and expanding the role for private or NGO sectors.

Selection, procurement, and distribution can, in principle, be effectively managed in centralized, partially decentralized, or fully decentralized systems. In a fully decentralized public-sector system, each authorized level, typically a province or a district, is responsible for independently procuring and supplying its own medicines. More commonly, in mixed systems, centers, provinces, and sometimes districts each supply a different set of medicines. Of the four main functions in the pharmaceutical management cycle, only local distribution and medicine use are, by their nature, decentralized. Most other functions could be performed at the national, provincial, district, or local level.

Much attention has been given to decentralization. But what is meant by decentralization? The term is used to describe at least three different approaches to transferring power from central authorities: delegation, devolution, and privatization. These can be described as follows—

Delegation describes the assignment of responsibility for specific tasks to lower-level units within the health system, with overall control remaining at the central level. For example, selection and quantification can be delegated to hospitals, while tendering, compiling pharmaceutical orders, and determining final order quantities remain central functions.

Country Study 8-4 Decentralization's effect on the supply of essential medicines in Indonesia

In Indonesia, the public-sector pharmaceutical supply situation was complex before decentralization occurred. Numerous vertical programs were managing program-specific commodity and medicine supply. A centralized procurement mechanism existed, but supply was locally administered for some essential medicines. The decentralization of the health system led to disruption and confusion because traditional lines of communication and authority were dislocated, and opinions conflicted on determining levels of responsibility. The laws and regulations relating to decentralization were unclear, and

program managers were making new, often inconsistent, interpretations of the existing regulations. In addition, different provinces and districts responded in different ways, developing and using differing methods and procedures, which resulted in conflicting information, sometimes even from within the same organization. The nature of the conflicting information made direct comparisons and data analysis difficult. However, even with the problems that were associated with Indonesia's decentralization process, evidence indicated that in 2004, medicine availability had not decreased.

Devolution refers to the transfer of power (responsibility, authority, and accountability) to lower-level units, which are then outside the direct control of the central level.

Privatization is properly defined as the transfer of ownership from the public to the private sector. But the term is also applied, less precisely, to contracting government services to the private sector (as with direct delivery contracts) or introducing private-sector features into the public sector (as with government-owned but semi-autonomous supply agencies). As mentioned in Section 8.4, contracting requires skillful management and careful monitoring.

Decentralization in any of these forms is intended to improve the responsiveness, quality, and efficiency of health services. Decentralization aims to achieve these benefits through greater local involvement, more direct public accountability, increased flexibility to adjust to local circumstances, more rapid and more accurate communication, and quicker adaptation to changing conditions. Improvements are far from certain, however. The loss of scale and purchasing power and the general lack of technical and managerial skills at the regional and district levels hinder decentralized systems from achieving efficient and effective supply management. This can be seen in the example from Indonesia in [Country Study 8-4](#). Problems that have occurred with attempts to decentralize pharmaceutical management functions include—

Lack of capacity: Decentralization of pharmaceutical management responsibility may be implemented without ensuring that sufficient local staff and management capacity are present to sustain services.

Lack of financial resources: Responsibility is sometimes decentralized without providing an adequate budget

or financing system at the levels where responsibility is placed. In this case, decentralization simply becomes abandonment of responsibility.

Increased corruption: Because of the money involved, interference for personal gain is common in pharmaceutical supply systems. Although decentralization is meant to improve accountability, it sometimes creates opportunities for local officials or other special interests to profit.

Increased cost: Decentralization of procurement usually means smaller order quantities. It can result in higher prices for essential medicines, although this problem can be overcome with central contracts coupled with decentralized ordering. Districts or facilities with purchasing power that choose to purchase from the private sector pay more for medicines.

Decreased product quality: Selecting reliable suppliers and monitoring medicine quality are difficult at the local level if no unified national system exists or if public entities are buying from unmonitored private-sector sources.

Untested private-sector providers: Private companies that have limited experience with providing large-scale health care services may underestimate the level of effort and resources necessary to fulfill the need, or the contracting authority may make the same mistake in assessing the capacity of the vendor.

In managing a pharmaceutical supply system, thinking in terms of a task-specific approach to decentralization is useful. Tasks better performed centrally include those that require specialized skills, involve economies of scale, or depend on extensive or rapidly changing technical information. Examples of such tasks include development of essential medicines lists, preparation of standard treatments, management of competitive tenders, selection and monitoring of suppliers, quality assurance, and development of training programs on rational medicine use.

Tasks that can be decentralized include those that do not require uncommon technical skills and those for which local information is required. Decentralization is appropriate when local circumstances vary significantly throughout the country and local interests favor improved performance. Examples of such tasks include adaptation of medicines lists or standard treatments to local needs, quantification of medicine requirements, coordination of local distribution, training in rational medicine use, and monitoring of medicine use at health facilities.

In the Philippines, the province of Pangasinan's approach to pooled procurement by government hospitals provides an example of a task-specific approach. Procurement is based on the national medicine formulary, treatment guidelines, and morbidity and mortality data, and hospital procurement plans must be approved by the provincial therapeutic committee. Suppliers are selected from those that have been prequalified. Tendering is centralized at the level of the General Services Office to obtain lower bulk prices, and all deliveries are made directly to the hospitals. Quantification of medication requirements, budgeting, receipt and storage, and supervision of medicine quality and use are all decentralized to the level of the individual hospital.

8.9 Analyzing options for supplying essential medicines

The following considerations are important in developing an appropriate strategy for drawing on the combined strengths of both public and private pharmaceutical sectors—

Analysis of the national policy framework: Within the context of economic, development, and industrial policy, what is the overall government approach to the roles of the public and private sectors? What have been the experiences in other sectors with the mix between private and public provision and financing of services?

Analysis of the legal framework: Is the legislation related to pharmaceuticals up-to-date? Is the drug regulatory authority adequately staffed, financed, and equipped? Does a national commitment exist to implement the measures necessary to ensure pharmaceutical quality, safety, and efficacy?

Pharmaceutical-sector analysis: What is the current status of the public pharmaceutical sector with respect to financing, human resources, physical infrastructure, management systems, and overall performance? What is the current status of the private sector with respect to these elements?

Comparative advantages of public and private pharmaceutical sectors: Given the current level of development in the public and private sectors, what are the advantages of promoting one over the other? Are clear benefits likely to result from changing the status quo?

Costs versus benefits of expanded private-sector involvement:

Any change involves costs and benefits. Do the potential economic and health benefits of expanded private-sector involvement outweigh the costs of such expansion?

Phasing-in of changes in the pharmaceutical sector: Even if good information and sound judgment lead to the conclusion that the public role in the pharmaceutical sector should change, planners should not assume that such a shift can occur immediately and in one step. Phasing-in of changes may lead to a smoother transition.

Monitoring of changes: Finally, the objectives of government action must be clearly specified, and indicators need to be identified and monitored to determine whether the objectives are being met. Such monitoring is especially important if changes are being made in phases and if an opportunity exists to hasten, delay, or modify implementation based on experience.

Clarifying public-sector roles in essential medicines programs should be a central concern in the development and review of national medicine policies. From a public health perspective, the objectives for government involvement with all pharmaceutical sectors, public and private, are to provide access to medicines by ensuring—

- Physical availability
- Affordability
- Geographical accessibility
- Acceptability (or satisfaction)
- Quality of products and services

Chapter 36 provides information on how to assess a pharmaceutical system.

Ultimately, the role a government assumes in providing essential medicines depends on the circumstances of the individual country. The spectrum of responsibility in supplying pharmaceutical products ranges from entirely public to primarily private. Most countries operate under a paradigm somewhere in between. Generally, countries that take advantage of the capacities of both their public and private sectors have better access to medicines. As mentioned, increasing challenges to pharmaceutical supply may encourage the formation of regional partnerships to increase the resource capacity for participating countries.

8.10 Implementing sustainable changes in pharmaceutical supply systems

Pharmaceutical availability and affordability are of particular concern when government health services do not exist or are not able to provide medicines for poor, medically needy, geographically isolated, or otherwise underserved populations. In countries where a large proportion of the popula-

tion is poor and government health services lack sufficient resources, ensuring universal access to medicines is particularly challenging.

These considerations must now be placed into a new and evolving context resulting from dramatic changes in public health care—especially in the pharmaceutical market—related primarily to HIV/AIDS but also to changes in treatment guidelines for malaria and other diseases. For example, from its founding in 2003 through 2010, the U.S. President's Emergency Plan for AIDS Relief is estimated to have contributed approximately 32 billion U.S. dollars (USD) through partnerships with more than 30 countries. In 2009, almost 14 percent of the budget was used to procure antiretrovirals. The Global Fund to Fight AIDS, Tuberculosis and Malaria approved grant proposals for over USD 19.2 billion through Round 9. Through Round 7, almost 60 percent of grants had been distributed in Africa, and 45 percent had gone to medicines and commodities (PEPFAR 2010; Global Fund n.d.).

For many countries, this increase in pharmaceutical funding has dramatically affected the size of their pharmaceutical market not only for these products but also for all pharmaceuticals. In addition, the high value of HIV/AIDS medicines and artemisinin-based combination therapies for malaria, as well as the sheer volume of products, will make security in the supply chain a much larger concern (see Chapter 43).

A key message is that a country cannot easily or quickly make major changes in the way it supplies medicines and health commodities; developing and implementing sustainable improvements is a complex and expensive process. A clear policy, legal, and regulatory framework must underpin planned changes, which requires the support and buy-in of stakeholders at all levels of the system. Substantial and sustained investments will be needed in a range of activities and technical areas, such as advocacy, information systems, logistics, infrastructure, and human resources development. Because the time frame for implementation will be years, changes must be addressed in phases, with appropriate technical assistance throughout. In addition, efficient decision making and project management must be in place to avoid delays in implementation.

The goal should be not only a more cost-efficient and effective supply system that maximizes access to pharmaceuticals, but also a system that—once in place—is able to function with minimum external support. Technical assistance and leadership, as well as donor and government funding and private investment, will be integral in countries that are implementing changes to their pharmaceutical supply systems, but the empowerment of stakeholders from the national level down to the local levels will help foster self-reliance and reduce dependence on outside support.

Each country must assess its own situation to determine which strategies appear best suited to its circumstances. The concepts tried in other countries and their experiences

of challenges and success should provide a framework for identifying options and making choices while keeping the key public health objectives in mind: increasing the availability and affordability of essential medicines, promoting rational use of medicines, and ensuring acceptable medicine quality. ■

ASSESSMENT GUIDE

National pharmaceutical financing and distribution

- Which pharmaceutical financing sources are used (government budgets, private out-of-pocket purchases, insurance, other sources)?
- What is the structure of the pharmaceutical distribution system (state wholesale monopoly, private wholesale distributors, NGO pharmaceutical supply agency, centralized distribution for government facilities, other distributors)?
- What is the national health care delivery context (decentralization, rapidly expanding demand for pharmaceuticals caused by rollout of artemisinin-based combination therapy for malaria)?

Pharmaceutical supply for government health services

- What system is currently used (central medical stores, autonomous supply agency, direct delivery, primary distributor, primarily private supply)?
- Is a kit system in place? Do current plans include kits, or is the goal to shift to an ordering system?
- Which alternative supply systems were considered?
- How well is the current system performing (see notes)?

Autonomous pharmaceutical supply agency (if applicable)

- Does the agency have an independent and effective management board?
- What are the qualifications of the senior managers?
- What measures to ensure efficiency and monitor performance are in place?
- Are financing and financial controls adequate?
- How is the system performing in terms of cost and delivery (see notes)?

Direct delivery and primary distributor contracts (if applicable)

- Does the legal framework permit outsourcing of services?
- Are contracts effectively monitored?
- Is competition sufficient to ensure low prices and good service?
- Are financing and financial controls adequate?
- How is the system performing in terms of cost and delivery (see notes)?

Performance indicators for pharmaceutical supply

- Are indicator medicines currently available at health facilities?
- What is the frequency of stockouts for indicator medicines at health facilities?
- What is the average duration of stockouts for indicator medicines at health facilities?
- What is the average time between order and delivery for indicator medicines for regular orders?
- What percentage of supplier medicine prices are the average distribution costs (administration, storage, transport)?

Measures affecting private supply channels

- How mature is the commercial pharmaceutical sector (how many companies, how large, how long in business)?
- Are companies interested in expansion? Do they have access to capital for investment? Are they prepared to take risks to enlarge their business?
- What is the capacity of NGOs that are providing health care services?
- What is the geographic reach of each company or NGO? Are they limited to urban distribution?
- Would additional supply responsibilities be easily absorbed, or would such responsibilities overwhelm their capacity?
- What licensing provisions and incentives are in place to increase geographic access through private wholesalers and retailers?
- Does the law permit the sale of any essential prescription medicines in nonpharmacy drug outlets?
- Can the drug regulatory authority ensure the quality of privately sourced medicines?
- Does the current supply system result in a greater reliance on the private sector for access to medicines?
- What kind of training and certification exists for pharmacy aides and other drug sellers?
- What types of policies, legislation, and regulations on clinician dispensing exist?

Notes: Supply system performance should be measured at least annually. Most indicators can be measured at regional and other supply depots as well as at health facilities. Whenever possible, annual figures should be compared for the most recent year and two preceding years (three years total). See [Chapter 48](#) for a discussion of indicator medicines. See [assessment guides for Chapters 18 and 22](#) for additional procurement and distribution indicators, respectively.

CHAPTER 9

Pharmaceutical pricing policy

Summary 9.2

- 9.1 The theory of determining prices 9.2
Demand and supply • Elasticity of prices
- 9.2 The reality of competition in a market-based economy 9.3
Market failure • Market power
- 9.3 Economic characteristics of pharmaceuticals 9.6
Patented medicines • Generic medicines • Branded off-patent medicines
- 9.4 Variable pricing for medicines 9.10
Differential pricing by the pharmaceutical company • Differential pricing caused by supply chain factors
- 9.5 Monitoring medicine prices by performing price comparisons 9.12
Challenges related to price comparisons • The WHO/HAI methodology for monitoring medicine prices
- 9.6 Obtaining value in pharmaceutical markets: buyer strategies 9.14
Assess the circumstances • Monitor prices • Analyze pharmaco-economics • Maximize buying power • Negotiate prices
- 9.7 Government intervention in the pharmaceutical market 9.17
Price controls on the manufacturer • Profit controls on the manufacturer • Reference pricing and brand premiums • Comparative pricing controls (international benchmarking) • Eliminating tariffs and taxes • Fixed margins • Digressive markups • Capitation systems
- 9.8 Influence of globalization on pharmaceutical prices 9.19
- 9.9 Conclusion 9.20

SUMMARY

In a market economy, the interaction of producers and consumers determines the price of goods and services. Understanding the theory of supply and demand helps explain how prices are determined, and this theory also explains how responsive (elastic) both supply and demand are to changes in price. For example, medicines that are not considered essential and that the buyer could credibly refuse to purchase will have more elastic prices, whereas the prices of medicines that are considered essential and that the buyer must obtain will be inelastic, meaning buyers will be less sensitive to higher prices.

Factors that interfere with the ability of the market to efficiently produce and allocate goods and services are said to result in “market failure.” An example of market failure is when buyers do not have the same level of knowledge; for example, some buyers might pay more than others for the same medicines because they are unaware of what everyone else is paying.

When buyers or sellers have market power (monopoly or monopsony), they can distort how the market price mechanism works. For example, in absolute monopolies (one seller) and oligopolies (a few sellers), the seller has significant ability to set prices, because the consumer has limited choices. This distortion allows the seller to command a price that is higher than would have prevailed under more competitive situations. In a monopsony, where the government has market power as the only large buyer in the market, the government acts on behalf of consumers to obtain better prices.

In addition to these economic theories of price determination, prices for medicines are influenced by the fact that medicines have certain traits that set them apart from other consumer products. For example, consumers need expert advice to make rational choices between using and not using a medicine and about what kind

of medicine to use. This advice is provided by prescribers, who may not know or even care about the price of medicines. Medicines also serve as an investment in future health, which may be difficult for the consumer to value.

The literature unanimously concludes that medicine price differences exist between countries, even when comparing between or within the strata of industrialized, middle-, and low-income countries. Price variation within countries is more likely in less price-regulated markets, such as the United States; however, prices vary in other countries, where public, private, and non-governmental (not-for-profit) sectors procure medicines separately. Variable prices for medicines within and between countries often result from—

- The pharmaceutical manufacturer selling the same product for different prices
- Intra- and intercountry differences in the margins charged in the postmanufacturing supply chain by wholesalers, distributors, and pharmacists, as well as taxes and co-payments levied by the state

Conducting pharmaceutical price comparisons is challenging, but such assessments can identify price variations and provide valuable information on their source and on interventions that can help reduce medicine prices. For example, margins and taxes charged along the pharmaceutical supply chain can add significantly to the final price of medicines; however, governments can control these markups by enacting price-control policies and eliminating tariffs and taxes. In addition, buyers of pharmaceuticals should assess their own position in the marketplace and use tactics such as price negotiations, pooled procurement, and information sharing to increase their market power.

9.1 The theory of determining prices

The history of economics, and therefore much of economic thought, is dominated by discussion of the theory of prices and how they are determined. This theory is underscored by the behavior of market participants—buyers and sellers. As noted in [Chapter 10](#), a scarcity of resources requires that buyers and sellers make choices about how resources will be used, whereas abundance allows limitless production and consumption. However, resources *are* always limited, and using a resource in one way means it is no longer available for alternative uses.

In competitive markets, producers need to decide, for a given amount of resources, what and how much to produce, while consumers, with a given amount of income, need to choose what and how much they will buy. Producers and consumers come together in the marketplace, and under certain assumptions, their interaction determines market prices.

Demand and supply

Demand is generated by consumers, while the supply is provided by producers. Critical to the theory is an under-

standing of what drives each group, because consumers and producers are not driven by the same forces.

Demand: Market theory places the consumer in the lead role for determining what will be produced. Consumers want to maximize their welfare through the total bundle of goods and services they buy with their income. The bundles of goods that consumers choose to buy at given prices tell producers what to produce. In theory, consumers make rational choices as to what is included in the bundle of goods; however, nothing in the theory suggests that these preferences are equitable or socially desirable, only that they represent choices. Prices of complementary products or substitute products affect demand, as does the number of consumers in the market and their desire—for example, if a consumer prefers to buy a branded medicine over a generic and is willing to pay more. Associated with the role of creating demand is the consumer’s ability to vote—with money—on what will be produced. Therefore, individuals with greater income have proportionally more votes (Bannock et al. 1984).

Supply: Producers want to maximize their profit. Profits are determined by the cost of production and the firm’s total revenue (or sales). To maximize profit, the seller has an incentive to use resources in the production process in the least costly way. In a perfectly competitive marketplace, firms receive “normal profits”; that is, they cover the cost of all production costs plus the minimum return required to keep them in business. If the firms’ returns were greater than this minimum, new firms would be encouraged to enter the market, and the competition would drive profits downward until normal profits were reached. If the returns were less than the minimum, low profitability would encourage firms to leave the market, raising the profits of the remaining businesses until they achieved normal profits. Other factors that affect the supply curve include the number of producers, which increases competition; technology, which can initially represent a cost to the producer but ultimately increases efficiency; and the cost of inputs.

Elasticity of prices

The intersection of supply and demand provides the tool for understanding price determination. However, a further aspect of supply and demand helps explain behavior, that is, how responsive each is to changes in price.

Elasticity of demand: On the demand side, if consumers really need a product to the extent that a significant price increase has little effect on the quantity demanded, demand is nonresponsive to price and is said to be *price inelastic*. The reverse situation is where demand is very responsive to price, such that a slight rise in price causes a proportionally larger fall in demand. Pharmaceutical demand varies across countries. It is also relatively *income inelastic*, meaning that a person’s income affects pharma-

ceutical purchases less than other factors (OECD 2008). The four determinants of price elasticity of demand are substitutability, proportion of income committed to the purchase, whether the item is a luxury or a necessity, and market timing (see [Box 9-1](#)).

Elasticity of supply: On the supply side, if suppliers do not respond to price changes, they are price inelastic, whereas suppliers who do respond are said to be price elastic. The determinants of the price elasticity of supply depend on timing (Jackson and McConnell 1989). In the immediate market period, say on the day of a significant price rise, producers may not be physically able to increase production. However, over time and assuming demand is maintained, suppliers will seek to increase production by using existing excess capacity and ultimately by expanding their production capabilities by increasing capital and labor.

9.2 The reality of competition in a market-based economy

An *economic market* is defined as a trade of goods or services between two independent players: (a) buyers and (b) sellers or producers. Price carries information about the value of the goods or services, with the buyers’ willingness to pay defined as *demand*, and the sellers’ willingness to produce the goods being the *supply*. The market is where the buyers and sellers interact, and the interaction of supply and demand determines price.

Most economic theory starts with an assumption of a perfectly competitive market where buyers demand goods and services until the marginal value of each is equal to their price, and producers adjust the supply until the marginal cost of each unit is equal to the market price. This interaction allows demand and supply to fluctuate until they are in equilibrium. When price equilibrium exists between demand and supply, then the resulting allocation of resources for the goods or services of that market is also in equilibrium. Such a market is perfectly competitive. The necessary conditions of a perfectly competitive market include—

- A large number of buyers and sellers or suppliers to form the market
- Buyers that have excellent information, act rationally, and have the time and ability to compare the prices of various suppliers
- Suppliers or producers that have free entry and exit from the market
- Homogenous products of known quality offered by different producers

A review of these characteristics shows that health care is not an example of a perfectly competitive market. Buyers do not have perfect information—patients must rely on health

Box 9-1 Factors that influence elasticity of demand

The degree to which the product can be substituted with another

For example, aspirin is produced by many companies. In a situation where the consumer sees no major difference between each firm's brand of aspirin, a rise in price by one firm will result in a proportionally greater fall in the quantity purchased. For example, if firm A decides to increase its price by 20 percent, the level of demand for A's aspirin line is likely to fall by a larger proportion (by more than 20 percent) because consumers will purchase the equivalent and cheaper products from firms B, C, or D. This scenario exemplifies *price elasticity*. However, where the product has no or few direct substitutes, demand will be less responsive to price changes. For example, a newly patented, innovative medicine that has no therapeutic equivalent (a single-source drug), which is also considered to be essential, will have demand that is *price inelastic*: that is, a 20 percent rise in price might not affect demand at all.

Proportion of income

If a product costs only a small proportion of income, it is likely to be price inelastic. For example, if the price of over-the-counter analgesics sold by all sellers, such as

paracetamol and aspirin, increases by 20 percent, the level of demand is only likely to fall slightly, because the price represents a small fraction of the consumer's average weekly income.

Luxuries and necessities

As their names suggest, the demand for necessities is likely to be price inelastic because consumers cannot live without them, whereas the demand for luxuries will vary significantly with price. Essential medicines are necessities.

Time

Time makes demand more price elastic as information spreads about alternatives and because firms making alternatives find starting to produce identical or similar products profitable. For example, the manufacturer of a patented, innovative medicine that has no therapeutic alternative will be able to reap monopoly profits. However, these profits will encourage other manufacturers to look for other ways to obtain the same therapeutic outcome with a different (nonpatented) technique (such as the development of "me-too" drugs). The arrival of me-too drugs makes demand more elastic.

care providers to give them information about treatment. Furthermore, the suppliers—health providers—do not have easy market entry because of various factors such as licensing and regulatory requirements. Finally, health care is not homogenous in that quality varies among health providers. The result is often a noncompetitive market with market failures, as described in the remainder of this section.

The best possibility for the seller to charge higher prices and earn larger profits is in the extreme situation of an absolute monopoly. In an *absolute monopoly*, a product has only one seller with no alternative. This situation prevails with many patented medicines, particularly if no effective alternative treatments exist.

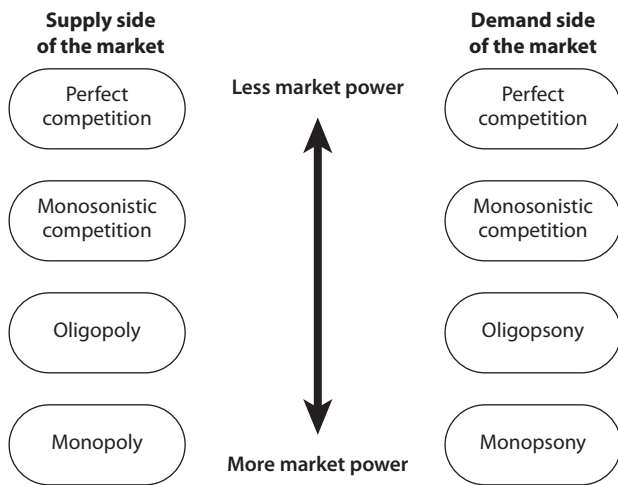

Oligopolistic competition occurs when only a few sellers operate in the market, so each seller can still influence price. *Monopolistic competition* involves multiple sellers, but they reduce the competition by allowing products to be differentiated (for example, by advertising); a single seller still has some influence over price or at least is able to vary prices without losing all sales. Similar descriptions apply to buyers in the market. Where a market has only one large buyer, which sometimes happens when governments purchase or subsidize pharmaceutical products, it is a *monopsony*. In this

case, the government acts on behalf of consumers to obtain better prices.

Figure 9-1 illustrates the range of buyer and seller market positions from perfect competition to monopoly and monopsony. Sellers in pharmaceutical markets are focused at the oligopoly and monopoly end of the supply spectrum. Depending on the influence of buyers, they can be located anywhere on the spectrum, from perfect competition to monopsony.

Market failure

Factors that interfere with the ability of the market to efficiently produce and allocate goods and services are said to result in market failure. Price distortions occur when the market fails to recognize and appropriately value important aspects of society, such as public goods. As noted in Chapter 10, public goods are those goods and services that people cannot be prevented from using, such as local roads, and goods and services whose costs do not vary if additional people use them, such as radio broadcasts. The price system cannot properly evaluate public goods because it has no means to value the level of each individual's demand for the

Figure 9-1 Market structures for buyers and sellers

Source: Jackson and McConnell 1989.

good or service and no means of excluding those who claim not to use the good or service.

For example, the evaluation of the safety of pharmaceuticals before human use, which is undertaken by a publicly funded body, is a public good because most individuals do not have the resources to conduct these assessments. Once the evaluation has been undertaken, the cost of sharing this information is almost zero: use of this information by one individual does not reduce anyone else's ability to use it. When consumers cannot be excluded from using the good or service, the market finds determining a price difficult, because potential consumers have an incentive to use the good or service without paying for it. Left alone, the free market would undersupply this information.

Pharmaceutical regulation, which can be considered a public good, can nevertheless contribute to market failure by creating a high barrier to companies that want to enter the market. Only large companies have the staff and resources to satisfy regulatory requirements, which reduce the number of companies that can compete in this market.

Market failure also occurs because of *externalities*, which are the benefits or costs associated with production or consumption that accrue to others. Immunization is one example: the benefits of disease prevention accrue not only to the person who is immunized, but also to others in the community who are exposed to a lower risk of infection. Externalities are not valued by the price mechanism because the individual who is to be immunized will assess only the benefit he or she directly receives, not the benefit received by others. When such externalities create public goods, governments may be willing to subsidize these prices.

Another type of market failure occurs when buyers do not have the same level of knowledge; buyers do not always know what others are paying for the same product, and the seller has an interest in keeping these prices hidden. That is, buyers pay more when they assume everyone else is paying the same price. For example, some large health care organizations in the United States negotiate deals with pharmaceutical manufacturers but do not make the purchase prices publicly available (Dougherty 2004). Alternatively, complex pricing arrangements can be set up that hide the ultimate price paid by the buyer (Country Study 9-1). In South Africa, the government has made such practices illegal in the private sector. Medicines have a single "exit price," which includes logistics fees; legislation also determines the markup and dispensing fee charged by the pharmacist. The intention is to make the pricing process transparent to consumers.

Country Study 9-1 Lack of transparency in medicine markets in New Zealand

Buyers commonly do not know the true price paid for individual products. For example, in New Zealand, a pharmaceutical company sells a range of medicines, including highly priced patented medicines. The public-sector buyer and the company negotiate a price for a bundle of medicines. The pharmaceutical company provides significant discounts to the buyer, but the company does not want other buyers to know that it will discount the patented medicines to make a sale. In the absence of an enforceable confidentiality agreement between the buyer and seller, what options does the pharmaceutical company have to maximize its profits? One way would be to make an agreement with the buyer to purchase the patented medicine at the stated market price in exchange

for a rebate at the end of some stipulated period. Alternatively, the company could hide the true price paid for a patented medicine by providing substantial discounts on other, possibly off-patent medicines sold by the company. This way, a buyer appears to be paying the market price requested by the company for the patented medicine, but in reality, the buyer is paying a much lower price for the basket of medicines. Naturally, the seller would prefer not to offer any discounts to anyone; however, if the buyer is in a position to exercise its own market power and negotiate lower prices, the seller will not want this price information to be freely available.

Source: McNee 2006.

So, to some degree, market failure in the pharmaceutical market is a price consumers pay for effective regulation. However, information asymmetry, high barriers to market entry, and monopolistic behavior have led to high prices for many patented medicines, which have made them unaffordable in many settings. Government intervention has been used to correct these distortions. Section 9.7 covers many approaches to price reduction.

Market power

Participants that exert market power can distort how the market price mechanism works. For example, in absolute monopolies (one seller) and oligopolies (a few sellers), the seller has significant ability to set prices, because the consumer has fewer choices. This distortion allows the seller to command a price that is higher than would have prevailed under more competitive situations (Jackson and McConnell 1989).

The same profit motive that drives sellers to seek new and more efficient means of production is also an incentive for them to form collectives where they can exert more power in the market. Antitrust and antimonopoly legislation aims to counter this anticompetitive tendency of markets. However, even strong, enforced legislation is no guarantee that firms will operate competitively. In 2006, five pharmaceutical companies were charged in Britain with colluding to set high prices (Dyer 2006). Despite the risk and cost of being caught, the large potential profits from price setting are a potent incentive to collude.

Sellers are not alone in their ability to influence the market. The strongest buying power is obtained from a monopsony buying position, that is, where a market has only one buyer. The most effective monopsony will have multiple sources for the product. In pharmaceutical markets, this situation translates into one buyer purchasing from several sellers of equivalent medicines. In this setting, the monopsonist can credibly purchase medicines from different sources, which creates a significant incentive for sellers to offer the best possible price. The least effective setting for a monopsony will be for patented, innovative medicines for which no alternatives are available (single-source medicines).

Negotiating with a monopoly removes some of the monopsonist's market power. However, even in this setting, the monopsony will have stronger buying power than several buyers (oligopsony) in negotiating with a single seller and even stronger power than when many buyers are negotiating with a single seller.

The extent to which the monopsony can offset monopoly pricing power will also depend on how necessary the medicine is. The offset will be strongest for medicines that are not considered essential and that the buyer could credibly refuse to buy. These medicines will have some elasticity of demand, and buyers will be price sensitive. The offset will be weak-

est for medicines that are considered essential and that the buyer must purchase. The demand for these medicines will be inelastic, and the need for the medicines will make buyers less price sensitive.

In some circumstances, a buyer emerges that has significant buying power. Examples of such large-scale buyers with purchasing power include health maintenance organizations in the United States (private sector) and, as shown in [Country Study 9-2](#), the Pharmaceutical Benefits Scheme in Australia (public sector, monopsony). Although regulation is a critical factor influencing prices, compared to large procurement agencies, smaller buyers have little leverage and will likely pay higher prices. However, buyers can form cooperatives or join to increase their market power, which is the theory behind pooled procurement, discussed in [Chapter 18](#).

It is intuitive to think that large buyers will have strong market positions to negotiate prices, if not by being the sole source of demand, then by the volume of the product they are expected to purchase. However, this association between a large buyer and low prices does not always hold true; the World Health Organization (WHO) reports that some government procurement operations are effective in obtaining low medicine prices, while others are not—usually because they purchase brand-name pharmaceuticals that are no longer under patent rather than lower-priced generic alternatives (Gelders et al. 2006). The buyer should be continually aware of the availability of generics entering the market.

The concern that a single large buyer can adversely affect producers appears uncommon in the area of pharmaceuticals but has been seen in some sectors of low-income countries. For instance, a large, powerful buyer can force down the prices of produce, such as fruit or coffee, to the extent that smaller producers suffer genuine hardship.

9.3 Economic characteristics of pharmaceuticals

Aside from the obvious characteristic of having health benefits, medicines have certain traits that set them apart from most other consumer products (see also [Chapter 1](#)).

First, when patients purchase a medicine, they do not gain an “asset” in an economic sense. In most countries, the patient cannot legally resell the medicine; its value rests in the knowledge that went into its development and the testing that determined the correct way to use it, such as dose, course of treatment, and contraindications. Particularly for recently introduced innovative medicines, the economic value of the pharmaceutical to the producer lies in this intellectual property rather than in the chemical constituents of the product.

Second, the patient is not a consumer in the traditional sense. She or he is usually directed by a third party, a doctor or other health professional, to purchase a medicine. The

Country Study 9-2 Australia's pharmaceutical benefits scheme

The Australian Pharmaceutical Benefits Scheme (PBS) requires consumers to make a maximum co-payment of 33.30 Australian dollars (AUD) for all medicines listed on the national formulary (as of 2010). Disadvantaged citizens in the community pay only AUD 5.40, and a safety net exists for people who exceed a maximum amount per year. Medicines not listed with the PBS may still be sold in Australia (provided safety and quality requirements are met), but at an unsubsidized price. However, since few patients will purchase full-price medications, particularly if a therapeutically equivalent medicine is available with a PBS subsidy, the Australian system operates as a monopoly, with the PBS as sole gatekeeper to medicines sold in the country. Pharmacists also receive an incentive each time they dispense a generic medicine to decrease the use of originator brands.

The Australian system of providing affordable access to medicines relies on public-private interactions. The public sector, through the PBS, determines what medicines will be subsidized by the government and at what level of subsidy. The government negotiates the agreed price with pharmaceutical manufacturers and the dispensed price with the Pharmaceutical Guild of Australia, including the markups and dispensing fees. Private-sector doctors are largely responsible for prescribing, and private-sector pharmacists are largely responsible for dispensing the medicine to the patient and collecting the co-payment at the point of sale.

The Australian Productivity Commission compared pharmaceutical prices in a range of industrialized nations. The commission found that—

- Prices for patented, innovative medicines in the United States were 104 percent higher than in Australia. While Australian prices were at the lower end of the price spectrum, prices in Spain were even lower.
- The price of me-too medicines was at least 57 percent more expensive in Canada, Sweden, the United Kingdom, and the United States than in Australia. However, Australian prices were similar to those in New Zealand and Spain.
- The price of generics was at least 40 percent more expensive in Canada, Sweden, the United Kingdom, and the United States than in Australia, but lower prices were recorded in New Zealand and Spain.

In general, countries with less price control (such as the United States) had higher medicine prices than those in the more controlled Australian system. Although the report could not identify specific causal factors explaining why prices tended to be lower in Australia, it was thought to be related to the policy environment and specific features of Australia's cost containment techniques—reference pricing, in particular. Overall, prices in Spain and New Zealand were close to those in Australia. All three countries have predominantly public coverage of medicines for all residents.

Sources: Australian Government Department of Health and Ageing 2010; Australian Productivity Commission 2001; Sansom 2004; Sweeney 2007.

doctor, as gatekeeper to the pharmaceutical market, does not pay for the medication and may not even know how much the prescribed medication will cost the patient. Thus, transmission of price signals between those who initiate demand for the medicine and those who supply it is blurred.

Third, without the expert advice of an intermediary, few consumers have sufficient information to make rational choices between using and not using a medicine, using a brand-name medicine versus a generic, or using a prescription medicine versus an alternative (nonpharmaceutical) therapy. This asymmetry of information affects the pricing mechanism because the consumer is not in a position to make informed choices. The pricing mechanism can be further distorted if the intermediary is influenced by pharmaceutical promotions.

Fourth, health services are a form of investment: investing in health services today is expected to have a return later (Grossman 1972; Johnson 2001). Medicines are a form of investment because people do not receive their benefits until some point in the future. Furthermore, some individuals' pharmaceutical investments may have no obvious return at all, as in the case of vaccines. These characteristics make estimating the monetary value of medicines difficult for the individual. For example, statin drugs can reduce the risk of heart disease in later life. In terms of seeing these medicines as an investment, individuals must assess the benefits of this protection without experiencing what the heart disease actually feels like, and they must judge the possible consequences of *not* taking the statin drugs.

The level of competition among different pharmaceutical product categories is important in understanding medicine pricing strategies. The three main product categories are patented medicines, generic medicines, and branded off-patent medicines.

Patented medicines

This group can be further categorized into—

- Patented, innovative, essential medicines, where no alternative medicine or intervention can provide the same therapeutic outcome, sometimes referred to as *single-source* medicines (such as Herceptin for the treatment of breast cancer)
- New medicines protected by patents, but for which alternative therapies are available (such as Tamiflu for the treatment of influenza)

The distinction between the two types is important because it reflects the degree of market power held by the seller and the price elasticity of demand. Demand for single-source medicines that are considered essential is likely to be inelastic, and combined with patent protection, the seller is in a strong market position compared to situations where alternative therapies are available.

A recent example is the breast cancer drug Herceptin. Because alternatives to this drug do not currently exist, the manufacturers have set a very high price in the knowledge that patients and their insurers (including governments) will be under heavy pressure to pay. This is a classic example of a single-source product with price inelasticity because of patent protection.

The effect of patents on the market stems from monopoly rights that, to varying degrees, are conferred for the life of the patent. These rights allow the monopolist to charge higher prices than would be possible under more competitive conditions, although the extent of the monopolist's price-setting power is not unlimited. For example, the state can counter the monopolist's price-setting power by establishing price regulations, forming a monopsony to purchase medicines on behalf of all residents, issuing a compulsory license to another producer, or using policy instruments such as restrictions on pharmaceutical company profits. More details on these techniques follow in Section 9.7.

Markets can also limit the monopolist's price structure. The potential profits the monopolist stands to make from an essential single-source patented medicine should stimulate other firms to develop medicines that have the same health outcome because patents are granted for the chemical compound rather than the therapeutic indication. The arrival of competitor products restricts the price-setting power of the monopolist, but their arrival on the market is not necessarily immediate. In the United States, competitor medicines

are estimated to arrive between one and six years after the original medicine is introduced to the market (Congressional Budget Office 1998).

When a large number of competitor products enters a particular market segment—more than is needed to satisfy clinical need and introduce genuine price competition—the term *me-too* medicines is often applied. Many examples exist, including gastric acid inhibitors, statins, and angiotensin-receptor antagonists. Although a degree of competition is desirable, the development and aggressive marketing of patented me-too medicines may consume pharmaceutical budgets and divert resources and development efforts away from treatments for less common diseases. From a societal point of view, whether the incremental benefit from me-too medicines is worth the cost of development is questionable.

Generic medicines

Generic or multisource medicines are not under patent and can be produced using the same compounds found in the originator product using either the same or a different process. Multisource pharmaceutical products are pharmaceutically equivalent products that may or may not be therapeutically equivalent; products may not be therapeutically equivalent because differences in the excipients or the manufacturing process can lead to differences in product performance.

Because patents are country specific, some countries can produce generic medicines using compounds that are still protected by patents in other countries. Where patents operate, generic medicines are allowed to enter the market only when the patent expires. Under special circumstances, such as a public health emergency, countries are allowed to manufacture patented medicines under compulsory licenses, which are sanctioned by the World Trade Organization's Agreement on Trade-Related Aspects of Intellectual Property Rights. Producers may also enter into voluntary licensing agreements with local companies. (See [Chapter 3](#).) Some countries in sub-Saharan Africa are using voluntary licenses to manufacture antiretroviral medicines to improve access to inexpensive treatment for HIV/AIDS.

In general, the absence of patent protection lowers the barrier to entry into the market because generic companies do not have to bear the high costs of research and development (R&D), including rigorous clinical trials to prove safety and efficacy of the medicine. Reduced R&D costs enable multiple companies to enter the market, resulting in a high level of competition. However, the expiration of patents does not mean that barriers to market entry disappear. As noted, the originator company develops significant marketing leverage while protected by the patent, which must be overcome by new generic medicines. Buyers may not always be aware of the availability of lower-priced generic medicines, they may be persuaded by promotional efforts not to change medicine

Figure 9-2 The effect of generic competition on the prices of antiretrovirals in Brazil

Source: MSF 2006.
USD = U.S. dollars.

brands, or they may view the generic product as inferior or of poor quality. For example, Malaysian buyers appear to prefer higher-priced branded medicines to cheaper generics (Babar et al. 2005).

Although the absence of patent protection can encourage the entry of generic medicines, strict regulation of medicine prices has been associated with a lower penetration of generic medicines into the market, because reduced profitability keeps generic firms from covering the costs of market entry. In countries with relatively little price regulation, such as Germany and the United States, generics have a greater market share than in the more heavily regulated markets of Australia (Lofgren 2004), France (Königbauer 2006), and Italy.

The entry of generics can be delayed for other reasons. Patent holders use a number of techniques to extend their period of market exclusivity, including making legal challenges to generic manufacturers trying to enter the market and developing minor variations in product characteristics that are sufficient to generate a new patent (known as *evergreening*). Another approach is for governments to grant data exclusivity rights to the manufacturers who introduced the pharmaceutical product. Such rights prevent pharmaceutical regulators from using the originator's data to make registration decisions about generic equivalents for a defined period (such as five years), thereby slowing the introduction of generic competition. Increasingly, such provisions are being guaranteed as part of bilateral trade agreements. Chapter 3 covers these issues in more depth.

The process of allowing generic medicines onto the market differs among countries. The United States passed a law designed to allow faster entry of generic medicines when patents expire. However, it also provides a significant pen-

alty if generic companies enter the market too early. In Europe, the entry of generics was made easier by forgoing the requirement of trials demonstrating safety and efficacy as long as the generic medicine is the bioequivalent of the originator and the originator is sold in the same market. Some patent-holding companies responded by removing the patented medicines from the market before the entry of the generic and then releasing a modified form of the original drug. This strategy effectively prevents generics from claiming bioequivalence of an existing medicine sold in the European market, thereby delaying entry of the generic product (Australian Productivity Commission 2001).

In general, introducing generic competition is the most effective way to lower medicine prices. The effect is not only because of the lower-priced generic products but also because originator companies often respond by lowering prices of their patented products. This effect has been very evident in the pricing trend of antiretroviral medicines for HIV/AIDS. According to Médecins Sans Frontières (MSF 2006), in 2000, when Brazil first introduced a generic antiretroviral medicine, the lowest originator price to treat one patient for a year was 10,439 U.S. dollars (USD). By July 2006, the generic version of the same drug cost USD 132, while the lowest price branded version cost USD 556 (see Figure 9-2). However, for increased competition to result in lower prices, purchasers must be informed about their medicine choices.

Branded off-patent medicines

A complicating issue in the generic market is when well-known branded medicines go off patent and the originator company produces generic versions of its own products

and retains the brand names that are recognizable through extensive marketing campaigns. Apparently, when the brand-name generic has a larger share of the generic market, the brand-name medicine will be more expensive; in addition, a higher market share held by the brand-name generic will result in higher generic medicine prices—among all companies (Hollis 2005). The market entry of brand-name generic medicines, if combined with a large market share for the manufacturer, will prevent prices falling to levels reached with more diverse competition. Therefore, by entering both branded and generic segments, large companies can exercise considerable market power.

9.4 Variable pricing for medicines

The literature unanimously concludes that medicine price differences exist between countries, even when the comparison is made between or within the strata of industrialized, middle-, and low-income countries. For example, price information compiled by WHO's Global Price Reporting Mechanism shows clear differences in prices paid by low- and middle-income countries for medicines treating HIV/AIDS. Importantly, low-income countries did not always obtain the lowest prices for medicines; as shown in [Table 9-1](#), the 2009 cost of stavudine 30 mg in low-income countries was 37 percent more than the price paid in middle-income countries.

Price variation within countries is more likely in less price-regulated markets, such as the United States; however, prices vary in other countries, where public, private, and nongovernmental (not-for-profit) sectors procure medicines separately. An example is South Africa, where the public sector achieves low prices through tendering; in contrast, medical insurance funds and individuals paying out of pocket typically pay higher prices, although government legislation has been introduced that aims to control medicine prices in the private sector.

Variable prices for medicines within and between countries often result from one of the following—

- The pharmaceutical manufacturer sells the same product for different prices.
- The margins charged in the postmanufacturing supply chain by wholesalers, distributors, and pharmacists, as well as taxes, duties, and co-payments levied by the state, differ intra- and intercountry.

Differential pricing by the pharmaceutical company

Price differentiation (also known as tiered pricing) occurs when a firm sells the same product at a different price to different groups of people. It is known as *equity pricing* when the intention is to improve the affordability of medicines in

low-income settings. The groups of people could be populations in different countries or subpopulations within a single country. From the buyer's perspective, tiered pricing may appear to be a form of market failure, particularly for those who pay the higher prices, but for the seller, it is another method of maximizing profits by ensuring each buyer group pays according to its willingness and ability to pay.

A seller can price differentiate if—

- It has monopoly rights over the product.
- Willingness and ability to pay are different among groups of buyers (varying price elasticities).
- Buyers cannot trade the item among themselves. That is, buyers who negotiate a low price do not resell the item, thereby undercutting the seller in markets that are able and willing to pay a higher price (Wagner and McCarthy 2004).
- An agreement exists to achieve more equitable access to essential medicines through differential pricing for needy populations. Examples of such agreements exist for medicines for HIV/AIDS, some vaccines, insulin, oral contraceptives, and some antimalarial medicines.

A common misperception is that the price paid by consumers reflects the cost of production plus a margin. In reality, manufacturers want to charge the highest price that the consumer will pay to maximize profits. Therefore, in terms of upward movements in price, the price paid by the buyer need not have any relationship to the cost of production. Evidence confirms that the relationship between production costs and medicine price is tenuous (Loff and Heywood 2002). In Brazil, South Africa, and Thailand, pharmaceutical companies have responded to pressure from court actions, government interventions, and the introduction of generic medicines by significantly reducing their originator medicine prices, which suggests that little relationship exists between medicine prices and the cost of production.

Differential pricing caused by supply chain factors

The pathway from manufacturing, transporting, storing, and then distributing medicines to the patients who need them is complex. Margins and taxes charged along this supply path can add significantly to the final price of medicines. Therefore, a pharmaceutical pricing policy must acknowledge the potential for the supply chain to significantly reduce the affordability of essential medicines to consumers.

As an example, a pharmaceutical pricing study in Ghana (Sarley et al. 2003) showed that although government policy limited margins on pharmaceuticals in the public-sector supply chain to a cumulative 40 to 50 percent, the actual margins averaged 100 percent and in some cases exceeded 300 percent by the time the medicines got to the patients. High markups occurred throughout the supply chain, but

Table 9-1 Median price paid by low- and middle-income countries for selected first-line antiretroviral formulations, 2005 and 2009

Antiretroviral medicine	USD per patient per year, 2005		USD per patient per year, 2009	
	Low-income countries	Middle-income countries	Low-income countries	Middle-income countries ^a
Stavudine (d4Tt) 30–40 ^b mg	58	44	30	19

dispensing facilities reported pricing their products slightly below those in private local pharmacies—no matter what the margin increase—because they perceived that patients would pay at least this amount.

Developing pharmaceutical pricing policies requires more than just an understanding of the supply chain, although that is clearly a good start. Prices, margins, and taxes change over time, and even unintentional adjustments throughout the supply chain can enormously affect medicine affordability. For this reason, stages in the supply chain should be continually monitored, so that changes in costs can be assessed and, if needed, acted upon to remedy unacceptable increases.

A key report from the advocacy group Health Action International (HAI) and WHO (Levison 2006) describes pricing throughout the pharmaceutical supply chain—

Supply chain, stage 1: the price from the manufacturer.

Called the manufacturer's selling price, if the manufacturer is located in the same country as the buyer, no further costs are added at this stage. If the medicine is imported, the price from this stage is the manufacturer's selling price, plus freight and transit insurance. The determinants of the price negotiated between the buyer and the manufacturer will be—

- The level of competition applying to the medicine (whether it is single source or multisource)
- The quantity sought by the buyer
- The number of alternative buyers in the same country for the same medicine (a single buyer will have stronger purchasing power than multiple smaller buyers)
- Pricing regulations and controls
- The price negotiated with the manufacturer

Supply chain, stage 2: the landed price. These are the fees and charges required to deliver the medicine to the

wholesaler. Determinants of the price at this stage will be—

- The fees, charges, and profits levied by transporters, insurers, and warehouses
- The level of taxes levied by the state (for example, stamp duty; value-added tax, or VAT; and goods and services tax, or GST)
- Tariffs on imported medicines and ingredients for locally manufactured medicines

Supply chain, stage 3: the wholesale selling price. This price is the landed price plus the wholesaler's costs of storage, transport, insurance, and profit margin. The wholesaler could be a private (for-profit) operation; a public operation; or a not-for-profit, nongovernmental organization. Increasingly, wholesalers are being replaced by distributors who have a relationship with suppliers and work with lower margins because they do not own the stock.

Supply chain, stage 4: the retail selling price. This is the wholesaler's price plus all costs associated with transporting medicines to the retailer, including transit insurance. Retailers could be a private, for-profit operation, a public operation, or a nongovernmental organization. After delivery to the retailer, storage and stock insurance are required. The retailer also adds a profit margin and sometimes a professional dispensing fee. Sizable mark-ups can occur in the retail stage, especially in the private sector and from dispensing doctors; a WHO study of thirty countries concluded that although pharmaceutical availability tended to be better in the private sector, it was also associated with higher medicine prices and therefore lower affordability (Gelders et al. 2006). Compared with international reference prices, private-sector prices were between three and one hundred times more.

Supply chain, stage 5: the dispensed selling price. The state can impose additional taxes such as VAT or GST on top of the retail price; such taxes are controllable by

the government. A European study of nine countries showed that nations applying VAT or GST to medicines ultimately had higher medicine prices, even if they had comparatively lower wholesale prices (Martikainen et al. 2005). Other studies have shown that significant reductions in price are possible with the removal of these taxes. For example, estimates for Peru indicate that the removal of VAT on medicines would reduce prices by 18 percent (Ewen and Dey 2006).

[Country Study 9-3](#) describes an analysis of supply chain markups in Malaysia.

9.5 Monitoring medicine prices by performing price comparisons

Although the literature shows that price variation exists within and between countries (Wagner and McCarthy 2004; Scherer 2004; Waning et al. 2010), the methodology used for many of these comparisons has been criticized because of the difficulties in validating the results (Danzon 2004).

Challenges related to price comparisons

Comparing pharmaceutical prices between countries is complicated: The same medicine is often sold in different countries in different strengths, pack sizes, and with various modes of administration; in addition, any assessment must determine whether the product is being sold in the public or private health care system and account for differences in tariffs, taxes, and other markups. Comparability is even more of a problem if the assessment is based on a basket of medicines. For this reason, comparing individual medicines

that have high usage and limited ranges of doses and modes of administration may be better.

Selecting which price to use as the basis for comparison is critical. Should it be the price paid by the patient, the third-party insurer, or in the case of a state purchaser, the government? Some argue that the price paid by the consumer is the most important because it represents the patient's out-of-pocket expense (Wagner and McCarthy 2004). The advantage of using this payment is that it includes all of the add-on costs after manufacture, such as margins paid to wholesalers, distributors, and pharmacists. The final price paid by the consumer can be more than doubled by the additional costs encountered in the postmanufacturing supply chain (Ewen and Dey 2006). Moreover, understanding the components of the final price identifies potential targets for price reductions. However, a disadvantage of relying solely on price as a measure of affordability is that a low price for a medicine in a low-income country does not make it affordable. Sometimes, a further measure is required, such as the number of days the country's lowest paid worker must work to pay for the medicine. This is one of the measures used in studies conducted by HAI and WHO.

Determining which price to use for comparison will ultimately depend on the intended use of the analysis. In many comparisons, the manufacturer's or wholesaler's price is the basis for measurement, and this can be a useful tool to improve procurement practices. The common resource for international reference prices is the *International Drug Price Indicator Guide*, which provides an indication of pharmaceutical prices on the international market. The guide includes actual prices paid by government agencies, pharmaceutical suppliers, and international development organizations for almost a thousand pharmaceuticals (see [Box 9-2](#)). The Global Fund requires principal recipients to submit

Box 9-2

International Drug Price Indicator Guide

Produced in collaboration with the WHO, Management Sciences for Health's *International Drug Price Indicator Guide* provides an indication of pharmaceutical prices on the international market. Updated annually, the guide contains a spectrum of prices from pharmaceutical suppliers, international development organizations, and government agencies. The 2008 edition has more than 1,100 items and prices from 30 sources.

Lower prices can be obtained through bulk purchasing, competition, skillful price negotiations, and sound supply management. The guide makes price information more widely available to improve procurement of medicines of assured quality for the lowest possible price.

Readers can use the guide to—

- Locate new supply sources
- Assess the efficiency of their procurement systems
- Determine the probable cost of pharmaceutical products for their programs
- Compare current prices paid to those available on the international market
- Assess the potential financial impact of changes to a medicine list
- Support rational drug use education

The *International Drug Price Indicator Guide* can be accessed at <http://erc.msh.org/priceguide>.

Country Study 9-3 Examples of supply chain markups: Malaysia

A price survey in Malaysia using the WHO/HAI methodology compared median price ratios of medicines distributed in the private and public sectors with international reference prices. Despite the expectation that the prices of medicines in the public sector would be relatively low, in some cases, public-sector prices were higher than the international reference price. The study also found that the postmanufacture margins charged in the supply chain were significantly driving prices upward in both the public and private sectors. The authors concluded that the lack of a coherent government policy to regulate medicine prices allowed excessive profits and reduced medicine affordability.

The survey also found substantial price differences within the private sector between dispensing doctors and pharmacies. Compared with pharmacies, brand-name medicines tended to be cheaper when purchased from a dispensing doctor, but generic medicines were more expensive. Overall, the study found that dispensing doctors had excessive profit margins, particularly

on some lower-priced generic medicines. This finding has been consistent in the literature: dispensing doctors, who benefit financially from the consultation and the prescription, have perverse incentives to prescribe expensive medicines and then charge a higher margin on these products. Because patients have little information about medicines, they have little recourse about taking the doctor's advice about the choice of treatment. This asymmetry of knowledge supports the argument that without regulation, doctors should not be allowed to sell the medicines that they prescribe to their patients.

The following table illustrates the percentage of markups encountered after medicine was purchased from the manufacturer for the public sector and for retail pharmacies and dispensing doctors in the private sector. Overall, the data confirm an expectation that public-sector prices tend to be lower than those offered by the private sector. Yet the supply chain analysis highlights several critical points where application of taxes, charges, and margins causes medicine prices to increase dramatically.

Percentage supply chain markups for generic and branded atenolol in the public and private sectors

Supply chain stage	Generic	Branded
Public sector		
Stage 1 MSP + insurance and transport	Price paid in stage 1 = MYR 7.78	Price paid in stage 1 = MYR 33.63
Stage 2 Customs and port charges	+ 22.2%	+ 5.6%
Stage 3 Distributor wholesale markup	+ 20.0%	+ 20.0%
Stage 4 Retailer or dispensing doctor markup	NA	NA
Stage 5 Other charges	NA	NA
Total markup over stage 1 price	46.5%	26.7%
Private sector: retail pharmacies		
Stage 1 MSP + insurance and transport	Stage 1 price = MYR 9.62	Stage 1 price = MYR 40.05
Stage 2 Customs and port charges	+ 17.9%	+ 20.4%
Stage 3 Distributor wholesale markup	+ 5.8%	+ 19.1%
Stage 4 Retailer or dispensing doctor markup	+ 100.0%	+ 25.4%
Stage 5 Other charges	NA	NA
Total markup over manufacturer's price	149.5%	79.8%
Private sector: dispensing doctor		
Stage 1 MSP + insurance and transport	Stage 1 price = MYR 9.58	Stage 1 price = MYR 41.17
Stage 2 Customs and port charges	+ 18.0%	+ 18.0%
Stage 3 Distributor wholesale markup	+ 15.0%	+ 11.1%
Stage 4 Retailer or dispensing doctor markup	+ 146.2%	+ 76.0%
Stage 5 Other charges	NA	NA
Total markup over stage 1 price	234.0%	129.0%

prices paid for medicines purchased with fund resources, which are made public. Other multinational resources for price comparisons include Médecins Sans Frontières' guide to antiretroviral prices in developing countries (<http://utw.msfaccess.org>) and WHO's Global Price Reporting Mechanism and website for medicine price information (<http://www.who.int/hiv/amds/gprm/en>). A new resource focuses on prices and sources for children's medicines (UNICEF/WHO 2010).

The WHO/HAI methodology for monitoring medicine prices

The goals of conducting a pricing survey include the ability to compare home-country prices with international reference prices, and to make intracountry price comparisons of medicines provided by different sectors, such as the government, nongovernmental organizations, and private facilities. The WHO/HAI methodology for comparing medicine prices (outlined in WHO/HAI 2008a) is based on simple techniques that have been field-tested and validated in many countries (see [Country Study 9-4](#) for some examples). The methodology is available to governments, nongovernmental organizations, and researchers and is designed to facilitate intra- and intercountry comparisons of medicine prices and ultimately to identify which sector delivers the best medicine prices to patients. Documentation in English is freely available from <http://www.haiweb.org/medicineprices>. Documentation in French, Russian, and Spanish is also available on the HAI website.

Selecting locations. The first location of the survey's sample is the major central urban center—usually the capital city. In addition, three other locations are randomly selected from a list of all areas that can be reached in one day of travel from the urban center. In each location, at least five public health centers are sampled, including the main public hospital. Five private-sector pharmacies are also included based on their proximity to the public health centers. If the country has private nongovernmental organizations or dispensing doctors that provide medicines to patients, five from each category are selected using the same methodology.

Selecting medicines. The surveyors collect price data at each facility for a list of core and supplementary medicines. WHO identifies the core medicines based on the global burden of disease, medicine availability and importance, and patent status. Supplementary medicines are selected based on the health issues in the survey country. To prevent the collected data from being distorted by medicines that might be counterfeit or of poor quality, the methodology stipulates the sampling of only registered medicines or those with market authorization.

Categorizing medicines. Price data are categorized by the innovator brand (which is or was under patent), the highest-volume generic sold, and the lowest-priced generic.

A generic drug can fall into both the highest-volume and the lowest-priced medicine categories. The brand name of the innovator product may vary by country, but unless licensed, generic equivalents cannot be labeled with brand names; for example, Valium is the name of the innovator product, and although generic medicines cannot use this name, they may use their own brand name or the nonproprietary name of the active ingredient, diazepam.

In countries where a medicine is under patent, only the innovator brand should be available. Exceptions might occur, for example, when the innovator brand is produced under license or where the country allows the sale of equivalent generics. If a patent is not in force, multiple generic equivalents for the innovator may be available. The WHO/HAI methodology defines generic medicines as those intended to be the equivalent of the innovator brand and that are produced after the expiration of patents or other exclusivity periods. The definition implies that the same active ingredient is used in the generic and the innovator. Medicines cannot be categorized as generic if they are produced under license to the innovator.

Analyzing price data. Prices are ultimately presented as a ratio of the median price in the surveyed country to the international reference price, provided by Management Sciences for Health's *International Drug Price Indicator Guide*. The ratio is called the median price ratio. To simplify data entry and analysis, WHO/HAI provide a computer program that facilitates data entry and automatically provides the outcomes from analysis. Apart from information on prices, the analysis reports on the availability, affordability, and components of medicine prices, which are the charges and markups that contribute to the final price. The methodology also provides instructions on presenting results so the findings can be effectively disseminated.

9.6 Obtaining value in pharmaceutical markets: buyer strategies

As mentioned in Section 9.1, the determination of price is related to factors influencing both supply and demand. Supply-side strategies target the seller and ensure the lowest possible medicine price is paid by the patient. The following strategies focus on the supply side with emphasis on pharmaceutical manufacturers and the pharmaceutical supply chain.

Demand-side strategies focus on the use of medicines: Are medicines being prescribed appropriately? Are generic medicines being substituted for more expensive brand-name products? Has promotion and advertising created patient demand that exceeds clinical demand? Demand-side questions are equally as important to medicine pricing as the supply-side pricing issues, but they are the topic of other chapters. Nevertheless, the development of a compre-

Country Study 9-4 Measuring medicine value: WHO/HAI survey methodology to compare prices and affordability in multiple countries

Price surveys using the WHO/HAI methodology have been undertaken in several countries, including China, India, Kuwait, Malaysia, the Philippines, Tajikistan, and Thailand. The surveys determined comparative prices in these countries and identified medicine prices that were different from the international reference price and by how much. Rather than using actual currency units for comparing prices, the surveys used ratios that identified the relative price in the target country compared with an international reference price.

Within each country, the surveys also compared prices in the public and private sectors, which facilitated policy recommendations, such as encouraging the use of generic medicines, increasing private-sector competition when only small price differences existed between innovator brands and equivalent generics, or reducing price markups in the supply chain.

Examples of medicine price survey findings for China's Shandong Province, Kuwait, the Philippines, Tajikistan, and Thailand follow.

Shandong Province, China

- In the private sector, innovator brands were 14 times more expensive than lowest priced generics.
- In the public sector, the difference was 4 times more than the lowest priced generics.
- Comparing public-sector procurement prices and public-sector patient prices for core medicines revealed that patients paid an additional 75 percent of the procurement price for generics and 22 percent for innovator brands.

Kuwait

- Private-sector procurement prices of medicines were 18.3 (innovator brands), 16.1 (most popular generic), and 15.9 (lowest priced generic) times the international reference price.
- Public-sector prices for innovator brands were 5

times the international reference prices and generic equivalents were 1.2 times the international reference prices.

Philippines

- Generic products markups ranged up to 355 percent at the retail level and 117 percent at the distributor level.
- VAT significantly increases the price of medicines in the country.

Tajikistan

In the private sector—

- Some innovator brands were 43 times the international reference price.
- The most popular generic equivalent and the lowest priced generic equivalent were 2.3 times the international reference price.

In the public sector—

- Prices tended to be slightly higher than those in the private sector: innovator brands in the public sector were 49 times the international reference price.
- The most popular generic equivalent and the lowest priced generic equivalent were 2.3 and 2.4 times the international reference price, respectively.
- The “brand premium” innovator product price was up to 20 times the price of the generic.

Thailand

- Public sector prices were higher than the international reference price: 32 percent for innovator brands and 75 percent for generics.
- In the private sector, patients paid 3.9 times more overall for originator brands than for the lowest price generics.

Sources: Ball et al. 2005; Drug Information Center Project ZdravPlus/USAID 2005; Qiang 2005; WHO/HAI 2006, 2008c.

hensive policy to contain the cost of medicines should consider strategies that correct distortions in both supply and demand as well as the government's role.

Assess the circumstances

The buyer strategies outlined below are used in different countries, with varying degrees of success. Any strategy

used on its own is unlikely to provide the best possible outcomes for reducing medicine prices. The best possible outcomes will require an assessment of which buying technique best suits the circumstances for each purchase of medicines and a clear understanding of the buyer's own position in the marketplace.

Examples of issues a buyer should address in an assessment include—

- The ability to join with others to purchase medicines (pooled procurement). Are cultural or political barriers preventing buyers from joining forces? Can these differences be resolved? Saving money can be a powerful motivator for tolerance.
- Whether the buyer is in the public or private sector and whether the buyer can influence government policy. For example, a public-sector buyer may be able to influence government policy to mandate the use of reference or differential pricing.
- The type and volume of medicine being purchased. Although the least powerful market position will be associated with buying single-source essential medicines compared to nonessential and multisource medicines, some large buyers have successfully negotiated price discounts on patented, single-source medicines. Successful negotiations can result from the size and certainty of the order and the effect on reducing the seller's risk (see maximizing buying power below). The seller's risk is reduced when the purchaser makes reliable payments.
- Whether the purchasing group has access to good advice on efficacy and cost-effectiveness of medicines in the country. A careful, independent assessment of the comparative performance of a new medicine can be a powerful tool when negotiating with a manufacturer or supplier.

Monitor prices

Knowing what prices other buyers paid for medicines helps buyers evaluate the value of their own medicine purchases. Although comparing medicine prices is not a straightforward task, without knowing what a medicine really costs to produce, comparing prices paid by other buyers is the next best measure. In addition, ongoing price monitoring is preferable to a one-time comparison, because markets continually change, and new products, new clinical data, or new treatments can mean that medicines that are a good value today can be overpriced tomorrow.

Analyze pharmaco-economics

Pharmaco-economic techniques, such as cost-effectiveness, cost-benefit, and cost-utility analysis, are of value to some pharmaceutical and health commodity buyers, but are labor intensive. The analyses do not set prices but assess the costs and outcomes from using certain medicines. The evaluator must decide whether the medicine or commodity represents good value at the price offered and then use this information in price negotiations. Pharmaco-economic and related medicine expenditure analyses, such as ABC and VEN (vital-essential-nonessential), are described in [Chapters 10 and 40](#).

Maximize buying power

As identified in [Figure 9-1](#), market power for sellers increases as the spectrum moves from a competitive market to an oligopoly and monopoly. Buyers can exert corresponding buying power as oligopsonies and monopsonies; therefore, buyers that pool their procurement can potentially lower prices by providing the seller more stable levels of demand, certainty of payment, and lower administrative costs compared with selling to multiple small buyers. In addition, the development of medicine insurance schemes that cover many members (such as the Australian PBS) and the use of a common formulary help shift the purchaser's buying power to this stronger market position.

Examples of organizations that combine buying power include the International Dispensary Association Foundation and the Clinton Health Access Initiative. For example, the Clinton initiative reports price reductions for antiretroviral medicines of 50 percent for first-line treatments and 90 percent for pediatric formulations (Clinton Health Access Initiative 2010).

Negotiate prices

Price negotiation models apply to large public- and private-sector buyers that have some degree of buying power. Examples are government programs purchasing medicines on behalf of the public and third-party payers, such as private health insurers. Formularies can be used as a bargaining tool (for example, lower prices exchanged for including more of a single pharmaceutical company's medicines on the formulary) and as a list used by prescribers to select the lowest-priced medicine available within a therapeutic class. Clearly, the formulary must include generics. The strength of these negotiation models might diminish when dealing with essential, single-source medicines, because there are no alternatives to negotiate.

Techniques used for price negotiations include—

Tendering, where the buyer issues a tender seeking price offers from different pharmaceutical suppliers. An initiative to introduce joint tendering in El Salvador resulted in lower medicine prices (SEAM 2007). Through improved tendering and other practices, New Zealand's Pharmaceutical Management Agency has saved; for example, the price of generic medicines in New Zealand is estimated at less than a quarter of the price of those in Canada (Cumming et al. 2010). However, supplier performance must be monitored to ensure the quality and reliability of supply. (See also [Chapter 21](#).)

Package agreements, which comprise contracts negotiated for multiple products from one company. These arrangements can entail rebates on the entire package or large discounts on out-of-patent medicines in return for pur-

chasing full-price patented medicines. These agreements tend to work best when a credible alternative is available, such as another supplier from which the package could be purchased (McNee 2006). Package agreements that include hidden discounts are attractive to the purchaser because of the immediate cost savings; however, the true price of the medicine is hidden from the consumer making the final purchase. Such arrangements are open to abuse (including fraud), and they may hamper attempts to create a uniform pricing structure for a pharmaceutical class or to introduce genuine competition, if key information is hidden from other suppliers.

Price/volume agreements, which work when uncertainty exists about the level of demand for a medicine. Under these agreements, when a certain threshold volume is reached, the manufacturer's price falls. This threshold can be determined by population and economic modeling. For example, a medicine may appear to be a cost-effective treatment at a certain price for individuals with a severe form of a disease but be cost-ineffective when used to treat less severe cases. The estimated number of individuals with severe disease represents a threshold volume of use above which the price automatically falls to a level where the medicine is considered cost-effective for less severe cases. Australia uses this technique to maintain the cost-effective use of medicines and protect against unintended use that can be encouraged by excessive promotion of medicines (Sansom 2004).

Rebates, which are payments that the pharmaceutical manufacturers make to the buyer. Rebates can, for example, be related to sales volumes, so that when a certain volume is reached, the manufacturer provides a rebate to the buyer. Rebates are sometimes required by legislation, usually for public-sector buyers, or included in private-sector contracts with the pharmaceutical company. As is the case with discounting, such arrangements should be completely transparent.

9.7 Government intervention in the pharmaceutical market

Government intervention in pricing is a controversial topic because market economists feel strongly that the market should be left to its own devices. However, as noted previously, market failure is common in the pharmaceutical sector. In theory, the market can efficiently determine prices for many goods and services. However, the price of medications can determine quality of life or when or if people die. In reality, an uncontrolled market can lead to the most vulnerable people paying the most for medicines—if they can afford them at all. In general, and particularly for single- or limited-source medicines, an unregulated medicine market is

unlikely to provide acceptable outcomes in terms of achieving public health equity.

More general government intervention in pharmaceutical markets should include the establishment of an essential medicines list and the development of policies that encourage the purchase of low-priced, quality generic medicines. The government should encourage the entry of generic products into the market, even if legislative changes are required to streamline the registration process for these medicines. If generic competition is weak or nonexistent, as in the case of an innovator brand that is still under patent, governments can consider regulating prices or requiring compulsory licenses (Gelders et al. 2006).

Some countries favor minimal regulation of pharmaceutical pricing, allowing suppliers, health sectors, and patients to determine an equilibrium. Most industrialized countries favor more intervention, with governments either subsidizing medicines or providing them free to their citizens (Henry and Lexchin 2002). Other forms of governmental interventions include price controls or limits on pharmaceutical profitability. For example, several countries of the Organisation for Economic Co-operation and Development require manufacturers to limit prices in exchange for receiving subsidies through country reimbursement schemes, which can cover a large percentage of the population (OECD 2008).

Countries that intervene take the view that providing affordable medicines is too important to be left to the market—that medicines are more than just consumables to be traded for the highest possible price. However, instituting price-control regulations takes substantial political will and can produce unexpected consequences; for example, some claim that price control of medicines in the Philippines is thwarting the market for generics (Hookway 2010).

The arguments against government interventions tend to focus on the potential negative effect on R&D of new pharmaceutical products. Most notably, regulations that restrict market-determined prices reduce profitability, which, in turn, can restrict research into new and innovative medicines. Several studies have shown that regulation of medicine prices, differential pricing of medicines, and profitability of pharmaceutical companies are associated with the level of R&D undertaken by a pharmaceutical firm (Danzon and Towse 2003; Scherer 2001; Vernon 2005). However, these findings do not suggest that, in the absence of price controls, R&D will increase for medicines for neglected diseases that affect health in the developing world. Profitable medicine lines are those that sell in large volumes in industrialized nations, which can afford to pay more.

The ethical question is whether medicine prices should be the main determinant of pharmaceutical R&D. Incentives other than high medicine prices that are used to encourage R&D include tax concessions and public grants. These

incentives are discussed in [Chapter 3](#) on intellectual property and access to medicines.

Government-imposed price controls can be used at different points in the supply chain, but probably the two most important broad stages can be defined as prices from the manufacturer and prices in the supply chain. Methods identified by the WHO that governments can use to influence the manufacturer's price (Dukes et al. 2003) are discussed in the following sections.

Price controls on the manufacturer

These price controls usually take the form of governments restricting medicine prices to the cost of production plus a profit margin (also called cost-plus pricing). However, accurate cost information from the manufacturer is difficult to obtain. The information might be more readily available from local manufacturers without production units in other countries, but the listing of R&D in the cost structure is likely to be controversial and almost impossible to obtain from multinational organizations.

As an example, under the United Kingdom's Pharmaceutical Price Regulation Scheme, the government has the right to refuse a pharmaceutical company's application to increase the prices of existing medicines. In addition, the government can (and has) demanded price reductions for medicines purchased by its National Health Service (ABPI and DOH 2009).

Profit controls on the manufacturer

Although profit controls are not widely used internationally, the United Kingdom caps the profits pharmaceutical companies can earn from sales to the National Health Service (ABPI and DOH 2009). Within this cap, companies are allowed to price freely. From a single country's perspective, multinational operations still have the ability to shift costs throughout their operations, leaving the reported profitability subject to a degree of manipulation. Profit controls in the United Kingdom have been criticized for being open to manipulation and having an allowable profit level that is set too high (Earl-Slater 1997).

Reference pricing and brand premiums

Reference pricing allocates a medicine to a therapeutic group of medicines that are considered equivalent on the basis of safety, efficacy, and outcome. Prices of all medicines in the group are tied to that of the lowest—or in some cases, the average—price. The reference price does not necessarily become the market price for all medicines in the same therapeutic class, but rather a benchmark price. Manufacturers can set prices higher than the reference, but in doing so, they need to compete against equivalent, lower-priced

medicines. Although typically a government intervention, large, private-sector buyers use it as well.

Brand premiums are often used in conjunction with reference pricing. They are used when a third party, such as an insurance company or the government, pays for medicines to which patients contribute a co-payment. The brand premium operates by reimbursing all medicines in a therapeutic class up to a certain amount—where the reimbursement is determined by the price of the least expensive generic (or an average of all medicines in the class). Patients pay the smallest co-payment if they purchase the medicine priced at the reference price, but if the patient buys a higher-priced medicine (say a branded generic), the patient pays the co-payment plus the difference between the reference price and the selected medicine's price (Sansom 2004). The two advantages of this technique are that price competition between supplying pharmaceutical companies is encouraged and patients have an incentive to switch to lower-priced medicines.

Comparative pricing controls (international benchmarking)

This technique compares the prices in one country with those in reference countries. The government limits price increases of existing medicines to the average increase recorded in a set of reference countries, and new medicines are priced at the average (or lowest) of the reference countries. The difficulties with comparative pricing are the same issues encountered when comparing prices in different countries. Strengths, pack sizes, and active ingredients tend to differ among countries, and unit prices are lowest when products are purchased in bulk. Additionally, the point in the supply chain at which the price is compared (manufacturer, wholesaler, retailer, patient) introduces further inter-country differences in terms of margins and taxes.

A given product may have several selling prices (public-tender price, private-sector uninsured price, etc.), so one has to be selected for the comparison. Choosing benchmark countries can also be difficult; for example, including countries at a similar stage of economic development may seem sensible, but such countries may not have an effective system for setting prices. Nevertheless, the Netherlands, Portugal, and Romania all use international benchmarking, and the Netherlands reported an average 20 percent decrease in the cost of pharmaceuticals when it introduced the comparative pricing technique in 1996 (Dukes et al. 2003).

Eliminating tariffs and taxes

As mentioned, sizable price increases can occur throughout the supply chain, some of which are imposed by governments in the form of taxes and tariffs. WHO estimates that high tariff structures in selected low-income coun-

tries increase the price of medicinal ingredients by 23 percent and the price of finished medicines by over 12 percent (WHO 2004). Although tariffs and taxes provide the opportunity for raising state revenue, their effect on medicines is to reduce affordability and substantially erode public health objectives. Sometimes the argument for tariffs is to protect emerging local industries until they become established; nonetheless, the effect on medicine affordability is the same. In terms of pricing policy, governments must minimize unnecessary add-on costs and should not impose revenue-raising charges on essential items such as medicines (Global Health Council 2007).

In addition to introducing price control measures and eliminating taxes and tariffs on pharmaceuticals, WHO has identified the following methods by which governments can influence medicine prices by controlling the margins charged by the retail pharmacy, and in some countries, by dispensing doctors (Dukes et al. 2003).

Fixed margins

These margins are a fixed percentage of the wholesale price. Commonly used in the United States and Europe, fixed margins tend to average about 30 percent of the wholesale price. Problems include the tendency for pharmacists to negotiate rebates and other discounts directly with the wholesaler that do not get passed on to the consumer. In some countries (for example, Denmark), these discounts are illegal (Dukes et al. 2003).

Digressive markups

These margins are a shifting percentage of wholesale prices: lower-priced medicines have a proportionally larger margin than more expensive medicines. This system tries to encourage the dispensing of less expensive medicines by using the pharmacist's profit-maximizing behavior as a driver.

Capitation systems

The pharmacist is reimbursed with a fixed sum based on the number of patients per year or a fixed fee per prescription. The system's goal is to keep pharmacists from benefiting from either the price or volume of medicines dispensed, but the system is open to manipulation if the pharmacist continues to add a margin on to the wholesale price.

9.8 Influence of globalization on pharmaceutical prices

As noted previously, the international system to protect intellectual property rights tends to keep the prices of patented medicines high. Countries can take some actions to

lower the cost of medicines under the World Trade Organization's Agreement on Trade-Related Aspects of Intellectual Property Rights (see Chapter 3). For example, compulsory licenses can be used in national emergencies or when a country needs a supply of a medicine for government use. If the required medicine is under patent, the patent may be broken to allow the medicine to be locally manufactured. If the country does not have the capacity to manufacture the medicine, it can be imported from another country where it is not already protected by patent. The granting of the license requires that the patent holder be paid a "reasonable" fee. Compulsory licensing is not an option that is available only to low-income countries. During an anthrax emergency in 2001, the U.S. government considered invoking this right to bring down the price of ciprofloxacin (Bradsher and Andrews 2001).

Parallel importation is common in the European Union, although it represents only about 2 percent of the European market (OECD 2008). A branded medicine may be sold relatively cheaply in one member state and then be imported into another country and sold below the usual domestic selling price. Such arrangements are attractive to the importing country, but parallel importation can undermine efforts to achieve equitable international pricing of essential medicines when manufacturers shy away from offering cheaper versions of their products in low-income countries for fear they will appear on the European market and undercut those prices. In addition, a study concluded that the benefit of parallel trade goes to the traders themselves, rather than to patients in the form of cheaper medicines and better access (Kanavos et al. 2004).

Voluntary price reductions offered by major pharmaceutical corporations (often under pressure from advocacy groups) have reduced the cost of antiretroviral therapy available in low-income countries dealing with HIV/AIDS epidemics. These pricing structures have resulted in significant price decreases but have not necessarily translated into improved access. Other factors, such as the inability of health systems to deliver medicines to those who need them, also hinder access. For example, despite the reduction in prices of antiretroviral medicines for HIV/AIDS, only an estimated 31 percent of the world's low- and middle-income populations living with HIV have access to treatment (WHO/UNAIDS/UNICEF 2009).

The Affordable Medicines Facility–malaria (AMFm) initiative is piloting a program to increase access to artemisinin-based combination therapies (ACTs) by paying a large proportion of the cost of ACTs to the manufacturers so the public and private sectors can buy the products at a greatly subsidized price (about USD 0.05 per treatment). The idea is that the subsidy will trickle down to the end user, resulting in a price reduction from about USD 6–10 per treatment to about USD 0.20–0.50. At that cost, ACTs would be cheaper than monotherapies, which would theoretically be crowded

out of the market. Social marketing strategies have used similar approaches to increase the availability of products such as contraceptives and bed nets. Launched in 2010 by the Global Fund to Fight AIDS, Tuberculosis and Malaria, the AMFm will be independently evaluated in 2012 in the nine pilot countries.

9.9 Conclusion

The international and domestic systems that determine the selling prices of pharmaceutical products are extremely complex. Although covering all the issues in depth is difficult, one can draw a number of important conclusions—

- Patented medicine prices tend to be high, and a competitive market for generic products is the most important mechanism for ensuring the affordability of essential medicines.
- Governments can intervene effectively in the pharmaceutical market by becoming large purchasers on behalf of their communities and by regulating the different markups along the supply chain, which can greatly affect the costs to consumers. Governments can also eliminate or reduce taxes on important medicines. To encourage the supply of generic medicines, governments can work to minimize barriers to their entry into the market.
- Health insurance that covers a core list of essential medicines with minimal consumer co-payments can be a major force in improving access to essential medicines. An insurer can use purchasing power and other techniques that reduce medicine prices. [Chapter 12](#) discusses different types of health insurance schemes.
- A number of mechanisms exist to control pharmaceutical prices, including tendering, generic substitution, reference pricing, international benchmarking, and pharmaco-economic analysis. No *one* mechanism will meet all of a country's needs, and the country must determine which mechanisms are best, based on assessing the context and monitoring it for change over time. Within a particular country, different methods may be appropriate for different market segments (for example, public versus private procurement).
- The total costs of medicines depend not only on selling prices but also on volumes of use. Unnecessary medicine use contributes to both costs and adverse clinical outcomes. The demand side of the pharmaceutical market is just as important as the supply side. ■

ASSESSMENT GUIDE

- Describe the buyers and sellers in the pharmaceutical sector. Is there one dominant buyer? Does one dominant seller have negotiating power in the market?
- Does the government have a policy regarding the promotion of generic medicines?
- What is the regulatory process that allows generic medicines into the market?
- For the three categories of medicines in the market, patented, generic, and branded off-patent, what is their percentage of use by volume and value? Are prescribers and patients more likely to use generic products if they are available?
- Do any data exist showing the variation of medicine prices in the public, private, and nonprofit sectors? For innovator products and lowest price generics?
- How do pharmaceutical prices in public and private sectors compare to those in other countries or to international reference prices?
- What are the markups on medicines throughout the supply chain? Does the government regulate any of the markups? Does the government or other authorities impose markups in the form of tariffs or taxes?
- Have pharmaceutical buyers used any strategies to maximize their power in the market, such as monitoring prices, negotiating prices, or pooling procurement?
- Does the government impose price controls at the dispensing level, such as fixed margins or banning or regulating the practice of dispensing doctors?

- International Project on Medicine Prices. <<http://www.haiweb.org/medicineprices/2005/PricingbriefingpaperFINAL.doc>>

SUMMARY

Economics can help managers make difficult resource-allocation decisions by providing a framework and a set of concepts and tools for evaluating alternatives in terms of their costs and benefits. Key economic concepts include—

Scarcity: the fact that resources are always limited

Opportunity cost: the benefits that are given up in choosing one option over the next-best alternative

Marginal costs and marginal benefits: the additional costs incurred and additional benefits gained by increasing output

Incentives: the factors related to both monetary and non-monetary rewards or to penalties that influence the behavior of individuals or organizations

Considerable debate exists about the appropriate role of government in the health sector. The “social welfare” perspective argues for broad government involvement, whereas the “market economy” perspective holds that government should become involved only when the market system fails. General support exists for the government to provide public goods, which are available for the benefit of everyone. Prominent examples include goods and services with positive externalities, such as immunization, and merit goods, such as health education, which private markets tend not to provide in sufficient quantities.

Policy makers must also be concerned with distribution issues—who pays for and who benefits from publicly supported services. Through the use of subsidies, governments can encourage the consumption of health

services beyond what individuals would pay for on their own.

The private sector is actively involved and often predominant in health care and especially the pharmaceutical sector. Government involvement with the private sector is often justified as a means of correcting “market failure,” which may result from equity considerations, failure of competition, information failure, and externalities. Governments are not always successful in correcting the failure.

Efficiency means getting the most output for a given quantity of resources. The tools of pharmaco-economic evaluation can help pharmaceutical managers identify the most efficient options. Different methods include cost-minimization analysis, cost-effectiveness analysis, cost-utility analysis, and cost-benefit analysis.

These methods are demanding and labor intensive, and although widely used in pharmaceutical access programs in high-income countries, their applicability is more limited in low- and middle-income countries. Essential medicines lists, standard treatment guidelines, generic substitution, tendering and reference pricing, and tariff and tax minimization can be more effective instruments for improving pharmaceutical purchasing and improving affordability.

Pharmaco-economic analysis can be very helpful, but should be used selectively, for instance, in assessing an entire public health program (such as childhood vaccination) or when an important product is expensive and available from only one source.

10.1 Economics as a tool for making choices

Health economics is about understanding both medical and nonmedical resource-allocation decisions that affect health under conditions of scarcity and uncertainty (Drummond et al. 2005). Pharmaco-economics is the area of health economics that focuses on the economic evaluation of medicines. Because budgets are never large enough, health managers must constantly decide which of several courses of action to follow. They may make choices among programs, among program goals or objectives, or among strategies or activities for achieving specific goals. This chapter introduces the concepts of health economic analysis and shows how these concepts can be applied to the selection of medicines.

Evidence-based medicine and pharmaco-economic analysis play a much greater role in medicine selection now than

they did ten years ago, because program managers are under increasing pressure to show that they are obtaining value for their purchases or subsidies. These methods have been used most effectively within health insurance/pharmaceutical subsidy schemes in high-income countries (Birkett et al. 2001; Hjelmgren et al. 2001; Pearson and Rawlins 2005), but the basic principles are relevant to low- and middle-income countries.

As covered in other chapters, pharmaceutical management is characterized by a complex series of processes, involving (a) research and discovery, (b) product development, (c) safety and efficacy testing, (d) manufacture, (e) distribution, (f) prescription, (g) dispensing, and (h) consumption. The first four elements constitute the costs incurred before the manufacturer’s distribution to wholesalers. The prices the manufacturer charges are usually many

times the marginal cost of production and are set in order to recover all of these costs and generate a profit margin. The patent system allows manufacturers to behave as monopolists, charging what the market will bear. Retail prices depend on this system and the last four processes listed. Therefore, the application of health economics methods to the selection of medicine must consider the complexity of these processes and the often conflicting roles of the different stakeholders.

Program managers can use economic analysis as a useful tool to augment, but not fully replace, experience and common sense. Economic analysis can lay out, sometimes in stark detail, the costs and consequences of different courses of action. However, real-world decision making must consider political, professional, and commercial realities. Achieving optimal value for money with every purchase or subsidy is a worthy but unattainable goal; however, judiciously and consistently applying appropriate pharmaco-economic methods will help deliver greater value for money in the longer term.

An important caveat is that health economics, done appropriately, is a rigorous, demanding discipline. Many problems with pharmaco-economic analyses arise because of limitations or biases in available clinical data, which result in unrealistic assumptions about clinical benefits and cost-effectiveness of medicines (Hill et al. 2000; Rennie and Luft 2000; Bell et al. 2006). Therefore, organizations must have access to clinicians, epidemiologists, statisticians, and economists to conduct pharmaco-economic analyses well. Because these professionals are often in short supply and expensive, many countries do not have the necessary resources. Regional cooperation is likely necessary to achieve widespread proficiency in the application of these methods.

In most low- and middle-income countries, complex health economic analyses of each individual medicine product are not necessary; rather, they are selectively applied to

public health programs, such as childhood immunization, or to expensive products from a single source. In fact, formal pharmaco-economic evaluations of pharmaceutical classes should be aligned with the basic elements of pharmaceutical management policy, including maintaining essential medicines lists, establishing generic medicines policies, ensuring efficient pharmaceutical procurement and distribution systems, minimizing tariffs and taxes, and encouraging rational use of medicines.

10.2 Some basic economic concepts

Economics provides methods for evaluating choices in terms of their costs and benefits. Table 10-1 lists examples of resource-allocation decisions that can benefit from using economic tools, moving from a more macro, or health system, level to the micro level of individual products.

Highlighting a few basic economic concepts critical for understanding issues in public health may be useful. They are scarcity, opportunity cost, marginal benefits and costs, and incentives.

Scarcity. Resources are never sufficient to do everything.

Choices have to be made about the best ways to use the resources that are available. Resources are not limited to money; time is a scarce resource as well, as every busy program manager knows.

Opportunity cost. Choices that entail opportunity costs go beyond money alone. They take into account potential benefits that are given up in order to follow a chosen course of action—benefits that could be derived from committing resources to the next-best alternative. For example, if running a training course in inventory management means that another course in rational medicine use cannot be conducted, the forgone course is the

Table 10-1 Examples of resource-allocation decisions at different levels of government

Central government	Central ministry of health	Pharmaceutical program managers
How much should the public sector spend for all recurrent budgets?	How much should be allocated to primary, secondary, and tertiary care?	How much should be spent on pharmaceuticals, training, and storage?
How much should be allocated to the different ministries?	How much should be allocated to different program activities?	What methods can be used to plan for international pharmaceutical purchases when the value of local currency is falling?
	How much should be spent on pharmaceuticals, personnel, and other operating costs?	
	How much should be allocated to different geographic jurisdictions?	Which pharmaceutical distribution strategy will deliver medicines to health facilities most efficiently?
	How much should be allocated to urban compared to rural, dispersed populations, for whom unit costs of services are higher?	Which medicines should be purchased and at what prices; to whom should they be given?

opportunity cost of running the inventory management course. The concept of opportunity cost is helpful in evaluating alternatives by looking explicitly at the trade-offs they involve.

Marginal benefits and costs. When resource-allocation decisions are made, the question is often not whether to allocate all or nothing to a particular activity, but whether to spend a bit more or a bit less. The additional costs of doing a bit more are called marginal or incremental costs, and the additional benefits that result are called marginal benefits. The relationship between the additional costs and benefits is usually called the incremental cost-effectiveness ratio.

For example, ministries of health are rarely faced with decisions about whether or not to provide vaccinations; however, a program manager might have to decide whether to keep the clinic open for another hour at the end of the day. To make this decision, the manager would estimate the marginal cost of keeping the facility open (in terms of extra salaries, utilities, and so forth) and compare this cost to the marginal benefit (in terms of numbers of additional children who would be vaccinated during the extra hour). The incremental cost-effectiveness ratio would be expressed as the cost per extra child vaccinated. The opportunity cost of keeping the clinic open for another hour would be the activities forgone as a result: for example, resources may no longer be sufficient to conduct an educational outreach session.

Incentives. An incentive is some kind of compensation (a reward or penalty that is monetary or otherwise) that influences the behavior of individuals or organizations. For example, governments may provide a financial incentive to parents to ensure that their children are fully immunized. Governments have an incentive to provide preventive health care because it should reduce the demand for and thus the cost of providing more expensive curative care. In practice, however, patients and communities strongly demand curative care. Governments can also create incentives to influence the behavior of individuals or organizations. In charging fees, for example, they can discourage individuals from making unnecessary visits to health facilities for minor complaints. This assumed tendency to overuse facilities if they are made available free of charge is known as “moral hazard.” However, many studies have shown that user fees reduce care-seeking behavior among poor patients, which may have negative health outcomes.

The carrot-or-stick approach can be extended to industry. For instance, by levying fines for the distribution of substandard products, governments can encourage pharmaceutical producers to maintain the quality of their products. By establishing certain kinds of controls and incentives, government can influence consumers and providers to choose lower-priced medicines.

10.3 Economics of the public sector

The appropriate role of the government in the health sector, as well as in the broader economy, has been debated for centuries by philosophers, economic theorists, and political thinkers. Since the 1980s, the debate has been heightened by a two-pronged dilemma. On the one hand, centrally planned economies have generally failed to ensure economic security for their populations; on the other hand, some market-focused economies have shown notable inability to ensure universal access to basic social services such as health care.

In appraising the role of government, considering the two extreme positions in this debate is useful. One can be called the social welfare perspective; it supports the vision of an active central government that provides virtually all social services and participates actively in the production of goods and services throughout the economy. This perspective assumes without question that education, health, and other social services will be fully provided by the government. What can be called the market economy perspective, at the other extreme, holds that the government should intervene only if and when the market system performs imperfectly. The economist’s perspective on the appropriate degree of government involvement is to weigh benefits against costs; in other words, both governments and markets can be imperfect, and the appropriate mix needs to be assessed on a sector-by-sector basis.

Goals of public expenditure

Historically, the role of the public sector has been undisputed for certain activities. Traditionally, these areas have included maintenance of law and order and national security; investment in infrastructure, such as roads, electricity, and communications networks; and provision of certain types of goods and services. Technically, these activities are termed *public goods*, *externalities*, and *merit goods*. However, none of these areas is now invulnerable to change, and many governments have experimented with privatizing areas previously regarded as the sole province of the public sector.

Public goods. Services that are widely agreed to be essential and that are consumed collectively (for example, national defense and policing), certain types of utilities and amenities (such as street lighting, sewage systems, and parks), and public health services (such as aerial spraying for vector control) are termed *public goods*. Public goods are often referred to as nonexcludable, meaning that they cannot be provided to some and withheld from others, and nonrival, meaning that no competition exists for the goods; consumption by one person does not reduce its availability to others (Cowen 2008). Because of these factors, public goods are often not sold in the market, and relying on the private sector to provide them may be impractical.

In practice, these definitions have limited applicability, and in recent years, governments have explored ways to engage the private sector in some forms of public infrastructure. For example, power and water companies, which are traditional public entities, have been privatized in many countries, and new highways are often built through partnerships between the public and private sectors. Currently, the overall effects of these policies are unclear, but they do represent a clear shift in government thinking about providing public goods.

Externalities. External effects, sometimes called social costs or benefits, extend beyond the party directly involved in the production or use of a good or service (Musgrove 1996). Examples of goods with positive externalities are immunization and communicable disease control; all members of the community enjoy the benefits of immunization or treatment because their chances of contracting these diseases are reduced as a result. Because private markets tend to underprovide public goods with positive externalities, governments usually take responsibility for funding public goods or subsidizing their use.

Merit goods. Merit goods are things that are good in themselves and include, for example, providing health services for the poor. If left to the market, merit goods would be underprovided. Populations want these services to be provided, but private markets tend not to take care of this group.

Government activity often extends beyond these three types of goods and services. Many people look to government to create a supportive environment for the private sector by encouraging stability and ensuring the availability of basic infrastructure to enforce laws and legally binding contracts. Arguments for a more active public sector are often most forcefully made in developing countries, where levels of private investment may be low, and the private sector is consequently less well developed. Nevertheless, the governments there are sometimes much less developed and can have issues with corruption and lack of transparency.

The roles that governments can play in the pharmaceutical sector are discussed in [Chapter 8](#) and range from total control and provision of all pharmaceutical services (increasingly rare) to minimal government intervention, with pharmacy services provided mostly by the private sector, without government support or interference.

10.4 Understanding the private sector

In contrast with the public sector, private-sector resource allocation decisions are determined largely by the interaction of buyers and sellers in the marketplace, mediated by price. Health program managers in the public sector sometimes think of the private sector as greedy, unscrupulous, unethical, and concerned only with profit at the expense of

equity and quality. They often see consumers as unable to judge the quality of health services and therefore vulnerable to manipulation by the private sector. However, the private sector usually plays a significant role in the health sector in the production, distribution, and sale of pharmaceuticals as well as in the direct provision of a significant proportion of health services through private clinical practices, private hospitals, and retail drug sellers. This fact alone is an important reason for better understanding the private sector, which, some believe, has advantages over the public sector in certain circumstances and for certain activities. Appreciating both the strengths and the weaknesses of the public and the private sectors is essential to good public-sector decision making.

Markets and competition

The private sector is characterized by buyers and sellers in the marketplace negotiating the exchange of goods and services through the mechanism of price. In the pharmaceutical sector, the sellers of medicines may be manufacturers, wholesalers, pharmacies, or retail drug sellers. Purchasers may be government, private, or nongovernmental health facilities, or individual consumers. When multiple suppliers act independently and large numbers of purchasers exist, markets are described as “competitive.” Through the use of prices as signals, competitive markets are able to allocate resources efficiently, making sure that resources get to the people who are willing and able to pay for them.

Suppliers enter the market when they see an opportunity to make a profit, that is, to earn revenues in excess of costs. With this incentive, they are willing to invest their own money and take a risk as they engage in new activities, expand into new markets, and respond to consumer demand. Under competitive conditions, suppliers can be expected to earn a reasonable level of profit; if they try to increase their profits above this level, another supplier will likely offer a lower price and take away their business. In this way, the price system functions as a control, or discipline, mechanism. Suppliers do not compete on the basis of price only; they may compete on quality (providing a higher quality for the same price), reliability, service, or capacity.

In practice, this type of competitive market is sometimes hard to achieve with pharmaceutical products. Because information is a public good, private markets will tend to underprovide it. The scientific advances that underlie innovative pharmaceuticals are an example of this phenomenon. Various mechanisms have been developed to encourage research and development in medicines and vaccines for neglected diseases. For example, an advance market commitment, a contract from a government or donor, guarantees a viable market for a new medicine or vaccine that would otherwise be too financially risky to develop—such as

a product that would benefit developing countries. In 2009, five countries and the Bill & Melinda Gates Foundation activated the first advance market commitment of USD 1.5 billion to speed the development of a vaccine for pneumococcal disease (GAVI Alliance 2009).

The intellectual property system, notably patents, also tries to address this shortcoming by giving innovators a time-limited monopoly in exchange for revealing the nature of their invention. Monopolies, in general, lead to higher prices and suboptimal use in the short run, but the intended trade-off (not always realized) is that this system produces a greater rate of innovation in the long run. Thus, the situation is far more complex than a simple competitive market.

In most countries, patents are now granted for twenty years, although the effective patent period of medicines is eight to fourteen years, because of the time development takes. After the patent on a medicine expires, generic suppliers are able to compete, and prices typically plummet to become much closer to the marginal cost of production. For both patented and generic products, the pharmaceutical marketplace is also distorted by the presence of public and private insurance.

In most developed countries, the government negotiates prices with pharmaceutical suppliers in an effort to provide a counteracting force (monopsony or single-buyer power) to offset the single-seller power of monopolists. Government intervention is the rule rather than the exception, especially in rich countries. The theoretically competitive model of multiple suppliers and multiple purchasers is often replaced by a more pragmatic model of multiple monopolistic suppliers of products and one or a few large purchasers (government or nongovernmental organizations) who can exercise considerable purchasing power. (See [Chapter 9](#) on pharmaceutical pricing policies.)

Economies of scale. In competitive markets, suppliers have an incentive to produce goods and services as efficiently as possible, using the least-cost combination of inputs. In some cases, the private sector is able to generate efficiency gains because of the size and diversity of its operations. Economies of scale occur when the production of larger quantities leads to lower average costs. For example, a plant that produces 4 million tablets a day is likely to do so at a lower cost per tablet than one that produces only 10,000 a day. Beyond some level of output, however, additional machinery or equipment may need to be bought, or more resources may need to be spent in supervising production, which may increase average costs.

Economies of scope. Economies of scope result when combining a number of different activities enables them to be done at lower average cost. Private distribution networks may benefit from economies of scope by combining the delivery of pharmaceuticals with the delivery of other goods and services.

Ethics and business

As previously mentioned, both nongovernmental organizations and public-sector groups have tended to attribute unethical and unscrupulous motives to the private sector. Although examples exist of suppliers that brazenly cheat by providing substandard medicines, for example, the long-term interests of private providers do not encourage engaging in this type of activity. As long as there is the prospect of a continued, profitable relationship with a purchaser, the supplier has an incentive to retain customers by providing good-quality services.

Much of the criticism of the last decade has been directed at manufacturers of patented pharmaceuticals. The main arguments have centered on the price at which they sell their products, particularly in poorer countries, and their lack of involvement in the development of new medicines for some diseases that are major causes of morbidity and mortality in those countries (Trouiller et al. 2002). With the help of intense lobbying from advocacy groups, however, the pharmaceutical industry appears to be recognizing its wider global responsibilities and is addressing its damaged reputation. As a result, modest progress is being made in some areas to provide greater access to some previously unaffordable medicines (for example, antiretroviral medicines for HIV/AIDS) and in the development of medicines for neglected diseases. In theory, many pharmaceutical suppliers will be quite happy to sell medicines at “differential” (lower) prices in poor countries, as long as those prices are above their marginal costs of production and distribution and prohibitions against reexporting to higher-priced markets (parallel trade) are enforceable (Danzon and Towse 2003).

Encouraged by the World Health Organization and the World Bank, some research-based companies have been using differential prices to sell their products on different markets (WHO and WTO 2001). This subject is discussed in more detail in the chapter on medicine pricing ([Chapter 9](#)). Products that have been the subject of differential pricing include contraceptives, vaccines, and antiretroviral medicines (GAVI n.d.).

In addition, nonprofit organizations are developing new medicines for conditions such as tuberculosis, malaria, leishmaniasis, and trypanosomiasis. Some are part of large international initiatives (Medicines for Malaria Venture, Drugs for Neglected Diseases Initiative, TB Alliance), and much funding has come from the private sector (for example, the Bill & Melinda Gates Foundation). Several initiatives are public/private-sector partnerships, involving pharmaceutical manufacturers (see [Chapter 3](#) on intellectual property and access to medicines). The result has been considerable blurring of the traditional barriers between the public and private sectors in pharmaceutical research, development, and distribution.

10.5 Government interaction with the private sector

Governments interact with the private sector in many different ways. In its simplest form, this interaction consists of government purchases of pharmaceuticals and supplies from private pharmaceutical companies. In theory and in relation to pharmaceutical products, much government involvement is motivated by a desire to correct “imperfect” private markets.

Market failure

A number of potential market failures exist in the medical marketplace in general, and the pharmaceutical marketplace in particular, that distort outcomes away from the efficiencies that would be expected under the simple competitive ideal—

- Insurance means that patients, and physicians as their agents, do not face the social costs of their decisions to use health care.
- Information is a public good, but the adoption of the patent system as compensation creates monopoly power, which can be abused.
- In general, purchasers do not have good information about the price and quality of the health care services they buy. This information asymmetry can work to the benefit of sellers.
- Regulatory requirements create high barriers for new manufacturers entering the market, which lessens competition.

Patients’ inability to assess the quality, safety, or efficacy of pharmaceuticals means they must rely on the clinicians who prescribe them, on pharmaceutical producers to maintain production quality standards, and on governments to intervene with regulatory activities. Inspection of medicines, registration and licensing of pharmacists, and medicine registration processes are all ways in which governments attempt to protect consumers from dangerous, ineffective, and poor-quality medicines (see [Chapters 6 and 19](#)). These demanding safety standards, although necessary, make entering the market difficult for new companies.

Achieving economic efficiency in the presence of market failure is one of the principal aims of pharmaco-economics; techniques for achieving efficiency are discussed later in this chapter. Efficiency in pharmaceutical management requires that the medicines are effective and affordable, represent value for money, and are used appropriately. But governments are not concerned only with efficiency. Most also try to achieve a degree of equity in the distribution of funds and services. Lack of access to essential medicines discriminates against those with the least ability to pay, leading to avoid-

able mortality, suffering, resentment, and in some cases, economic decline. Governments are in the best position to correct these inequities, and access to essential medicines is now regarded by some as a human right. Because private-sector decision making is driven more by profit than by equity considerations, equity is often the first motivation for government involvement in essential medicines programs. The relatively high cost of pharmaceuticals compared to that of other goods suggests that without government involvement, the poor would be denied access to lifesaving medicines. This probability is especially high in remote areas, where cash incomes are usually lower and delivery costs higher.

Types of government interventions

In a broad sense, arguments are that government interventions are needed to correct market imperfections, ensure the safety and efficacy of medicines, and improve access and affordability. These aims can be advanced by various types of legislation; in addition, governments can influence prices by becoming large purchasers (or subsidizers) of medicines and using their extensive purchasing power. Pharmaco-economic analysis can facilitate the use of this approach as a tool for calculating social willingness to pay, as discussed below.

The term *regulation* refers to the set of tools that governments use to ensure that private-sector actions are consistent with the broader welfare of society. The objectives of regulation are usually improvements in quality, efficiency, or equity. Pharmaceutical legislation and regulation are discussed further in [Chapter 6](#).

With pharmaceuticals, the instruments used to regulate the private sector (for example, manufacturers, distributors, pharmacies) include controls on medicine and service quality through mandatory inspection programs; controls on imports (restricting imports of dangerous products or permitting the import of only essential medicines); and registration and licensure of pharmacists. Restrictions have also been widely imposed on the prices at which pharmaceuticals can be sold. For example, in Australia, a section of the National Health Act prevents the national medicines selection body (the Pharmaceutical Benefits Advisory Committee) from listing a new product on the schedule at a higher price than the comparators unless it offers better efficacy or safety (see [Country Study 10-1](#)).

A number of issues should be considered in evaluating the potential effect of regulation: the extent of coverage (for example, does it include both public and private sectors?), the capacity of government to monitor compliance, the extent of enforcement and exemptions, and the extent to which the private sector can circumvent or evade regulations (for example, through the emergence of an uncontrolled parallel market for nonessential or banned medicines).

Country Study 10-1**Australia: Ten years of using pharmaco-economics in decision making**

In Australia, the federal government subsidizes the use of pharmaceuticals through the maintenance of a “positive” formulary, called the Pharmaceutical Benefits Schedule (PBS). Recommendations to list new medicines on the PBS are made to the health minister by a Pharmaceutical Benefits Advisory Committee (PBAC), based on the importance of the medicine, the need for it in the community, its efficacy and safety compared to other medicines or treatments for the condition, and, since 1993, its cost-effectiveness. In addition, the committee considers the financial implications of adding the medicine to the formulary.

The PBAC analyzes the relative clinical performances and costs of both the potential new medicine and comparable medicines already listed on the PBS. The PBAC bases its decisions on the principle that if a medicine is no better than a comparable product, it should not cost more. If the product is superior to existing therapies but more expensive (a common situation), and funds are available, any extra expenditure should represent “value for money.” Costs are not limited to each product’s acquisition cost, but can include savings in other areas—for instance, decreased use of other medicines or fewer consultations, tests, and hospital admissions.

Incremental cost-effectiveness ratios for the new medicine compared to existing medicines are then developed. These economic data inform decision making, but no formal “threshold” exists for what is cost-effective. Other issues, including clinical need and social values, are influential. Decisions projected to cost more than 10 million Australian dollars (AUD) per year must be approved by the cabinet of the federal government.

More than ten years’ experience in using pharmaco-economic evaluations in PBAC decision making has resulted in several observations. The processes have survived multiple technical and ethical challenges, notably but not exclusively from industry. A government productivity commission criticized the PBAC about the level of disclosure in its decision making. In 2002, the Department of Health and Aging began publishing summaries of PBAC’s positive recommendations on its website, but so far full details of the assessment process are still not provided.

No evidence suggests that Australia has been denied access to important medical advances by the demand that a new medicine demonstrate “value for money,” with the PBS subsidizing a comprehensive range of medicines for patients. The PBS is a positive formulary, in that the PBAC does not seek to limit choice or restrict the numbers of medicines within a classification. However, pressures on the system are real; for example, patient advocacy groups with particular clinical needs continue to seek relaxation of decision-making criteria that affect them.

As in most other countries, the costs of medicines are a concern, and the viability of the PBS has been questioned. To curtail growth in pharmaceutical costs, the PBAC increasingly relies on restricting subsidies by defining eligibility criteria that target patients in whom the new medicine has been demonstrated to be cost-effective. During the decade in which the PBAC has used pharmaco-economic analyses, expenditure on the PBS has risen from about AUD 1 billion per year in the early 1990s to about AUD 6 billion in 2005. This increase does not mean that the use of economic information in decision making has been a failure—rather, it suggests that the other side of the cost equation, the demand side, has been less well managed. Prescribers often ignore restrictions, and the use of new medicines for indications and patient populations in which the medicine has not been shown to be cost-effective has contributed to the rapid growth in PBS costs.

Using pharmaco-economic analyses in decision making is not a panacea for rising pharmaceutical budgets. However, such techniques do make the trade-offs between the costs and benefits of the medicine more transparent. Although considerable progress has been made in the technical aspects of the conduct of pharmaco-economic analyses, progress on managing prescribing practices has been notably less successful. The challenge ahead is how to use the available information on cost-effective medicine use to influence how medicines are prescribed and used in the Australian community.

Source: Birkett et al. 2001; Hailey 2009.

When regulations are in place, they should be regularly evaluated to determine whether they are achieving the desired effects or, as is frequently the case, the government intervention has had unforeseen and negative consequences.

Legislation designed to improve the affordability of medicines is harder to implement when the government does not subsidize medicines and thus is unable to use its extensive purchasing powers. For example, since 1997, South Africa has tried to regulate medicine prices in the private sector, but it has met stiff resistance from stakeholders, including pharmaceutical manufacturers, wholesalers, and retail pharmacists (Republic of South Africa 1997). To achieve greater control over prices and improve affordability and access, the South African government plans to introduce a form of national health insurance before 2014 (*ANC Today* 2009).

The capacity required to implement and monitor the effects of regulations—and the costs of monitoring them—needs to be carefully weighed against the proposed benefits.

Challenges to government interventions

Arguments in favor of government involvement often contrast private-market failure with “perfect” government intervention, but this result is never achieved in practice. The private market may fail, but government intervention also fails sometimes. Governments in all countries at all levels of development are subject to threats to their effectiveness. Informed decisions about public involvement in essential medicines programs must acknowledge the sources of government ineffectiveness, including inefficiency in service delivery, inequities in revenue collection, interest-group pressures, lack of good governance, and widespread corruption.

Inefficiency in service delivery arises from a lack of individual incentives for good performance, bureaucratic inflexibility, and political pressure to create employment. Overexpenditure on staff and underexpenditure on pharmaceuticals, for example, could result in having idle staff who are unable to meet the needs of patients. Inefficiencies in government accounting systems that cause lengthy delays in payments may result in suppliers’ raising their prices or deciding not to bid at all on government contracts.

Inequities in revenue collection can result in a reduction in health services, which is felt most acutely by lower-income groups, which are most dependent on them. If the more affluent members of society succeed in avoiding taxes and other government levies, the financial burden for government activity falls on those with fewer means and options.

Even honest, well-meaning politicians and officials are subject to interest-group pressures. Political supporters, members of the same ethnic group, and concerned business organizations can influence bureaucrats to allocate services and resources in ways that do not promote equity. Generally,

the more affluent are able to exert such pressures; ironically, the less well-off may lose directly and indirectly—by paying more in taxes as well as by receiving fewer services.

Finally, lack of good governance and corruption can be revealed in self-interested manipulation of the medicine selection process, corruption in the award of tenders, nepotism in the appointment of key staff, sales of medicines on the outside by health staff, and other destructive practices. Indeed, the World Bank has identified corruption as one of the greatest obstacles to a country’s economic and social development (see <http://www.worldbank.org/anti-corruption>).

10.6 Efficiency concepts

Efficiency concepts form the basis for understanding the use of pharmaco-economic analysis. Whereas effectiveness concerns the degree to which services are provided or outputs are produced (for example, how well does a medicine work in practice?), efficiency can be understood as getting the most output for a given quantity of resources committed or, alternatively, achieving a given level of output at minimum cost. In this field, efficiency is usually referred to as “cost-effectiveness” (Drummond et al. 2005).

Several types of efficiency concepts exist, with a variety of definitions that are characterized by some lack of agreement. Generally, *economic efficiency* refers to economic systems that can provide more goods and services to society without using more resources. *Scale efficiency* occurs when the production costs are reduced because of higher production volume. *Productive efficiency* in a health system refers to maximizing health outcome for a given cost, or the minimizing cost for a given outcome. Because types of efficiency relate to the pharmaceutical sector, this chapter takes a pragmatic approach by referring to the concepts of allocative efficiency and technical efficiency. *Allocative efficiency* is the broad concept of undertaking the best combination of activities to achieve the greatest net benefit to the community; for example, should we spend money on preventing cardiovascular deaths or childhood illness? Or should we spend money on education or health? *Technical efficiency* is concerned with determining the right quantities of different inputs and the least-expensive combination of inputs to achieve a given outcome; for example, what is the most cost-effective way to reduce cardiovascular deaths? The concepts of allocative and technical efficiency are closely linked and in real life cannot be separated.

Allocative efficiency

Allocative efficiency has relevance to pharmaceuticals, not least because medicines can consume 25 to 65 percent of entire health budgets in some low-income countries (WHO

2010). In some countries, 20 to 30 percent of pharmaceutical expenditure is for products that have no relevance to the main health problems of the population—clearly an inefficient allocation of scarce resources, which might be better used in public health programs or education (WHO 2010).

Decisions affecting allocative efficiency are most often made at the policy level, for example, deciding whether to allocate additional funds to the ministry of health or the ministry of education. Within the ministry of health, decisions involve how much to spend on primary, secondary, and tertiary care or whether to spend additional program funds on controlling tuberculosis or treating sexually transmitted infections. Such allocative decisions can have unintended and undesirable effects; a decision to reduce spending on pharmaceuticals and supplies in order to pay salaries could lead to inefficiency if staff are then underused because of other shortages (for example, a surgeon who cannot perform operations because the operating-room equipment has not been maintained or because anesthetics are in short supply).

Technical efficiency

Technical efficiency means obtaining the maximum physical output from the physical inputs in pursuit of a particular goal, such as reducing deaths from HIV/AIDS by increasing the number of individuals receiving and adhering to effective antiretroviral medicines. Technical efficiency includes not only the cost-effectiveness of the medicines, but also the system that selects, procures, distributes, and dispenses the medicines to consumers.

Selection of medicines should consider the medicines' comparative efficacy and cost-effectiveness, measured in terms of the money spent in achieving an adequate and sustained suppression of the AIDS virus, for example.

In procurement, the use of competitive international tendering has advantages. As discussed in [Chapter 9](#) on medicine pricing, improving the efficiency of the tendering process can result in substantial price reductions. Determining the appropriate quantities of medicines to buy also affects efficiency: overstocking brings risks of expiry, and stockouts reduce program output and lead to expensive emergency orders.

In pharmaceutical distribution, when not enough transportation is available or vehicles are often inoperative, personnel may be underused. The same output could be achieved with fewer personnel, or output could be dramatically increased with a slightly greater expenditure on vehicle maintenance. A program manager might consider the costs and benefits of changing from using a fleet of program vehicles to contracting delivery to a commercial transportation firm in an effort to increase efficiency.

Rational use of medicines has the potential to improve efficiency; for example, prescribing excessive courses of

antibiotics is inefficient, because the same outcome could be achieved using fewer. Similarly, a subtherapeutic medicine dose fails to achieve the desired clinical outcome and wastes resources because the patient is likely to return for further treatment. Polypharmacy leads to lower rates of adherence to treatment and is inefficient; resources are consumed, but the desired clinical outcome is not achieved.

Program managers can control only some of the factors that affect technical efficiency. For example, program managers may not have control over the allocation of funds among different line items, such as personnel and fuel, making it difficult to use inputs in the most efficient combinations. Incentives and management structures are important. If a more efficient use of resources leads to tangible benefits for health workers, they are more likely to make more efficient choices. If they are penalized (for example, if underspending a budget leads to less money being allocated next year with no offsetting incentives), health workers are unlikely to behave in an efficient and cost-saving manner.

Information is important in increasing technical efficiency: managers and health care providers who have information about the costs of alternatives are more likely to make efficient use of their resources than those who do not. Formulary manuals, standard treatments, and therapeutic guidelines are intended to provide such information to health workers. Relatively simple performance indicators have been developed using information that should be available to most supply system managers; such indicators can be used to monitor supply system efficiency on a routine basis (see [Chapter 48](#)).

Health care decision makers can use information on efficiency to improve the current situation and make better plans related to performance, costs, and staff utilization. In addition, efficiency is an important economic concept because demonstrating that existing resources are being used efficiently provides powerful support to requests for additional resources. But achieving both allocative and technical efficiency depends on access to information on both costs and outcomes of competing treatment programs. Exploring the relationships between costs and benefits lies at the center of economic evaluation.

10.7 Economic evaluation of pharmaceutical products

Although concepts of efficiency are vital to all aspects of pharmaceutical management, including procurement, distribution, and dispensing, as well as to the selection of essential medicines for formularies and reimbursement lists, pharmaco-economics is defined as the analysis of the costs and benefits of medicine therapy to health care systems and society (ISPOR 2003).

The essential characteristic of pharmaco-economic analyses is that they involve *comparisons*—usually a new medicine is compared with the best existing treatment; therefore, decisions are almost always made “on the margin.” The best analyses are those that are based on high-quality clinical studies (Birkett et al. 2001).

The term *economic evaluation* refers to a set of analytical tools that can help identify which of several alternative treatments offers the greatest benefit compared with its cost. These analytical tools can help address questions such as: What medicines should be included on the formulary? What are the patient outcomes of various treatment modalities? How do two options for providing pharmacy services compare?

Four methods of economic analysis are commonly distinguished and are described here in increasing order of methodological and practical difficulty (Drummond et al. 2005).

1. *Cost-minimization analysis (CMA)*: calculating the cost of two or more alternatives that have the same outcome to identify the lowest-cost option
2. *Cost-effectiveness analysis (CEA)*: measuring both costs and benefits of alternatives to find the strategy with the best ratio of benefits, measured in therapeutic (clinical) or program effects, per money unit of expenditure
3. *Cost-utility analysis (CUA)*: same as cost-effectiveness analysis, except that benefits are measured in “utility” units, which in theory can be compared across different disease states
4. *Cost-benefit analysis (CBA)*: comparing the costs and benefits of an intervention by translating the health benefits into a monetary value, so that both costs and benefits are measured in the same unit

The distinctions among these four methods mainly concern the benefits of intervention.

Cost-minimization analysis

In cost-minimization analysis, the benefits have to be measured in the same or equivalent units, and all the alternatives considered need to produce the same quantity of benefits. The choice (which appears deceptively simple) is to identify the lowest-cost alternative, and the analysis is limited to calculation of the costs. For example, if two medicines have the same therapeutic benefits, have the same safety profile, and are of equivalent quality, the medicine with the lower cost would be selected.

In practice, CMA can be more demanding than it appears. The first challenge is to define an acceptable degree of therapeutic equivalence before comparing the costs of two regimens. Generally, *noninferiority* is the term used to define equivalence (Djulbegovic and Clarke 2001). In other words,

a new treatment should be no worse than an existing medicine. A noninferiority boundary is set during the statistical analysis, to represent the tolerable maximum level of inferiority that will be allowed (for example, 10 percent); the statistical confidence interval around the difference between the two treatments must lie below this level. The costs of the medicines can be compared on that basis. Because the costs of medicines tend to vary somewhat with dose, the doses at which the products can be considered equivalent must be determined. These equivalent-effective doses are then used to establish the relative price of the new product. The costs of administration must also be included. An oral medication replacing an intravenous form with identical efficacy and safety will have the advantage of not requiring nursing time and injection equipment.

Cost-effectiveness analysis

With cost-effectiveness analysis, the unit of output of the alternatives is the same, but the quantities of output, or effectiveness of the strategy, differ. The outcomes are often described in natural units; for instance, resolution of pneumonia or cases of malaria prevented must be consistent for the treatments being compared. CEAs of this type are useful in judging technical efficiency. Sometimes the outcome measured is deaths avoided or life years gained by the use of a new treatment compared with an existing therapy. The challenge is to identify the option with the lowest cost per unit of benefit gained. For example, different vaccination strategies (fixed point, outreach, campaign) may reach different numbers of children and have varying levels of effectiveness, but cost-effectiveness analysis can help identify the one that has the lowest cost per fully immunized child.

Cost-effectiveness must be considered alongside therapeutic effectiveness. Generally, but not always, the new treatment is considered superior to the old one. Occasionally, it is less effective but much cheaper. If the budget is fixed, purchasing the lower-cost medicine may enable more patients to be treated and more lives to be saved, although the medicine is less efficacious. When working with a fixed budget, comparing the cost-effectiveness ratios of each medicine with no treatment is important. Usually, the medicine with the lowest ratio of cost to units of health gained is preferable. If the budget is not fixed and some growth is possible, the incremental cost-effectiveness ratio, which compares the new (more effective) medicine with existing treatment, should be used to commit additional funds.

CEA's main challenge is to compare different therapies: Is 5,000 dollars per heart attack avoided or 50 dollars per symptom-free period for asthma patients a better deal? Or is spending 1,000 dollars per life-year gained by reducing disability from a stroke or 5,000 dollars per life year gained for a breast cancer survivor better? In the latter instance, although the “outcomes” seem to be the same, they are not,

Table 10-2 Using economic analysis methods to make choices

Type of analysis	Medicine therapy choice: antibiotic A versus antibiotic B for treating childhood pneumonia	Transportation scheme choice: program fleet versus contracted private firm
Cost minimization	Of two medicines with equal effectiveness, which is the least expensive?	Assuming that both options are identically effective, which is the least expensive?
Cost-effectiveness	Two medicines have different degrees of effectiveness: What is the cost per child cured using antibiotic A versus antibiotic B (allowing for different efficacy of drugs A and B)?	The two options have different performances with respect to on-time delivery: What is the cost per medicine kit delivered using program transport versus a contracted firm? (Perpetually late deliveries are factored in as a smaller level of desired output.)
Cost utility	What is the cost per QALY saved of treating childhood pneumonia with drug A versus treating tuberculosis with short-course chemotherapy? (Note: This method is controversial for comparing medicine therapies.)	Because the outcome of interest is the same in both cases (that is, medicines delivered on time), no need exists to use a specially constructed measure of output.
Cost benefit	What is the cost-benefit ratio (value of costs per value of life saved) for treating childhood pneumonia versus the cost-benefit ratio for saving lives through improved road lighting? (Note: This method is normally not used to compare alternative therapies.)	Because the outcome of interest is the same in both cases (that is, medicines delivered on time), no need exists to use a specially constructed measure of output.

because quality of life will differ between stroke and breast cancer survivors. For this reason, health economists have sought different metrics that enable them to make comparisons across different disease states.

Cost-utility analysis

Cost-utility analysis is cost-effectiveness analysis conducted with the program outcomes measured in utility units. The most common utility measures are the quality-adjusted life-year (QALY) and the disability-adjusted life-year (DALY), which is more commonly used in studying developing countries (Drummond et al. 2005).

The DALY is a measure of health outcome used to compare interventions with different types of output (Murray 1994). This approach is useful for making decisions about allocative efficiency because it enables comparisons of treatments for different conditions, such as malaria, depression, and heart disease. DALYs combine mortality and morbidity (or disability) into a single measure by weighting the life-years saved by the amount of disability associated with a specific outcome.

For example, diagnosis and treatment of African trypanosomiasis costs 15 dollars per DALY saved; treatment for zinc deficiency costs 73 dollars per DALY saved; and measles vaccination costs 4 dollars per DALY saved (Laxminarayan et al. 2006). By contrast, interventions such as cancer treatment and environmental control of dengue fever both cost thousands of dollars per DALY saved. The 1993 *World Development Report* (World Bank 1993) was the first major analysis to use this outcome measure.

QALYs are similar to DALYs in that they calculate program benefits in terms of life-years saved, except that in the

case of QALYs, the years are weighted by the “quality” of those years when they are lived in less-than-perfect health. Like DALYs, QALYs also allow comparison of interventions with different outputs. QALYs are controversial because individual qualities of life and preferences are difficult to compare. Furthermore, survey-based quality-of-life scales are not perfect measures, nor are they easily translated into QALYs.

Cost-benefit analysis

In cost-benefit analysis, both costs and outcomes are measured in financial units. Cost-benefit analysis is rarely undertaken in the health sector because of the difficulty and equity implications of assigning a monetary value to life-years saved (Drummond et al. 2005). Its main advantage is that it allows the comparison of programs with different outcomes—for example, investment in health versus investment in education.

Table 10-2 shows how each of these tools can be applied to make a range of choices, for instance, between alternative medicine therapies or alternative transportation schemes.

Steps for conducting a cost-effectiveness evaluation

Conducting a cost-effectiveness evaluation has six key steps.

Step 1. Define the objective. For example, in terms of program output—

- Which medication regimen should be the therapy of choice for the treatment of childhood pneumonia?
- What is the best approach to transporting essential medicines to health facilities?

Step 2. Enumerate the different ways to achieve the objective. For example—

- Short-course chemotherapy with more expensive medicines (option 1), versus traditional long-course chemotherapy with cheaper medicines (option 2)
- Purchase of program vehicles for delivery of medicines to health facilities (option 1) versus a contract with a private transport firm for delivery of medicines (option 2)

Step 3. Identify, measure, and value the benefits of each option. In the step 2 medicine-choice example, benefits could be measured in DALYs, which would require measures of therapeutic effectiveness and epidemiological data on the course of illness without treatment. For the transport example, an indicator of performance could be used, such as on-time delivery of pharmaceutical consignments to a health facility.

In the clinical arena, the benefits of competing treatments are usually measured in controlled clinical trials. The highest level of clinical evidence to use in economic analysis is a systematic review and meta-analysis of all available high-quality trials that compare interventions. Failure to use high-quality clinical data often leads to suboptimal pharmaco-economic analyses.

Step 4. Identify, measure, and value the costs of each option. All the inputs required for each option should be identified and the costs determined. Capital as well as recurrent costs should be included. [Box 10-1](#) lists different types of costs that should be considered (see also [Chapter 41](#)). During this process, defining a relevant timeframe for these analyses is important. For instance, the efficacy of statins in the prevention of heart attacks and strokes has to be measured over years, not weeks or months.

Step 5. Calculate and interpret the cost-effectiveness of each option. The incremental cost-effectiveness ratio is the difference in total cost between the intervention and comparison options, divided by the difference in the number of units of output. Better overall efficiency is indicated by a lower cost per unit of output.

Step 6. Perform sensitivity analysis on the conclusions. Sensitivity analysis measures how various assumptions made in the course of estimating costs and outputs affect the conclusions. Sensitivity analysis deals with uncertainty in assumptions that underlie the analysis or with problems of imprecise measurement. In practice, sensitivity analysis identifies the values or assumptions about which uncertainty exists; determines their likely range of values; and recalculates study results based on a combination of the “best guess,” most conservative, and least conservative estimates of these key values. The question of interest is whether the conclusions of the analysis would be changed with these extreme values.

Although certain costs or benefits cannot be measured accurately, it may be possible to show that the results of the analysis do not change over any reasonable range of cost or benefit. Alternatively, the difficulties in measurement may indicate that the results are very sensitive to error in measurement and that caution should be used in interpreting the results of the study. Sensitivity analysis is easy to do and is essential to properly use and defend study results.

Conducting pharmaco-economic evaluations

As noted, conducting full pharmaco-economic analyses that deal adequately with all of the sources of uncertainty is very demanding of time and resources. For the analyses to be valid and error-free, they must draw on the skills of epidemiologists, biostatisticians, and economists. Given the need to integrate a variety of information of varying quality, pharmaco-economic analysis can be prone to errors—and even manipulation—that can make any product look more economically attractive than it really is. To guard against this possibility, systematic checklists (see Drummond et al. 2005) are helpful for critical review. The principles of economic analysis are best understood by further reading and through exercises that involve the calculation and interpretation of cost-effectiveness ratios (see References

Box 10-1 Types of costs

Recurrent cost: The cost of goods that are consumed or used up over the course of a year (for example, staff, pharmaceuticals, fuel).

Capital cost: The cost of goods that are intended to last for longer than a year (such as buildings, vehicles, medical equipment).

Annualized capital cost: Capital cost per year of useful life for a building, vehicle, or other capital item.

Fixed cost: Cost that does not change with the level of output (for example, building, equipment, salaries to a certain extent).

Variable cost: Cost that changes, depending on the amount of services delivered (for instance, pharmaceuticals and supplies).

Total cost: The sum of recurrent costs and annualized capital costs.

Average cost per unit: Total cost divided by the number of units produced (for example, cost per patient treated, per immunization given, per cure dispensed).

Marginal cost: The cost of producing or providing one additional unit.

SUMMARY

Medicines save lives and improve health, but they are costly. Nevertheless, they are necessary to make effective use of staff and other health resources. Financial sustainability requires establishing a balance among the demand for medicines, the cost of meeting this demand, and the available resources. Otherwise, shortages result and quality of care declines.

A pharmaceutical financing strategy should begin with efforts to make better use of available funds. If improved efficiency in selection, procurement, distribution, and use of medicines does not create the necessary balance, options for increasing funding include making the case for greater government funding of medicines, introducing or strengthening health insurance coverage for medicines, or obtaining donor assistance.

In recent years, the increase in the international community's commitment to global health and access to pharmaceuticals has resulted in global health initiatives, private foundations, and public-private partnerships playing much larger roles in financing the health sector in developing countries. However, many countries have a hard time absorbing additional resources because of a lack of human and infrastructure capacity, and donor funding presents problems because of its unpredictability, making planning difficult for countries.

Globally, 57 percent of health care is publicly financed, with the share increasing with national income. For health care, and especially for medicines, private spending usually represents a higher share of health financing in lower-income countries. Expanding private and nongovernmental organization (NGO) health services, including providing essential medicines, can shift demand away from overstretched public resources. But quality of care and equity must be ensured.

Public financing through national and local government budgets is a major but sometimes inadequate source of financing for essential pharmaceuticals. The case for public financing of pharmaceuticals can be strengthened through better quantification of medicine needs, per capita pharmaceutical budgets, demonstration of medicines' effect on health, recognition of political benefits, improved management, expenditure trend

analysis, and comparative expenditure analysis. Efforts should be made to ensure that available public resources are targeted to those most in need.

User charges may exist in the form of government revolving drug funds (RDFs), community medicine schemes, and retail purchase of medicines. Experience indicates that user charges pose many difficulties, but countries need to have an alternative funding strategy in place to make up the difference before discontinuing user-fee programs.

Health insurance covers a small but growing portion of the population in most developing countries. Important elements of insurance include risk sharing and prepayment. Plans vary in the extent of and mechanisms for insurance coverage for medicines. National social insurance schemes, private voluntary insurance, and community prepayment schemes can increase access to essential medicines. Insurance programs can be designed to encourage cost control and rational medicine use.

Voluntary and other local financing can contribute to improving the overall health care and pharmaceutical financing situation. Donor financing and development loans can help a country develop more efficient pharmaceutical supply systems and alternative financing approaches. For the poorest countries, some external financing for medicines may be needed to ensure universal access to essential medicines. And countries that are scaling up access to antiretroviral therapy for HIV/AIDS or changing first-line malaria treatment to artemisinin-based combinations must rely on external funders, such as the Global Fund to Fight AIDS, Tuberculosis and Malaria (Global Fund) and the U.S. President's Emergency Plan for AIDS Relief.

Financing mechanisms can be compared in terms of access to medicines, rational medicine use, efficiency, equity, sustainability, and administrative requirements. Financial sustainability may require a pluralistic approach in which needs are met through a combination of financing mechanisms, and no one strategy will be applicable to all countries.

11.1 Why pharmaceutical financing is important

In 2000, at the United Nations Millennium Summit, world leaders agreed to a set of measurable targets for combating poverty, hunger, disease, illiteracy, environmental degradation, and discrimination against women. Known as the Millennium Development Goals (MDGs), they provide a framework for the United Nations system and other global and national stakeholders and donors to work collaboratively (UN Millennium Project 2005). Because three of the eight goals concern health, the MDGs have put financing for health systems and pharmaceuticals in a brighter spotlight. In addition, large global health initiatives and increased spending by private sources, such as the Bill & Melinda Gates Foundation, are making unprecedented funds available for health systems in general and pharmaceuticals in particular.

Besides the major role medicines play in the MDGs and other large global health initiatives, financing of pharmaceuticals is a critical issue for several reasons. First, because medicines save lives and improve health, pharmaceutical financing must ensure access to essential medicines for all segments of the population. Second, medicines are costly. For most ministries of health, medicines represent the largest expenditure after staff salaries. Most low-income households spend over half of their health expenditures on medicines, and in some countries, over 80 percent of a household's health-related spending is on medicines (Hammond et al. 2007). In contrast, medicines commonly represent about 20 percent of total public and private health expenditures in developing countries (WHO 2004c). Third, inadequate funding for medicines means that expenditures for staff salaries and other health care costs may be used inefficiently or simply wasted.

This chapter considers the factors that determine financial sustainability, sources of health care financing, and strategies to achieve financial sustainability of pharmaceutical supplies.

11.2 Balancing the financial sustainability equation

Financial sustainability, as illustrated in [Figure 11-1](#), is achieved only when resources are in balance with costs and are sufficient to support a basic quality of care for a given level of health care demand. If demand for medicines exceeds available resources, the health system is left with only four options—

1. Improve efficiency.
2. Reduce demand.

3. Increase financial resources.
4. Accept a decline in quality of care.

In most settings, promising high-quality services and constant availability of essential medicines without also ensuring a high level of efficiency, achieving adequate financing, and controlling demand for medicines defies economic reality.

The same financial sustainability equation applies to NGOs. When demand surpasses available resources, they face the same choices: improve efficiency, control demand, increase financial resources, or accept a decline in quality of care.

For all sectors—public, for-profit private, and not-for-profit private—pharmaceutical financing should not be approached simply as a question of where do we get the money? It must be approached in terms of methods to improve efficiency and to ensure that demand is appropriate.

Improving efficiency

Two broad categories of efficiency were defined in [Chapter 10](#): allocative and technical efficiency. *Allocative efficiency* applies to the distribution of services within the population. Spending the majority of a country's pharmaceutical budget on essential medicines for primary health care, rather than on specialized medicines for national referral hospitals, is likely to save more lives and thereby results in allocative efficiency.

Technical efficiency is achieved if resources are used to produce a given output at the lowest possible cost or to produce greater outputs for the same cost. Pharmaceutical financing decisions are concerned mostly with technical efficiency, which has two components: therapeutic efficiency (improved selection and use) and operational efficiency (improved management of procurement and distribution).

Efforts to balance the financial sustainability equation should always emphasize finding ways to improve efficiency.

Controlling demand

Because the demand for health care services may be virtually unlimited, something always controls demand. In practice, health systems control demand—by intent or by neglect—through combinations of six possible measures—

1. Increase cost to the patient.
2. Impose rationing or other administrative controls.
3. Provide attractive alternatives.
4. Increase waiting time.
5. Decrease quality of services.
6. Provide targeted education.

Figure 11-1 Financial sustainability equation

Some health services unintentionally control demand through a combination of long waiting times and poor quality (medicine shortages, for example). In the worst examples of user-fee programs, fees are introduced without quality improvements. Not surprisingly, increased cost—added to long waiting times and low quality—further reduces use. User fees can both increase financial resources and reduce demand, but measures needed to ensure access for the poor are difficult to implement successfully.

Increasing financial resources

The components of financial sustainability can be brought into better balance by increasing financial resources. The remainder of this chapter considers ways to maintain or increase financial resources through public financing, user charges, health insurance, community and other voluntary financing, donor financing, and development loans.

11.3 Health and pharmaceutical financing

Pharmaceutical financing must be viewed in the overall context of health financing. Funding for recurrent operating costs and long-term development costs of health services comes from public sources (national and local government budgets and national social health insurance); private sources (direct payment by patients, private health insurance, employers, and NGOs); and external development aid.

Health expenditures among countries

The relative importance of each funding source varies dramatically among regions and among countries within a region and evolves over time. Health expenditure data categorized by region and income level are shown in [Table 11-1](#). Data in this section are quoted from the World Health Organization (WHO 2009b), unless otherwise noted. Several observations can be made about levels and sources of financing for health.

Health expenditures vary widely among regions and countries. Total per capita health expenditures vary ten-fold among regions. Among developing countries, annual health expenditures vary from less than 10 U.S. dollars (USD) per capita in Madagascar, Myanmar, Niger, and several other countries to more than USD 100 per capita in several countries in Latin America, the Caribbean, and southern Africa.

Total health spending depends on economic output, but some countries spend more than others. Health expenditures are directly related to national economic output as measured by gross domestic product (GDP). Developing-country health spending is lower than that of developed countries (with a global average of 8.7 percent of GDP), but some developing countries spend relatively less on health (for example, 2.1 percent of GDP for Congo and 2.5 percent for Indonesia), and others spend more (for example, 7.0 percent for Uganda and 6.4 percent for Bolivia).

As a share of the total, public-sector spending increases as national incomes rise. Globally, health expenditures are

about 57 percent public and 42 percent private in origin. Excluding the United States (where private spending is 54 percent of the total spent on health), about 70 percent of health costs are publicly supported in established market economies. But in developing countries, private spending (generally out of pocket) is a higher proportion, rising to about 80 percent in the Lao People's Democratic Republic and about 86 percent in Guinea. In addition, low-income countries have more difficulty collecting revenue; for example, in the early 2000s, high-income countries collected about 32 percent of their GDP in revenue (for example, taxes), compared with an average of 18 percent for low-income countries (Schieber et al. 2006).

Developing countries devote a lower share of public spending to health. Total government spending as a share of GDP is higher among high-income countries. Lower public health spending in developing countries reflects the lower share of health expenditures in the national budget: about 15 percent of government spending in Europe is on health, whereas in Africa, the share is close to 9 percent and less than 5 percent in Southeast Asia. However, governments in low-income countries recognize the need to devote more resources to public health. African leaders vowed to increase spending to 15 percent of their overall budgets in the 2001 Abuja Declaration on HIV/AIDS, Tuberculosis, and Other Related Infectious Diseases (Schieber et al. 2006); however, as mentioned, collecting the needed revenue is challenging.

The combined result of lower proportional allocations to health and lower overall income is that government spending on health in low-income countries is roughly USD 8 per capita, compared with USD 225 in the upper-middle-income countries and almost USD 2,500 in high-income countries.

Developing countries have a high disease burden but low health expenditures. Developing countries have over 80 percent of the world's population and carry 90 percent of the global disease burden, but they spend only about 12 percent of the global total on health (Lopez et al. 2006). In contrast, the thirty member countries of the Organisation for Economic Co-operation and Development make up less than 20 percent of the world's population but spend 90 percent of the world's resources on health.

Insurance coverage increases with income. People in most high-income countries are covered by some form of public or private health insurance; however, the median coverage is only 35 percent in Latin America, 10 percent in Asia, and 8 percent in Africa (WHO 2004c). This differential coverage creates significant variation in out-of-pocket health spending, which is 90 percent of total private health spending in low-income countries, compared with 15 percent in high-income countries (Schieber et al. 2007.)

Foreign aid is a major contributor in certain regions. Foreign sources account for more than 20 percent of health expenditures in almost half of the countries in the WHO's African region (Kirigia and Diarra-Nama 2008). Moreover,

Table 11-2 Pharmaceutical expenditures by country income, 2000

although many countries have recently seen large increases from disease-focused funding and global health initiatives, the United Nations Millennium Project estimates that an additional USD 74 billion will be needed by 2015 to meet the MDGs (Schieber et al. 2006).

Private health expenditures in Table 11-1 include those derived from voluntary, religious, and other NGOs as well as spending by individuals and private companies. NGOs play an important role in financing and providing health services in many countries.

Thus, the relative contributions of public and private spending, external aid, and health insurance differ considerably among regions and countries. Level of economic development has a significant influence. But national policy, commitment to health, political and historical factors, and other influences result in substantial differences among countries within the same region and countries at similar levels of development.

Pharmaceutical expenditures among countries

Data on pharmaceutical expenditures are much less complete than data on overall health expenditures. Regional pharmaceutical expenditures as of 2000 based on WHO (2004c) figures are shown in Table 11-2, from which the following observations can be made—

Per capita medicine consumption varies widely among regions and countries. Pharmaceutical expenditures vary greatly among regions. Like total per capita health expenditures, pharmaceutical expenditures vary up to tenfold among countries within a region.

Spending on pharmaceuticals depends on country income level. Spending on pharmaceuticals is related to the country's income level. In 2000, high-income countries accounted for almost 80 percent of the global expenditures on pharmaceuticals, whereas low-income countries accounted for only about 2 percent. The share of high-income countries decreased from 1990, because middle-income countries increased their share from 17.1 to 18.8 percent.

Private spending represents a greater share of total spending on pharmaceuticals in developing countries. Among established market economies, private spending on medicines averages over 40 percent of total pharmaceutical spending; the remaining pharmaceutical costs are paid through public budgets and social insurance. In contrast, less than one-third of pharmaceutical expenditures is publicly funded in developing countries for which estimates are available. In many countries of Latin America and Asia, a large proportion of pharmaceutical expenditures are privately financed. Exceptions include countries such as Papua New Guinea and island nations in the South Pacific, where private-sector coverage is low and public supply predominates.

Spending on pharmaceuticals accounts for a greater share of total health expenditures in lower-income countries.

In high-income countries, pharmaceuticals account for an average of 9.8 percent of total health expenditures. In low-income countries, however, the proportion of government spending dedicated to pharmaceuticals has significantly decreased: in 1990, the average was 21.5 percent, whereas in 2000, the figure was down to 16 percent. Countries most affected included those that carried a high debt burden, major disease burdens, such as HIV/AIDS epidemics, or both.

Therefore, overall spending on pharmaceuticals is related to economic development. In lower-income countries, pharmaceuticals consume a higher share of total health expenditures, although large global initiatives, such as the Global Fund, are accounting for larger shares of pharmaceutical spending in select countries. Private expenditures play a major role in overall pharmaceutical financing.

Financing options for essential medicines

Funding options for pharmaceuticals are essentially the same as those for health care in general: government revenues (national and local); direct payment by patients (fee for service); health insurance (national social insurance or voluntary insurance); community, employer, and other vol-

Box 11-1 Funding mechanisms for essential medicines

Public financing (government budgets)

- National government
- Local government

User fees

- Public-sector RDFs
- Community pharmaceutical schemes
- Direct private medicine purchases (out-of-pocket purchases)

Health insurance (prepaid health schemes)

- Social insurance (compulsory health insurance or social security)
- Private insurance (indemnity insurance that is voluntary or through an employer)
- Community health insurance
- Health savings accounts

Voluntary and other local financing

- Private voluntary (NGOs)
- Voluntary community mechanisms
- Cooperatives
- Employer-provided health care

Donor financing

- Bilateral grants
- Multilateral grants
- Private foundations
- Global health initiatives

Development loans

- World Bank
- Regional development banks

untary local financing; donor financing; and development loans (see [Box 11-1](#)).

Financing arrangements affect the relationships among patients, providers, and the payers or financiers of health services ([Figure 11-2](#)). With direct purchase of medicines by consumers, for example, the relationship is primarily between the patient, who is paying for the medicines, and the pharmacy, which is providing the medicines. The government's role is to regulate pharmaceutical quality and sales outlets.

With managed care, the provider and payer (insurer) are closely linked, if not a single organization. Although this arrangement may help control health care costs, it creates a potential conflict of interest between cost control and quality of care. Public supervision and competition are important to promote quality of care.

With each financing arrangement, the role of the government is different. Governments must adapt policies as the mix of financing arrangements in the country changes.

11.4 Private-sector financing: medicine sales and user fees

The most common form of pharmaceutical sale is the direct purchase of medicines by consumers from commercial pharmacies, licensed and unlicensed drug sellers, and other retail medicine outlets. Excluding high- and middle-income countries with large social or private health insurance coverage, retail purchase is the most common source of medicines.

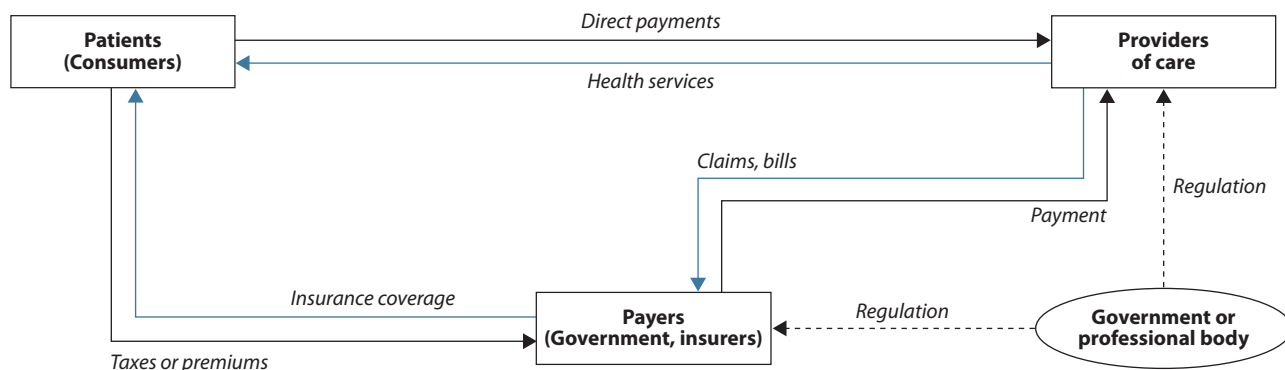

For government, NGO, or community health care programs, user fees for medicines are often part of an RDF or community pharmaceutical scheme. In an RDF, revenues from medicine fees are used to replenish pharmaceutical supplies. Many different forms of RDFs exist, but the common element is a direct link between fees charged and medicines dispensed. Often, an RDF is simply one component of a comprehensive system of fees for publicly provided health services, which may include fees for outpatient consultation, laboratory investigations, and inpatient care. Over the past decade, the debate over user fees has intensified within the context of a global call for increased access to medicines: many in the international health community are calling for all user fees to be abolished; however, eliminating existing user fees in resource-limited countries does not necessarily improve access to medicines and services unless sufficient resources are available to take up the slack and ensure equitable access.

Although many countries offer free medicines for targeted populations (most commonly for tuberculosis or indigent patients), few countries offer all medicines at no cost through their public health facilities (see [Table 11-3](#)).

In the context of community health initiatives (see [Chapter 31](#)), community medicine-sales schemes often have broader objectives. These may include furthering health education; providing preventive services such as immunization; and raising sufficient revenue from medicine fees to help finance salaries, medical supplies, or other costs.

Public-sector RDFs and community medicine-sales schemes are distinguished from private medicine outlets by

Figure 11-2 Relationships in health care financing

Source: Adapted from WHO 1993.

an emphasis on providing essential medicines, a concern with affordability, and a direct connection between diagnosis by a health worker and appropriate medicine treatment. Proponents of user charges for health care believe the following—

- Revenue can be raised by user fees.
- Medicine availability and the quality of care are improved.
- Equity is promoted because limited public resources can then be targeted to those most in need.
- Decentralization is reinforced through local control of resources.
- Efficiency is fostered by fees, which reinforce the use of local rather than referral services.

In contrast, opponents of user fees believe as follows—

- Net revenue collection is often very low, considering the additional administrative costs of collecting fees.
- Medicine availability and quality of care often show no improvement.
- User charges replace, rather than supplement, government funding.
- People are dissuaded from seeking essential health care, especially the very poor.
- Incentives are created for overprescribing.

Considerable experience with RDFs and broader user-fee programs provides examples that support both proponents and opponents of user charges. Programs that have implemented high fees with no preparation of the public and little improvement in quality have seen significant decreases in use; programs designed with little attention to management and accounting systems have seen substantial abuse and little revenue compared with the cost of fee collection; RDFs established without a reliable source of low-

cost medicines have quickly ceased to revolve; and some schemes with medicine charges have had problems with overprescribing.

Chapter 13 provides additional information on RDFs. In summary, RDFs and community pharmaceutical schemes are not easy to implement. Many factors can undermine their intended benefits, and large-scale successes in government health services are limited.

11.5 Public financing through government budgets

Health officials and managers of essential medicines programs argue for increasing expenditures for pharmaceuticals, sometimes without appreciating the dynamics of public expenditure. Public financing of pharmaceuticals can occur through national and local government budgets or through compulsory programs such as social security and national social insurance schemes. This discussion focuses on central government funding of pharmaceuticals; public funding through insurance is covered in Chapter 12.

Determinants of public pharmaceutical expenditures

Actual public expenditures for pharmaceuticals are determined by a combination of economic factors, national budget decisions, and internal decisions by health ministries. Major factors include—

- National economic output (GDP)
- The share of GDP collected in taxes as revenue for government expenditures (average of about 15 percent in low- and lower-middle-income countries)
- The share of government spending devoted to health (5 to 10 percent in most developing countries)
- The relative share of government health spending

Table 11-3 Medicines provided at no cost in public health facilities, 2003

Types of medicines	Country income level					
	Low		Middle		High	
	Number of countries	Percentage of countries	Number of countries	Percentage of countries	Number of countries	Percentage of countries

^a Inconsistencies in reporting noted.

devoted to recurrent operating expenses compared to long-term development

- The relative share of recurrent health expenditures for salaries, medicines, utilities, supplies, and other expenses
- Variations in exchange rates, which determine the international purchasing power of local currency allocations
- Unexpected fluctuations in the national economy caused by devaluations, global changes in commodity prices, political factors, or other events
- The level of corruption in the health and pharmaceutical sector (an estimated 10 to 25 percent of public expenditure in the health sector is lost to corruption; WHO 2009a)

Government economic and development policies influence GDP growth and, to an even greater extent, the share of GDP collected as revenue for government operations. Within the government, resource allocation decisions result from a combination of historical precedent, local political forces, external pressures such as those from donors or development banks, and systematic program planning. Development banks have instituted debt-relief initiatives (Chapter 14), but those measures do not necessarily result in more resources or make reallocation of existing country resources to health easier (Gottret and Schieber 2006).

Arguments for expenditures on essential medicines

The case for increasing expenditures on essential medicines can be made in the ministry of health or the ministry of

finance. Obtaining a higher share of the budget for pharmaceuticals requires changing the balance between staff and nonstaff expenditures or between curative health services that depend on essential medicines and preventive services such as immunization and health education. Managers must be prepared to respond to the argument that, with limited resources, expenditures on preventive services are more cost-effective than pharmaceutical treatment, even at the primary level.

In addition to demands from the health sector, public treasuries are faced with demands from education, other social services, industry, agriculture, national development, and defense. Because pharmaceuticals often constitute such a large and visible share of health expenses, the case for increased expenditure on pharmaceuticals can sometimes be taken directly to the ministry of finance.

Arguments and approaches that can be used to support central government spending on essential medicines include—

Health impact: As noted in Chapter 1, pharmaceuticals are a highly cost-effective component of health care. This point is sometimes lost when policy makers focus on symptomatic pharmaceutical treatments. The case for pharmaceutical allocations is strengthened by emphasizing the vital role of medicines in reducing morbidity and mortality from acute respiratory infection, diarrhea, HIV/AIDS, malaria, tuberculosis, and other common killers. For example, appropriate treatment of sexually transmitted infection greatly reduces transmission of HIV/AIDS, and simple prenatal iron-folate preparations reduce maternal and neonatal morbidity.

Quantification of medicine needs: Systematic documentation of specific medicine needs has convinced ministries in some countries to increase allocations for essential medicines (see [Chapter 20](#)).

Expenditure trend analysis: Budget allocations are typically based on a percentage increase in the budget from the previous year. This method may be reasonable for salaries and local currency expenses, but because of the high foreign exchange component for pharmaceuticals, the last-year-plus approach may lead to a steady decline in purchasing power over time. Appropriate adjustments for both inflation and exchange rates (see [Chapter 41](#)) are needed simply to purchase the same quantities of pharmaceuticals.

Budget gap analysis: Combining quantification of pharmaceutical needs and expenditure trends reveals any gap between need and historical budgets and expenditures.

Per capita pharmaceutical budgets: Population size and patient utilization rates for public facilities are major determinants of pharmaceutical requirements. Per capita pharmaceutical budgets establish a fixed amount per person per year—for example, USD 0.50 per capita. Each year, the per capita amount is adjusted for purchasing power (inflation and exchange rate fluctuations), and the total pharmaceutical budget is calculated by multiplying the adjusted per capita figure by the current population estimate.

Effect on use: When medicines are out of stock, patient attendance rates drop, reducing the use and effect of all health services.

Political visibility: The public often equates pharmaceutical availability at government health facilities with quality of services. Pharmaceutical shortages make for bad press; an adequate supply of medicines makes for good press.

Transparency assessment: Countries can assess the level of transparency and potential vulnerability to corruption of some key components in medicine procurement. WHO suggests that the national assessment be carried out by independent national investigators using the standardized WHO assessment instrument (WHO/EMP/MAR 2009). Results can provide a basis for developing and institutionalizing a national infrastructure of transparent procedures and ethical practices that by addressing corruption can decrease the loss of health resources available for pharmaceuticals and boost public trust in the health system.

Improved management: Central pharmaceutical supply units sometimes have a history of inefficiency and susceptibility to influence. Restructuring central pharmaceutical supply services, improving management, and strengthening accounting control can help convince officials to increase government pharmaceutical allocations.

Comparative expenditure analysis: Measured in absolute or percentage terms, some governments spend much less on

essential medicines than others. Relevant regional comparisons by ministry officials and essential medicines program managers may help strengthen the case in countries that are underspending on pharmaceuticals relative to other countries.

Program managers should carefully consider which of the preceding approaches, adapted to the local situation, will be most convincing in their own circumstances.

Management of public pharmaceutical expenditures

Securing an adequate budget for essential medicines is important, but proper financial management is also necessary. Common problems include difficulty gaining access to budgeted amounts, often due to shortfalls in government revenues; inability to spend budgeted amounts as a result of delays in the procurement process; increasing the transparency of the pharmaceutical and distribution process; and difficulty obtaining adequate foreign exchange, even if sufficient local funds are available. Although developing countries are generally moving toward decentralizing their health systems, this process has been slow to include pharmaceutical financing (Enemark et al. 2005).

Financial planning and management are discussed in [Chapter 41](#). Problems of disbursement of government funds and foreign exchange may be reduced with autonomous central supply agencies (see [Chapter 8](#)).

11.6 Health insurance

Decisions that affect the availability of health insurance in a country are important to all aspects of health service delivery but are largely outside the control of national medicine policies and essential medicines programs.

WHO recommends that countries include a prepayment mechanism as part of a health care financing strategy with a goal of achieving universal health care coverage (WHO 2005c). Therefore, as insurance assumes a greater role in health care in many countries, understanding health financing, and specifically insurance concepts, becomes increasingly important.

Insurance concepts

The basic purpose of insurance is risk sharing. If an individual suffers serious illness, the cost of treatment can pose a large financial hardship. So individuals find sharing the risk through regular payment of insurance premiums worthwhile to protect themselves from ever having to pay the full cost of a catastrophic illness. Insurance spreads the burden of payment for illness among all the members of the scheme whether they are ill or healthy, poor or not.

In principle, risk sharing through insurance is most worthwhile when the event insured against is largely unpredictable, infrequent, costly as well as unwanted, unplanned, and uncontrollable by the insured. These principles apply most clearly to life, fire, and car insurance. However, applying this traditional view of insurance to medical care presents some difficulties: people can control some aspects of use; some services are low cost; some conditions are frequently or continuously experienced (for example, chronic illness); illness is difficult in some cases to define; people sometimes want to incur the hazard (for example, pregnancy); and the availability of insurance increases the use of services. Despite these difficulties, the concept of risk sharing through insurance has become highly developed in the health sector. Four categories of health insurance can be described—

1. *Social health insurance*: The most typical understanding of social health insurance is that membership is compulsory for a designated population; financial contributions into the system, which are often deducted directly from wages, link to the receipt of benefits; cross-subsidization occurs between high- and low-risk groups and high- and low-income groups; and management usually has some degree of independence from the government.
2. *Private health insurance*: Voluntary private indemnity insurance is provided through employers, mutual societies or cooperatives, or directly by companies. Hospital and physician services are usually covered, but limited or no benefits may be available for preventive services, primary care, or outpatient medicines. Voluntary health insurance contributes to less than 5 percent of the health expenditures in developing countries and usually supplements care for middle- and high-income sectors (Gottret and Schieber 2006).
3. *Community prepaid schemes*: In many countries in Asia, Africa, and Latin America, prepayment plans based on the concept of pooling risk and resources have been developed for rural populations, groups in informal employment, or others without access to other health insurance. Such schemes are based on community affiliation, and the community is highly involved in managing the system. However, evidence suggests that most community-based systems cover a small percentage of people and do not reach the poorest members of the community (Schieber et al. 2006).
4. *Health or medical savings accounts*: Not strictly a form of insurance, medical savings accounts encourage individuals, often by providing tax advantages or subsidies, to save for the expected costs of medical care, enlist health care consumers in controlling costs, and mobilize additional funds for health systems. Only a few countries, including China, Singapore, and the United States, use the concept of health savings accounts.

Insurance systems face several problems that can undermine the potential benefits of prepayment and risk sharing—

Moral hazard: When members of a health insurance scheme use services or consume medicines more frequently than if they were not insured, the phenomenon is called “moral hazard.” Deductibles and co-payments are commonly used to avert this problem.

Adverse selection: This term describes the tendency for people at greatest health risk and people with chronic illnesses to join voluntary insurance programs, whereas the healthiest people, whose premiums should be used to pay the bills of the sicker members, avoid joining.

Skimming: This problem occurs when insurers use various screening measures to avoid insuring people at greatest health risk (and therefore greatest expense to them). Skimming reduces the equity benefits of insurance by excluding those who are most in need.

Cost escalation: Rising costs can result from improvements in or greater use of technology, increased use (greater demand caused by insurance coverage), and increases of both the population in general and older populations.

In addition to these problems, insurers, particularly in developing countries, frequently have to deal with the public’s and health providers’ lack of understanding of the insurance concept. Members may think that premiums are like deposits in a savings account, which leads to unrealistic demands that everyone receive at least as much as he or she has paid in. Insurance is not sustainable in this environment, because no risk sharing occurs. Other members may avoid using their insurance because they believe that they can claim only as much as they have contributed in premiums. Considerable effort may be needed to educate members, the general public, and health providers.

Many countries see the initiation or promotion of one or more insurance schemes as a way to address health financing issues. Yet the complexity of the issues involved is often poorly understood. Ideally, insurance schemes should be designed in the context of an overall health policy and health financing strategy. Issues to address when designing a health insurance scheme include policy objectives, population coverage, benefits to be included (outpatient, inpatient, medicines, and so forth), organization of health services, premium calculation and payment mechanisms, utilization and cost-control measures, and administrative arrangements.

Provision of pharmaceutical benefits

Should social health insurance, private health insurance, or community prepaid health care schemes include pharmaceuticals in their list of benefits? At least three strong arguments favor including medicines in insurance schemes.

First, pharmaceuticals are an essential component of modern health care. Second, early treatment of acute illnesses such as malaria and treatment of chronic illnesses such as diabetes can reduce costly care for complications and hospitalizations. Third, because medicines make up such a large share of household health costs in many countries, their inclusion in an insurance program will make the program more acceptable and desirable.

[Chapter 12](#) discusses health financing through insurance in detail.

11.7 Voluntary and other local financing

The cost of providing health care, including essential medicines, may be supported by a variety of community, employer, or other local financing sources.

NGOs play a significant role in the health services of some countries. NGOs often attract foreign and local donations of pharmaceuticals, medical supplies, equipment, and cash. Direct user charges often provide the major share of financing for these services, and markups on pharmaceuticals often subsidize salaries, immunizations, or other NGO costs.

NGOs that are able to provide significant amounts of health care and remain financially viable help balance the overall national sustainability equation (see [Figure 11-1](#)). Thus, as described in [Chapter 8](#), facilitating NGOs' efforts to provide essential medicines as part of their overall package of services is in the interest of governments.

Aside from community pharmaceutical schemes and other Bamako Initiative-type programs, a host of voluntary community mechanisms exists in different countries to help support local health services (see [Chapter 31](#)). In some countries, villages maintain sick funds to pay the health costs, including medicines, of the poorest members of the village. Monies come from periodic assessments or special fund-raising events. Aside from structured insurance-like schemes, however, informal community fund-raising has not been able to sustain the supply of medicines for entire communities.

In many countries, some private companies and cooperative societies (coffee growers or mining companies, for example) provide health care for employees or members by maintaining a company health service, by reimbursing local private health providers ("self-insurance"), or by contributing to private insurance for employees. Companies may also work with local government health facilities, supplementing government funding with company funding for medicines, medical supplies, or other expenses.

Such arrangements also help balance the financial sustainability equation. They should be supported with information about the essential medicines concept, with copies of the national essential medicines list and standard treatment

guidelines, and perhaps, on a selective basis, with access to public supply services.

11.8 Donor financing and development loans

As mentioned previously, the landscape of donor development assistance has been changing dramatically. Traditionally, donor assistance has come from multilateral institutions such as WHO, the United Nations Children's Fund, and development banks; from bilateral arrangements with donor governments; or from charitable organizations, other NGOs, and foundations. In recent years, the international community's commitment to global health and access to pharmaceuticals has increased—almost fourfold from 1990 to 2007 (Ravishankar et al. 2009). As a result, in addition to traditional sources of funding from bilateral and multilateral institutions, global health initiatives, private foundations, and public-private partnerships are playing much larger roles as resources to improve health in developing countries; for example, global health initiative resources have contributed to an aggregate increase in overall health financing (WHO Maximizing Positive Synergies Collaborative Group et al. 2009). Because funding for health comes from out-of-pocket sources in many developing countries, donors are being called on to finance health system scale-up to reach the MDGs.

Many developing countries have a hard time absorbing additional resources, however, because of a lack of human and infrastructural capacity, and donor funding presents problems because of its unpredictability, making planning difficult for countries (Hecht and Shah 2006). Funding that goes through a country's administrative structure rather than through independent initiatives can help build national financial capacity (Hecht and Shah 2006).

Development assistance has typically been targeted toward long-term health-sector development, often concentrating on specific areas such as primary health care, essential medicines, or immunization. Since the late 1990s, donor funding has been directed more toward the entire health sector as part of a sector-wide approach to aid or toward the national government budget instead of toward specific programs or interventions, which means that health program managers may have to take additional steps to get access to funding for specific health programs or pharmaceuticals. In addition, development banks now require countries to use poverty reduction strategy papers as a mechanism to coordinate funding in a way that contributes to an overall development strategy. [Chapter 14](#) has more information.

Multilateral and bilateral organizations generally do not support recurrent costs for personnel, regular supplies of essential medicines, and other operating costs. International and local religious organizations and NGOs have supported recurrent costs, but such funding has become more difficult

to obtain. Loans may be used for the long-term development of health care systems, human resources, and physical infrastructure. They may provide working capital to establish an RDF. But loans generally should not be used to finance the current cost of personnel, medicines, medical supplies, or other routine operating expenses.

For essential medicines, donor assistance has been used effectively in many countries to provide short- and long-term staff training, to develop and implement national medicine policies, to improve storage and transport systems, to improve supply management, to promote rational medicine use, and to strengthen pharmaceutical regulatory and quality assurance capacity. In addition, large initiatives, such as the U.S. President's Emergency Plan for AIDS Relief and the Global Fund, have provided resources to introduce and scale-up antiretroviral treatment programs, including procuring antiretrovirals, and to roll out artemisinin-based combination therapies for malaria. With an increasing global emphasis on strengthening health systems, more funding is available for long-term initiatives that will use systems strengthening as a way to increase access to medicines and commodities; for example, the GAVI Alliance has an innovative grant program designed to help countries clear health system bottlenecks that decrease immunization coverage, such as work force, management, and supply chain issues (WHO 2007). The grant funding is contingent on meeting performance outcomes.

In the poorest countries—with minimal foreign exchange earnings, limited cash income among the population, and no local production capacity—combined public and private resources may be insufficient to provide all essential medicines needs, even with the best selection, procurement, distribution, and use of medicines, especially in those countries that have a high HIV/AIDS or drug-resistant malaria burden. For such countries, outside assistance may be needed to fund some basic essential medicines requirements and is certainly needed to fund expensive antiretrovirals and new, expensive antimalarials.

Nevertheless, long-term human, financial, and institutional sustainability is an essential consideration in all development projects. Intensive financial support and large teams of advisers may achieve short-term success, but to achieve sustained success, a realistic transition to local staffing and financing must be planned from the outset.

Finally, governments can coordinate assistance from donors by establishing national health and pharmaceutical policies, by inviting donors to participate in the development of a master plan as a framework for action, and by convening regular donor coordination meetings (see [Chapter 14](#)). Sector-wide approaches, medium-term expenditure frameworks, and poverty reduction strategy papers help provide countries a framework for development planning, but donors need to harmonize procedures and reporting requirements to help countries handle mul-

iple external funding streams. Also, donors are encouraged to make long-term commitments to assistance in the form of predictable on-budget financing (Hecht and Shah 2006).

11.9 Comparing financing mechanisms

Few health systems rely on a single funding mechanism. Political, economic, and social factors influence options for health financing. But financing mechanisms should meet certain stated policy objectives, and discussions about financing should be informed by a clear understanding of the choices.

Criteria for evaluating financing mechanisms

Access to medicines, rational medicine use, efficiency, equity, sustainability, and feasibility are among the most common and important criteria for evaluating funding mechanisms for pharmaceuticals.

Access to medicines: Are the availability and affordability of medicines improved? With user charges, for example, medicines may become more available but less affordable. In the end, are more people receiving the essential medicines they need?

Rational medicine use: Does the financing mechanism create incentives for overuse, underuse, or misuse of medicines? Patient demand is high when medicines are free, but provider-induced demand may be high if revenue from medicine charges is used for staff salaries. An insurance plan may achieve a uniquely effective balance if it stimulates patient demand by expanding access, uses cost controls to contain demand, and promotes standard treatments by providers.

Efficiency: Does the financing mechanism encourage the maximum output or health benefit from available resources? As noted earlier and in [Chapter 10](#), two broad categories of efficiency exist—allocative and technical. Pharmaceutical financing decisions often try to improve technical efficiency related to pharmaceutical management.

Equity: Who benefits, and who pays for services? Equity in health care means that essential care is provided according to need and financed according to ability to pay. Equity implies universal access (availability and affordability) to basic health services, including medicines, regardless of income level.

Sustainability: Will a reasonable level of funding be maintained over time? Both the amount of revenue generated and the reliability of funding over time are important. A major problem with relying on donor funding is its volatility.

Administrative requirements: What are the administrative and managerial requirements to make the funding mechanism operational? For instance, managing a viable RDF is many times more demanding than managing a system in which medicines are free. Insurance programs require a host of new administrative arrangements. In contrast, government financing systems are usually well established, and donor administrative requirements, though often tedious, are usually well defined.

Other criteria that may be used to evaluate health financing options include acceptability, community involvement, flexibility, and health impact. Acceptability refers to the balance of support and resistance from the public, providers, and politicians. With financing mechanisms that meet other criteria, acceptance often grows with experience and understanding. Community involvement may be valued for its own sake, but it is often considered with the other criteria because it may contribute to efficiency, equity, and sustainability. Flexibility is the extent to which funds can be used for various purposes. Donor funds tend to have the greatest restrictions, and community financing schemes have greater flexibility. Improved health impact is the ultimate objective of pharmaceutical financing reforms, but data that directly link funding and impact are scant. Access to essential medicines becomes a more immediate measure of potential impact.

Application of the criteria for evaluating funding mechanisms

Using these evaluation criteria helps structure the comparison of funding mechanisms. Experience, local circumstances, and degree of subjectivity affect the way individual criteria are applied to financing mechanisms. [Table 11-4](#) provides an illustrative comparison of funding mechanisms according to the preceding evaluation criteria. Several overall observations can be made.

Stereotyping and oversimplification should be avoided. Free government services may appear equitable, unless (as in some countries) political forces result in public pharmaceutical supplies being concentrated at national and regional referral hospitals in urban areas. User fees for poor rural populations may appear inequitable, but equity is actually improved if a situation of constant shortages requiring out-of-pocket purchase in the private sector at high prices is replaced by a community pharmaceutical scheme providing a reliable supply of low-cost medicines. Some national social health insurance programs provide health benefits so that low-income members are actually subsidizing high-income members. For example, in some countries, social security taxes are imposed only on wages below a certain level, so those with higher earning capacity do not have to pay taxes on much of their income. These wealthier people are often

city dwellers who have the greatest access to, and make the most use of, government health services, thereby benefiting disproportionately from the payments of those with lower incomes.

Examples of common misperceptions about access, rational use, efficiency, sustainability, and administrative requirements could also be cited. The point is that comparisons of financing mechanisms should be based on clear analysis, experience, and the best available information, rather than on untested assumptions or stereotyped thinking.

Evaluation often depends on effectiveness of implementation. Proponents of RDFs cite their potential for financing a sustainable supply of low-cost medicines. Opponents cite numerous programs that generate minimal revenue with much effort, and nonfunctioning exemption programs for the poor. As noted earlier, the financial performance and health impact of a user-fee program are highly dependent on the way the program is managed and monitored.

Similarly, insurance programs are complex undertakings. A successful insurance plan must organize the registration of members and dependents, the definition of services covered, accurate projections of payments to set premiums, collection of premiums, handling of claims, payment to providers, utilization review, quality monitoring, and cost control. Bad planning or poor implementation of different elements can result in a program that is inefficient, inequitable, unsustainable, and administratively chaotic.

In short, it is important to distinguish between a financing mechanism that is inappropriate for a given setting and one that might be appropriate but is ineffectively implemented.

Seek improvement, not perfection. Policy makers sometimes discard a new financing alternative because it has certain limitations, potential inequities, or other undesirable features. The question is not whether a specific financing mechanism meets all criteria—none do. The question is whether it will, on balance, improve the pharmaceutical financing situation.

Doing nothing about pharmaceutical financing is often the easiest course for an uncertain policy maker or a nervous manager. But if financial resources are inadequate, access and quality of care will decline. Analysis of financing mechanisms should aim at identifying actions that will lead to significant improvements, not at finding perfect solutions.

11.10 Developing a pharmaceutical financing strategy

Because pharmaceutical financing is part of health financing, in many countries, complementary financing arrangements are evolving for different health care needs and population groups. Although each financing mechanism has benefits and limitations, the net effect of the pluralist

Table 11-4 Comparison of funding mechanisms by evaluation criteria

Funding mechanism	Access to essential medicines	Appropriate medicine use	Efficiency	Equity	Sustainability	Administrative requirements
Public financing (government budgets)	↑ If budget sufficient and management adequate	↑ With good selection and prescribing	▫ No incentive for improvement	↑↓ Depends on who pays taxes and who receives services	↑↓ Depends on economic growth and government revenues	▫ No new requirements
User fees						
Government RDFs	↑ Access decreases for poor unless exemptions and other protections in place	↑↓ Fees may discourage overuse or lead to underuse; may encourage overprescribing if revenue for staff	↑ Success depends on supply management improvements	↑↓ Higher-income contribute more; poor benefit if supply improved; exemption plans rarely work	↑ With good management, reliable pharmaceutical supply	↑ Much more demanding than free system
Community pharmaceutical schemes	↑ Same as RDFs	↑↓ Same as RDFs	↑ Same as RDFs	↑ Local control and targeting support equity	↑ Same as RDFs	↑ Improvements require significant local management capacity
Direct private medicine purchases	↑ Primarily benefits urban and higher-income people	↓ Prices create affordability problem, which often leads to inadequate doses	↑ Strong financial incentive	↓ Poor cannot afford essential medicines	↑ For population that can afford medicines	↑↓ Systems exist in private sector
Health insurance						
Social	↑ If pharmaceutical benefits included in benefit package	↑↓ Appropriate use if insurance cost controls in existence; inappropriate use if patients exert pressure on provider for medicines	▫ No efficiency incentive	↑ Should be very equitable	↑ Requires good management, adequate premiums	↑ Substantial administrative requirements for new system; requires fraud and abuse controls
Private	↑ Same as social insurance	↑↓ Same as social insurance	↑ Some incentive	↑↓ Increased equity depends on membership	↑ Requires good management; sufficient number of members to maintain sustainability	↑ Same as social insurance
Community financing (different mechanisms have different effects)	↑↓	↑↓	↑	↑	↑	↑↓
Donor financing						
Bilateral and multilateral grants	↑	↑↓ Similar to public financing	▫ Similar to public financing	↑ Usually involves transfer from richer countries	↓ Not sustainable	↑ Reporting requirements
Development loans	↑	↑↓ Same as grants	▫ Same as grants	↑↓ Depends on terms and sources of funds for repayment	↓ Not sustainable	↑ Reporting requirements

Note: ↑ = increases; ↓ = decreases; ↑↓ = may increase or decrease; ▫ = no change.

approach is to distribute the burden of health financing across several sectors. No one health financing strategy will fit all countries—each country's context must dictate the best approach.

If the essential medicine supply is adequate, the challenge for policy makers and essential medicines program managers is to maintain the funding, pharmaceutical supply system, and medicine use patterns that ensure this adequacy. If the supply of essential medicines is inadequate, efforts should be made to use available funds better through more efficient selection, procurement, distribution, and use of medicines. Efforts to balance public resources and the demand for health care may also include measures to encourage private and NGO health providers.

When efforts to improve therapeutic and operational efficiency and to moderate demand for medicines do not balance the sustainability equation, additional funding is needed. Managers can make the case for greater government funding of pharmaceuticals, introduce or strengthen user fees for medicines, introduce or expand health insurance coverage for medicines, or seek donor assistance. In each case, efforts should be made to ensure that available public resources are targeted to those most in need.

The challenge for policy makers, essential medicines program managers, NGO managers, and others concerned with pharmaceutical financing is to make optimal use of every available source of financing. Success depends on political commitment, adaptation of financing mechanisms to local circumstances, good leadership and management, and modification of financing systems based on experience. Equity of access, quality of medicines, and rational use remain key objectives for any financing strategy. ■

ASSESSMENT GUIDE

Pharmaceutical financing policy and needs

- Is pharmaceutical financing included in national health and national medicine policy?
- Has a comprehensive estimate been made of pharmaceutical financing needs?
- Has a formal budget gap analysis been done recently?

National economic and health financing indicators

- What is the per capita GDP?
- What is the total national health expenditure (public and private) per capita?
- What is the total national health expenditure as a percentage of the GDP?
- What are total government expenditures as a percentage of the GDP?
- What percentage of total public expenditures do health expenditures represent?
- What is the percentage breakdown of health spending by source (public, private, NGO, donor)?

National pharmaceutical financing indicators

- What is the total per capita pharmaceutical consumption (from all sources)?
- What percentage of total health expenditures (from all sources) do pharmaceuticals represent?
- What is the percentage breakdown of pharmaceutical spending by source (public, private, NGO, donor)?

Public pharmaceutical financing indicators

- What is the total public expenditure on pharmaceuticals?
- What is the per capita public expenditure on pharmaceuticals?
- What is the percentage breakdown of public health expenditures (personnel, medicines, other)?

Efficiency of public pharmaceutical expenditures

- Allocative efficiency: Is the pharmaceutical budget appropriately distributed to ensure a supply of essential medicines, address priority health problems, and serve groups most in need?
- What percentage of the public pharmaceutical budget is used for national and referral hospitals?

- Therapeutic efficiency: Are an essential medicines list and standard treatments used? Is medicine use rational?
- Operating efficiency: Are procurement and distribution well managed?

User charges for medicines (see Chapter 13)

- Are user fees charged for medicines and services at government facilities?
- Is revenue used as a revolving fund specifically to resupply medicines?
- What percentage of government pharmaceutical expenditures is recovered through user charges?

Health insurance (see Chapter 12)

- What types of health insurance presently exist: compulsory, voluntary, community?
- What percentage of the population is covered by health insurance?
- What percentage of those insured have policies that cover pharmaceuticals?
- What methods exist for supply and payment for pharmaceutical benefits?

Donor financing (see Chapter 14)

- What percentage of total government health expenditures is represented by international assistance?
- What is the total value of international aid for pharmaceuticals?
- What are the major sources of donor funding for the pharmaceutical sector?

Effects of current pharmaceutical financing arrangements

- What is the availability of medicines in the public and private sectors?
- How affordable are pharmaceuticals in the public and private sectors?
- How equitable is access to medicines for rural, poor, and medically needy populations?
- What are the incentives for rational or irrational medicine use?

Note: It is preferable to compare budgets and expenditures in terms of local currency, U.S. dollars, and international dollars. Data for the three most recent years should be used to show expenditure trends. Both budgeted and actual expenditure data should be included. Price basis for pharmaceuticals should be clarified (producer, wholesale, retail).

SUMMARY

Health insurance is a mechanism for spreading the risks of incurring health care costs over a group of individuals or households, protecting the individual from a catastrophic financial loss in the event of a serious illness. Insurance, therefore, spreads the burden of payment for illness among all the members of the scheme whether they are ill or healthy, poor or rich. By their very nature, insurance schemes act as financing agents: they receive funds from employers, households, and the government and use these funds to purchase health care for their beneficiaries. Therefore, the main components of insurance schemes are collecting revenue, pooling resources and risks, and purchasing quality goods and services.

Many countries see the initiation or promotion of one or more insurance schemes as a way to address health financing issues and achieve universal health care coverage for citizens. Health insurance is appealing to governments because it takes the entire financial burden and spreads the total cost of insured health care among various partners. However, when governments consider instituting health insurance, they need to be aware of the realities of implementation; the complexity of the issues involved is often poorly understood. No one, widely accepted model of universal health insurance would be accepted in all societies, and how best to develop one in a resource-poor setting is still a matter of considerable debate. Whatever type of health financing mechanism a country decides to adopt, the transition to universal coverage may require several years, even decades.

This chapter covers four models of health insurance—

- Social or public health insurance
- Private health insurance
- Community-based health insurance
- Health or medical savings accounts

Any health insurance model may or may not cover medicines. Some insurance schemes incorporate medicines as part of a comprehensive care package, others compensate for them separately, and others do not cover them at all. However, strong arguments favor including medicines in insurance schemes because proper use of medicines can help prevent serious illness and death, and because pharmaceuticals make up such a large share of out-of-pocket spending in countries around the world.

Health insurance coverage for medicines offers significant potential to reduce the burden of disease and poverty. Using their power as large-scale purchasers, health insurance programs with pharmaceutical benefits can expand access to medicines at affordable prices to vulnerable populations and enforce better prescribing by clinicians and more cost-effective use by consumers. Furthermore, carefully designed insurance-based financing for medicines is both scalable and sustainable.

In part because of the pervasive potential for “moral hazard” (which in this case refers to more frequent use of services or medicines by members of an insurance scheme than would occur were they not insured), well-managed health insurance programs—whether public or private, mandatory or voluntary—are always looking for ways to manage costs efficiently. Public and private insurance programs control pharmaceutical expenditures through measures related to payment, management, prescribing patterns, dispensing practices, and use. Such programs can therefore profoundly affect the quality of prescribing by making reimbursement depend on adherence to treatment guidelines or restricted formularies. Ultimately, cost-control measures should aim to optimize access to and rational use of essential medicines, which remain a highly cost-effective element of health care, particularly for vulnerable populations.

12.1 The challenge of providing universal health coverage

In many countries, especially those with the fewest resources, poor people are often caught in a vicious cycle of poverty that causes ill health, and ill health in turn sustains poverty. Much of health care in developing countries is financed out-of-pocket, a system that places the largest burden on the poorest people. For example, household spending accounts for more than 60 percent of total health spending in low-income countries (Gottret and Schieber 2006), of which 60 to 90 percent may be spent on medicines

(WHO 2000). In addition to those direct costs, income is lost when family members are sick, and this loss reinforces the poverty-illness cycle. Women are especially vulnerable, because they are usually the main family caregivers.

The objective of universal health coverage is to ensure that all of a country’s citizens have access to adequate and affordable health care. Traditionally, governments have provided a national health service for all citizens with financing through tax revenue. Many of these health systems have not worked well or consistently provided needed medicines, a gap that has led to increased out-of-pocket spending for health care services and medicines in the private sector,

thereby worsening household poverty. Evidence from multiple countries has shown that a lack of health insurance is a key condition related to catastrophic household spending for health care (Xu et al. 2003). In an attempt to make health financing systems more equitable and increase coverage to the entire population, many low- and middle-income countries are exploring ways to strengthen such systems, including through various health insurance models.

People in most high-income countries are already covered by some form of public or private health insurance; however, the median coverage is only 35 percent in Latin America, 10 percent in Asia, and 8 percent in Africa (WHO 2004a). Health insurance coverage that includes pharmaceuticals has expanded access to medicines in many countries, including Argentina, China, Egypt, South Africa, and Vietnam (WHO 2004b).

Health insurance schemes appeal to both citizens and their governments because they help manage the financial burden by spreading the total cost of insured health care among various partners. In addition, donors and international financial institutions, such as the World Bank, are finding health insurance to be an increasingly feasible health financing mechanism for developing countries. Nevertheless, no one model of universal health insurance would be widely accepted in all societies, and although universal health coverage—where no citizens face the risk of losing their life savings because of catastrophic medical expense—is a highly desirable goal, how best to achieve it in a resource-poor country with underdeveloped private or public insurance schemes is still being debated.

This chapter presents an overview of how health insurance plays a role in financing health services, in general, and medicines, in particular. The chapter describes the main components of health insurance and potential problems with insurance systems. Four common types of health insurance schemes are described, with examples of how they are operating in different countries. Finally, although this chapter describes many options and potential paths, the right direction to take will depend greatly on the context of cultural expectations and the status and existence of other legal, financial, and regulatory institutions.

12.2 What is health insurance?

Health insurance is a mechanism for spreading the risks of potential health care costs over a group of individuals or households, with the goal of protecting the individual from a catastrophic financial loss in the event of serious illness. Insurance, therefore, spreads the burden of payment for illness among all the participants of the scheme, whether they are ill or healthy, poor or rich.

In principle, risk sharing through insurance is most worthwhile when the event insured against is largely unpre-

dictable, infrequent, costly, unwanted, and uncontrollable by the insured. A good example is insuring a house against fire. The event is unlikely and unpredictable but would be very costly if it occurred. Many people are prepared to pay a regular premium for a lifetime to gain peace of mind against a catastrophe that they hope will never happen.

Applying this traditional view of insurance to medical care presents some difficulties: people can control some aspects of use; some services are low cost; some conditions are frequently or continuously experienced (for example, medicines needed for chronic conditions); in some cases illness is difficult to define; people sometimes want to incur the risk (for example, pregnancy); and the presence of insurance increases the use of services. Despite these difficulties, the concept of risk sharing through insurance has become highly developed in the health sector.

The principal aims of well-managed insurance schemes are to reduce catastrophic financial loss in the event of a serious illness and to guarantee the funds or access needed to secure necessary, if expensive, medical services. Health insurance provides this financial protection by evening out household health expenditures. In addition, purchasing, payment, and monitoring mechanisms within health insurance schemes can contribute to efficient use of resources and improved quality of care (Eichler and Lewis 2000); for example—

- Access and affordability can be improved by removing financial barriers and by giving providers incentives to serve the covered population.
- Equity can be improved if higher-income people contribute more than lower-income people and relatively healthy people subsidize those who consume more system resources and are relatively sick (risk pooling).
- Efficiency can be improved if incentives are incorporated into the system to encourage appropriate use of resources.
- Quality can be improved if the system is structured to reward providers who deliver high-quality services and penalize those who do not.

This chapter covers four models of health insurance, defined below. Any model may or may not cover medicines as part of its benefit package.

Social or public health insurance: The most typical understanding of social health insurance is that membership is compulsory for a designated population; financial contributions into the system, which are often deducted directly from wages, link to the receipt of benefits; cross-subsidization occurs between high- and low-risk groups and high- and low-income groups; and management usually has some degree of independence from the government (Gottret and Schieber 2006). Social health

insurance schemes have existed in different parts of the world for some time, especially in Western Europe; Germany launched its program in 1883 (Carrin and James 2005).

Private health insurance: Private indemnity insurance is (usually) paid for by voluntary contributions from employers, mutual societies, cooperatives, or individuals. In high-income countries, private health insurance either replaces or supplements public coverage. The Netherlands has the greatest proportion of population covered by some sort of private health insurance, while the United States and Uruguay are countries with the highest private health insurance expenditures relative to total health expenditures (Sekhri and Savedoff 2005).

Community-based health insurance: In many countries in Asia, Africa, and Latin America, prepayment plans based on the concept of pooling risk and resources have been developed for rural populations, groups in informal employment, or others without access to other health insurance. Such schemes are based on community affiliation, and the community is highly involved in managing the system.

Health or medical savings accounts: Not strictly a form of insurance, medical savings accounts (MSAs) encourage individuals, often by providing tax advantages or subsidies, to save for the expected costs of medical care, enlist health care consumers in controlling costs, and mobilize additional funds for health systems. Only a few countries, including Singapore, China, and the United States, use the concept of health savings accounts.

12.3 Main components of health insurance financing

Decisions that affect the availability of health insurance in a country are important to all aspects of health service delivery but are largely outside the control of national medicine policies and essential medicines programs. As insurance assumes a greater role in health care in many countries, however, understanding health financing, and specifically insurance concepts, becomes increasingly important.

By their very nature, insurance schemes act as financing agents: they receive funds from employers, households, and the government, and they use those funds to purchase health care for their beneficiaries. Therefore, the main components of insurance are collecting revenue, pooling resources and risks, and purchasing goods and services (Gottret and Schieber 2006; WHO 2000).

Generally, insurance can be classified as using either a *single payer* or *multiple payer*. In *single-payer systems*, one organization (usually the government) collects and pools revenues and purchases health services for the whole population. All citizens are included in a single risk pool, and single-payer

insurers have powerful influence as the only buyer of health services (a situation known as *monopsony*). In *multiple-payer systems*, several different organizations perform all functions for specific parts of the population. Their insurance pools have different levels of risk, and consumers may be able to choose their own insurer.

Other basic issues related to sources of health care financing and achieving financial sustainability for pharmaceutical supplies are covered in [Chapter 11](#).

Revenue collection

Revenue collection is the process by which the health system receives money (usually taxes or premiums) from households, organizations, and companies, as well as from donors. Health systems have a limited set of mechanisms for collecting revenue, such as general taxation, mandated social health insurance contributions (usually salary related and almost never risk related), voluntary private health insurance contributions (usually risk related), or out-of-pocket payments from individuals.

Most high-income countries rely on either general taxation or mandated social health insurance contributions. As a country's income increases, so does the proportion of revenue that its government collects. Estimates show that in the early 2000s the average percentage of gross domestic product (GDP) collected by central governments as revenues was related to wealth (Gottret and Schieber 2006; Gupta et al. 2004). Therefore, low- and middle-income countries struggle to collect enough revenue to finance basic health services equitably and efficiently. In general, low-income countries depend far more on out-of-pocket financing, because of their low levels of income (resulting in a limited tax base), large informal sectors, and weak administrative capacity (Schieber and Maeda 1997).

Risk pooling

Risk pooling spreads the financial risk associated with health care among large groups. Pooling requires some transfer of resources (or cross-subsidization) from healthy people to sick people and from rich to poor. Without such pooling, poor people are exposed to serious financial hardship when they get sick; the more extensive the risk pooling in a health financing system, the less individuals will have to bear the financial consequences of their own health risks, and the more they are likely to have access to the care they need (Carrin and James 2004).

In a successful pooling scheme, contributions, whether through tax or insurance premiums, are not based on risk but based on the ability to pay. If the pooling is voluntary, high-risk people and poor people will join the pool because they see personal benefit, while healthier and richer people see less value for themselves (known as "adverse selection").

Fragmentation of the pool, or the involvement of too many small organizations in revenue collection, pooling, and purchasing, restricts the efficiency of all three tasks. In fragmented systems, the number of existing pools and purchasers does not matter, but rather the issue is that many of them are too small to be sustainable. Large pools are better than small ones because they have a bigger share of contributions that can be allocated exclusively to health services. A large pool can take advantage of economies of scale in administration and purchasing and reduce the level of the contributions required to protect against uncertain needs, while still ensuring that funds are sufficient to pay for services without any risk sharing.

When all payments for health care services and pharmaceuticals are made out-of-pocket, this situation represents the highest degree of pool fragmentation. In this case, each person constitutes a pool and thus has to pay for his or her own health services.

Prepayment

Prepayment is a feature of all types of health insurance. Because it unlinks expected health expenditures from the ability to pay, prepayment is a critical mechanism for attaining health care equity. Without prepayment, consumers pay entirely out-of-pocket for health care, purchasing it, like any other service, whenever it is needed. The fairness of health financing is often measured by the amount of prepayment required, because any out-of-pocket spending opens the consumer to financial risk (WHO 2000).

Risk pooling coupled with prepayment redistributes health spending between high- and low-risk individuals (risk subsidies) and high- and low-income individuals (equity subsidies). Pool members pay for expected costs in advance, which relieves them of uncertainty and ensures compensation should a loss occur. However, few systems are able to meet the entire cost of health care from the prepaid and pooled funds. Most require some type of co-payment for the use of health services or the purchase of medicines, which households must pay out of pocket.

Prepayment without pooling simply allows for advance purchase of health services or purchase on an installment basis, such as in the example of health or medical savings accounts, which is presented later.

Purchasing health care services

Purchasing is the process by which pooled funds are paid to providers to deliver health goods and services. All health financing systems face similar challenges in choosing which health services to buy or provide, who should provide them, and which payment mechanisms are used. The fact that a government takes responsibility for collecting revenues for the health system does not necessarily mean that it should

also provide care. To provide services, most health systems use a variety of methods involving a mix of public, private for-profit, and private not-for-profit providers.

The advantages of using pooled resources to purchase services include not only economies of scale but also strengthened capacity to bargain with providers regarding price, quality, and opportunity of services. Purchasing agreements can provide incentives for health service providers—including the promotion of rational medicine use—through contracting, budgeting, and payment mechanisms (see Section 12.5). The purchasing process should include an ongoing search for the most cost-effective services to purchase, the most cost-effective providers to purchase from, and the most efficient mechanisms and contracting arrangements to pay for such services.

Three categories describe the financial relationship between the insurer and the service providers in health insurance. The first is *reimbursement*, where providers are paid after they deliver the services. An example of the reimbursement approach is called *indemnity insurance*, where no contractual arrangements exist between insurers and providers, and the provider is paid a fee for the service. The second is *contracting*, where the insurers negotiate payment agreements with certain doctors, hospitals, and health care providers, to supply a range of services and possibly medicines at reduced cost to those insured. This method can free the patient from the need to pay for health care up front and also helps contain costs and control quality by giving the insurers direct purchasing power over providers. Third is *integration with providers*, when the roles of health care purchasers and providers are under one organizational umbrella (such as a government). One example is a health maintenance organization, where the providers are salaried employees of the insurer (OECD 2004).

12.4 Potential problems with insurance systems

Market failure is the term used by economists to describe circumstances that constrain the smooth operation of the market (Normand and Weber 1994). Economists generally agree that governments need to develop structures and policies to counter the effects of market failure. In the case of health services, the major sources of market failure are the monopoly power of providers and ignorance and uncertainty among consumers (Normand and Weber 1994).

Monopoly power of providers: To protect the public and ensure a basic level of competence, entry into the health care professions is restricted by licensing and other rules that govern access to health care. Thus, the health care professions exercise monopoly power, limited to some degree if providers must compete against one another. A

country's health policy should ensure that this monopoly power does not work against the interests of the patient. In addition to the power exercised by professionals, a "natural monopoly" occurs when only one service provider is available in a particular area who can provide care efficiently. In the case of access to medicines, people in rural areas may have little choice but to buy pharmaceuticals from a retail drug seller or a dispensing doctor if other sources are too far away.

Ignorance and uncertainty among consumers: Consumers depend on health care professionals to inform them of which services are appropriate and also to provide those services. This asymmetry of information further reinforces the monopoly power of professionals. In addition, the time at which any one person will need access to health services or medicines is usually very uncertain. When uncertainty and ignorance about the need or options for health care are combined with the high cost of specific types of care, market failure often results.

In addition, insurance only works if some people pay more in contributions than they take out in services, to compensate for those whose care costs the scheme more than they pay in. An insurance contribution is not a payment for a service but rather the price for insuring a particular risk (Normand and Weber 1994). Therefore, insurance systems face several problems that can undermine the potential benefits of prepayment and risk sharing—

Moral hazard: When members of a health insurance scheme use services or consume medicines more frequently than if they were not insured, the phenomenon is called "moral hazard." Deductibles and co-payments are commonly used to avert this problem. Moral hazard can be overcome by clearly describing the benefit package and trying to coordinate the co-payments and the provider payment methods with incentives for necessary care only.

Adverse selection: This term describes the tendency for people at greatest health risk and people with chronic illnesses to join voluntary insurance programs, whereas the healthiest people, whose premiums should be used to pay the bills of the sicker members, avoid joining. The effect of adverse selection is to raise costs and reduce the risk-sharing effect of insurance, which makes financial sustainability much more difficult to achieve; for example, in Senegal, unstable insurance schemes showed evidence of adverse selection compared with financially stable schemes that registered a larger proportion of household members—both healthy and unhealthy (Atim et al. 2005).

Skimming: This problem occurs when insurers use various screening measures to avoid insuring people at greatest

health risk (and therefore of greatest expense to them). Skimming reduces the equity benefits of insurance by excluding those who are most in need.

Cost escalation: Rising costs can result from improvements in or greater use of technology, increased use (greater demand caused by insurance coverage), and increases of both the population in general and older populations. Private indemnity insurance suffers from the tendency toward cost escalation because the insurer usually has no contractual relationship with the provider. Thus the tendency is both for insureds to increase their use of medicines and services and for providers to overprovide services. The other models allow for greater cost controls.

Unrealistic expectations: In addition to these problems, insurers, particularly in developing countries, frequently have to deal with misunderstanding of the insurance concept by the public and by health providers. Members may think that premiums are like deposits in a savings account: "If I have paid 10 dollars each month in premiums this year, I must be sure to receive 120 dollars' worth of health services in a year." This belief leads to unrealistic demands that everyone should receive at least as much as he or she has paid in. Insurance is not sustainable in such an environment, because no risk sharing occurs. Other members may avoid using their insurance because they believe that they can claim only as much as they have contributed in premiums. Considerable effort may be needed to educate the insured, the general public, and health providers.

Country Study 12-1 shows some of the problems experienced with a new insurance scheme in Bolivia that targeted women and children. Experienced public and private insurance organizations have developed measures to counter moral hazard, adverse selection, skimming, cost escalation, and lack of familiarity with insurance. Policy makers, government insurance regulators, and insurers need to work together to implement these measures.

12.5 Provider payment mechanisms

Methods of provider payment are a crucial part of the design of all insurance schemes. Each method affects the administrative costs of the scheme according to the complexity of approving claims and making payments. Similarly, all payment methods include incentives that may reduce or increase demand for treatment or medicines by the insured and reduce or increase costs and quality of care by the provider. It is most important that, whichever method of provider payment is chosen, mechanisms are incorporated to contain costs while maintaining needed access and quality of care for the sick.

Country Study 12-1 Financing maternal and child health services in Bolivia

Bolivia has higher maternal and child mortality rates than any other country in Latin America. Most of those deaths occur in the poorest sectors of society and are preventable with adequate health care. In 1996, Bolivian officials began the National Insurance for Mothers and Children (SNMN) program in an effort to lower economic barriers to health care for mothers and children.

Through the program, women and children under five years of age receive free medical care and medicines for certain medical conditions that are common causes of maternal and child mortality, such as unattended births for women, and diarrhea and acute respiratory illnesses for children. All levels of care are covered in the program, including primary care facilities and hospitals.

Since the implementation of the SNMN program, use of health services covered by the program, especially among the poor, increased. However, this increase lowered the motivation levels of health workers because of the influx of patients, which was unaccompanied by an increase in remuneration. As a result, SNMN patients were reportedly being treated unfairly in medical facilities, and amenities received, length of stay, and even treatment prescribed have reportedly all been used to discriminate against insured patients.

In 1999, SNMN was expanded to become the Basic Health Insurance plan, which expanded coverage to

other additional health priorities that had previously been addressed by vertical public health programs, such as tuberculosis. New changes in 2002 doubled the financing, expanded the benefit package, revised reimbursement schedules, and introduced performance agreements between the different levels of the Ministry of Health's decentralized system.

Results suggest that the reforms further increased coverage of priority maternal and child services; for example, between 1998 and 2002, pneumonia and diarrhea coverage for children under five years increased from 69 percent to 100 percent and 29 percent to 43 percent, respectively. Despite these increases, however, after a few years, coverage rates began tapering off and even decreasing. In addition, despite the introduction of public health insurance, households remain an important source of financing for the sector, with out-of-pocket expenditures contributing 30 percent of national health spending.

To encourage additional gains, the government added a matching grant program with conditions to encourage mothers to use health services for themselves and their children; however, this program does not target certain populations, a situation that could exacerbate stubborn rural-urban coverage gaps.

Sources: Partnerships for Health Reform n.d.; Camacho et al. 2003; Narváez 2009.

Designing payment mechanisms for medicines is more challenging because insurers find it more difficult to establish reimbursement schemes that cover all the places that sell medicines, such as pharmacies, clinics, and informal drug sellers, than to administer payments to hospitals for inpatient care, for example.

Cost sharing through co-payment

One of the most common methods used to reduce excessive demand for services and pharmaceuticals, as discussed more fully below, is to have consumers share costs through co-payments or user fees, so that choosing treatment has a personal financial consequence, thereby reducing excess demand and moral hazard as well as increasing revenue levels. If co-payment charges are too high, however, they can discourage people from seeking timely care, which can negatively affect health and longer-term costs. Of course, cost sharing is also likely to be detrimental to poor people's access to care and medicines.

As an incentive to encourage rational medicine use and lower costs to the system, co-payments for medicines can be set at different levels depending on whether the medicine is on an essential medicines list or formulary, or whether it is generic or brand name (see Section 12.6 for a more detailed discussion of tiered payments).

Another cost-sharing mechanism is a *deductible*—a set amount that each person in the insurance scheme must pay each year before he or she can tap into the benefits of the plan.

Capitation payment

A capitation payment is where providers receive a prospective, fixed payment for each person served under the scheme for a particular period of time. Administration is relatively simple and inexpensive. Specific health services are often not explicitly defined, meaning that providers have some flexibility in terms of what they provide. In this system, no incentive exists to provide excessive health care. In fact, the

incentives are actually to provide minimal care and to needlessly transfer patients to higher levels of care. Competition among providers can decrease the tendency to underproduce, because poor service may cause patients to change providers.

Fee for service

Fee for service is a payment mechanism in which the insurer pays providers for each service provided to a patient. Its perceived strength is in encouraging providers to provide health services—particularly preventive care. Administrative costs are likely to be high, because of the costs of billing and reimbursement as well as monitoring fees.

However, this method of payment may also encourage an overdelivery of health services (supplier-induced demand). The same effect can be seen on pharmaceutical sales. Wherever fees depend on medicine sales, the number of medicines prescribed increases. The potential overdelivery can be counteracted by combining fee for service with maximum budgets or by adjusting fees after a specified quantity of services is exceeded. Some co-payment by the patient may decrease the demand and counteract the overdelivery of services.

Case payment

An important example of a case payment is the diagnosis-related group payment method, wherein health facilities or providers are paid an inclusive flat sum for a patient's treatment (including medicines) according to the diagnosed condition. Case payments can be easier to administer than reimbursement from an itemized list, and requiring documentation of adherence to treatment according to guidelines to receive payment can have a positive effect on the use of medicines.

Payment for performance (incentive payments)

In a variation on fee for service or as an adjunct to capitation, doctors or health facilities may be paid or partly paid based on whether they achieve predetermined quality-based performance indicators. Such indicators may include appropriate prescribing of antibiotics, immunization coverage, blood pressure screening, or cervical smears. Performance can also include appropriate management of people with chronic conditions such as HIV/AIDS (based on CD-4 counts) or diabetes (measured through blood sugar levels).

Budget transfer

Many countries use a budget to pay for public health services; for example, in Central Asian countries, governments provide annual budgets to tuberculosis hospitals (Liu and

O'Dougherty 2005). Budgets can be set for providers, which, if strictly fixed, can help contain costs. Budgets can also be earmarked specifically for medicines and supplies. Similar to what happens with use of capitation, savings occur because no link exists between the quantity and mix of health services given to the individual and the amount received by providers. Providers' ability to contain overall costs, though, is limited if the budget is insufficient and results in others having to provide the necessary care. Focusing on the pharmaceutical budget alone, however, without considering the interaction with other service providers—known as the “silo mentality”—can result in suboptimal health care or cost shifting (Drummond and Jonsson 2003).

Salary

Health workers employed by institutions are usually paid a salary. Salaries provide a neutral incentive to providers' actions—what services the provider recommends and what he or she prescribes is based on the needs of the patient, the knowledge of the provider, and the availability of resources (Liu and O'Dougherty 2005). However, as with both budgets and capitation, salaried employees can suffer from low motivation and underproduction, especially when salaries are perceived as low. When the institution is part of the government health system, low motivation can influence providers to seek better remuneration in the private sector or to moonlight in the private sector. To improve productivity, performance-related conditions and incentives can be implemented in addition to salaries.

12.6 Including medicines as part of insurance benefits

Should insurance schemes include medicines in their list of benefits? According to the insurance concepts previously discussed, pharmaceuticals might not be a top priority for insurance coverage: common illnesses for which medicines are needed occur frequently, patients and providers may reinforce overprescription and overuse of medicines, and the potential for fraud and abuse is substantial. Some insurance schemes will incorporate medicines as part of a comprehensive care package, others will compensate for them separately, and others will not cover them at all. [Table 12-1](#) shows that the number of countries with private health insurance that covers medicines has increased from 1999 to 2003.

However, there are strong arguments for including medicines in insurance schemes. First, pharmaceuticals are an essential component of modern health care. Second, early treatment of acute illnesses, such as malaria, and treatment of chronic illnesses, such as diabetes, can reduce costly care for complications and hospitalizations (for both patients and systems). Third, because pharmaceuticals make up

Table 12-1 Countries with medicines covered by health insurance in 1999 and 2003*

Medicines coverage	Country income level					
	Low-income		Middle-income		High-income	
	Number of countries (%)		Number of countries (%)		Number of countries (%)	
	1999	2003	1999	2003	1999	2003
Public health insurance	8/23 (34.8)	8/23 (34.8)	27/35 (77.1)	26/35 (74.3)	8/9 (88.9)	7/9 (77.8)
Private health insurance	8/17 (47.1)	13/17 (76.5)	16/29 (55.2)	24/29 (82.8)	5/6 (83.3)	6/6 (100.0)

* For countries with data on both years.

such a large share of household health costs in many countries, their inclusion in an insurance program will make the program more acceptable and desirable and help prevent catastrophic expenditures that increase poverty. Fourth, it is possible to pay only for medicines included in standard treatment guidelines or essential medicines lists, thereby significantly reinforcing the quality use of essential medicines.

Country Study 12-2 shows how extensively a lack of insurance coverage for medications affects the elderly in the United States.

Inpatient pharmaceutical supplies for insured individuals are usually provided by the hospital as part of routine inpatient care. Insurance coverage for outpatient medications may be provided through private pharmacies, insurer-affiliated pharmacies, in-house pharmacies, or pharmaceutical benefits management schemes (see below). The pharmaceutical supply mechanism depends in part on whether the insurer functions only as the financier of services or whether, as with managed care, insurance is linked to specific health providers.

When private pharmacies are used, insurers either reimburse members after they have purchased medicines or reimburse the pharmacy directly. This system provides flexibility for the member but has high administrative costs and is open to considerable fraud and abuse. Insurers may require that prescriptions be filled only at specific insurer-affiliated pharmacies that have a contract or working agreement with the insurer. The member's choice is limited, but administrative costs are less, and abuse is easier to control.

Managed-care organizations and polyclinics often maintain their own in-house pharmacies. Pharmacy staff may be on salary, or the entire pharmacy service may be contracted out. In either case, the insurer-provider can exert greater control over which medicines are available and what prices are charged.

Pharmaceutical benefits management (PBM) schemes contract with insurers to manage pharmacy services. The PBM provider negotiates pharmaceutical prices with suppliers, sets the formulary of medicines to be used, reviews and adjudicates claims, reviews patterns of use by patients

and providers, audits the program to prevent fraud and abuse, and implements programs to make medicine use more rational. PBM may provide such services through subcontracts with local pharmacies and through mail-order pharmacy services. Although unheard of in most countries, purchase of medicines by mail—especially medicines for chronic diseases—has existed for many years in North America and is widely accepted. Although PBM appears to add another middleman and additional expense, successful PBM schemes reduce costs to insurers.

Controlling the costs of medicines through insurance programs

Well-managed insurance programs—whether public or private, mandatory or voluntary—always look for ways to control costs while ensuring quality. Controlling the cost of individual services allows an insurance scheme to keep premiums down, expand benefits, or (for commercial insurers) increase profits. Public and private insurance programs control pharmaceutical expenditures through measures related to payment, management, prescribing patterns, and use. Control methods can be used separately or in combination.

1. Control of payment

- Co-payments are payments made by the member, such as a charge of 1 U.S. dollar (USD) per item for generic medicines and USD 2 per item for brand-name medicines. Co-payments are intended to prompt the patient to consider carefully whether the medication is useful or not; however, they may discourage poor patients from taking needed medications.
- Tiered co-payments require patients to pay different amounts for their prescriptions, depending on how the medicines are classified. A simple tiered plan will include generics and brand-name medicines (as above). Other tiers may include preferred branded versus nonpreferred branded or even a mail-order program.

Country Study 12-2**Patterns of medicine use by senior citizens in the United States**

The social health insurance system for older citizens in the United States, Medicare, did not include pharmaceutical benefits until 2006. In anticipation of the addition of medicines as a benefit, a nationwide survey of over 17,000 older Americans looked at issues that included patterns of medication usage and adherence, current pharmaceutical insurance coverage (from a supplemental plan to Medicare), and out-of-pocket costs.

Results showed that almost 90 percent of those in the survey took prescription medications, even though three-quarters of them had no prescription insurance coverage. Nearly half reported taking five or more prescription medications. Not surprisingly, out-of-pocket costs were high—nearly one-third spent over USD 100 per month for their prescription medications—and 37 percent of seniors without prescription insurance cover-

age reported not adhering to their regimen because of cost (for example, not filling a prescription, skipping doses, or taking smaller doses).

In another study, researchers looked at middle-age and elderly groups who reported taking less medication than prescribed for chronic conditions because of cost. In the two to three years of follow-up, more of the patients who restricted their medication use reported a significant decline in their health status, such as those with cardiovascular disease having suffered higher rates of angina, nonfatal heart attacks, and strokes. Therefore, patients not adhering to treatment regimens because of lack of insurance coverage for medicines may suffer worse health outcomes.

Sources: Safran et al. 2005; Heisler et al. 2004.

- Co-insurance is a specified percentage to be paid by the member—for example, 25 percent for drugs used in serious and chronic illnesses, 50 percent for most other pharmaceuticals, and 75 percent for symptomatic treatments for minor illnesses.
 - A deductible is a specified initial amount the insured must pay before services are covered. It is usually a set amount per quarter or per year.
 - Maximum allowable cost or maximum reimbursement price (benefit capping) specifies the highest reimbursement amount for each item to control medicine charges, encourage generic substitution, or establish co-payment levels.
2. Control of prescribing patterns
 - Provider pharmaceutical budgets encourage providers to work within a total pharmaceutical budget for a patient population. Prescribers may be offered a financial incentive for meeting budget targets.
 - Prior authorization requires the insurer to approve the individual prescription before it can be dispensed. This control can be used to enforce adherence to a formulary or essential medicines list or to limit the use of a certain class of medicines.
 - Step therapy restricts a patient from receiving the most expensive therapy first without trying the less expensive alternatives.
 - Selective reimbursement of medicines on formulary lists or essential medicines lists encourages compliance. The use of other products or therapeutic categories, including nonprescription medications, vitamins, and minerals, can be discouraged by lack of reimbursement.
 - Voluntary or mandatory prescribing or dispensing of generic equivalents lowers costs if the brand-name premium is significant.
 - Standard treatment guidelines are recommended to prescribers, especially in managed care programs, for common or high-cost diseases.
 3. Control of use
 - Prior authorization by the insurer is sometimes mandated for all prescriptions but is more common for specific medicines or medicine categories, such as “lifestyle” medicines, vitamins, or over-the-counter medications. Alternatively, coverage could be limited to people with a specific condition (for example, making Cox-2 inhibitors available only to those with documented gastrointestinal problems).
 - Caps on services may be instituted, such as limits on the quantities dispensed, number of items given at one time, frequency of refills, or total expenditures. Commonly, insurance schemes will limit the amount of medication per prescription, such as a thirty-day supply or 100 units. In the case of expenditure limits, the scheme may cover only a certain amount of money’s worth of medicines per month or year; however, this control method penalizes those most in need of medications, resulting in higher medical costs overall (Hoadley 2005).
 - Use review identifies overprescription or other forms of inappropriate prescribing or dispensing.

This control examines the specific prescriptions for inappropriate use rather than overall usage patterns; for example, identifying a prescription that should not be dispensed to a pregnant woman.

Reference price systems for pharmaceuticals are a cost-containment method introduced in the late 1980s. The basic premise is that a cluster of similar medicines is associated with one specific price accepted by the government for reimbursement purposes. Should a physician prescribe a product priced above this reference price, it is the patient who pays the difference. This policy is meant to increase the cost-consciousness of patients and to incite them to demand reference-priced medicines. For more information on reference pricing, see [Chapter 9](#) on pharmaceutical pricing policies.

These cost-control measures vary in terms of their administrative complexity, effect on access to medicines, effect on rational use of medicines, and acceptability to members and health care providers. Schemes that fail to ensure service quality *and* control costs are not likely to be sustainable.

Access to medicines and rational medicine use

Cost-control measures must not reduce access to essential medicines, which are a highly cost-effective element of health care. Yet insurers, particularly those in new programs and low-income countries, are wary of the costs of overuse and fraud. In an extreme response to this problem, one Latin American country in the mid-1990s proposed omitting medicines entirely from its national health insurance scheme.

Unfortunately, those most in need are often the most affected by cost-control measures. Experience in developed countries has demonstrated that overly restrictive cost-control measures can reduce medicine use but increase total health care costs because of deferred treatment and increases in hospitalization and other costs. A study of Medicare beneficiaries in the United States showed that a cap on medicine benefits resulted in a 31 percent savings in pharmaceutical costs, but that those savings were offset by poorer clinical outcomes and increased hospitalization rates and visits to the emergency department (Hsu et al. 2006).

Rational medicine use in the context of insurance schemes requires a careful balance between controlling costs and ensuring access to needed medications. As mentioned previously, control measures can be used to provide financial incentives for prescribers, dispensers, and patients to follow standard treatment guidelines, formularies, and essential medicines lists, as part of a strategy to promote rational medicine use. Furthermore, a group of members of an insurance scheme serve as a defined population for implementing such rational-use strategies and can also provide data to monitor the effects of these strategies. Essential medicines

or formulary lists, standard treatment guidelines, prescriber and dispenser training, public and patient education, and other measures described in Part III are relevant to improving medicine use in the context of insurance schemes.

12.7 Social health insurance

Social health insurance is a compulsory system, such as a social security fund or national health insurance fund, that includes members of a designated population. Payments to the system are linked to the receipt of health benefits, so only members of the designated population may access services. Key features of a successful social insurance plan include (WHO/SEARO 2003)—

- Compulsory or mandatory membership
- Prepayment contributions from payroll deductions based on income and not risk
- Cross-subsidization and coverage of a large proportion of the population
- Benefit based on need
- Arrangement of social assistance to cover vulnerable populations
- Collected revenue administered by a quasi-independent body

Financial contributions into the social health insurance system can come from workers, employers, the self-employed, and the government—either as an employer of civil servants or as a subsidizer for people not in the formal employment sector. Workers and employers generally contribute based on the worker's salary, while the self-employed make contributions based on estimated income or a flat rate. The government may pay for the unemployed, elderly, or others who cannot afford to pay into the system. These schemes typically contract with a mix of public and private providers to offer a specified benefit package. Social health insurance funds may cover preventive and public health care, or the ministry of health may retain these responsibilities.

One of the fundamental principles of social health insurance is that contributions are not based on risk but are instead based on ability to pay, reflecting an objective of equal access to health care and opting for a certain degree of equity in financing. Countries are relatively successful at collecting wage contributions from people employed in medium and large firms. However, care must be taken to ensure that imposing deductions on wages for health insurance will not distort the labor market by increasing tax evasion or reducing the size of the formal sector. Collecting from the informal sector, from small businesses, and from independent workers has proven to be extremely difficult, and countries should include within their system framework mechanisms to protect the poor.

Services may be provided through government facilities, insurer-operated facilities, private facilities, or a combination of these. Medicines may be provided through contracts with pharmacies. Often, the schemes have an independent agency that manages the health insurance fund, thereby separating the financing of care from the provision of care.

Challenges of social health insurance systems

Low-income countries often find generating enough tax revenue to finance social health insurance difficult. Economic growth may be too modest and compliance among the income earners may be insufficient. These countries also have difficulty introducing or enlarging a social health insurance plan because it requires consensus among disparate partners to accept that those with similar health care needs should receive similar health service benefits, regardless of their level of contribution—an acute issue when countries have a significant disparity between rich and poor.

Moreover, governments need a strong organizational and managerial framework to support a social health insurance scheme because of the complexity of the collection and purchasing activities, which can generate huge funds. Therefore, good governance and transparent practices are extremely important. Often, the challenge is compounded by communication and infrastructure problems such as inadequate roads, telecommunications, and banking facilities that inhibit the scheme from collecting contributions and organizing reimbursements, managing revenues and

assets, and monitoring the related health and financial information. A lack of adequate human resources with the necessary expertise can also result in management weaknesses and increased costs. WHO provides useful guidance for the design of social insurance schemes (Carrin and James 2004; Normand and Weber 1994).

Finally, social health insurance requires strong political support, which can be impossible in countries with political instability or economic insecurity. For many low-income countries, social insurance may not be feasible because “the fundamental problem in these countries is not ineffective financing. The real problems are the systems of political governance that regularly under-finance health care services or spend public funds inefficiently. Under such conditions, even the best-designed social insurance system will fail” (Savedoff 2004, 184).

12.8 Community-based health insurance

Low-income countries often have large populations that live in rural areas and work in informal sectors, which limits how well the government can effectively collect taxes to fund social health insurance or other tax-based health funds. Because of this difficulty reaching certain groups, community-based health insurance schemes (also known as mutual health organizations or *mutuelles de santé*) have been one way to fill government gaps and protect marginalized population groups against the cost of illness. According to one analysis (Preker et al. 2002b), community-based health financing (CBHF) schemes appear to extend cover-

Country Study 12-3

The effect of HIV/AIDS on a community-based health program in Tanzania

The Community Health Fund (CHF) is a voluntary prepayment scheme that entitles members to access health care for a year, without restriction based on their health status. However, the scheme was designed without considering the effect that HIV/AIDS would have on the community. A study was conducted in the Hanang district to measure the level and costs of HIV/AIDS-related services that CHF members and nonmembers sought during 2002.

Results showed that CHF members used outpatient services 2.5 times per year compared with 2.1 visits for nonmembers; however, although the overall numbers of visits did not vary much, CHF members with HIV/AIDS used outpatient services on a more regular basis, suggesting that membership created a culture of seeking health care more expediently. As a result, the difference in the

number of inpatient visits between members and nonmembers was dramatic: CHF members were 40 percent less likely to be hospitalized than nonmembers, resulting in a sizable cost savings. In addition, when members were hospitalized, their stays were significantly shorter than the stays of nonmembers. Because the region had been experiencing shortages of hospital beds, this result benefited all patients in the district, not just those with HIV/AIDS. Overall, the study concluded that CHF members were managing their HIV/AIDS conditions better through regular outpatient services than nonmembers and that a focus on identifying HIV-positive patients and getting them into treatment earlier would result in further benefits to the community.

age to a large number of rural and low-income populations that would otherwise be excluded from collective arrangements to pay for health care.

Membership in community-based health insurance schemes is usually voluntary, and the organizations are always nonprofit and based on the concepts of mutual aid and social solidarity. Membership may be based around geographical entities (villages or districts), trade or professional groupings (such as trade unions or agricultural cooperatives), or health care facilities. Such schemes have been around for many years, but recently they have attracted increased interest; for example, in Ghana, the number of community-based health financing schemes increased to 159 from only four in about two years. Estimates place the numbers of these schemes worldwide in the hundreds or even thousands (PHRplus 2004).

All community-based health insurance schemes share the goal of finding ways for communities to meet their health financing needs through pooled revenue collection and resource-allocation decisions made by the community. Like all insurance schemes, they allow members to pay smaller premiums on a regular basis to offset the risk of having to pay large health care fees upon falling sick. This system also removes the financial barrier at the time of need, so people are more likely to seek health care services earlier. [Country Study 12-3](#) shows how people living with HIV/AIDS in

Tanzania have improved their health-seeking behavior with the help of a community-based health insurance plan.

Community-based management

Unlike other insurance plans, community-based health insurance schemes usually depend upon members to help manage and run the scheme; therefore, the fund managers are accountable to the interested households rather than to the government. Perhaps the most fundamental role of management is to administer the scheme's resources and activities to ensure that income is sufficient to cover the fund's expenses each year. The plan managers need to discern the community's needs and preferences and take them into account in the scheme design.

Most community schemes make a collective decision on what to purchase. Schemes cover different levels of care depending on the needs and preferences of the scheme members, their ability to pay, and the availability of services in the area. The more extensive the package of services offered by the scheme, the larger the premium needed to sustain the scheme, reaching cost levels that may discourage people from joining. Contributions have to be set low to encourage people to join but also have to be balanced against the expected benefits. [Table 12-2](#) shows how selected community-based schemes are organized in West Africa.

Community-based management can certainly be cost-effective, but it can be difficult to do well. A recent assessment of twenty-seven community schemes in Thiès, Senegal, concluded that, overall, financial performance was poor (Atim et al. 2005). The main reasons for this poor performance were adverse selection, low dues recovery, unrecovered loans, frequent changes to benefit packages without changes to premiums, and limited use of financial tools.

Because the schemes are normally voluntary, if households do not trust those managing the fund they may withdraw their membership. Evidence shows that people are more likely to enroll if client households are directly involved in the design and management of the schemes, whereas top-down interference with the design and management of the schemes appears to stunt their sustainability (Preker et al. 2002a).

Challenges with community-based health insurance

Community-based health insurance schemes are small in size, a condition that affords them the benefits of social regulation mechanisms by peer pressure, solidarity, and the neighborhood nature of social control. Their small size is also their main challenge; financial reserves tend to be small because of the low income of the contributing population. Schemes that share risk only among the poor and sick deprive their members of much-needed cross-subsidies from healthier groups with higher incomes. In addition, schemes that operate outside of formal health systems may limit their members' access to a more comprehensive range of care.

A Nigerian study in rural, urban, and peri-urban communities showed that fewer than 40 percent of the people were willing to pay for community-based health insurance; the figure was less than 7 percent in the rural community (Onwujekwe et al. 2010). Even if premiums are minimal, the poorest people may find community-based health insurance plans difficult to join. Cash-poor households may be excluded because few schemes allow payment in kind (because of the added complexity of management). Governments and donors can help by subsidizing premiums for the poorest segment of the population; some schemes set aside a certain percentage of total funds to pay for care for the indigent (PHRplus 2004). For example, in Rwanda, the government and more than ninety community-based schemes have decided to subsidize premiums for the poor to access a defined package of services (Gottret and Schieber 2006).

Although mutual health organization membership in Ghana, Mali, and Senegal offered protection against catastrophic expenditures related to hospitalization, membership did not affect how much members paid for medicines, which represented the largest proportion of the cost of outpatient care (Chankova et al. 2008).

Country Study 12-4 shows the results and recommendations from an assessment of the sustainability of community-based insurance schemes in Uganda.

A proposed solution to the size issue is to create an organization that offers “reinsurance” to several community-based health insurance schemes, thereby spreading the risk among multiple programs. The management of such an organization remains a challenge, but this approach could be a way of protecting several schemes against catastrophic liabilities while maintaining the advantages of community stewardship (see Fairbank 2003 for an extensive discussion).

12.9 Private health insurance

Private health insurance refers to schemes that are financed through private health premiums, which are usually (but not always) voluntary. With private insurance, the money can be paid directly to the insurance company either through employers or communities or individually. The insurance company may be either for profit or not-for-profit.

Although the government often regulates this type of insurance, the pool of financing is not usually channeled through the general government. In developing countries, private insurance schemes are offered primarily by employers, but the proportion of the population covered by private insurance tends to be very small.

One frequently cited characteristic of private insurance is that premiums are risk related; meaning that if the client is older or has a chronic disease, the premiums will be higher than if the client is young and healthy. Sometimes, an insurer will use historical data on a community or employment group to determine the risk of future claims compared with those of other communities or employment groups.

Worldwide, varied private insurance models exist, with some arrangements blurring the boundaries between public and private insurance. A recent proposal for a taxonomy of health insurance (OECD 2004) classified four types of private insurance, each of which has a different way of determining contributions—

Private mandatory health insurance: Insurance is legally mandated and premiums may or may not be risk related.

Private employment group health insurance: Insurance is a benefit of employment and is usually not risk related.

Private community-rated health insurance: Policies are voluntarily taken up by individuals or groups, and insurers are legally required to apply community-related rather than risk-related calculations for premiums (no discrimination based on age, health status, claims history, or other factors).

Private risk-related health insurance: Policies are voluntarily taken up by individuals or groups, and insurers apply risk-related premiums.

Country Study 12-4**Strengthening and sustaining community-based health insurance schemes in Uganda**

An assessment of fourteen community-based health insurance schemes in Uganda investigated activities and best practices that were contributing to the schemes' financial stability and sustainability.

Findings and recommendations included—

Quality of life: Scheme members reported a significant improvement in quality of life as a result of membership. The addition of local outpatient clinics to the package of covered benefits allowed more convenient and cheaper access to primary care for some members.

Management and governance: Management and governance structures varied across schemes; each scheme should include a community-based representative as part of the decision-making process.

Financial management and viability: A larger number of members was a better predictor of cost recovery than the amount of premium payments; therefore, an increase in premiums could result in a loss of members, which would be detrimental to cost recovery. Schemes need to improve accounting mechanisms and improve the financial management skills of scheme managers.

Risk management: Schemes used different ways to manage financial risk, such as co-payments to decrease moral hazard and membership restrictions to avoid adverse selection. Some of these control mechanisms may have limited the growth of membership and thus the size of the risk pool, and the effectiveness of these measures depended on how well the members understood and supported them. Schemes are strengthened when their members are informed about insurance concepts.

Marketing and membership incentives: Schemes with more members are financially more secure, so schemes

must always be recruiting new members and working to retain current members. Marketing research improves the ability to enroll new scheme members. Some schemes successfully used insecticide-treated net subsidies as an incentive to recruit new members.

By the mid 2000s, community-based health insurance schemes had lost much of their momentum in Uganda. While about a dozen schemes continued, with approximately 30,000 people enrolled, few new schemes had been launched since the late 1990s. An evaluation carried out on two schemes found explanations from both the supply and demand side.

Demand-side problems included—

Lack of understanding: Members and potential members did not understand the basic principles of community-based health insurance schemes.

Lack of trust: There was widespread mistrust of financial institutions among Ugandans due to the collapse of some financial institutions in the 1990s.

Inability to pay premiums: Eight out of ten people interviewed cited inability to afford the required contribution.

Supply-side problems included—

Limited interest or knowledge: Health care providers and managers were often unaware of or unexperienced with community-based health insurance.

Lack of coherent government framework: Uganda had no specific procedures in place regarding community-based health insurance, despite mentioning such programs specifically in health policy documents.

Sources: Derriennic et al. 2005; Basaza et al. 2007.

The main market imperfections of private insurance models are the insurers' incentives to avoid insuring people at greatest health risks (skimming). Conversely, because private insurance plans are usually voluntary, people at greatest health risk and people with chronic illnesses have an incentive to join the program and the healthiest have an incentive to avoid joining (adverse selection). Adverse selection raises costs and reduces the risk-sharing effect of insurance.

Expansion of private health insurance

Some think that the development of a private insurance market may form the foundation for the future evolution of social insurance by creating capacity within a coun-

try (Pauly et al. 2006). In countries with limited public resources, health insurance allows tax revenues to be targeted at services to provide health care for the poor. However, close government regulation is critical, and regulatory capacity is often weak in developing countries; in the worst-case scenario, governments may take resources from the poor to support the establishment of the health insurance system.

Private insurance can exist alongside single-payer systems, such as social health insurance, by substituting for social health insurance, by complementing it by covering services not otherwise included, or by supplementing it by providing improved coverage to what is already covered (for example, providing access to elective surgery without

Country Study 12-5 Percentage of insurance in health care spending in twenty-four countries: Social insurance versus private insurance

An analysis of insurance in twenty-four countries in three regions showed that Latin America and the Caribbean had the most developed social insurance markets, whereas in East and Central Africa, neither social nor private insurance funds a significant proportion of health expenditures. In the Middle East and North Africa, social insurance schemes generally covered civil servants and those employed in the formal sector.

Region and country	Social insurance	Private insurance
Latin America/Caribbean		
Bolivia	37.7	2.5
Dominican Republic	4.8	7.5
Ecuador	21.5	10.3
El Salvador	20.5	1.1
Guatemala	27.8	3.9
Mexico	34.3	1.4
Nicaragua	10.5	Not available
Peru	24.6	3.1
<i>Average</i>	22.7	4.3
East/Central/South Africa		
Ethiopia	0.0	0.0
Kenya	4.0	3.0
Malawi	0.0	1.0
Mozambique	0.0	0.0
Rwanda	0.0	0.0
South Africa	1.0	41.0
Tanzania	0.0	3.0
Uganda	0.0	0.0
Zambia	0.0	0.0
<i>Average</i>	1.0	5.0
Middle East/North Africa		
Djibouti	20.0	0.0
Egypt	12.4	<1.0

waiting on a list) (Anderson and Hussey 2005). Although all citizens wishing to access private coverage for one of these purposes are eligible to buy it, where it is available, only high-income individuals are likely to take the opportunity, creating an equity gap in access to health care (Anderson and Hussey 2005). [Country Study 12-5](#) shows the extent of coexistence of social and private health insurance in twenty-four countries.

A number of countries have encouraged the expansion of private health insurance; for example, South Africa has a tax-based public system that primarily serves the low-income population, but it is supplemented by a private insurance system that mostly higher-income people purchase to supplement the public system. The government has increased regulation of the private insurance market to increase the equity between the public and private systems (Anderson and Hussey 2005).

12.10 Health or medical savings accounts

Health or medical savings accounts are individual accounts established to encourage consumers to save for expected costs of medical care, enlist health care consumers in controlling costs, and mobilize additional funds for health systems. MSAs are not considered a form of insurance because no pooling of risk occurs between healthy and sick and rich and poor. Because individual savings alone generally cannot protect someone from the financial risk incurred through catastrophic illness or long-term chronic disease, MSAs, in practice, have been used in conjunction with social insurance schemes. They may be administered by public organizations, as in China and Singapore, or by private entities, as in the United States and South Africa.

Medical savings accounts were introduced in Singapore in 1984; elsewhere, experience is limited to few countries, and mainly in the form of demonstration or pilot projects. Even in Singapore, government budget and out-of-pocket payments still play the predominant role in health spending, with MSAs accounting for only a small proportion (see [Country Study 12-6](#)).

Contributions may be mandatory or voluntary. If MSAs are voluntary, other benefits—such as tax exemption—are usually included to create incentives for participation. In this case, maximum contribution levels may be required to prevent the program from being used purely as a tax shelter. Singapore has instituted a compulsory minimum level of contribution with the aim of ensuring that individuals accumulate enough funds to cover health care in their older age.

An alternative model proposed in Canada is for third parties, such as the government, to fund savings accounts. Local health authorities would pay equal amounts into each individual's medical savings account instead of purchasing health care services for the entire population.

Challenges with medical savings accounts

The theory behind MSAs is that they will help control health costs by creating an incentive for consumers to purchase health services wisely, because money left in the account can be used for future health care needs. Proponents argue that with comprehensive health insurance, neither doctors nor patients have incentives to consider the cost-effectiveness of proposed treatments. But the counterargument is that moral hazard arises more among providers than among consumers because of the information asymmetry between service providers and patients. From this perspective, the existence of money in a person's MSA influences providers much like the existence of third-party insurance (Hanvoravongchai 2002).

Another concern about the MSA model is that it is less equitable than comprehensive benefit systems. Those who are indigent or suffer from chronic illnesses are unlikely to be able to accumulate enough savings to cover their needs.

MSA schemes that include high deductibles can also prevent the poor from accessing health services.

Increasing an individual's resources may improve access to needed medicines; however, with the issue of supplier-induced demand and where a provider's income depends partially or totally on profits from pharmaceutical sales, an incentive exists to prescribe multiple medicines (poly-pharmacy) and to use brand-name as opposed to generic medicines. These tendencies can be combated by strategies that restrict prescribing to an essential medicines list (China) or through large co-payments (United States).

12.11 Implementing an appropriate insurance scheme

Many countries see the initiation or promotion of one or more insurance schemes as a way of addressing health financing issues progressively and equitably. The concept of

Country Study 12-6 Medical savings accounts in Singapore

In 1984, Singapore adopted a system of compulsory, individually owned medical savings accounts to help people pay for their medical expenses. The government implemented three different health financing programs depending on need: Medisave, Medishield, and Medifund. The funds are invested and managed by the government; private insurance is not encouraged.

The Medisave program is a national health care savings program. Citizens begin contributing 6 to 8 percent of their wages, which increase according to their age. These funds can then be used to pay for specified inpatient (at both public and private hospitals) and certain expensive outpatient services, such as renal dialysis. Primary care and medicines cannot be paid for from this account. Medisave accounts are not taxed and earn tax-free interest.

The Medishield program was established in 1990 as a catastrophic insurance program to supplement Medisave accounts, which alone are not sufficient to pay for prolonged hospitalizations and treatment for chronic illnesses, especially for low-income workers who contribute less to their accounts. Premiums vary, increasing with age.

The Medifund program was established in 1993 for low-income workers whose medical bills still may not be covered by the other two programs. The government funds this program from the budget surplus, so it is not

guaranteed, reinforcing the government's position that health care is not an entitlement. Funds are distributed on a case-by-case basis.

The combination of subsidies and MSAs appears to provide a safety net, yet the system still has many limitations. In 2002, out-of-pocket spending still accounted for one-third of total health spending in Singapore, while Medisave, Medishield, and Medifund combined accounted for less than 10 percent. The remaining 60 percent came from government health spending on subsidies and from employer-provided benefits.

This limited role of the MSA thus far can be attributed to strict spending criteria, such as caps on per day cost of hospital stays and surgical procedures, and high deductibles and co-payments. The high co-payments in the Medishield program can still be a financial barrier for some people. The extent of this burden, and possibly a sign of the inequality of the system, is seen in the increase in applications for assistance from Medifund. The number rose from 58,000 in 1997 to 91,000 in 2000. Nevertheless, the MSA system is estimated to have contributed to Singapore's relatively low spending on health care (3.3 percent of GDP in 2006). A more extensive evaluation will not be available until 2030, when the system is expected to achieve full implementation.

Sources: Gottret and Schieber 2006; Massaro and Wong 1996; Hanvoravongchai 2002; WHO 2009.

cross-subsidization of the young for the old and the well for the sick is a valuable way to expand the pool of those covered and to maximize risk sharing. However, when governments are considering instituting health insurance, they need to consider the realities of implementation; the complexity of the issues involved is often poorly understood.

When examining the implications of various insurance proposals, it is critical to consider the “enabling environment” of the country (Eichler and Lewis 2000). These factors include all circumstances of the country that affect the health sector, such as the economy, the government’s ability to assume leadership and regulatory roles, the realities of the current health financing and delivery system, and cultural factors (such as the acceptance of social responsibility). Assessing the enabling environment reveals existing constraints and points to interventions that might be needed to facilitate reform (see [Box 12-1](#)).

Besides the immediate issue of deciding who and what will be covered under the insurance plan, other crucial issues to address include policy objectives, organization and geographic availability of health services, premium calculation and payment mechanisms, use and cost control measures, and administrative arrangements. In the case of medicine coverage, questions that policy makers need to answer include—

- Who receives a medicines benefit?
- Which medicines are covered (limited to formularies or generics over brand names)?
- In which settings are medicines covered (inpatient, outpatient, emergency)?

Box 12-1

Assessing a country’s enabling environment for insurance reform

What obstacles and facilitating elements exist in the “enabling environment” of the health sector?

- National income is a constraint.
- Governments lack the capability to effectively collect taxes.
- National reforms such as decentralization affect the health sector.
- Laws and regulations may seriously limit the range of feasible insurance reform options.
- The legal and regulatory framework for the health sector may be inadequate.
- The government may not be ready to assume a leadership and regulatory role.
- Powerful interest groups must be considered.

Source: Eichler and Lewis 2000.

- What will the cost be to the member, the member’s family, the insurance program?
- How can the insurance program influence access to and quality use of medicines?
- What are the desired and undesired effects of medicine policies in insurance, and how can these be routinely monitored?

The ability to administer the health insurance scheme efficiently is a central element of sustainability. The requirements for an active management system to ensure revenue collection, determine co-payments that optimize efficiency and quality care, and manage the benefit package are crucial and demanding. Any insurance system lacking an effective monitoring system that allows frequent changes to accommodate differing circumstances is likely to become insolvent or fail to provide adequate service.

An initial factor to consider when designing or reforming a health insurance scheme is the potential for building on existing successful institutions. For example, if a country already has a well-run tax-based health care system, continuing with this approach may be appropriate. Or if a tradition of community-based health insurance exists, the country may decide to build on it. In all cases, government stewardship and a strong political will to undertake the necessary health financing reform are essential.

The overall structure of the social health insurance scheme should be laid down in a health insurance law. Details that may be subject to frequent change can be established in regulations. Appropriate legislation should specify issues of membership and population coverage; organization, responsibilities, and decision-making authority; the method of financing; and the relationship with providers and the benefits provided by health insurance. Including legislation to protect consumers is particularly important if public faith in the schemes is to be maintained. Therefore, honest and fair marketing regulations need to be put in place and a transparent process for reporting, investigating, and resolving disputes needs to be ensured.

Whatever type of health financing mechanism a country decides to adopt, the transition to universal coverage may take several years, even decades. For example, in Japan, thirty-six years elapsed between the enactment of the first law related to health insurance and the final law implementing universal coverage (Carrin and James 2005). ■

ASSESSMENT GUIDE

General health financing

- What is the country's GDP per capita?
- What is the total national health expenditure (public and private) per capita?
- What is the total national health expenditure as a percentage of GDP?
- What is the percentage breakdown of health spending by source (public, private, nongovernmental organization, donor)?
- What percentage of health care costs is paid out of pocket?
- Does the country already have an efficient tax-based health care system that might form the basis for a tax-based insurance program?
- Does a tradition of community-based insurance exist in the country or region that might facilitate the introduction or expansion of this sort of scheme?
- Are national laws or regulations related to health insurance in place?
- Is there a plan for universal health coverage through insurance?
- Is the government's organizational and managerial framework strong enough to support its role in administering a health insurance scheme?

Insurance systems

- What types of health insurance currently exist: social, private, community? Are existing plans compulsory or voluntary?
- What percentage of the population is covered by each form of health insurance?
- What are the benefit packages? Do limitations exist, such as co-payments and deductibles?
- What are the characteristics of the covered populations: formally employed? high-income?
- What percentage of those insured has policies that cover medicines? What medicines are covered and what restrictions exist on medicines?
- What are the premiums for each form of insurance? Are the premiums calculated on degree of risk?
- What conditions are covered by each form of insurance?
- Is reimbursement dependent on insurance company treatment guidelines or a medicine list for each form of insurance?
- How are providers chosen and reimbursed for each form of insurance?

Glossary

Adverse selection: The tendency for people at greatest health risk to join voluntary insurance programs, while the healthiest people, whose premiums should be used to cross-subsidize the bills of the sicker members, avoid joining.

Capitation payment: A prospective, fixed payment to providers for each person served under the scheme for a particular period of time.

Case payment: An inclusive flat sum paid to health facilities or providers for a patient's treatment (including medicines) according to the diagnosed condition.

Co-insurance: A specified percentage to be paid by the member for the service or medicine; for example, 25 percent for medicines used in serious and chronic illnesses, 50 percent for most other pharmaceuticals, and 75 percent for symptomatic treatments for minor illnesses.

Community-based health insurance (also known as mutual health organizations): A usually voluntary prepayment plan to pool risk and resources centered on the concepts of mutual aid and social solidarity. Membership may be based on geographical entities, trade or professional groupings, or health care facilities.

Co-payment: Cost-control measure in insurance schemes in which the member pays a set charge per item received; co-

payments may be lower for generic medicines, higher for brand-name medicines.

Cross-subsidization: A risk-sharing concept, where the healthy subsidize the ill and the rich subsidize the poor.

Deductible: A set amount that each person in the insurance scheme must pay each year before he or she can tap into the benefits of the plan.

Exemption: A release from payment of fees for specific population groups or disease or medicine types, employed in many revolving drug fund schemes to promote access to services.

Fee for service: A payment mechanism where the insurer pays providers for each service provided to a patient.

Health insurance: A financing scheme characterized by risk sharing, in which regular payments of premiums are made by or on behalf of members (the insured). The insurer pays the cost or a set portion of the cost for covered health services.

Health maintenance organization (HMO): A type of managed care organization that provides health insurance that is fulfilled through hospitals, doctors, and other providers with which the HMO has a contract. Unlike traditional indemnity insurance, care provided in an HMO generally follows a set of care guidelines.

Health or medical savings accounts: Not strictly a form of insurance, medical savings accounts encourage individuals, often by providing tax advantages or subsidies, to save for the expected costs of medical care.

Indemnity insurance: A type of insurance where no contractual arrangements exist between insurers and providers and the provider is paid a fee for the service.

Managed care: Insurance systems in which the insurer plays an active role in overseeing the utilization and quality of service, for example, through health maintenance organizations (HMOs), preferred provider organizations (PPOs), and managed indemnity insurance.

Market failure: A term used by economists to describe circumstances that constrain the smooth operation of the market (Normand and Weber 1994).

Maximum allowable cost (MAC) or maximum reimbursement price (MRP): Cost-control measure in insurance schemes that specifies the highest amount that will be reimbursed for each pharmaceutical item dispensed.

Moral hazard: In the context of health financing, when members of a health insurance scheme use services or consume medicines more frequently than if they were not insured.

Multiple-payer system: Where several different organizations collect and pool revenues and purchase health services for specific parts of the population.

Mutuelles de santé: Term used in West Africa for community-based health insurance plans.

Out-of-pocket spending: When a person pays a nonreimbursable fee directly to a health service provider at the time of service or to a dispenser for a medicine or other health commodity.

Payment for performance (or incentive payments): A variation on fee for service in which doctors or health facilities are paid based on whether they achieve predetermined quality-based performance indicators.

Pharmaceutical benefits management scheme: Mechanism in which organizations contract with insurers to provide pharmacy services, often through subcontracts with local pharmacies and through mail-order pharmacy services.

Premium: In private insurance schemes, the money that is regularly paid to the insurance company for health insurance coverage.

Prepayment: A payment made in advance that guarantees eligibility to receive a service when needed at limited or no additional cost. Prepayment is a feature of all types of health insurance.

Prior authorization: Cost-control measure in insurance schemes in which the insurer retains the right to approve medicine use before medicines are dispensed to the patient.

Private health insurance: A scheme that is usually paid for by voluntary contributions from employers, mutual societies, cooperatives, or individuals.

Purchasing: The process by which pooled funds are paid to providers to deliver health goods and services.

Reference price systems: A cost-containment method for pharmaceuticals where a cluster of similar medicines is associated with one specific price accepted by the government for reimbursement purposes.

Reimbursement: A system where providers are paid after they deliver the services.

Reinsurance: When a direct insurer contracts with a second insurer to share risks that the direct insurer has assumed for its members. Often associated with small community-based plans, reinsurance protects the direct insurer from catastrophic liabilities.

Risk pooling: A method that shares the financial risk associated with health care among large groups. Pooling requires some

transfer of resources (or cross-subsidization) from healthy people to sick people and from rich to poor.

Single-payer system: Where one organization (usually the government) collects and pools revenues and purchases health services for the whole population.

Skimming: A problem that occurs when insurers use various screening measures to avoid insuring people at greatest health risk (and therefore greatest expense).

Social or public health insurance: A compulsory system, for civil servants, people in the formal employment sector, and certain other groups through programs such as social security funds, national health insurance funds, and other systems. Premiums are often deducted directly from salaries or wages.

Step therapy: A restriction on a patient from receiving the most expensive pharmaceutical therapy without first trying the less expensive alternatives.

Tiered co-payments: The different payments that patients make for their prescriptions, depending on which tier the medicine falls in; for example, generic or brand name.

Universal health coverage: The concept of ensuring that all of a country's citizens have access to adequate and affordable health care.

User fee: An out-of-pocket payment made by the patient at the time a health service is provided.

SUMMARY

Many governments, nongovernmental organizations, and community health programs have implemented user fees to fund or partially fund the cost of pharmaceuticals or other health services. Many different forms of revolving drug funds (RDFs) exist. Their common element is that fees are charged for medicines dispensed. In the context of the Bamako Initiative, community pharmaceutical schemes often have cost-recovery objectives that include the financing of health education, immunization, and other aspects of primary health care.

During the 1990s and early 2000s, the debate over user fees intensified within the context of a global call for increased access to medicines: evidence supports arguments from both sides, and opinions still differ about the feasibility of creating and sustaining an equitable cost-recovery system based on user fees (Meessen et al. 2006). Supporters assert that RDFs can raise substantial revenue, improve pharmaceutical availability and quality of care, promote equity by making pharmaceuticals more accessible to the poor while charging those who can afford to pay, reinforce decentralization through local control of resources, and encourage efficiency in pharmaceutical management and medicine use. Others caution that collection costs may exceed revenue collected, no improvement may occur in pharmaceutical availability or other quality measures, user charges are a form of “sick tax” that substitutes for public spending, people are dissuaded from seeking essential health care, and incentives are created for overprescribing. Note that some critics judge RDFs separately from health system user fees (for example, Save the Children 2002).

Planning and implementing an RDF require simultaneous commitment to public health goals and sound business management. A number of steps are involved—

Feasibility: Determine whether the concept of an RDF is politically acceptable, economically viable, and realistic in terms of managerial requirements.

Organizational structure and legal status: Decide which RDF functions will be centralized and which decentralized. Seek government or legal endorsement for such issues as retention of revenue at the facility or district level. Community involvement is often essential for the acceptability, credibility, and accountability of RDFs.

Pricing and exemptions: Establish policies that ensure access to services and also maintain the financial integrity of the RDF. Determine fee collection mechanisms as well as fee levels. Consider willingness to pay and cost data in setting pharmaceutical prices.

Financial planning: Ascertain initial capitalization requirements and recurrent costs. The availability of government and donor subsidies helps determine the RDF’s cost-recovery objectives.

Supply management: Consider management requirements because weaknesses in any area can threaten the RDF’s service performance and financial viability.

Public communications: Tailor target audiences, messages, and media to each stage of RDF implementation.

Monitoring and supervision: Put in place recording, reporting, supervisory, and other measures to monitor effect on patients, financial performance, pharmaceutical availability, and medicine use.

Establishing and sustaining RDFs have been difficult in practice. Improved pharmaceutical availability, equity, and efficiency are more likely with local control and retention of revenue; reliable supply of low-cost essential medicines; locally appropriate fee schedules; protection mechanisms to ensure equitable access; continued or increased levels of government funding for health; businesslike orientation to personnel, financial management, and supply management; strict measures to ensure accountability; and implementation in phases or through a well-conceived pilot approach.

13.1 Introduction

Revolving drug funds (RDFs) are difficult to implement. Examples of successful large, national RDFs are limited. Revenues are often much less than expected. Use of health services and, therefore, equity of access often decrease. Reliable pharmaceutical supply, management, accountability, and rational medicine use are challenges for any RDF.

Countries and programs that implement RDFs should do so with a full understanding of the problems other programs have faced and the solutions that have succeeded elsewhere. (Country Study 13-1 illustrates the number of years and tremendous political commitment needed to establish an RDF in the Sudan.)

At the same time, many countries providing “free” health services have found that public resources are insufficient to

Country Study 13-1

Establishing a successful revolving drug fund in Sudan

With initial capitalization and technical support from Save the Children, the Ministry of Health in Sudan's Khartoum state phased in an RDF from 1989 to 1996. A 2006 evaluation included record review and interviews with policy makers, health care practitioners, patients, and households in the catchment area of facilities operating under the RDF. A control group comprised facilities not affected by the RDF.

The results showed that the RDF facilities had a higher level of medicine availability (97 percent) compared with controls (86 percent). Clients reported the medicines to be affordable—the average cost of a prescription amounted to only 2 percent of the lowest monthly government salary.

Key success factors included autonomy that allowed the RDF managers to keep their funds separate from other government accounts, government tax and licensing exemptions, and an innovative currency swap agreement that allowed the RDF to access hard currency at official rates.

The table below lists the lessons learned in Khartoum's RDF experience. Based on the results, the Ministry of Health is expanding the RDF to the rest of the country in phases—by the end of 2006, nineteen of twenty-five states were part of the RDF.

Lessons learned from the RDF in Khartoum state

	Factor for success	Components/results
1	Substantial investments	<ul style="list-style-type: none"> • Helping RDF to absorb devaluation loss • Allowing RDF to mature until sustainable
2	Gradual implementation	<ul style="list-style-type: none"> • Allowing time for necessary preparation • Testing of drug supply and cash collection systems • Proper staff training
3	Management style	<ul style="list-style-type: none"> • Adopting transparency • Flexible organization structure • Business-oriented management • Joint management between national Ministry of Health and expatriate Save the Children staff
4	Political commitment	<ul style="list-style-type: none"> • Tax and import duty exemptions • Independent account • Import license exemption • Monopoly
5	Currency swap agreement	<ul style="list-style-type: none"> • Safeguard against devaluation • Permitting importation of low-cost and quality medicines • High markup on cost covering the RDF operating expenses while keeping retail prices lower
6	Price revision	<ul style="list-style-type: none"> • Protecting the RDF against devaluation • Keeping pace with market prices • Maintaining users' ability to pay
7	Community acceptance	<ul style="list-style-type: none"> • Increasing RDF turnover • Permitting replenishment of exhausted stocks • Avoiding the tie-up of funds • Ensuring revenue available to cover RDF operating expenses
8	Focus on common diseases	<ul style="list-style-type: none"> • Short list for treatment of common diseases • Avoiding the wastage of limited resources • Increasing coverage by purchasing large quantities
9	Reliable supply system	<ul style="list-style-type: none"> • Regular availability of medicines • Low-cost medicines • Maximizing RDF sales • Allowing RDF to make medicines regularly available
10	Supervision	<ul style="list-style-type: none"> • Prohibiting medicine leakage • 100% cash collection rates • Reducing losses due to expiration and deterioration of medicines

Sources: Ali 2009; Hamed and Ibrahim 2009.

meet rising costs and increasing demand. When funds are limited, provision of essential medicines is among the first components of health care to suffer: medicine shortages become common even when selection, procurement, distribution, and use are efficient and rational.

On the basis of research showing that user fees can easily cause a decrease in the use of preventive health care services, most international agencies discourage implementing user fees for preventive care, including the World Bank and World Health Organization (WHO). (Nevertheless, even when preventive services are free, they are still underused in both developed and developing countries, as reported by Liu and O'Dougherty 2005.) In addition, many in the international health community are calling for all user fees to be abolished; however, eliminating existing user fees in resource-limited countries does not necessarily improve access to medicines and services unless sufficient resources are available to take up the slack and ensure equitable access. For example, the elimination of medicine fees at public facilities may result in more stock-outs, leading patients to pay more in private pharmacies that have reliable stock (James et al. 2006; Xu et al. 2006). Although user fees can contribute to budgets for services and pharmaceuticals that would otherwise not be available, evidence shows that fees are usually a major detriment to access to the poorest people in the community, because exemption plans that are supposed to act as a safety net for needy patients are often nonfunctional (Gottrett and Schieber 2006).

Proponents on both sides of the issue recognize the challenges of providing sustainable financing for pharmaceuticals that maximizes equitable access, especially for long-term treatment, such as that for HIV/AIDS. WHO now promotes minimizing fees for health care and medicines and encourages countries to use taxes or insurance schemes to finance health expenses (Foster et al. 2006). Ghana is one country whose government decided to abolish its national “cash-and-carry” system of financing health services and replace it with a national health insurance system while maintaining local facilities’ autonomy in managing their RDFs. [Chapter 12](#) discusses health insurance in detail.

Cost sharing through medicine fees is one of several pharmaceutical financing strategies described in [Chapter 11](#). That chapter is concerned with programs in which medicine fees are used to finance essential medicines at the national level, at the district level, at individual institutions such as teaching and referral hospitals, or through community pharmaceutical schemes.

Medicine fees may be simply one component of a broader program of user fees. Although such programs may not think of themselves as RDFs, this chapter should be useful for any program involved in setting medicine fees and using the revenue to resupply medicines.

13.2 The revolving fund concept

What is a revolving drug fund?

In an RDF, a sum of money (contributed by the government, donors, or the community) is used to purchase an initial stock of essential and commonly used medicines to be sold, ideally at a price sufficient to replace the stock of medicines and ensure a continuous supply (see [Figure 13-1](#)). Reasons usually given for establishing an RDF are—

- Essential medicines are a critical component of effective preventive and curative care.
- Patients perceive the increased availability of pharmaceuticals as a real improvement in the quality of care.
- Pharmaceuticals are tangible, and most patients are willing to pay for them.
- The public spends significant amounts of money for pharmaceuticals from the private sector, often buying inadequate quantities at high prices. Medicines supplied through an RDF are generally more affordable.
- Patients may attach greater value to medicines for which they have paid. A potential result is improved patient adherence to treatment.
- RDFs linked to essential medicines programs offer the potential for increasing the efficiency of pharmaceutical services as well as generating additional revenue.
- Increased price awareness by prescribers and patients may result in improved use of medicines.

Whereas the primary objective of private pharmacies is to maximize profit, the objective of RDFs is to maximize access. If current public financing is sufficient to ensure universal access to essential medicines without charge, medicine fees are unnecessary. If current financing is inadequate, an RDF can provide supplementary resources to make low-cost essential medicines more accessible (Uzochukwu and Onwujekwe 2002; Xu et al. 2006).

Experiences with RDFs

There are numerous examples of experiences with user-fee programs and, in particular, with RDFs. From these experiences, proponents of user charges suggest the following—

- Substantial revenue can be raised by user fees, which add to central allocations.
- Pharmaceutical availability and quality of care are improved with the additional revenue.
- Equity is promoted because limited public funds can be targeted to the most needy while the rest pay.
- Decentralization is reinforced through local control of resources.

Figure 13-1 The RDF cycle

- Efficiency is fostered through lower fees at first-level facilities to reinforce the referral system and through higher fees at higher-level hospitals to reduce the disproportionately large expenditures typically made on pharmaceutical supply for referral hospitals.

Not all governments or health financing experts favor user fees for medicines. Opponents observe the following—

- Collection costs may exceed revenue collected when the full cost of developing the system and all additional administrative costs are considered.
- No improvement may take place in pharmaceutical availability and other quality measures (as has occurred in some user-fee programs).
- User charges may become a form of “sick tax,” substituting for rather than supplementing central allocations.
- People, particularly the poor and other target groups, are dissuaded from seeking essential health care.
- Incentives for overprescribing are created if revenue is used to support staff salaries.

Decades of experience with RDFs and user fees for services demonstrate the need for thoughtful design that includes community involvement, careful implementation associated with quality improvement, and good management. However, experience also shows that cost-recovery programs are rarely able to achieve these standards in the long term.

Programs that have implemented large fees with no preparation of the public and little improvement in quality have seen significant decreases in use; programs designed with little attention to management and accounting systems have resulted in abuse and generated little revenue compared with the cost of fee collection; programs that have not reinvested revenues to improve quality have resulted in a decline in public confidence and use; RDFs without a reliable source of low-cost medicines have quickly ceased to revolve, and some schemes with pharmaceutical charges have led to overprescribing.

Steps for planning and implementing an RDF

The planning and implementation of a successful RDF require simultaneous commitment to public health goals and sound business management principles. Each of the following steps requires careful attention—

- Carry out a situation analysis and feasibility assessment.
- Prepare a financial plan that considers cost-recovery objectives, capitalization requirements, and long-term financial needs.

- Determine the organizational structure, staffing, and legal status of the RDF.
- Develop an implementation plan.
- Determine pricing and exemption policies.
- Develop the necessary systems for pharmaceutical management and financial management.
- Prepare public communications for introducing the RDF.
- Monitor impact and adjust the program accordingly.

13.3 Situation analysis and feasibility assessment

Governments considering whether to introduce cost recovery must address questions of political, economic, and managerial feasibility, given local circumstances (see [Figure 13-2](#)).

Similarly, governments that are considering discontinuing such programs must take measures and have the resources in place to handle the consequences of losing revenue, such as increased medicine stockouts and upsetting health care providers who have come to rely on fees to supplement income (Gilson and McIntyre 2005).

Political issues

Three political issues are key in establishing an RDF: acceptance of the user fee concept, local retention of fee revenue, and political and administrative decentralization.

Acceptance of user fees. Although many believe strongly in the concept of universal access to health care, a policy of free medicines is worth little if medicines are unavailable. When RDFs have been proposed in settings where pharmaceuticals at health facilities have been scarce, public reaction has generally been positive. Moreover, when an RDF has resulted in a noticeable increase in the availability of pharmaceuticals, public acceptance has been much greater than government officials anticipated. Studies have shown that the public’s willingness to pay for government health services is closely tied to people’s perception of quality and the value that they are getting for their money (Shaw 1995). Conversely, if people have experienced a steady supply of medicines provided free of charge by the government, they are more likely to oppose any introduction of fees. In this setting, the need for an RDF should be carefully considered.

Local retention of fee revenue. The “law of the treasury” often requires that revenues earned by any arm of government be remitted to the central government. RDFs will not revolve, however, unless the facilities that collect medicine fees can retain this revenue to replenish their pharmaceutical supplies. Reinvestment of revenues in the collecting facility also promotes a sense of community ownership, which further protects and strengthens the RDF. Facilities

Figure 13-2 Cost-recovery potential determined by patients and costs, not by policy

in a pilot project area are often permitted to retain revenues, but replication on a broader scale requires permanent changes in government policy.

Political and administrative decentralization. The question of local involvement and autonomy can be politically sensitive. Successful revolving drug funds often involve community participation and supervision, which ensures financial sustainability and greater community interest in the local health facility. Local empowerment must be accepted and supported by higher levels of government (which must give department or provincial authorities the authority and flexibility to design policies appropriate for their areas). An RDF's local autonomy in the Lao People's Democratic Republic provided financial flexibility and allowed it to avoid decapitalization during a period of rapid inflation (Murakami et al. 2001).

Economic issues

Can sufficient funds be recovered to justify the effort required to make an RDF successful? The answer to this question depends on national and local economic strength, patients' ability and willingness to pay, "competition" from other sources of supply, the availability of capital, policies on exemptions and subsidies, and the program's overall ability to balance public health and economic objectives. All these issues should be carefully considered. Household and patient surveys that ask people about their choice of health services and health care expenditures can reveal a great deal about both willingness and ability to pay for health treatment.

Economic feasibility is also influenced by the level at which fees are introduced. Should RDF implementation be top-down, starting first in hospitals, or bottom-up, begin-

ning in the community? Each approach has advantages and disadvantages.

Despite the many concerns related to economic feasibility, health service use and equity may actually improve with medicine fees (Murakami et al. 2001). A brief explanation of the economic underpinning of this observation may be illuminating. Although opponents of cost sharing often speak about the increase in cost, purchasing medicines locally often avoids the high travel and time costs of seeking care elsewhere, and paying a fee for a medicine as part of an RDF may cost less than paying for it in the private sector (Xu et al. 2006). The key lesson is that price must be examined from the perspective of the patient.

Managerial issues

Given the human and physical infrastructure, can a cost-recovery system be made to operate? Accountability, a businesslike orientation, supply management capacity, and human resources capacity are especially critical when a revolving drug fund is initiated at the community level, because management systems and capacity may need to be developed.

Demonstrated commitment by the government (and often by the donor) is essential. Is support available to help maintain the fund until self-sufficiency is reached?

13.4 Financial planning

RDF financial planning involves defining the cost-recovery objective, the roles of government and external funding, the capitalization requirements, and foreign exchange issues. Because the goal of an RDF is to maintain steady

pharmaceutical supply while serving as many people as possible, careful analysis is necessary of both recurrent costs and regular government and donor contributions. Pharmaceutical sales must make up any shortfall between these costs and revenues. Many countries that are eager to commence cost-recovery programs fail to do a careful financial analysis before embarking on such programs. As a result, a well-intentioned RDF may quickly decapitalize; some revenues are raised, but a direct relationship does not necessarily exist between revenues and stock replacement.

Cost-recovery objective

The cost-recovery objective for an RDF may be set by policy, but the actual level of cost recovery depends on the response of patients to medicine fees, the number of exemptions, and collection efficiency, among other factors. Although some programs attempt to cover all primary health care costs through user fees, many countries have found recovering full costs on a large scale extremely difficult.

Cost-recovery alternatives. The level of cost recovery reflects the relationship between the total operating costs and the total revenues collected. Possible cost-recovery objectives include—

- Partial recovery of pharmaceutical costs, which require continued subsidy from government or other sources
- Full recovery of pharmaceutical costs
- Full recovery of pharmaceutical costs plus some local operating costs
- Full recovery of all pharmaceutical costs and local operating costs

Tension between public health and financial objectives is inherent in the RDF concept. Because RDF fees are intended to increase the availability of essential medicines at the local level, they must not serve as financial barriers to people receiving needed services. The RDF must improve total access to service, not decrease it. Yet the fees must be high enough to ensure replenishment of supplies and financial sustainability of the RDF.

Establishing a realistic cost-recovery objective depends on striking a balance among operating costs, revenue collection, and government and other funding.

Operating costs. Pharmaceutical costs should be calculated based on the full replacement cost of medicines. This cost includes the original purchase price (with insurance and freight), price increases caused by inflation and currency fluctuations, and the cost of losses caused by expiration, spoilage, and pilferage. Other recurrent costs include management of the procurement office, transportation, storage at various levels, and perhaps repackaging. In addition to pharmaceutical costs, local operating costs include health

workers' salaries, fuel for vehicles, consumable items such as dressings, cold-chain costs, and utilities (see [Chapter 41](#)).

Revenue collection. Revenue collection in RDFs is determined by patients' willingness to pay, exemption rates, and collection efficiency; it is often far below target levels.

The price at which most patients will buy medicines at a government health facility, which is a reflection of their willingness to pay, depends on several factors—

- Household income, which can vary dramatically by season, especially in rural areas
- Availability and cost of alternative sources of medicines and health care (the “competition”)
- Perceived quality of the pharmaceuticals and associated health care services
- Severity of the illness
- Cultural factors, such as the priority given to health care for men, women, and children

Basing RDF prices only on actual costs sometimes leads to a dramatic and dangerous decline in health facility use. Because of differences in access, perceived quality, and usual quantities of pharmaceuticals purchased, direct comparison with private-sector prices can be misleading. Estimates of willingness to pay can be made using the techniques described in Section 13.7 on pricing.

Exemption rates are another major determinant of actual revenue collections. In cost-recovery programs with broad exemption criteria, over 50 percent of patients do not pay; a high level of cost recovery is difficult, if not impossible, in such circumstances. Exemption criteria, administrative arrangements, and mechanisms for financing exemptions are considered later in this chapter.

Finally, total revenue reflects collection efficiency: What share of expected revenues is actually collected? When the number of patients treated, quantity of medicines dispensed, pharmaceutical prices, and exemption rates are considered, how much money should have been collected, and how much money actually was? It is not unusual to find that actual collections are less than two-thirds—sometimes as little as one-third—of expectations.

Reasons for collection inefficiency include simple laxity in implementing fees, unofficial (“backdoor”) exemptions, and pilferage of medicines and cash. A high collection rate depends on sound pharmaceutical management systems, well-developed financial management and accountability measures, regular monitoring and supervision, and when necessary, vigorous use of disciplinary and legal measures. Collection inefficiency is a major threat to RDFs.

Role of government and external funding

Government and external funding are often necessary to plan and implement an RDF and to cover the cost of exemp-

tions, subsidize high-cost medicines, and fund other health system costs not financed through user fees.

Maintaining government funding. If continued government funding is needed for pharmaceuticals, how can it be secured? What strategies can ensure that RDF revenue supplements, rather than substitutes for, central treasury allocations?

The simple but vague promise of “continued funding at present levels” may be difficult to monitor and enforce in practice. Trends in government revenues, allocations among ministries and within the ministry of health, local inflation, and foreign exchange fluctuations (which usually have a major effect on pharmaceutical purchasing power) all make increases or decreases in pharmaceutical budgets difficult to predict.

At least three budgeting strategies exist: (1) maintaining an annual per capita pharmaceutical budget; (2) establishing a budgeting formula and an agreed-upon list of groups of patients or treatments for public support (for example, children, prenatal supplements, tuberculosis treatment); and (3) excluding RDF revenue entirely from all national or local budget information and expenditure analysis.

The last approach has been implemented in one East African country by showing user-fee revenue as a nominal amount in official budget figures and excluding it from historical comparisons and budget analyses. As a result, rising user-fee and insurance revenue has not measurably affected central government allocations for health.

Funding from donors and development loans. Grants and development loans can be instrumental in planning and implementing an RDF. This category of funding may include financing of start-up capital, development costs, and price subsidies during the first few years of operation. Such funding should not be relied on for long-term subsidy, however, because it puts the RDF’s financial sustainability at risk.

In an RDF, donated medicines should normally be sold through health facilities at regular RDF prices, and the revenues from such sales should be used to support health services, as determined by the community. Distributing donated medicines without charge creates confusion for health staff and patients. Medicines provided to support programs such as leprosy or tuberculosis control, which are often included in the list of exempt health conditions, would be an exception.

Start-up financing

Starting or expanding a revolving drug fund requires working capital, support for the development of management systems, and sometimes partial subsidy of pharmaceutical costs.

Capitalization requirements. Capitalization means filling the RDF pipeline—from central warehouses through

peripheral medicine stores—with appropriate inventories at each level before pharmaceutical sales begin. Only when the pipeline is filled is the drug fund able to revolve. Gaps in the pipeline result in missed deliveries from one level to the next and eventual stockouts at the point of service delivery.

The central government or an external donor may provide seed stock for RDF capitalization, or it may be contributed at the local level by the community. Pipeline calculations for an RDF are illustrated in [Box 13-1](#). The pipeline is affected by inventory management decisions ([Chapter 23](#)), distribution system design ([Chapter 22](#)), and cost-saving measures related to pipeline management ([Chapter 40](#)).

Overcapitalizing RDFs wastes money, but RDFs that are undercapitalized quickly break down—for example, when fees are collected from pharmaceutical sales, but funds are inadequate to replenish pharmaceutical stocks. When revenues intended for pharmaceutical purchases are inadequate to purchase all necessary medicines, funds may be used for emergency purchases of small quantities at higher-than-expected prices or to pay other expenses, further decapitalizing the fund.

Development and implementation of management systems. Support may be needed to develop pharmaceutical and financial management systems and for training, community orientation, monitoring, and other implementation activities.

Price subsidies. Lower prices and broader exemptions may be needed at the beginning to gain acceptance for the system. The total development cost of an RDF, therefore, may need to include funds to partially subsidize prices for the first few years.

Foreign exchange

Foreign exchange is an extremely important issue that requires support and cooperation from government groups outside the health sector. Where local currency is not freely convertible and the demand for foreign exchange exceeds supply, government commitment is required to provide the foreign exchange necessary to replenish pharmaceutical supply on a regular basis. Because revolving drug funds are designed by health policy makers but foreign exchange allocations are made outside the health sector, often by the ministry of finance, central bank, or national planning ministry, the issue of foreign exchange can be problematic. Coordination among different arms of government is difficult but essential to ensure the sustainability of supply.

Liberalization of foreign exchange markets has greatly improved the situation in many countries. Even where governments continue to allocate foreign exchange for government ministries, an RDF may be able to obtain a waiver for foreign exchange on the open market.

Box 13-1 Pipeline calculations for capitalizing an RDF

A revolving drug fund must have sufficient working capital (pharmaceuticals and cash) to start revolving and keep revolving. Working capital depends on the amount of pharmaceuticals and cash in the pipeline. The length of the pipeline is measured in numbers of months. It is determined by the number of levels in the distribution system, the safety stock at each level, and the average working stock (which depends on the delivery interval—see [Chapter 23](#)). The diameter of the pipeline is determined by the final outflow—the total value of pharmaceuticals dispensed per month.

The following example illustrates a pipeline calculation for establishing an RDF to serve a network of 210 community pharmacies. It includes a central supply agency, district stores, and community pharmacies.

The pipeline for the proposed pharmaceutical sales program begins with the disbursement of funds for procurement and ends at the point where funds are collected and made available for purchasing replenishment supplies. The pipeline can be broken down into a number of segments, as illustrated below.

Average monthly sales. The number of low-, medium-, and high-volume community pharmacies and the average monthly sale per pharmacy are estimated in the table opposite.

Capital requirements. With an average pipeline length of sixteen months and an average consumption for all 210 pharmacies of 65,000 U.S. dollars (USD) per month, total capital requirements would be as follows—

$$16 \times \text{USD } 65,000 = \text{USD } 1,040,000$$

Sources of capital and possible cost savings. Working capital can be supplied from various sources: the purchase pipeline and safety stock could be financed by donations, the working stock for central and district levels by government allocations, and the community pharmacy funds from community fund-raising efforts. Improved procurement payment terms, more rapid flow of medicines through the system (faster turnover), and more efficient bank transfers could shorten the pipeline and reduce capitalization costs.

Cash and pharmaceuticals in the pipeline	Months
Purchase pipeline: In this example, it is assumed that roughly 50 percent of pharmaceuticals will be purchased from international sources and 50 percent from local sources. For international purchases, an average of six months will elapse between the provision of a letter of credit and the receipt of the pharmaceuticals at the central supply agency. For domestic purchases, payment will be made upon receipt. Therefore, the average purchase pipeline will be three months.	3
Central supply agency safety stock: A three-month safety stock will be maintained at the central supply agency.	3
Central supply agency working stock: The supply agency will tender once a year but will receive deliveries every four months, which implies a maximum working stock of four months and an average working stock of two months.	2
District safety stock: The district medical stores of the supply agency will maintain a two-month safety stock.	2
District working stock: The district medical stores will receive shipments from the central supply agency every two months, implying a maximum working stock of two months and an average working stock of one month.	1
Community pharmacy safety stock: The community pharmacies will maintain a one-month safety stock.	1
Community pharmacy working stock: The community pharmacies will be resupplied once a month, implying a maximum working stock of one month and an average working stock of half a month.	0.5
Community pharmacy cash on hand: The community pharmacies will use their revenues once a month when they purchase their resupplies from the district medical stores. On average, these funds will have been held half a month by the community pharmacies.	0.5
District to center cash transfer: Money received by the district medical stores will be deposited within the week at the local branch of the national bank. On average, this money will take one month to be credited to the account of the supply agency.	1
Cash on hand: In general, purchases made by the supply agency will represent one-third of its annual turnover. As a result, money will sit in the agency's central account up to four months, or an average of two months, before being used to make a purchase.	2
Total pipeline =	16

13.5 Organizational issues

Organizational issues for RDFs include their structure, pharmaceutical supply system, need for a multidisciplinary team, community involvement, and legal matters.

Organizational structure

RDFs can be managed through a highly centralized structure, a decentralized approach, or a mixed approach in which different functions are managed at different levels. Centralized systems have the potential advantages of a standardized medicine list, bulk purchasing, and national uniformity in pricing policies. Decentralized price setting, determination of exemption policies, and adjustments in the medicines list, however, may make an RDF more responsive to local circumstances.

In practice, many RDFs combine the two approaches. For example, procurement may be centralized, and policies with regard to prices and exemptions may be determined locally. Or the central government may provide training and supervision, and all other management systems, including procurement and distribution, may be decentralized. The important issue is to identify the key requirements for RDF implementation and to clarify

where responsibility lies for each. Major routine functions include—

- Product selection (review and revision of the essential medicines list)
- Procurement and distribution
- Price setting
- Determination of exemption policies
- Audit and financial oversight
- Local representation and oversight

Pharmaceutical supply system

RDF survival depends on a regular supply of low-cost, high-quality medicines; if procurement and distribution are not reliable, the RDF will quickly stop functioning. RDFs may be established as part of a major effort to revitalize government pharmaceutical supply systems, including central medical stores (CMS), or in conjunction with the establishment of an autonomous pharmaceutical supply agency.

RDFs may also be supplied through a direct-delivery system, in which tenders establish the supplier and price for each item and suppliers deliver medicines directly to districts and major facilities. Pharmaceuticals may be supplied through a primary distributor system, in which the

government establishes a contract with a single private distributor (or prime vendor) as well as separate contracts with pharmaceutical suppliers. The primary distributor manages pharmaceutical distribution by receiving medicines from the suppliers and distributing them to districts and major facilities. Finally, some RDFs that have the authority (that is, they are not required to buy from the public-sector supplier) may procure pharmaceuticals through the local private sector, especially in cases where the government supply is unreliable. The Nyamira district RDF in Kenya normally procures from the district medical store; however, it uses a private procurement agent to fill gaps (Enemark, Alban, and Vazquez 2004). In the Lao P.D.R., the RDF often buys medicines from private pharmacies, which are also its competition (Murakami et al. 2001).

Pharmaceutical supply strategies—including the CMS system, autonomous agencies, direct delivery, and primary distributors—are described in detail in [Chapter 8](#). Because a reliable supply of medicines is essential to the success of RDFs, decision makers and managers involved in planning or implementing RDFs must carefully consider the best pharmaceutical supply strategy.

Multidisciplinary team

Just as an immunization program needs staff specialized in cold-chain maintenance, epidemiology, and community mobilization, RDFs need staff specialized in certain areas. In addition to staff with clinical and pharmacy training, RDFs need staff with skills in economics, business, and accounting. Such skills are often found in other ministries and in the nongovernmental sector. Recruitment of some specialized staff may be needed.

Community involvement

Community involvement is essential for the acceptability, credibility, and accountability of RDFs. Informal involvement may include advising on program development and the collection and use of revenue and participating in public awareness campaigns. Formal involvement may include participation in generating start-up funds, setting fees, determining who receives exemptions, ensuring accountability, and monitoring the use of revenues. For example, cases in sub-Saharan Africa showed that by involving communities in initial cost-sharing strategies, the community-based management committees were empowered to make more complicated management decisions down the road (Shaw 1995). Also, rural districts in Uganda where communities owned and managed funds from user fees had improved service quality and increased usage, while urban districts, which had little community involvement, saw decreases in service usage (Kipp et al. 2001).

Community stakeholders must be a part of the design and planning process, so that they become owners of and therefore advocates for the program. Garnering community support and providing information to the public are particularly important at the outset, when user charges are just being introduced or when major program changes occur. [Chapter 31](#) discusses community participation in greater detail.

Legal aspects

Government-run RDFs and broader user-fee programs often involve policies and actions that are not strictly legal under current law or whose legal status is unclear. Examples include the policy that user-fee revenue will add to, not replace, central government allocations; retention of revenue at the facility or district level; opening of local bank accounts; carrying forward of unspent funds to the next fiscal year (as opposed to returning funds to the treasury); and independent external audits of RDF financial accounts and stocks.

Depending on local conventions and the policy or action involved, official endorsement may require various combinations of ministry circulars, legal notices, cabinet approval, acts of parliament, and presidential decrees (executive orders). Generally, the more cumbersome the method (such as an act of parliament), the harder it is to reverse. This fact can provide a degree of protection from future political whim. Therefore, if some principles are vital to the success of the RDF (such as local retention of fees or additivity to treasury allocations), the effort to have these principles endorsed through legal notice or even an act of parliament may be worthwhile.

13.6 Implementation planning

Implementation planning involves decisions about bottom-up versus top-down implementation, phasing and pilot testing, and development of RDF procedures.

Bottom-up versus top-down implementation

Bottom-up versus top-down development of user charges is both a policy question and an implementation question. Introducing fees at all levels at the same time is rarely feasible. Therefore, should fees be introduced first at the hospital level or at the community level?

Arguments favoring starting at the top include the following (Griffin 1988; Blakney, Litvack, and Quick 1989)—

Equity: Higher-level facilities generally serve populations that are better able to pay for services and have access to other health providers.

Reinforcement of referral system: Introducing charges at higher levels encourages the use of cost-effective lower-level services.

Revenue potential: Higher-level facilities provide large volumes of more costly pharmaceuticals and other services.

Administrative capacity: Senior managers, pharmaceutical management staff, accountants, and other necessary staff may be better equipped to undertake the additional administrative burden.

Impact evaluation: The health care and financial effect of user fees is easier to monitor at a smaller number of more accessible facilities.

Arguments favoring starting at the level of the community or primary care facilities include the following—

Demand: Communities are actively interested in ensuring a regular supply of essential medicines.

Lack of alternatives: Rural populations often have fewer choices in health care; if the government or community cannot provide medicines, they may go without.

Support for prevention: Increasing pharmaceutical availability at the primary health care level also attracts people for essential preventive services.

Community involvement: A bottom-up approach provides greater opportunity for community involvement. Also, government or donor start-up funds may be supplemented by community contributions.

The relative strength of the case for bottom-up versus top-down implementation varies with local circumstances. Too often, however, the choice is strongly influenced by local political pressures or donor interests rather than by the merits of each approach.

Experience and careful monitoring can help determine the viability of an RDF at each level. The cost of establishing and maintaining user fees at the lowest level may be greater than the revenue collected.

Phasing and pilot testing

Most countries find implementing an RDF at all levels and in all parts of the country at the same time unworkable. Success depends on developing and testing fees, pharmaceutical supply procedures, and financial management systems. It is best done through pilot testing or phased implementation.

Pilot testing an RDF in one province or one district before it is implemented nationally enables systems to be developed and monitored under close supervision. In countries such as Nepal, Nigeria, and Liberia, different approaches to RDFs in different parts of the country allowed cross-fertilization of experience.

Pilot tests can be misleading, however, if they are conducted only in more accessible, better organized areas;

if they are conducted with much more intensive technical and financial support than could be expected with national implementation; or if they result in systems suitable to the pilot area but less suitable to other parts of the country. Circumstances can also change; for example, Azerbaijan successfully piloted RDFs in populations of refugees and internally displaced persons. The pilot experience showed that RDFs were feasible and relatively sustainable. However, plans to expand the funds were canceled when market prices of pharmaceuticals dropped lower than what the RDF would have to charge to recoup procurement and overhead charges (Holley, Akhundov, and Nolte 2004).

Phased implementation, beginning at the higher levels of the system, offers the advantage of firmly establishing effective pharmaceutical supply, financial management, pricing, exemption, and accountability systems at each level before proceeding to the next level. A phased approach can help build public acceptance, test and revise fee structures, develop management capacity, and train staff over a reasonable period of time.

With phased implementation, the high-level facilities in each area serve as training and demonstration centers for the next level: provincial hospitals establish their systems, then become training sites for district hospitals; district hospitals develop their systems and become training sites for health centers; health centers become training sites for health posts or community health workers. It may take six to eighteen months to develop, implement, and reinforce RDF management systems at each level.

With either a pilot or a phased approach, an RDF cannot expand any faster than the capacity of the supply system to provide a steady supply of essential medicines.

Development of RDF procedures

An essential aspect of any approach is the development of procedures for pharmaceutical and financial management. Normally, a procedural manual or set of manuals should be developed. Shorter versions of these manuals, including one-page checklists, can be prepared to address the information needs of specific levels and functions.

13.7 Pricing and equity of access

RDF pricing and exemption policies are critical for ensuring that patients in need of essential medicines and medical supplies receive them and that the RDF does not decapitalize. These two requirements pull in opposite directions, creating a constant tension. Prices, as well as the accompanying policies with regard to exemptions, are the mechanism by which the necessary balance is achieved.

Pricing strategies

Pricing for RDFs involves two related questions: what type of medicine fees should be charged, and what should the level of fees be?

Types of medicine fee. Alternatives include course-of-therapy fee, prescription fee, item fee, multilevel item fee (price bands), and variable item fee (see [Table 13-1](#)). These mechanisms can be compared with respect to the following criteria—

Effect on prescribing practices: Does the fee create incentives for prescribing more medicines or fewer medicines, higher-cost or lower-cost medicines?

Effect on patients: Is the fee likely to dissuade patients from buying needed medicines, or does it create incentives for patients to use medicines more cost-effectively? Will patients feel they have paid a fair price?

Ease of collection and accounting: How easily can health staff calculate the required payment, make change, and keep accurate payment records?

Balancing pharmaceutical costs and revenues: How closely do the fees received for individual medicines balance the actual cost of medicines dispensed? Can fund managers easily ensure that the collected funds are sufficient to resupply the medicines dispensed?

The effect of fees on prescribing practices is not shown in [Table 13-1](#) because that correlates with whether health staff salaries or bonuses depend on revenue derived from medicine fees. Like private practitioners, government and community health care providers are likely to prescribe more medicines and more costly medicines if their income depends on pharmaceutical sales.

Course-of-therapy fees, multilevel item fees, and variable item fees can all differ for individual medicines. In such instances, the fees charged to patients can be based on the actual cost of the medicine, an assessment of the health impact of the medicine, or a combination of these factors. Pricing can be based on the VEN (vital, essential, nonessential) system (see [Chapter 40](#)): for example, the equivalent of USD .10 per item for vital medicines, USD .20 per item for essential medicines, and USD .30 per item for nonessential medicines. With this approach, vital medicines may be sold at prices lower than their replacement cost.

With the variable item fee, the price can be based on a fixed percentage markup over cost, a variable percentage markup, actual cost plus a fixed dispensing fee, or another formula (see the discussion of retail margins in [Chapter 9](#)). For example, higher-cost medicines or medicines with a greater health impact may have a lower markup.

Ease of collection and accountability are important considerations, because administrative and accountability

Table 13-1 Comparison of types of medicine fees

Type of fee	Example	Effect on patients ^a	Ease of collection and accounting ^b	Balancing pharmaceutical costs and revenue ^c
Course-of-therapy fee Fixed fee for diagnosis based on standard treatment	USD .20 for one course of malaria treatment; USD .30 for one of pneumonia treatment; USD 1 for one month of hypertension treatment	<ul style="list-style-type: none"> • Promotion of standard treatments • No incentive to overuse or underuse medicines 	+++	0
Prescription fee Standard medicine fee per visit	USD .40 per visit (regardless of number, amount, or type of medicines)	<ul style="list-style-type: none"> • Patient pressure for more medicines • No incentive for cost consciousness 	+++	0
Item fee Standard fee per medicine	USD .20 per item (regardless of amount or type of medicines)	<ul style="list-style-type: none"> • Patient pressure for high-cost medicines • Incentive to use fewer medicines 	++	+
Multilevel item fee Three to five levels or price bands	Fee based on pharmaceutical category: A USD .10 per item B USD .20 per item C USD .30 per item	<ul style="list-style-type: none"> • Preference to buy low-cost medicines • Incentive to use fewer medicines 	+	++
Variable item fee Variable fee per medicine, based on type or cost of medicine	Medicine cost plus 20 percent for all items	<ul style="list-style-type: none"> • Preference to buy low-cost medicines • Incentive to use fewer medicines • More cost consciousness 	0	+++

^a Medicine prescribing is influenced by whether the prescriber's salary depends on pharmaceutical revenues (see text).

^b 0 to +++ = range from hardest to easiest for collection and accounting.

^c 0 to +++ = range from hardest to easiest to balance pharmaceutical costs and revenues.

problems are major constraints on the success of RDFs. Unfortunately, course-of-therapy and prescription fees—which are the easiest to implement and are in some respects the most equitable—make it difficult to ensure that revenues collected are sufficient to pay for medicines dispensed.

One approach is to begin with fees that are easy to implement and then move to more complex but financially sustaining fees as the program evolves. More complex fees require more staff training and more sophisticated accounting systems, which can be implemented over time.

Level of medicine fee. What level of fee is appropriate? With an item fee, for example, should the fee be the equivalent of USD .10 per item, USD .15 per item, or USD .20 per item? If the system is introduced first at rural hospitals, prices can be set on the low side, and patient response can be monitored. Prices can be adjusted accordingly during the first year or two, before moving to the next level.

For RDFs, as in business, there are two basic approaches to price setting: (1) the willingness-to-pay, or market, approach and (2) the cost-based, or accounting, approach. Pricing decisions should draw on information gained through both approaches.

In the willingness-to-pay approach, price levels can be set by using any feasible combination of the four methods used by private companies—

- *Consumer opinion:* Survey questionnaires and focus groups ask community members what they would be willing to pay for specific services.
- *Expert opinion:* The most efficient way to set prices is by asking someone who really knows the product and the population. The expert must have firsthand knowledge of the population being served and how people value medicines. Ministry officials and essential medicines program managers are usually not expert at price setting.
- *Comparative pricing:* Surveying private facilities, mission hospitals, retail pharmacies, patent medicine sellers, and other nongovernmental providers to find out their medicine charges may be useful. However, results must be interpreted in light of differences in income level and perceived value of services.
- *Test pricing:* Companies sometimes use early experience in a small area to establish national prices; the response to initial prices can be used to adjust subsequent prices.

In the cost-based approach, prices are established according to the cost-recovery objectives. Because RDF revenues are used to purchase replacement stocks, a factor for inflation and anticipated stock losses must be built into the calculation of sales price. Some programs include a factor for “stock replacement reserve” and “general reserves,” and

any program offering exemptions must adjust for them (see [Chapter 41](#)). In the cost-based approach to pricing, the markup percentage must also be determined. Many programs use a fixed percentage, with the more expensive medicines thus producing higher revenues. Other programs use variable markups.

In determining pricing strategies, it must be remembered that the sustainability of the RDF depends on covering some or all of the costs of the system. (What that portion is, and exactly which costs are to be covered, may vary.) The objective is not to maximize profits but to maximize service delivery at a certain basic quality level. Willingness to pay is usually as important as cost data in determining pharmaceutical prices. For example, before the RDF is introduced, estimated sales prices for all pharmaceutical items should be compared with those of similar medicines sold by the private sector. If, after accounting for the replacement costs of pharmaceuticals and exemptions, RDF prices are higher than private-sector prices, the whole RDF strategy must be reconsidered.

Pricing decisions must be made in full recognition of the tension between cost-recovery objectives and social policies regarding access to care. At the same time, administrative requirements for collecting fees must be considered. Most experiences in pharmaceutical cost recovery suggest that when equity-oriented exemption policies and administrative realities are considered, simply recovering the full replacement cost of pharmaceuticals and delivery is often a struggle. Ultimately, cost-recovery potential is determined by patients’ willingness and ability to pay for medicines, and not by a policy that mandates a specified markup (see [Figure 13-2](#)).

Financial sustainability of RDFs depends on keeping medicine fees in line with changes in the cost of medicines. During periods of high local inflation and foreign exchange fluctuation, frequent price adjustments may be required. Fee increases may present a short-term hardship to patients, but unless certainty exists that the government or a donor will finance the shortfall, such increases are imperative for the survival of the RDF.

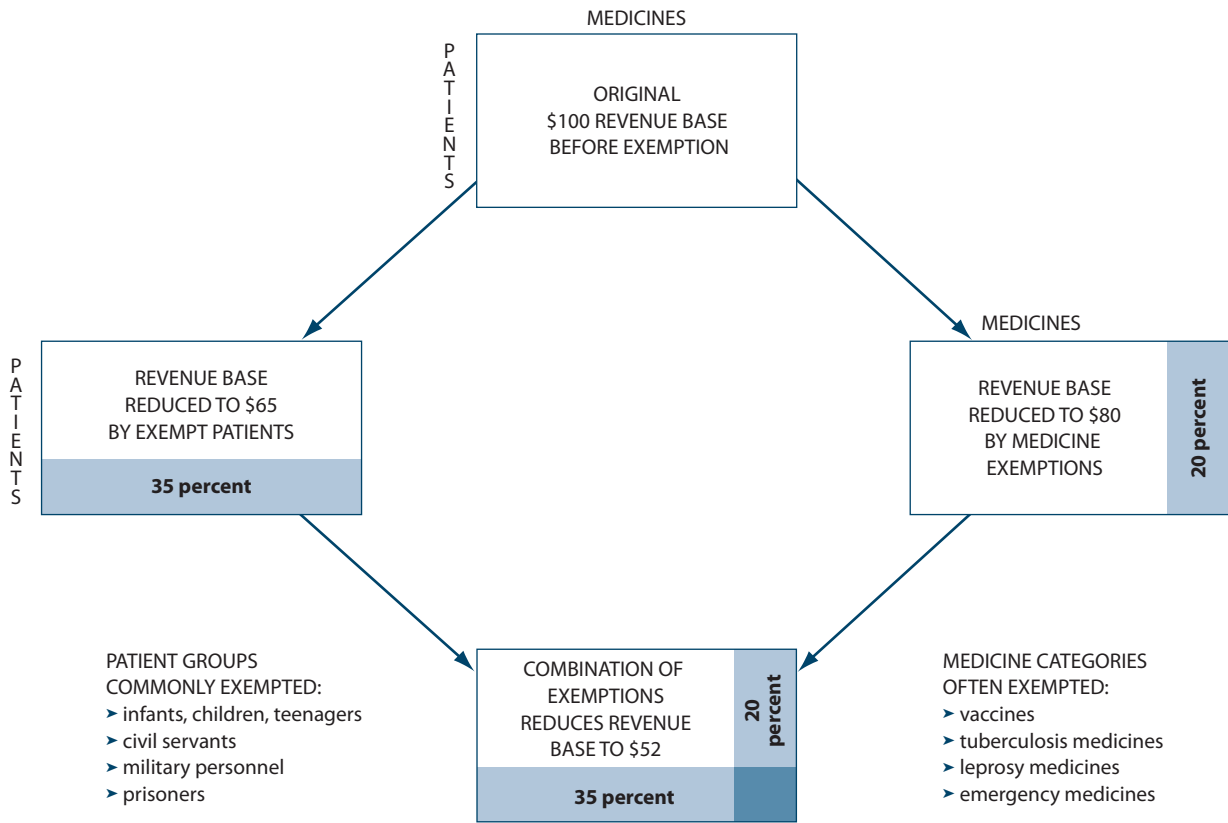

Ensuring equity of access

Protection mechanisms—a safety net—are needed to ensure continued access to essential medicines for the poor, the medically needy, and other target groups.

Many programs would like to establish generous exemption policies. But if the RDF is to be viable over the long run, the revenues collected, along with budget subsidies, must be sufficient to purchase replacement pharmaceutical stocks.

As illustrated in [Figure 13-3](#), calculation of the anticipated cost of exemptions leads to determination of the “base” for cost recovery: the total costs that must be recovered

Figure 13-3 Effect of multiple exemptions on the cost-recovery base of an RDF

Note: Reducing the patients to 65 percent of original and the medicines to 80 percent of original leaves a revenue base of $.80 \times .65 = .52$ of \$100 = \$52.

to ensure that the RDF does not decapitalize. Assessment of total costs to be recovered and government subsidies available determines cost-recovery targets (that is, what percentage of total costs must be recovered from paying patients). This, in turn, suggests various pricing strategies.

As Figure 13-3 shows, the lower the pharmaceutical subsidy provided by the government, the greater the burden of generous exemption policies on the local community. Because of this burden, local communities should contribute to the discussion on establishing exemption policies.

Types of protection mechanisms. Exemption from payment, partial exemption (sliding scale), and differential prices are the most common protection mechanisms. Differential pricing is the setting of different price levels by type of patients, level of the health system, or type of pharmaceuticals. Fee levels may be higher for adults than for children, for example. Pharmaceutical and service fees also may be graduated by level of care, with referral hospitals charging the highest fee for a given medicine or service, district hospitals charging lower fees, health centers charging even lower fees, and community health workers charging the lowest fees. In addition to reinforcing referral patterns,

this approach seeks to improve equity by making pharmaceuticals more affordable through community health workers and lower-level health facilities. Differential pricing by the VEN classification helps make the most essential medicines available at the lowest prices.

The type of fee may also provide some protection. Registration or consultation fees paid before seeing a clinician may dissuade people from seeking needed care, even if they would have been exempt from payment. But when medicine fees are in effect, the most acutely ill patients will have been identified before the issue of payment arises.

Exemption criteria. Criteria used to grant full or partial exemptions fall into three main categories—

- *Poverty:* people below a certain income or standard of living
- *Personal factors:* children (usually those under five), the elderly, the disabled, prisoners, and some categories of students
- *Health conditions:* pregnancy, to encourage proper prenatal care; communicable diseases, such as tuberculosis, HIV/AIDS, and sexually transmitted infections, to encourage treatment or control their spread

For political reasons, user-fee programs sometimes begin with broad exemptions that include civil servants, teachers, members of the military, war veterans, older children, and other groups that are able to pay and for which no equity or public health arguments exist for exemption. Financial sustainability depends on narrowing the list of exemptions as the RDF gains acceptance and as systems develop to target those truly in need.

Administering exemptions. The practicalities of administering exemptions often present the greatest barrier to ensuring equity in RDFs. Procedures should be administratively feasible, exempt the correct groups, and prevent abuse by those who do not meet exemption criteria. An assessment of the Ghana pharmaceutical sector showed that reimbursement delays and exemptions management have substantially contributed to the decapitalization of RDFs (MOH Ghana 2002).

Exemptions and differential pricing based on objective criteria, such as pregnancy, age, or diagnosis, are easier to implement than more subjective criteria. Even verification of age can be difficult, however. Exempting children under five years of age (who are usually known to the staff of well-child clinics) is easier to enforce than exempting children under fifteen years of age (who may be difficult to distinguish from young adults).

Although policy makers usually agree that the poor should be exempt, defining who is poor is difficult, particularly in noncash economies. Measures used to assess poverty level include type of employment, household income (cash and noncash), household expenditures (for example, total cash and noncash expenditures during the last month), and wealth (housing, land, livestock, and other personal holdings).

Verifying poverty or other exemption criteria may not be difficult in a local dispensary where patients are well known to staff. But in a busy, less personal health center or hospital outpatient department, it can be quite difficult. For example, at a hospital in Ghana, only 2 of almost 42,000 patients were identified to receive “pauper” exemptions (Nyonator and Kutzin 1999). Involving the community in deciding who should receive waivers has been successful in some settings (Holley, Akhundov, and Nolte 2004; Jacobs and Price 2006).

Experiences from many countries have shown that exemption plans are rarely effective or functional—either because the system is not well understood or because pressure is great to generate revenue in the facility—and that even if a user-fee system is well organized, the lack of waivers will likely entail a trade-off between financial sustainability and access to the poor (Nyonator and Kutzin 1999; Xu et al. 2006).

Financing the cost of exemptions

An effective system of exemptions and other protection mechanisms is essential to ensure equity of access. Unless

someone pays the cost of these exemptions, however, an RDF will soon cease to revolve. Exemptions can be financed through any combination of the following—

- Central government recurrent budget allocations
- Higher markups on medicines for patients who can pay
- Community contributions
- Local or external donors

A certain level of government financial support is usually necessary to ensure equitable access for the poor and other target groups; otherwise, prices for paying patients must be increased to cover the cost of exemptions. In practice, using higher markups for paying patients to finance exempt patients usually fails, unless the proportion of exempt patients is low and collection efficiency is high. In community pharmaceutical schemes, village health committees sometimes maintain “poor funds” to pay for those who cannot afford medicine fees. In Cambodia, some public hospitals established health equity funds for poor people that used a community-based third-party-payer arrangement to administer the scheme. These hospitals saw an increase in services given to the poor (Jacobs and Price 2006).

Finally, exemptions may be financed by local or external donors, but few are willing to provide long-term subsidies. In some cases, however, donors support exemptions through in-kind contributions (medicines for acute respiratory infection, diarrheal disease, or nutritional support), with the understanding that treatment will be dispensed without charge if the patient meets established exemption criteria. As discussed in [Chapter 15](#), country program managers and policy makers, rather than donors, should decide how donations will be handled in cost recovery.

13.8 Management of pharmaceuticals and money

RDFs face much more demanding management requirements than free systems. The concepts of service performance and cost control must pervade the management of RDFs.

Pharmaceutical supply management

Selection, procurement, quality assurance, distribution, management information, and medicine use are all handled somewhat differently in the context of an RDF.

Selection. The essential medicines list for the RDF (its “product line”) must be based on essential medicines selection criteria (see [Chapter 16](#)), but provider perspectives and patient preferences must also be considered. For

example, if two medicines are therapeutically equivalent and similar in price, the more popular (“sellable”) one should normally be purchased. Supplying high-cost, low-volume medicines with limited health effect is probably best left to the private sector, because such medicines can tie up working capital and result in losses caused by expiry.

Procurement. Regardless of the level at which procurement is managed, a reliable source for the purchase of resupplies is essential. Turning to local distributors or private pharmacies to cover delayed shipments from normal sources often raises costs beyond what can be recovered through sales. Even if the RDF is managed by a government entity (as opposed to a parastatal or private organization), the procurement cycle must be freed from the treasury cycle to ensure that pharmaceuticals can be bought when needed and tenders are not automatically canceled between fiscal years. Procurement must ensure maximum bulk discounts (such as one-year competitive contracts) while controlling inventory-holding costs (for example, by arranging three or four deliveries per year of high-volume items).

Quality assurance. Quality assurance procedures must ensure both the reality and the appearance of quality. For example, dispensing containers should protect the medicine, but their appearance may also influence whether patients feel they have paid a fair price for the medicine inside.

Distribution and inventory control. Distribution must be through a “pull” system, based on actual demand. Inventory records must be accurate to ensure the purchase of correct quantities. Underestimates result in lost sales and gaps in health service for clients, and overestimates can lead to costly expirations. Transport arrangements must ensure steady supply.

Management information. Giveaway systems can sometimes afford not to know what happens to medicines after they are distributed, but RDFs need good information on which products are in demand and which ones are not. Information on stockouts is needed from facilities because inventory records at distribution depots may not fully reflect undersupply problems.

Rational use. If health workers benefit directly from pharmaceutical sales, monitoring must ensure that workers are not irrationally catering to patient demands (for more injections, for example) or overprescribing. Prescribers and dispensers must ensure that poorer patients, who cannot afford to buy everything prescribed, know which are the necessary, curative medicines (for example, co-trimoxazole for pneumonia) and which are the optional, symptomatic medicines (such as paracetamol). Dispensing staff must guard against patients buying subtherapeutic quantities of all pharmaceuticals prescribed, rather than therapeutic quantities of only the curative medicines.

Financial management and accountability

Traditional accounting systems for governments and not-for-profit organizations are designed primarily to account for funds spent. RDFs require systems that ensure reliable collection of fees, safekeeping of revenue, and proper expenditure of revenue.

Systems and procedures. Standard procedures must be implemented for fee collection, stock control and valuation, reporting, banking, auditing, and control of expenditures. Potential sources of theft, fraud, and abuse must be monitored to minimize losses.

Examples of accountability problems include clerks who charge patients the full fee but record only half the fee and pocket the difference; dispensing staff who give a patient ten tablets, record having issued twenty tablets, and keep the difference; accounting staff who record and deposit less than the full amount collected; and procurement staff who authorize payment to suppliers for pharmaceuticals never received and share the payment with the supplier.

Chapter 41 describes procedures and systems for financial management and accounting in the context of RDFs. In government-operated RDFs, procedures must be consistent with the law. In Ghana, for example, although the law defines standard markups for pharmaceuticals, actual fees varied dramatically by district and facility—patients paid from 11 to 275 percent over the approved prices (Nyonator and Kutzin 1999). It is therefore important that governments make the fee schedules transparent and that accounting officials review and endorse RDF accounting procedures.

Enforcement. Even the best-designed systems for financial management and accountability require enforcement. At each level, regular supervision should focus on areas of potential abuse. Disciplinary procedures provide a range of possible responses, from warnings through dismissal, depending on the severity and frequency of the offense. RDF managers should be prepared to invoke disciplinary procedures and to bring criminal charges when necessary. Government procedures on misuse of public funds must be visibly and vigorously applied to ensure full collection and proper expenditure of revenue. Well-publicized prosecution of one prominent offender can be a highly effective method for improving overall adherence to procedures.

13.9 Preparing health staff, patients, and the public

Introducing or expanding an RDF requires building support from health staff, patients, and the public through orientation programs, training, and good communication.

Orientation and training for health staff

For RDFs at the national, institutional, or community level, orienting senior officials to the objectives and organization of the program is important. Even if most such officials will have no direct program responsibility, their work may be indirectly affected and, in practice, their support (formal or informal) may be needed.

Training should consider the information needs of pharmacy, pharmaceutical management, accounting, and other staff directly involved in the RDF, as well as the needs of health workers and unskilled staff whose cooperation is necessary. Training should focus on new knowledge, skills, and attitudes needed by each group. In addition, all staff should receive basic orientation that will enable them to correctly inform patients and the community about the RDF.

Communications for the public and patients

Public and patient acceptance are vital for the implementation and further development of RDFs. A communications strategy should systematically address the following issues:

Target audiences: Target groups include national leaders, community leaders, local opinion leaders (who may be different from official community leaders), health workers, patients currently attending facilities, and the general public.

Opinion survey: A “market survey” using questionnaires, in-depth interviews, or focus group discussions can help assess how high-priority target groups might respond to fees, and how much pricing elasticity may exist.

Messages: Building on the positive aspects of user fees, without making promises that cannot be kept, is important. Clarifying exemptions, such as for maternal and child health, is good public relations and good public health policy. If the RDF fees are for pharmaceuticals only, promote this: “The doctor is still free.” Community participation and management, if appropriate, can be important concepts to convey.

Media and methods: Choice of media for communication depends on local availability and practices. Print media, radio, television, and local meetings are all appropriate options. In countries such as Nigeria, Kenya, and the Philippines, where newspapers have good coverage, stories of small successes can be distributed regularly as press releases at low cost to the program (through print media, radio, local meetings).

After the preceding issues have been addressed, an effective communication plan can be developed to support the implementation plan for the RDF. [Chapter 33](#) is aimed primarily at public and patient communications for improved

medicine use, but it also provides useful information for preparing an RDF communication plan.

13.10 Monitoring and supervision

Regular monitoring and supervision are essential to assess the effect of RDFs on patients and financial performance. Supervisory visits should focus on patients’ responses to user fees, implementation of exemption procedures, pharmaceutical availability, and key aspects of the collection and accounting system. A supervision checklist can help ensure that critical functions are reviewed. Routine reporting systems must be adapted to handle financial and pharmaceutical supply information, as well as health care information. Some systems have a community-based management committee that monitors operations. In cases where a lack of human resource capacity makes monitoring and supervision difficult, a larger community role can ease the burden on the system.

Visits should be targeted to facilities whose reports indicate poor performance or for which routine reports are not available. An RDF in the Caribbean uses routine reports to classify community pharmacies as red, yellow, or green and to direct supervision efforts accordingly. In East Africa, a national cost-sharing program uses routine reports similarly, to classify districts for the purpose of targeted supervision.

With new RDFs, major new fees, or other major changes, supervisory visits should be as frequent as possible, and a reporting system should be used to identify and address early problems. Sentinel sites and special studies may be needed to guide the development of the program and to assess its effect. [Chapter 48](#) describes these and other relevant aspects of monitoring, and [Chapter 49](#) discusses information system design. Key issues for RDF monitoring appear in the assessment guide at the end of this chapter.

Decapitalization must be avoided, because it quickly leads to failure and loss of community confidence. Each health center operating an RDF should be visited every month or two to ensure that procedures are being followed and that the RDF will not become decapitalized.

If possible, a formal evaluation should be planned within the first three years of a new program to assess its overall impact, equity, sustainability, efficiency, and long-term prospects. [Chapters 36](#) and [48](#) describe methods for such an evaluation.

13.11 Common pitfalls and lessons of RDFs

Although the concept of RDFs is simple, the successful establishment and long-term sustainability of such schemes have been fraught with difficulty. Often, the monies

Table 13-2 Effect of introducing user fees in health care

Change in service level	Outpatient medicine fees	Inpatient medicine fees	Who retains funds	Exemption	Effect on quality
Service usage decreased					
Burkina Faso	Yes	Yes	40 percent at hospitals	No	No improvement
Ghana	Yes	No	Distributed between district, ministry of health (MOH), and treasury	Yes	Medicine shortages persisted
Kenya	Yes	No	75 percent facility/25 percent district	Yes	Improved rating in provincial hospitals
Lesotho	Yes	Yes	MOH	Yes	Equivocal
Mozambique	Yes	Yes	Unknown	Yes	Equivocal
Zimbabwe	Yes	Yes	100 percent at national hospital/ other facilities to treasury	Yes	No evidence
Service usage increased					
Benin	Yes	Yes	75 percent facility	Yes	Improved medicine availability in public health centers
Burundi	Yes	Yes	100 percent community	Yes	Improved medicine availability in public health centers
Cameroon	Yes	Yes	100 percent health centers/ 50 percent hospitals	No	Improved medicine availability in public health centers
Guinea	Yes	Variable	100 percent facility	No	Improved public perception
Mauritania	Yes	Yes	Unknown	Yes	Improved medicine availability in public health centers
Senegal	Yes	Yes	Unknown	Yes	No evidence
Sierra Leone	Yes	Yes	Majority to RDF/remainder at facility	No	Improved medicine availability in public health centers
Togo	Yes	Yes	100 percent facility	No	Improved medicine availability in public health centers
Service usage response mixed					
Gambia	Yes	Yes	MOH or RDF	Yes	Improved medicine availability
Guinea Bissau	Yes	Yes	National facilities to MOH/Bamako Initiative related to community, facility, region	No	Improved medicine availability in some facilities
Mali	Yes	Yes	Unknown	Yes	Improved medicine availability
Nigeria	Variable	Variable	Variable from facility to state level	No	Improved medicine availability
Uganda*	Variable	No	100 percent community	No	Variable improvement
Zaire (D.R. Congo)	Yes	Unknown	100 percent community	Yes	Variable improvement

* The government of Uganda eliminated user fees in 2001.
Source: Singh 2003.

collected are insufficient to replenish the original stocks, and the fund soon becomes depleted. An important factor in RDF failure is a resistance to thinking of the fund in business terms. A lack of careful economic and financial analysis in planning the fund, or weaknesses in financial management or in management of the supply system, can lead to failure.

Table 13-2 illustrates the experiences in twenty African countries that instituted user fees, including RDFs. Results shown include the effect on health care service usage.

Common pitfalls

Specific causes for RDF decapitalization include the following (see Figure 13-4)—

- Unanticipated increases in procurement cost caused by inflation or changes in exchange rates
- Underestimation of the capitalization costs of the supply system

Figure 13-4 Cycle of terrors: Causes of RDF decapitalization

- Rapid program expansion for which additional capital funds are not made available
- Unanticipated losses of pharmaceuticals through theft, deterioration, or expiry
- High operating costs that exceed budget amounts
- Prices set too low for intended level of cost recovery
- Too many exemptions that are not subsidized
- Funds tied up in the national banking system or ministry accounting systems
- Delays in collecting subsidies and other payments from government agencies
- Foreign exchange limitations that restrict international purchases for resupply

Guidelines from RDF experiences

No guaranteed strategies exist for designing and implementing an RDF. However, experience with RDFs suggests some guidelines that may increase the chance that an RDF will improve pharmaceutical availability, ensure equity of access, and promote greater efficiency.

Local control and retention of revenue: Keeping the money locally creates an incentive for revenue collection and promotes the use of revenue to improve quality. When fees are remitted to a general government account, there is little incentive to collect fees and virtually no visible improvement occurs in the supply of pharmaceuticals or the quality of care. Community supervision of an RDF is important to ensure its proper management and accountability.

Reliable supply of low-cost essential medicines: RDFs require a dependable source of medicines. Some governments have established independent pharmaceutical services specifically to supply RDFs.

Locally appropriate fee schedules: The types and levels of charges cannot be determined simply as a matter of policy. Pricing decisions must consider both the cost of pharmaceuticals (and services) and the demonstrated willingness to pay. Fees must be adjusted regularly to reflect increases in real costs.

Protection mechanisms to ensure equitable access:

Exemptions, partial exemptions, and other protection mechanisms are necessary to ensure that patients are not denied essential services. Lower fees or free services at the lowest levels of health care encourage patients to use local facilities first.

Continued or increasing levels of government funding for health: Government allocations are still needed for preventive services and to subsidize the poor and other target groups. Collection of user fees should not lead to a reduction of government allocations.

Businesslike orientation: Personnel management, financial management, supply management, and “customer rela-

tions” systems provide built-in checks and balances. Qualified staff must be explicitly assigned to RDF activities. District and facility managers must set collection targets, monitor performance against targets, and take corrective action. Active community involvement is important for the acceptability, credibility, and accountability of RDFs. Public communications should explain the program and ensure that charges and protection mechanisms are understood.

Strict measures to ensure accountability: In addition to systems for the control of pharmaceuticals and revenues, dependable monitoring (often with local community involvement) is important: spot checks, periodic independent audits, and vigorous use of legal and disciplinary mechanisms when abuses are uncovered. Systems that fail to respond effectively to theft of pharmaceuticals are unlikely to fare any better when cash starts disappearing. Government procedures on the misuse of public funds must be visibly and vigorously applied to ensure full collection and proper expenditure of revenue.

Planned implementation: Phased implementation or a well-conceived pilot approach can help build public acceptance and develop management capacity before the system expands to cover the entire country.

Implementation of RDFs depends on a host of issues and, ultimately, on good management. Government and, in many cases, donor commitment are necessary for several years to ensure that sustainable organizational arrangements, financial management, and pharmaceutical supply management systems are in place. The success of an RDF lies in the details of planning and implementation. ■

ASSESSMENT GUIDE

Policy, organization, and implementation

- Are key functions related to pricing, exemptions, supervision, and other aspects of pharmaceutical management and financial management clearly assigned and effectively performed?
- Are central, district, facility, and community roles clearly and appropriately identified and communicated to all concerned?
- Are policy or legal clarifications needed with regard to exemptions, local retention of revenue, or banking and accounting procedures?
- Are policy makers oriented, have health staff been trained, and has the public been adequately informed about the RDF?

Pharmaceutical management and financial management systems

- Does the RDF have a reliable source of pharmaceuticals through the CMS, an autonomous supply agency, or some other pharmaceutical supply mechanism?
- What types of medicine fees are used: course-of-therapy fee, prescription fee, item fee, multilevel item fee, variable item fee? Should the type of fee be revised to create incentives for more rational use of medicines or to improve accountability?
- Are fee levels set on the basis of medicine costs, assessment of ability to pay, or a combination of the two factors?
- Is there a system for regular supervision at each level and a supervision checklist?
- Are revenues, expenditures, stock levels, and other measures reported and reviewed on at least a quarterly basis?
- Are financial management systems backed up by administrative and legal actions to ensure accountability?

Effect on patients and households

- Is the number of patients decreasing, or are people being dissuaded from seeking necessary care?
- What is the effect of medicine fees on the poorest households? Is access increasing or decreasing? Are expenditures on other household essentials such as food being affected?
- What are the expected and actual percentages of patients exempted from payment? Do specific exemption criteria exist, and are they implemented as intended to ensure equity of access?
- Is the availability of essential medicines, and therefore the quality of care, increasing?
- Are medicines being rationally prescribed and bought? Are health staff overprescribing or underprescribing? Are patients overpurchasing or underpurchasing?

Financial performance

- What costs were intended to be covered by medicine fees: a portion of medicine costs, full medicine costs, or medicine costs plus a surplus to cover other recurrent costs?
- What percentage of the cost-recovery objective is being achieved?
- What percentage of MOH pharmaceutical expenditures is funded by user fees? What level of continued government funding has been planned, and what level is actually being provided?
- How is the cost of exemptions, different prices, and other protection mechanisms being funded? Can protection mechanisms be sustained to ensure access to the poor and other target groups?
- Is the current level of capitalization sufficient to ensure a steady supply of pharmaceuticals?

Note: This assessment guide assumes that an RDF exists. Section 13.3 discusses feasibility assessment when an RDF does not exist.

SUMMARY

The international community's commitment to global health and access to pharmaceuticals has been increasing; in addition to traditional sources of funding from bilateral and multilateral institutions, such as development banks and United Nations (UN) agencies, private foundations and public-private partnerships are playing much larger roles as resources to improve health in developing countries. The types of assistance available include—

- Financial assistance (loans or grants)
- Commodities
- Technical expertise
- Training, study tours, and fellowships
- Research funding

Some donor funding is being directed toward the entire health sector as part of a sector-wide approach (SWAp) to aid or toward the national government budget instead of to specific programs or interventions, which means that health program managers must take additional steps to get access to funding for specific health programs. Ministries of health need to collaborate with other government ministries, which are likely to carry out negotiations with donor agencies. Ministries of health must be able to justify the demand for additional funding for pharmaceutical management activities.

Challenges associated with donor assistance include a country's inability to use donor funds effectively

because of limited infrastructure, the unpredictability of donor assistance from year to year, and the complex monitoring and evaluating requirements that vary by donor. In recognition of some of these challenges, donors and recipient countries have been working together to improve collaboration and harmonize funding requirements. Performance-based funding is another trend being used to improve the effectiveness of development aid.

With heavy demand for assistance funds, proposals must satisfy donors' concerns about consistency with government policies, government commitment, health care reform, project impact, and sustainability. Many donors follow a two-stage proposal process, requiring the submission and approval of a project profile or letter of intent, followed by a more detailed project proposal. Project documents often include—

- Project goals (development objectives)
- Project purpose (immediate objectives)
- Outputs
- Activities
- Inputs and resources

Private foundations tend to follow more flexible procedures for reviewing grant proposals and overseeing grant-funded projects, but most donors require periodic progress reports and evaluation.

14.1 The role of donors in development

The resource requirements for meeting the health needs of populations in developing countries are increasing significantly because of the introduction of new technologies, the dual burden of addressing communicable and chronic disease patterns, and the growth and aging of populations; as populations age, demand for higher-cost medical treatment increases. As a result, the need for additional resources in the health sector is growing faster than government health expenditures. In addition, the health spending patterns and health needs of rich and poor countries vary greatly: developing countries account for 84 percent of the world's population and 90 percent of the global disease burden, but they represent only 12 percent of global health spending. High-income countries spend 100 times more than low-income countries spend on health (Gottret and Schieber 2006).

As a result of globalization, the international community's commitment to the Millennium Development Goals

(MDGs), and emerging health threats such as severe acute respiratory syndrome and avian influenza, global health is becoming a more important part of the international policy arena. Along with this increased focus on global health, new foundations and public-private partnerships have emerged that are committed to contributing to solutions to the world's health problems. These partnerships are funded by donor governments and private foundations such as the Bill & Melinda Gates Foundation and the United Nations Foundation.

Governments have a few options for expanding available resources for health. One option is to reprioritize health care activities toward lower-cost and more cost-effective programs and services within the ministry of health budget. A second option is to increase the allocation of total government expenditures to the health sector. A third option is for countries to identify new and innovative sources of financing, such as taxes earmarked for health. A final approach is to expand the number of resources through additional external funding. For low-income countries,

external sources of financing account for almost one-fifth of total health expenditures (WHO 2010, Table 7: Health expenditure). Expanding resources for the health sector is sometimes referred to as expanding the resource envelope, or expanding fiscal space.

International development assistance, also called external cooperation, can provide the necessary funds and technical expertise to complement national efforts. Development assistance can serve as a catalyst for major health system reforms that would otherwise be difficult to accomplish. Policy makers and managers can strengthen their health initiatives and programs by understanding where to obtain such assistance, the criteria that must be met, and the ongoing commitments that must be fulfilled to establish and maintain fruitful relationships with donor and funding agencies.

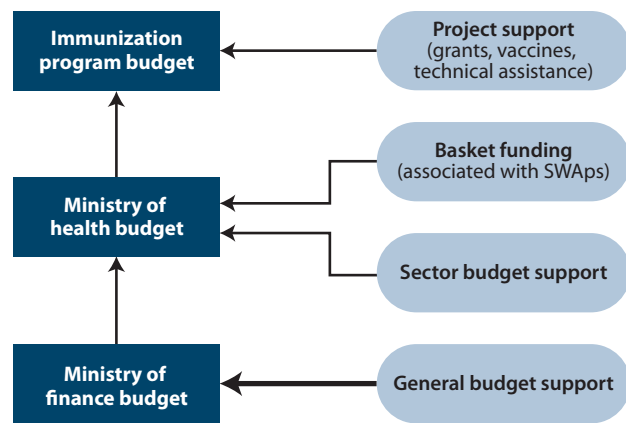

Traditionally, donor funding has come directly to specific programs or interventions in the form of grants, commodities, or technical assistance. Although global funding initiatives that focus on a specific disease, such as HIV/AIDS, have changed the landscape of health-related development funding, the trend is for external funding to be directed more toward the entire health sector or toward the national government budget. This trend results in additional steps that policy makers and program managers must take to access funding and technical assistance for specific health programs and interventions. The process is illustrated in Figure 14-1. The ministry of health needs to work in cooperation with ministries of planning, external relations, and finance, which are likely to carry out negotiations with donor agencies. Ministries of health must be able to justify the need for additional funding and for expanding their resource envelope.

Health programs and projects supported by external assistance will continue to include activities related to pharmaceuticals that range from the straightforward (procurement of medicines for a specific program, such as malaria control) to the complex (reorganization of the public-sector supply system). The funding for these activities is expected to grow in parallel with the growth in overall funding for health projects.

14.2 Development assistance challenges

Development assistance comes with challenges. Project support is typically outside the regular health budget, making it difficult for the government and its partners to monitor and evaluate. As a result, ministries of health often do not know the extent and intended priorities of donor funding. In addition, ministries of finance strive to roll development assistance into national budgets, to improve transparency and accountability and to strengthen national planning efforts. In countries where the health budget is constrained,

Figure 14-1 Modalities of donor financing

SWAs = sector-wide approaches.

the addition of donor funding forces ministries of health to make better decisions about funding priorities, because usually some donor assistance replaces rather than adds to budget resources.

In addition, countries may have limited absorptive capacity. In other words, they cannot use donor funding effectively because of a lack of human resources or infrastructure, or the level of donor funding may be too high relative to how quickly a country can spend it, either because of bureaucratic procedures in procurement or disbursement, or because of *fungibility*, which refers to the country's limited capacity to use the funds for their intended purposes.

Countries also face multiple reporting, procurement, and monitoring requirements for each donor. The High Level Forum on Aid Effectiveness was created to improve government and donor coordination, alignment, and harmonization for scaling up the MDGs. In a series of three meetings, senior government policy makers in developing countries and donor agencies developed a set of principles to improve harmonization of requirements that donors and global partnerships are committed to implementing (see Box 14-1). The "Three Ones" principles aim to build a coordination framework for HIV/AIDS funding among governments, donors, international organizations, and civil society (UNAIDS 2005). In addition, the International Health Partnership Plus (IHP+) was established to improve coordination of development assistance in health in 2007. IHP+ seeks to strengthen national health systems and to achieve better health results by mobilizing donor countries and other development partners around a single-country-led national health strategy. Eight of the largest institutions in health—including the World Health Organization (WHO); the Global Alliance for Vaccines and Immunization (GAVI); the Global Fund to Fight AIDS, Tuberculosis and Malaria (Global Fund); and the Gates Foundation—agreed to collaborate within the context of the IHP+ processes.

Box 14-1**Best practice principles for engagement of global health partnerships at the country level****Ownership**

1. To respect partner country leadership and help strengthen their capacity to exercise it.

Alignment

2. To base their support on partner countries' national development and health-sector strategies and plans, institutions, and procedures. Where these strategies do not adequately reflect pressing health priorities, to work with all partners to ensure their inclusion.
3. To progressively shift from project to program financing.
4. To use country systems to the maximum extent possible. Where use of country systems is not feasible, to establish safeguards and measures in ways that strengthen rather than undermine country systems and procedures.
5. To avoid, to the maximum extent possible, creating dedicated structures for day-to-day management and implementation of global health partnership (GHP) projects and programs.
6. To align analytic, technical, and financial support with partners' capacity development objectives and strategies; make effective use of existing capacities; and harmonize support for capacity development accordingly.
7. To provide reliable indicative commitments of funding support over a multiyear framework and disburse funding in a timely and predictable fashion according to agreed schedules.
8. To rely, to the maximum extent possible, on transparent partner government budget and accounting mechanisms.
9. To progressively rely on country systems for procurement when the country has implemented mutually agreed standards and processes; to adopt harmonized approaches when national systems do not meet agreed levels of performance; to ensure that donations of pharmaceutical products are fully in line with *WHO Guidelines for Drug Donations*.

Harmonization

10. To implement, where feasible, simplified and common arrangements at the country level for planning, funding, disbursement, monitoring, evaluating, and reporting to government on GHP activities and resource flows.
11. To work together with other GHPs and donor agencies in the health sector to reduce the number of separate, duplicative missions to the field and diagnostic reviews assessing country systems and procedures. To encourage shared analytical work, technical support, and lessons learned and to promote joint training.
12. To adopt harmonized performance assessment frameworks for country systems.
13. To collaborate at the global level with other GHPs, donors, and country representatives to develop and implement collective approaches to cross-cutting challenges, particularly in relation to strengthening health systems, including human resource management.

Managing for results

14. To link country programming and resources to results and align them with effective country performance-assessment frameworks, refraining from requesting the introduction of performance indicators that are not consistent with partners' national development strategies.
15. To work with countries to rely, as far as possible, on countries' results-oriented reporting and monitoring frameworks.
16. To work with countries in a participatory way to strengthen country capacities and demand for results-based management, including joint problem solving and innovation, based on monitoring and evaluation.

Accountability

17. To ensure timely, clear, and comprehensive information on GHP assistance, processes, and decisions (especially decisions on unsuccessful applications) to partner countries requiring GHP support.

Source: Adapted from High Level Forum on the Health MDGs 2005.

A final challenge related to donor assistance for health is the predictability, volatility, and fragmentation of the funding, because donor funding for the health sector fluctuates widely from year to year. In 2006–07, more than two-thirds of health aid commitments were for less than 500,000 U.S. dollars (USD), and significant portions were earmarked (Norad-AHHA 2009). Under these conditions, governments find both planning their own funding for the sector and influencing how donor funds are spent difficult.

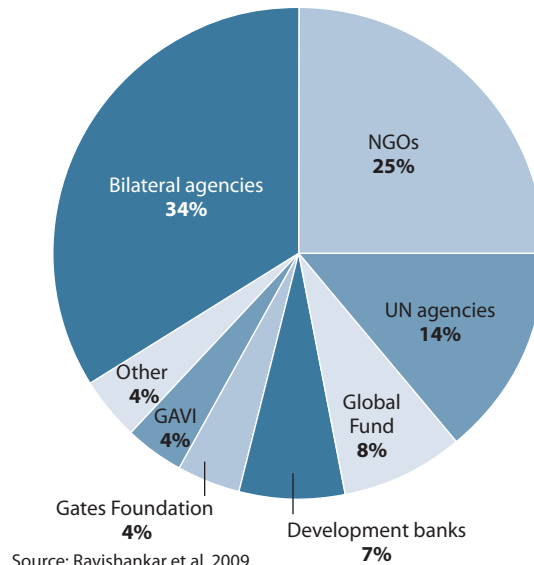

14.3 Sources of international assistance for health

Government donations and concession loans that include at least a 25 percent nonreimbursable component (in effect, a 25 percent donation) are referred to as *official development assistance*, and they are the major source of external funding for the health sector in the developing world. Total development assistance for health increased from USD 5.6 billion in 1990 to USD 21.8 billion in 2007 (Ravishankar et al. 2009). About 40 percent of assistance was allocated to Africa and almost 30 percent to Asia in 2006–07 (OECD DAC 2009). Much of this increase came from new global partnerships and foundations, and the funds targeted specific diseases, such as AIDS, tuberculosis, malaria, and vaccine-preventable diseases; for example, funds mobilized by UN agencies and development banks decreased, whereas funds provided by the Global Fund, the GAVI Alliance, and the Gates Foundation all increased substantially (Ravishankar et al. 2009). The fastest-growing segment of health assistance has benefited HIV/AIDS programs, which grew from 25 percent to 39 percent of global development assistance between 2000 and 2006 (OECD DAC 2009). HIV prevalence is the biggest predictor of health aid to low-income countries, and countries with low HIV prevalence but high mortality are disadvantaged by the inequity; for example, Zambia receives USD 20 per person for health, whereas Chad receives USD 1.59 (Norad-AHHA 2009).

The Gates Foundation is the largest single source of private health funding, but much of its funding is disbursed to other channels, including the GAVI Alliance, the Global Fund, and UN agencies. In addition, government donations to health increased from 2002 to 2007, with the United States representing the biggest share. Governments use different mechanisms to channel their funds; some use multilaterals (for example, Finland, France, and the Netherlands), while others such as the United Kingdom and the United States use bilaterals or nongovernmental organizations (NGOs) (Ravishankar et al. 2009).

The major sources of international assistance to support health and pharmaceutical activities and projects include multilateral institutions, bilateral agencies, NGOs, foundations, and public-private partnerships (see Figure 14-2).

Figure 14-2 Major channels for funding development assistance for health, 2007

Multilateral institutions

Multilateral institutions pool resources from many donors and provide technical and commodity assistance globally or regionally through cash grants, commodity transfers, technical assistance, or loans. They are focused around sector areas of work, such as health or economic development. Multilateral institutions include the World Bank, the regional development banks, and the UN agencies, including the United Nations Children's Fund (UNICEF), the United Nations Development Programme (UNDP), the United Nations Population Fund, and WHO.

Bilateral agencies

Bilateral agencies are linked to national governments and involve government-to-government exchanges of goods and funding on a grant basis. Examples of bilateral agencies include the Norwegian Agency for Development Cooperation, the Swedish International Development Cooperation Agency, the U.K. Department for International Development, and the U.S. Agency for International Development (USAID). Bilateral agencies may work in countries through contracted organizations to provide technical assistance to projects.

Nongovernmental organizations

NGOs can operate not for profit or for profit and may be affiliated with religious institutions or other groups or agencies. Although development funds have traditionally been provided to recipient governments, an alternative

mechanism is to target funds directly to NGOs, particularly those based in the community. The role of NGOs as conduits for health aid has increased substantially—increasing from 13 percent in 1990 to 25 percent in 2006 (Ravishankar et al. 2009).

The objectives of NGOs tend to be targeted to specific diseases and population groups. The procedures these organizations follow tend to be less stringent than those of bilateral and multilateral agencies; in addition, in the approval process, NGOs favor an affinity of mission or ideology between donor and recipient organizations and the existence of a positive, ongoing relationship. This funding mechanism, which has gained acceptance as a way to ensure that resources reach target populations at the local level, tends to be favored by NGOs and foundations in developed countries. Bilateral and multilateral agencies are generally more reluctant to become directly involved in small projects because of the high costs of reviewing, supervising, and evaluating such initiatives.

Private foundations

Foundations now account for a significant share of total health assistance to developing countries, usually through

cash grants. For instance, in 2004, total health assistance from the Bill & Melinda Gates Foundation was nearly equal to total health lending by the World Bank, and the Gates Foundation's endowment is expected to increase from USD 29 billion to USD 60 billion, making it the world's largest charitable organization. Private foundations sometimes follow more flexible procedures for reviewing grant proposals and overseeing grant-funded projects.

Public-private partnerships

In addition to these major sources of donor assistance, global public-private partnerships that tend to focus on specific diseases or health conditions have proliferated. Examples include the GAVI Alliance; the Global Fund; the Medicines for Malaria Venture; the Partnership for Maternal, Newborn & Child Health; Roll Back Malaria (RBM); Stop TB Partnership; and the Millennium Challenge Corporation. [Box 14-2](#) describes some of the major health alliances.

Despite rapid increases in development assistance for health, the resources available are still short of the funding needed to achieve the health MDGs, which is estimated to range from an additional USD 25 billion to 70 billion per year (World Bank 2006b) up to USD 135 billion by 2015

Box 14-2

Selected global public-private partnerships in health

GAVI Alliance

<http://www.gavialliance.org>

The GAVI Alliance is a public-private partnership focused on increasing children's access to vaccines in poor countries. Partners include the GAVI Fund, governments, UNICEF, WHO, the World Bank, the Bill & Melinda Gates Foundation, the vaccine industry, public health institutions, and NGOs. GAVI provides countries with resources to strengthen routine immunization and health systems services; finances the introduction of new and underused vaccines, such as those for hepatitis B, Hib disease, and yellow fever; and supports safe injection practices through safe injection commodity assistance. Although the GAVI Alliance procures only selected vaccines for countries, its funding helps strengthen immunization systems overall, which increases a country's capacity to deliver all necessary vaccines to children.

Seventy-two of the poorest countries, containing half the world's population, are eligible to apply for support from the GAVI Alliance, and as of 2008, seventy-one had received GAVI support. The GAVI Alliance has made commitments of USD 4 billion to seventy-five countries between 2000 and 2015.

Global Fund to Fight AIDS, Tuberculosis and Malaria

<http://www.theglobalfund.org>

The Global Fund is a partnership among governments, civil society, the private sector, and affected communities. Its purpose is to attract, manage, and disburse resources to fight AIDS, tuberculosis, and malaria, including the procurement of pharmaceuticals and commodities. The Global Fund does not implement programs directly but rather relies on the knowledge of local experts. As a financing mechanism, the Global Fund works closely with other multilateral and bilateral organizations involved in health and development issues to ensure that newly funded programs are coordinated with existing programs. The Global Fund finances programs only when it is assured that its assistance does not replace or reduce other sources of health funding; it actively seeks to complement other donor funds and to use its own grants to catalyze additional investments by donors and by recipients themselves.

Since 2002, the Global Fund has approved USD 19.3 billion in funding to support more than 572 programs in 144 countries.

The Partnership for Maternal, Newborn & Child Health

<http://www.who.int/pmnch>

The Partnership for Maternal, Newborn & Child Health was created to support sixty countries' efforts to achieve MDGs related to maternal and child health. The partnership works to promote and harmonize national, regional, and global action to improve maternal, newborn, and child health. The partnership is made up of a broad constituency of more than 300 members representing partner countries, UN and multilateral agencies, NGOs, health professional associations, bilateral donors and foundations, and academic and research institutions. The partnership supports country-led efforts to provide complete coverage of essential interventions for maternal, newborn, and child health by focusing on country support; advocacy; promoting the assessment, scaling up, and implementation of cost-effective interventions; and monitoring and evaluating stakeholders to ensure they meet their financial and policy commitments.

Roll Back Malaria

<http://rbm.who.int>

The global RBM effort was announced by the heads of WHO, UNICEF, UNDP, and the World Bank in November 1998. The RBM partnership consists of malaria-affected countries, UN agencies, the private sector, industry, countries of the Organisation for Economic Co-operation and Development, development banks, community-based organizations, research entities, and the media. The initiative aims to reduce global malaria mortality by 50 percent by the year 2010. Partners are working together to scale up malaria-control efforts at the country level, coordinating their activities to avoid duplication and fragmentation and to ensure optimal use of resources. The strategy to achieve this goal relies on six core elements: (1) early detection, (2) rapid treatment, (3) multiple means for prevention, (4) well-coordinated action, (5) a dynamic global movement, and (6) focused research.

One initiative of RBM is the Malaria Medicines and Supplies Services (MMSS), which works to support procurement and supply management efforts for nets, insecticides, medicines, and diagnostics that are needed to achieve malaria-related health goals. MMSS collects, consolidates, and disseminates information on the demand and supply of medicines and other commodities and helps advise countries on how to procure medicines efficiently. MMSS does not procure itself, but it establishes links with procurement agencies.

Stop TB Partnership

<http://www.stoptb.org>

The Stop TB Partnership, established in 2000, involves a coalition of 517 governments, national and international NGOs, and public and private donors committed to controlling and eventually eliminating tuberculosis (TB) as a global public health problem. Partners work in seven specific areas: DOTS expansion; TB/HIV; multi-drug-resistant TB; new TB medicines; new TB vaccines; new TB diagnostics; and advocacy, communications, and social mobilization.

Stop TB Partnership's Global Drug Facility

<http://www.stoptb.org/gdf>

The Global Drug Facility (GDF) was established in response to difficulties that countries had in finding and funding stable TB medicine supplies to support DOTS expansion. The GDF uses a combination of grants and direct pharmaceutical procurement to eligible countries. The mechanism links demand for medicines to supply, competitively outsources all services to partners, uses product packaging to simplify pharmaceutical management, and links grants to TB program performance. Besides procuring quality TB medicines, the GDF provides technical assistance in TB pharmaceutical management and monitoring of TB medicine use.

UNITAID

<http://www.unitaid.eu>

The founding countries of Brazil, Chile, France, Norway, and the United Kingdom, with the backing of international organizations such as WHO, UNAIDS, UNICEF, the Global Fund, and NGOs and private foundations, such as the Clinton Foundation, have launched an international drug purchase facility called UNITAID. The facility is funded by an innovative financing mechanism—a levy on airline tickets—to help scale up access to treatment for HIV/AIDS, malaria, and tuberculosis in developing countries. By 2010, UNITAID had twenty-eight supporting countries plus the Gates Foundation. In three years, the levy had contributed USD 1.3 billion to UNITAID's assistance fund.

The goal of UNITAID is to provide multiyear contributions for a long-term and predictable supply of medicines and diagnostics by leveraging price reductions and increasing the availability and supply of medicines. The program initially focused on funding pediatric formulations for TB and HIV/AIDS, scaling up second-line anti-retroviral medicines and artemisinin-based combination therapies, and supporting the WHO prequalification program to ensure quality pharmaceuticals.

(UN Millennium Project 2005). Governments have committed to increasing official development assistance to up to 0.7 percent of their respective gross domestic products by 2015 to support scaling up to achieve the MDGs (UN General Assembly 2002). New and innovative financing mechanisms, such as the airline ticket levies used by UNITAID, are being developed to raise the necessary additional resources.

14.4 Types of assistance

The types of assistance offered (and the conditions attached) can vary widely—

- Financial assistance (loans or grants)
- Commodities
- Technical expertise
- Study tours and fellowships
- Research funding

In negotiating development assistance of any type, governments are advised to ensure that the assistance supports their national health priorities rather than diverts attention

from them. Information describing the level, duration, and type of assistance available, as well as the timing for presentation of proposals, is generally available at the country level through development banks, embassies, and offices of UN agencies. Table 14-1 lists major donors to international health and their websites.

Financial assistance

Loans issued by the World Bank are one of the largest sources of financial assistance in the health sector. Lending for health and nutrition averaged USD 825 million a year over the first decade of the 2000s (World Bank 2010b). In fiscal year 2010, lending to developing countries totaled over USD 72 billion. The bank itself comprises two development institutions that are owned by 187 member countries—the International Bank for Reconstruction and Development (IBRD) and the International Development Association (IDA). The IDA and IBRD, as well as their regional counterparts, such as the Asian, African, or Inter-American Development Banks, provide low-interest loans, interest-free credit, and grants to developing countries for education, health, infrastructure, and communications. The IBRD

14.10 FINANCING AND SUSTAINABILITY

focuses on middle-income countries needing capital investment and advisory services, while the IDA helps the poorest countries of the world increase economic growth. The IDA is mostly funded through contributions from the governments of richer member countries. [Box 14-3](#) describes the initiative that the World Bank has put in place to help relieve the debt of the poorest countries.

World Bank assistance has focused on strengthening health systems, with some targeted programs aiming at population, nutrition, and other priority public health areas. Approximately 200 World Bank projects between 1991 and 2002 have had some type of pharmaceutical component—funding for procurement of pharmaceuticals and vaccines, strengthening of the pharmaceutical sector, or improving regulatory frameworks and institutional capacity. Total lending over this period amounted to nearly USD 3 billion, which represents about USD 250 million per year over the twelve-year period.

Loans are also provided on a government-to-government basis as part of bilateral agreements that, in turn, reflect political commitments. Such loans are much more favorable than those from commercial banks: interest rates are lower, repayment schedules are adjusted to a country's financial capabilities, and loans frequently have a nonreimbursable grant component.

Because these loans become part of the national debt and must be repaid by future government administrations, they should be accepted only after thorough study of the costs and benefits. In general, loans should be used for investment—for the development of infrastructure and national capability—and not to cover recurrent health expenditures or to pay for consumables, such as pharmaceuticals. In addition, a bank's internal procedures may raise the real cost of the loan (for example, by including the total cost of preproject planning expenses, as well as the time and travel of bank representatives and consultants, which can be substantial). Concessionary loans with low interest rates and lengthy repayment periods, however, often end up being the equivalent to a grant when inflation outstrips the interest rate.

Grants, which do not require repayment, are a much sought after source of assistance. However, the Global Fund, for example, requires recipients to reach specific targets throughout the life of the grant. Many countries that have not been able to meet their performance goals have had funding cut off, which can cause programmatic challenges. Other costs are not always obvious. For example, a grant can include a requirement that the recipient demonstrate commitment to the work by the assignment of counterpart resources (staff and infrastructure) to complement those of the grant. Such commitments can siphon scarce resources from other, more important health programs. National priorities can become distorted if disproportionate attention is given to an issue simply because it is the

fashionable “cause of the year” and can attract grant money or loans.

Commodities

Funds are often made available for the purchase of commodities such as pharmaceuticals, medical supplies, laboratory reagents, equipment, or computers. The conditions for commodity purchase should be subject to negotiation to ensure not only that price and quality are acceptable but also that the commodities meet country needs and do not lead to an unacceptable level of dependence on a foreign source. Pharmaceutical products should correspond to those on the national list of essential medicines and should be labeled in a language understood in the country.

Only as a last resort should loans be used to buy pharmaceuticals. This essential, recurring expenditure should be within the national financial capacity.

Some assistance agreements limit the provision of critical supplies to periods of economic crisis or emergencies caused by natural disasters. The guidelines for donations included in [Chapter 15](#) are relevant not only for donated commodities but also for those purchased through grants or loans.

Technical expertise

Donors can provide funds to obtain the managerial or technical expertise required for project execution, both short term (for example, two weeks to set up a laboratory instrument and to train staff in its use) or long term (for example, management of a four-year project). The work must be carried out with in-country counterparts to transfer technical competence to the recipient country and not perpetuate a relationship of dependence.

Training, study tours, and fellowships

Study tours, fellowships, and other forms of training are important investments in a country's professional capacity and are attractive to the individuals who benefit directly. Such opportunities can provide a powerful incentive to improve job performance, particularly for officials and employees receiving low government salaries. Arrangements should be in place, however, to ensure that individuals who have benefited from this assistance return to share their knowledge and skills with fellow workers and that they remain in their jobs for a sufficient length of time to justify the investment.

Research funds

Funds are increasingly available for operational research and evaluation. This is in recognition of the fact that a project's chances of success are enhanced by a clear under-

Box 14-3 The Debt Relief Initiative for Heavily Indebted Poor Countries

Economic crises in the 1980s resulted in many low-income countries becoming overwhelmed with huge debts that they were unlikely to ever be able to pay back. In 1996, the International Development Association and the International Monetary Fund launched the Debt Relief Initiative for Heavily Indebted Poor Countries (HIPC) as a way to help the poorest countries get out from under the debt burden that was stifling poverty-reduction efforts. The HIPC Initiative calls for all creditors—multilateral, bilateral, and commercial—to voluntarily forgive a specified percentage of debt to countries that meet certain qualifications. A country is potentially eligible for HIPC status if it meets criteria related to per capita income and level of indebtedness. In 2006, 40 countries were potentially eligible (World Bank 2006b). A series of steps begins the process whereby countries put policies in place to reduce poverty and create a plan to clear any arrears from foreign creditors. The last step leads to the *completion point*, where the country has shown satisfactory performance in its strategies and in other indicators such as improvements in health, education, and governance. At the completion point, the debt relief from participating creditors becomes irrevocable. As of 2010, 30 of 40 countries had reached the completion point (IMF 2010).

To supplement the HIPC Initiative, additional relief is available in the form of the Multilateral Debt Relief Initiative (MDRI), which was implemented in 2006. Under the MDRI, countries that have successfully reached the completion point of the HIPC Initiative are then eligible to have forgiven 100 percent of their debt owed to the IDA, the African Development Fund, and the International Monetary Fund. Although eligible countries do not have to meet any new conditions to benefit from the MDRI, they may have to show that their performance has not deteriorated since they reached the completion point of the HIPC Initiative. The three institutions together will forgive more than USD 50 billion over 40 years. To compensate for the resources lost through the debt forgiveness program, donors have agreed to contribute additional funds to ensure IDA's financial capacity.

To avoid the need for future debt relief initiatives, the World Bank has instituted a debt sustainability framework for low-income countries that puts loan responsibilities on both the borrowers and the lenders. Countries seeking loans must take measures to strengthen their ability to manage debt, and lenders must consider long-term debt projections and economic analyses as part of the loan process.

Sources: World Bank 2006a, 2006b; IMF 2010.

standing of the environment in which the project is to take place, by ongoing monitoring during project implementation, and by an impact evaluation after completion. Well-designed research proposals may be a prerequisite for funding approval.

14.5 Improving aid effectiveness by working with the donor community

Since the 1990s, health projects and vertical health programs funded by donors at the country level have proliferated. Donor assistance can be critical to a country's ability to deliver high-priority health services. Therefore, the efficient use of this assistance is vital. Too often, donor-supported projects are developed and negotiated independently, and their funding remains largely outside the official government budget. Donors often work in selected areas within countries, resulting in overlap in some program areas and expanding gaps in others. These factors have led to an increasing lack of accountability of governments to their

constituencies and reduced managerial control over support to the health sector by countries. In addition, the lack of fiduciary management has resulted in a misallocation of scarce government resources.

Sector-wide approaches to aid

One important advance has been the creation of sector-wide approaches for the health sector. Although no standard definition of a SWAp exists, it is generally characterized by a strong and well-articulated health-sector plan that is then supported financially and technically by the government and its development partners through one "market basket." External aid is moved on budget and roles and responsibilities are clearer, allowing the ministry of health to direct and manage the health sector as a whole.

Ministries of health are in a powerful position to influence donor cooperation. Although they may be motivated by a desire to reduce duplication of effort, they may also find an important opportunity to build support and momentum for health program priorities such as essential medicines

Country Study 14-1**Attempting to meet financial goals through a health-sector SWAp in Mozambique**

The government of Mozambique, in consultation with its donor partners, established a SWAp for health programming in 2000. Following a lengthy civil war, what was left of the health system was highly fragmented and oriented toward urban areas. As the country began to rebuild, development partners often took responsibility for providing health services in some areas, which exacerbated the fragmentation. When the SWAp was established, the goal was to coordinate external assistance and develop a transparent and collaborative relationship between the Ministry of Health and donor partners to share a set of common principles, objectives, and working arrangements that included the following—

- Health-sector strategic plan endorsed by partners, which prioritizes funding and interventions
- Code of conduct describing the basic arrangement with partners
- Set of working arrangements for communication and consensus building
- Sector financing framework
- Mechanisms to evaluate health-sector progress

The SWAp's financial goals were to increase government health expenditure and to raise the proportion of external funding going to common funding and budget support rather than through vertical programs. Mozambique achieved those goals. Between 2001 and 2005, the government more than doubled its total health expenditures; however, funds to vertical programs also increased (primarily because of global HIV/AIDS programs).

The gains in common funding enabled the Ministry of Health to fund government priorities that were described in operational plans and budgets. Progress in the areas of financial management and planning resulted in Mozambique being the first country to integrate resources from the Global Fund to Fight AIDS, Tuberculosis and Malaria into the SWAp's common fund. In addition, better financial harmonization has allowed the SWAp to become more efficient in its health procurement. The Ministry of Health was also given the full responsibility to manage the funds for procuring medicines.

By 2009, Mozambique had twenty-eight development partners supporting the health sector, and fifteen partners had signed a memorandum of understanding to support the sector through pooled funding (the fund is called Prosaude). Although the government's financial contributions to the health sector had been increasing under the SWAp, the trend leveled off. Donor fragmentation was still a problem, and donors were still channeling vertical funds according to their defined priorities through a network of implementing NGOs—even those who had signed the memorandum of understanding. This arrangement undermined Ministry of Health ownership by creating a parallel network through NGOs instead of strengthening the Ministry of Health. In addition, assessing the effectiveness of these contributions was difficult, and the predictability and disbursement of the funds did not always follow the government budget cycle.

Sources: Martinez 2006; WHO/AFRO 2009.

programs. Donors such as USAID, however, do not contribute to a SWAp market basket because of the perceived loss of control over how governments use the funds. [Country Study 14-1](#) describes Mozambique's experiences with establishing a SWAp.

Concomitant to development of a SWAp for the health sector, many countries have moved toward improving public expenditure management through the development of a medium-term expenditure framework (MTEF). An MTEF is usually a three-year rolling budget that is built on individual sector budget proposals, such as health, relative to an overall budget ceiling. The MTEF seeks to harmonize the recurrent and development aspects of the budget, as well as to generate greater transparency by rolling development assistance on budget. Countries with an MTEF face an added challenge in accepting additional donor funding when the value may replace rather than add to the government budget.

Poverty reduction strategy papers

Poverty reduction strategy papers (PRSPs), which were initiated by the International Monetary Fund and the World Bank in 1999, describe a country's macroeconomic, structural, and social strategies to promote growth and reduce poverty, as well as the country's external financing needs. Governments prepare PRSPs in collaboration with civil society and development partners—striving to promote national ownership of the strategy through broad-based participation. The goal of the PRSP approach is to link national policies and programs, donor support, and the development outcomes needed to meet the MDGs. PRSPs also serve as the guide for International Monetary Fund and World Bank lending and for debt-relief initiatives mentioned in [Box 14-3](#) (IMF 2010).

Health authorities may find finance and planning agents difficult to convince that financing the health sector is an

investment in the economy rather than a consumption good. Including health-sector priorities in the PRSP provides the basis for resource-allocation judgments at the national level, thus making the PRSP the national planning and resource-allocation document and the lens through which development assistance is viewed and evaluated.

Performance-based funding

One of the trends in improving donor aid effectiveness is the notion of performance-based funding, or results-based management. Donors are increasingly requiring that programs achieve quantitative targets before renewing aid to them. The popularity of this approach comes from its objectives of helping donors focus resources on programs that are effective, identifying problems early in the program implementation and making modifications, and improving future programs (Radelet 2006). [Box 14-4](#) describes an innovative mechanism to forgive loans using performance-based objectives.

As mentioned previously, the Global Fund approves initial grants for two years, then uses performance-based guidelines to make decisions regarding continued funding (Global Fund 2003). The indicators that the Global Fund uses to measure performance are categorized along a continuum of (1) short-term, (2) medium-term, and (3) long-term expectations—

1. *Process indicators:* These are what need to be completed to achieve improvements; for example, “training program for antiretroviral treatment (ART) adherence established.”
2. *Coverage indicators:* These track changes in key variables that demonstrate that individuals in target groups are being reached and are benefiting; for example, “percentage of patients achieving 95 percent adherence to ART (% target against baseline).”
3. *Impact indicators:* These measure changes in morbidity and mortality or the burden of disease in the target population that indicate that the primary objectives of the interventions have been achieved; for example, “Percentage of treatment failure among population taking antiretroviral medicines (% target against baseline).”

Multiple donors requiring monitoring and evaluation based on multiple indicators can be a huge challenge to recipient countries, however, because of the amount of time meeting these requirements takes away from already overstretched personnel. The Global Fund encourages its grantees to use existing systems for monitoring and reporting to avoid duplicate reporting whenever possible.

14.6 Securing donor interest

Health authorities should take the initiative to approach appropriate donor agencies regarding their interest in supporting specific program areas, such as essential medicines. Even at an early stage, a donor appreciates receiving a written proposal, however preliminary and general it may be, to determine if sufficient interest exists to proceed further.

Box 14-4

The Investment Partnership for Polio: An innovative financing mechanism

The Investment Partnership for Polio, comprising the World Bank, the Bill & Melinda Gates Foundation, Rotary International, and the United Nations Foundation, is a program to fund immunization of children in polio-endemic countries. As part of the partnership, the International Development Association created an innovative credit buy-down system in which the partnership “buys down” a country’s IDA loans after the project successfully reaches agreed performance goals—in this case, the completion of the country’s polio eradication program. In this way, the loans ultimately revert to grant funding. To fund the buy-downs, the partnership established a trust fund with USD 50 million. The first two countries to take advantage of the loan buy-down mechanism were Nigeria and Pakistan.

The buy-down mechanism is designed to enhance the efficiency of the IDA’s assistance in priority areas; to mobilize additional resources from other partners; and to focus the attention of governments, partners, and World Bank staff on clearly defined performance objectives. Ultimately, countries are rewarded for contributing to the worldwide effort to eradicate polio.

In Pakistan, the partnership approved two projects for USD 42.71 million in 2003 and for USD 74.27 million in 2006 to purchase the oral polio vaccine and help the country’s Polio Eradication Initiative. The number of polio cases decreased from 1,147 in 1997 to 31 in 2007. After the project was completed, a credit of USD 42 million was converted into a grant and written off for the government of Pakistan.

14.14 FINANCING AND SUSTAINABILITY

Information describing the level, duration, and type of assistance available, as well as the timing for presentation of proposals, is generally available at the country level through development banks, embassies, and offices of UN agencies. [Table 14-1](#) lists major donors to international health and their websites.

As demand for assistance funds increases, donor agencies have become more selective about the project proposals they will consider. Proposals must meet general criteria regarding government policies and commitment, private-sector involvement, impact, and sustainability to satisfy the concerns of donors.

The conditions for assistance may require recipient governments to take steps toward reforming or even restructuring the health sector. Where pharmaceuticals are concerned, this requirement may mean profound changes in how the pharmaceutical supply is managed. For example, it may mean moving from a centralized government agency that handles all aspects of procurement, warehousing, and distribution to a system that limits central government involvement to coordination and supervision and delegates operational aspects to provincial and local levels or to the private sector.

Government policies

Project proposals must be consistent with the priorities of the recipient country and, most important, with the PRSP. Pharmaceutical projects should refer to official policies in this area, particularly if the country has a national medicines policy and action plan to improve the availability of essential medicines and to promote the rational use of medicines.

Government commitment

The commitment of the recipient government to the objectives of the proposal should be reflected in its assignment of staff, space, and equipment to these objectives. The external contribution is generally intended to complement the counterpart contribution, not the other way around.

Health care reform

Extensive health system reforms are under way in many countries. Their aim is to restructure the organization, financing, and provision of health services to achieve greater equity, efficiency, and quality using available resources. This reform often includes stimulation of competition and greater involvement by the private sector. Donors may require that pharmaceutical reforms be undertaken as part of health care reform. Thus, representatives of the health professionals' associations and of the local pharmaceutical industry may be included in the formulation of a project

and in the identification of strategies for its implementation. Private-sector involvement in pharmaceutical supply is discussed in [Chapter 8](#).

In addition, several major global health initiatives, such as the GAVI Alliance, the Global Fund, and the U.S. President's Emergency Plan for AIDS Relief, have shifted some focus and funding from disease-specific activities to strengthening countries' overall health systems. Evidence indicates that these efforts have resulted in some successes, including increases in overall health financing and improved health system governance and accountability (WHO Maximizing Positive Synergies Collaborative Group 2009). In the area of pharmaceutical management, the accomplishments in HIV/AIDS programs, in particular, have enhanced the pharmaceutical sector overall in areas such as pharmaceutical development, procurement, and distribution as well as human resource and information management systems (Embrey, Hoos, and Quick 2009).

Impact

The expected impact of a project should be explicitly stated in the proposal; donors are wary of projects that simply propose to do more of what is already being done. They are interested in supporting initiatives that will noticeably change the status quo at the policy-making or operational levels or both. How will the project improve existing conditions? Will it result in an integrated and intersectoral program that will be more cost-effective than the present one? Although the effect of a single project may be difficult to quantify, an effort should be made to explain its expected impact.

Sustainability

Donors are increasingly interested in the sustainability of their investments. Even at the proposal stage, they want assurance that achievements will not disappear after external funding has ended. In numerous examples, project funds have been used unwisely to support unusually high salaries or luxurious offices; when the funding for these salaries and offices ends, so does the interest in the activities launched.

To prevent such backlash, project activities should be designed to be carried out as much as possible within normal structures and working environments. Also, arrangements should be in place before the project ends to institutionalize the project's achievements, that is, to provide the funds for the staff, infrastructure, and supplies required to continue the activities started. Special attention is required in projects that include the purchase of essential medicines as a central element: in these cases, financial mechanisms must be installed to ensure that the medicines continue to be available when external aid has ended.

14.7 Obtaining grants from private foundations

Private foundations are an important source of international assistance, especially for NGOs whose philosophies, missions, and values correspond with those of the donors. Foundations' procedures for reviewing and approving grant proposals and for overseeing grant-funded projects tend to be considerably more flexible than those of bilateral and multilateral agencies. Nonetheless, four important steps should be followed.

Step 1. Identify potential foundations

Funding groups and directories identify foundations of potential interest, describe the interests and funding priorities of individual foundations, and provide broad guidelines and criteria for application. Foundation websites often have a section with information for those seeking grants.

Step 2. Target selected foundations

Reviewing annual reports of the foundations under consideration for information about their programs, geographic areas of interest, monetary range of grants, and proposal guidelines is useful. This review can help grant seekers develop a list of foundations whose funding criteria fit their interests.

The development of foundation proposals takes time, persistence, and the cultivation of personal relationships: introduction to foundation staff, discussion of mutual areas of interest with program officers, and making a case for support are all necessary before a proposal is formally submitted.

Step 3. Develop proposal

A foundation proposal should generally include the following key elements. The guidelines for proposals will designate the page number limit.

- Description of the organization
- Problem to be addressed
- Proposed solution
- Statement of objectives and methodology
- Plan for project management
- Timeline
- Evaluation plan
- Budget

A cover letter summarizes the proposal and provides a strategic link between the proposal and the foundation's mission and interests. In addition, the letter makes a specific request for funding the proposed activities.

Step 4. Submit proposal and follow up

Foundations do not generally have deadlines for submission of proposals but review them on a rolling basis. Staff members look at the proposal whenever it is received to determine its compatibility with the foundation's current interests and priorities, its technical merit, and the financial and management capacity of the submitting organization.

If a proposal is deemed appropriate, the board of trustees reviews it for final consideration and approval. Meetings of the board are usually scheduled quarterly. The review process can take up to six months to complete.

When an award is made, the foundation presents a payment and reporting schedule to the grantee. Grant funds are restricted to those activities outlined in the proposal. At the end of each grant period, a narrative and a financial report on the specific use of funds are usually required.

14.8 Project formulation documents

Many donors follow a two-stage proposal process for new projects, requiring submission and approval of a project profile or letter of intent, followed by a more detailed project document. Donors may be willing to assist in preparing these documents, or governments may request assistance through local offices of WHO, UNICEF, or UNDP.

The project profile

The project profile or letter of intent should contain sufficient information for preliminary discussion and decision making. It should describe and reflect broad agreement within the government or the requesting organization regarding the problem to be solved, the proposed solution, and the estimated cost. Requirements to include at the project profile stage are the problem analysis, goals, objectives, and activities, including expected results and a time frame. Other elements can be outlined, and a skeleton budget should be included. Often, donors will require that the proposal show in-kind support from in-country partners. Quantitative information should be included, if possible. [Annex 14-1](#) contains the instructions for submitting a letter of inquiry to the Bill & Melinda Gates Foundation.

All parties that may be affected or involved in the project must be included in early planning discussions to avoid the sense that a particular project belongs to a specific official or unit. Such an attitude discourages the participation of other individuals or institutions and limits the coordination required to ensure that project goals are pursued in an appropriate manner.

The project profile is submitted for review to the donor agency. Months may go by before a response is received. The response, even if highly positive, almost always contains

recommendations for changes or additions to ensure that the proposal complies with donor requirements, some of which, at first sight, may not seem relevant. The recommendations, however, should not be overlooked. More likely than not, they reflect a political decision of the donor country or institution that any project to be funded must address certain issues of national or global interest. The issues vary according to the source of funds, but common ones include environmental protection, the role of women, alleviation of poverty, and human rights.

Once the donor institution is satisfied that its concerns will be addressed in the project and confirms its support, the complex work involved in preparing the project document begins.

The proposal document

The proposal document is more detailed than the profile because it is intended to guide project implementation and to serve as the reference for monitoring and evaluation. It often serves as the legal basis for the commitments assumed by the donor and recipient.

Donor agencies usually require that the project design be systematic and comprehensive; many favor the logical framework approach, which is described in [Chapter 38](#) and in the World Bank's *Logframe Handbook* (World Bank 2005). The Logframe uses a hierarchy of key elements to design the project—

- Project goals (development objective)
- Project purpose (immediate objective)
- Outputs
- Activities
- Inputs and resources

Like the project profile, the proposal document is submitted to the funding agency for review. Once donor comments and recommendations have been received and the recipient has satisfactorily responded, donor approval of the project follows. Disbursement of funds for each project year is approved after submission of an annual workplan, which should include an introduction, specific objectives and strategies, planned activities, and a budget.

14.9 Use of local and international consultants and advisers

Regardless of funding source, expert advice can be required at various stages of a project, such as design, implementation, specialized problem solving, and external evaluation. If the donor or recipient does not have the required expertise available in-house, the donor or recipient commonly contracts with outside professionals. In some cases, the donor

may require the use of an external consultant, to ensure that the appropriate technical expertise is applied and to provide a degree of independence from local political pressures. Recipients, whether governments or NGOs, may seek outside consultants who are respected for their technical or managerial competence and who can provide impartial input to overcome the objections of special-interest groups and support new or controversial initiatives.

Clear and early identification of what is expected from a consultant is crucial. This is done with clear terms of reference that define what is to be produced, a specific time frame, and supervision and reporting responsibilities.

Consultants' education and experience (qualifications) should also be spelled out. For a specific, highly technical, and short-term assignment, such as training government inspectors in good manufacturing practices, five years of experience as an inspector in a well-established regulatory agency, plus knowledge of the local language, may be sufficient. A consultant who will be managing a four-year project to develop a national essential medicines program should have extensive experience in similar projects internationally; counterparts in the host country will benefit from the consultant's experience in other parts of the world.

The process of selecting a consultant can vary from an informal interview for a short-term job to a highly structured process for a project manager or specialist who will serve for one year or longer. In the latter case, the donor, the host government, and any participating agencies often work together to advertise the search and ensure the prompt review of applications by a selection committee. Although a formal process may take six months or longer, it provides legitimacy and authority to those selected for key project posts. The hiring process needs to be transparent and competitive—all qualified consultants should be given an opportunity to compete for the position. The World Bank has guidelines on selecting and employing consultants (World Bank 2010).

The selection of consultants for specific short-term assignments (for example, advising warehouse staff on good storage practices) should be carried out in a much shorter time. This can be achieved with the cooperation of international and bilateral organizations such as WHO, UNICEF, USAID, and the Danish Agency for Development Assistance; they have rosters of specialized consultants who have worked with them and for whom they can provide references.

Government-to-government requests for expert assistance are also common and are promoted by international agencies through technical cooperation among countries (TCC) projects. In the TCC process, countries work together to develop human resources or technical capacity through cooperative exchanges, which may include experts or consultants. The expert exchanged is not a consultant *per se* but a professional who does the same job in his or her own country. Under a TCC project, the host government covers

travel and local expenses, and the cooperating government continues to pay the official's salary. Ideally, TCC activities should be managed by the governments with the participation of public and private institutions and organizations.

Joint consultancies with an international and a local consultant should be considered. They combine the advantages of the international consultant's insights from similar projects in other parts of the world and the local consultant's knowledge of the environment and local contacts. A positive side effect is the mutual transfer of knowledge, allowing both consultants to further their professional development.

14.10 Progress reports and evaluations

Donors' demands may increase as the project progresses, because funding officials need to know whether their investment is resulting in the positive changes envisioned in the project plan. Toward this end, donors may request a semi-annual status report and an annual report accompanied by a financial statement. Reports provide the project manager with an opportunity to describe the project's achievements, problems encountered and actions taken to overcome them, and any discrepancies between the original workplan and actual implementation. Any potential changes in project objectives should be discussed and approved in advance by the funding agency. As mentioned, efforts are under way to harmonize reporting requirements between governments and donors.

Project evaluation provides a structured environment for donor-recipient interaction, whether carried out midway through the project or as a final exercise. The mission of the evaluation team, which includes donor representatives, is to determine whether planned objectives were achieved and the reasons for successes and failures. The project document serves as the basic guide in this work, and the value of having developed clear objectives, clarified the assumptions and risks, and selected manageable indicators becomes evident. (See [Chapter 36](#) for a more detailed discussion of indicators for pharmaceutical-sector assessment.)

Before the evaluation team arrives, the project manager should prepare a summary of major project accomplishments; the more specific it is the better. Arrangements should be made for evaluators to visit sites where project activities have taken place. Presentations on the results achieved should be made by those directly responsible for the activity or, better yet, by those benefiting from it.

Providing the evaluation team with information about achievements as well as difficulties that were overcome is in the project manager's interest. The government's commitment to the project should also be highlighted, in part by quantifying the administrative support and space provided and the staff and resources assigned. The most convincing

evidence is documented changes in government policies that would lead to institutionalization of the goals pursued by the project.

A favorable evaluation facilitates future discussion with the donor agency regarding extension of the present project or preparation of new initiatives. However, successful completion of the original project should not lead a recipient country to assume that continuing funding is assured and that an expanded or new project can be launched. A major goal of donor agencies is to promote greater self-reliance, and after a certain period of external support, donors expect recipients to absorb the costs for consolidating and expanding the gains achieved under the project. Donor's priorities also change, often for reasons that may have little or nothing to do with the recipient country. This further emphasizes the importance of staying up-to-date regarding what sectors and program areas are priorities for international development assistance. ■

ASSESSMENT GUIDE

Sources and types of assistance

- Describe current development assistance received from international sources. Is the assistance provided through official development assistance or through bilateral agencies, multilateral institutions, NGOs, foundations, or public-private partnerships?
- Does the international assistance support national health priorities and programs? To what extent is it useful in catalyzing health system reforms that would otherwise be difficult to accomplish?
- Does funding coincide with a sector-wide approach to aid or does it follow a poverty reduction strategy paper?
- What types of international assistance are provided—for example, funds (loans or grants), commodities, technical assistance, training?
- When loans are provided, are they used for investment purposes rather than to cover recurrent health expenditures?
- Is the country eligible for the Debt Relief Initiative for Heavily Indebted Poor Countries?
- When the assistance is provided in the form of commodities, are purchase terms negotiated to ensure appropriate products, price, and quality?

Ministry of health involvement

- Have health-sector priorities been clearly articulated to support national development policies?
- Does the ministry of health take an active role in identifying sources and types of assistance and representing its interests to the ministries of planning,

external relations, and finance, which are likely to carry out negotiations with donors?

- Does the ministry of health facilitate the cooperation of multiple donors by communicating national policies and programs, inviting donors to participate in the development of a master plan, hosting regular donor coordination meetings, or giving periodic progress reports to donors?

Project development

- Are project proposals written in a way that is consistent with government policies, specifically the national medicine policy (if one exists)?
- Is government commitment reflected in the assignment of staff, space, and equipment to project objectives?
- Do project proposals include plans for monitoring and evaluating impact and sustainability and other issues of concern to donor agencies?
- Does each proposal include a description of the problem to be addressed? Are project goals, purposes, and strategies clearly stated? Are outputs, activities, and inputs specified?
- Are all involved parties included in project planning?
- Are external consultants employed in project design, implementation, or evaluation to provide specific technical expertise and independence from local political pressures? Has the consultant been hired using competitive and transparent procedures?

Annex 14-1 Bill & Melinda Gates Foundation Global Health Letter of Inquiry Instructions

Formatting

Please use 10-point font and 1-inch margins. Page size must be set to U.S. letter standard 8.5 x 11.0 inches.

Instructions

Please provide the legal name of the organization that will manage the proposed project, the submission date, the project title, and the name and email address of the person who can answer questions about the proposed project.

General Questions

Please answer the questions to the best of your ability. Your answers to these questions will help the foundation to determine how to appropriately route your LOI for internal review and have no bearing on whether the foundation will decide to approve or decline your request. This section will not count against your four-page limit.

Response to the following sections is limited to a total of four pages

I. Project Purpose and Background

Describe the purpose of the project and how it will impact the health problem being addressed. Provide a brief overview of the prior work leading to your project. Describe how the proposed project relates to the broader context of ongoing activities in the field.

II. Project Framework

The foundation uses a modified logical framework model to help you present your project in a clear, concise, and logical way. The Project Framework is not intended to show every detail of the project or to limit its scope. It is simply a convenient, systematic summary of the key factors from which foundation staff will assess how your project aligns with foundation priorities. In the event you are requested to submit a full proposal the Project Framework will form the basis of your dialogue with foundation staff and you will be required to fully elaborate on the details of your plan.

Using the table provided, please build your framework accordingly:

Step One – Building from the top down

Strategic Area – From the list provided identify the foundation strategic area to which your project will directly contribute. If other strategic areas are applicable or secondarily relevant, please describe.

Project Goal – Identify the ultimate impact your project will have if you achieve your stated objectives. This should be a clear, singular goal.

Objectives – List a small number of objectives or major components of the project required to achieve the project goal and a brief summary of your approach to achieving the objectives. *In the event you are requested to submit a full proposal you will be required to identify the actual activities or tasks that will be needed to meet the stated objectives.*

Step Two – Working across the framework

Indicators of Success – What will success of the project look like? Identify the quantitative or qualitative ways of measuring or assessing: the impact of the project on the strategic area; progress toward the project goal; and progress toward achieving the stated objectives. Indicators of success can be either outputs or outcomes. Outputs are direct, tangible products or services of the project (e.g., reports produced). Outcomes reflect changes or benefits measuring the impact expected to occur as a result of the project (e.g., performance gains through application of new knowledge, health benefits). *Please note: you are not expected to quantify or specify specific measures at this time; only to indicate the methods that will be used.*

Monitoring and Evaluation – Identify the methods and sources by which you will measure and evaluate the progress and impact on the strategic area, project goal and stated objectives. *Please note: monitoring and evaluation may not be relevant at the strategic area level for your project.*

III. General Approach

Describe in general how you plan to approach this project. Provide a summary of the activities required to support achievement of the stated objectives.

IV. Major Assumptions

Describe any external factors that could influence the success of the project but are likely beyond your direct control.

V. Budget

Provide a preliminary project budget by the stated objective(s) and by year using the table provided. In addition, please indicate the total organization revenue for the most recent financial year. If applicable, indicate whether additional support (in-kind or financial) will be provided for this project by other organizations. All financial figures must be provided in U.S. dollars.

Please refer to the foundation's Indirect Cost Policy when building the preliminary budget. Projects chosen to submit a full proposal will be required to adhere to the policy.

VI. Organizational Experience and Collaborative Partnerships

Briefly describe the relevant experience and comparative advantage your organization brings to accomplishing the targeted objectives of the project. If the project will involve a consortium or collaborative partnership, please provide this information for each organization along with a rationale for your selection of collaborators. The rationale should include how the work will be distributed, how duplication will be avoided, and how the efficiency of the collaboration will be maximized.

VII. Certification

By submitting this letter of inquiry, you certify to the Bill & Melinda Gates Foundation that you are authorized to apply for this project on behalf of your institution.

Additional Information**Global Access**

A principal goal of most activities funded by the foundation within the Global Health Program is to ensure that innovations (and related rights) are managed and public health solutions are optimized for the purpose of facilitating (i) the broad and prompt dissemination of data and information to the scientific community (as further described below in the section entitled “Data Sharing and Publication”) and (ii) the access (in terms of price, quantity, and functionality) to affordable health solutions for the benefit of people most in need within the developing world. We refer to the goal of these two objectives as achieving “Global Access.” We believe that the achievement of Global Access is a critical component to achieving the fundamental aim of reducing health inequities in the developing world.

With respect to your proposed project, ensuring that disadvantaged markets and populations in developing countries can one day readily access or otherwise directly benefit from the intended health solutions, should they prove effective and be commercialized (as applicable), is of paramount importance. Similarly, the other results of your work, such as incremental technological advances or discoveries, as well as data and other information arising out of the project, may also ultimately prove critical to addressing global health concerns.

While the science is and will continue to be the principal focus of the foundation, an essential aspect of your work is to identify and shape the path forward in managing the complex technologies and collaborations, fostering the necessary relationships with various sectors of the global health community, and in developing the intended project outcomes – all in a manner that facilitates the furtherance of the Global Access Objectives. The foundation believes strongly that, regardless of the nature or stage of your project, reasonable steps can and must be taken to help assure that you and your collaborators (as applicable) have provided for the achievement of these objectives.

Data Sharing and Publication

The generation of new evidence-based knowledge, technologies and practices that will result in significant improvements in the health of the populations of developing countries are among the most important charitable goals of projects supported by the foundation. Recognizing the possibility of securing intellectual property, grantees will be expected to prepare findings for timely publication and dissemination. You must consider publication strategies that will maximize the probability of your work reaching both the scientific and civil society communities in the developing world. The costs involved with making data widely available may be included in the proposed budget and will be subject to review and approval.

SUMMARY

Most pharmaceutical donations are given with the best of intentions but can nevertheless create problems at the receiving end. Often, donated pharmaceuticals are not relevant to the needs of the recipient, or they arrive unsorted or close to expiry. They may be labeled with a brand name or in a language that is not understood. Many pharmaceutical donations counteract government policies or violate national regulations of the recipient country and can be expensive for the country to store or destroy.

Guidelines for pharmaceutical donations are needed for a number of reasons. Donors and recipients do not communicate on equal terms, and recipients often need assistance in formulating their needs. Many donors do not understand the potential difficulties at the receiving end and need guidance. Medicines require special regulations because they are different from other donated items. Pharmaceutical donations that occur without input from the recipient countries should be discouraged.

The four core principles for a useful pharmaceutical donation are—

1. A donation benefits the recipient to the maximum extent possible.
2. A donation should be given with full respect for the wishes and authority of the recipient.
3. Items that are not acceptable in the donor country for quality-related reasons are also not acceptable as donations: there should be no double standards in quality.
4. Effective communication between the donor and recipient is necessary before any donation.

These principles have been translated into a set of guidelines for pharmaceutical donations. First, recipients should review and adopt these guidelines and present them officially to the donor community. Only then can they be implemented and enforced. Second, recipients should develop and publish administrative procedures for pharmaceutical donations. Third, recipients should indicate to the donors, as clearly as possible, how they want to be helped, specifying the medicines they need, the quantities, and the priorities. Donors should inform the recipients well in advance which pharmaceutical donations are coming, and when.

15.1 Introduction

In the face of disaster the natural impulse is to reach out and help those in need. Donations of medicines can alleviate peoples' suffering, and international relief efforts benefit enormously from donations by private individuals, groups, and organizations. Organizations may donate pharmaceuticals or medical supplies for a variety of reasons. Some may seek tax deductions that can result from charitable donations; some may be seeking positive publicity; while others may want to dispose of unwanted products without having to pay for destruction. Unfortunately, many pharmaceutical donations have caused problems instead of helping.

This chapter summarizes the problems with inappropriate pharmaceutical donations, describes a set of guidelines for donations, and offers some practical recommendations for recipients and donors.

15.2 Problems with pharmaceutical donations

Many different types of pharmaceutical donations exist, and each has its own set of specific problems. The types covered in this section are—

- Pharmaceutical donations in emergency situations

- Pharmaceutical donations between governments as part of development aid
- Donations of returned or unwanted pharmaceuticals

Pharmaceutical donations in emergency situations

A sizable disaster does not always lead to an objective assessment of the emergency medical needs, based on hard facts and past experience. Frequently, an emotional appeal for massive medical assistance is issued. In times of emergency, the term “medical supplies” has special emotional connotations that can impede an objective approach. Although [Country Study 15-1](#) provides examples of targeted emergency donations guided by quickly published lists of needs (e.g., in Haiti and Lebanon), more often than not, emergency pharmaceutical donations are inappropriate, which is why donors are often urged to respond to a disaster with cash rather than products (Pinheiro 2008). The main problems can be summarized as follows—

- Donated pharmaceuticals are often not relevant for the emergency situation, for the disease pattern, or for the level of care that is available.
- Health workers and patients are not always familiar with the donated pharmaceuticals.
- The pharmaceuticals are often not registered for use in

the recipient country and may not comply with local treatment guidelines.

- The pharmaceuticals that arrive are frequently unsorted, difficult to identify, unknown in the recipient country, labeled with brand names, or labeled in a language that is not locally understood.
- The quality of the pharmaceuticals does not always comply with standards in the donor country. Donated pharmaceuticals may have expired or may expire before they reach the patient; they may be returned pharmaceuticals (half-finished packages that have been returned to the pharmacy or free samples given to health professionals) (see Ette 2004); or they may be unwanted by the donor because they are close to expiration or the product is being discontinued (donating such products is also known as *drug dumping*). Donations may spoil or become damaged, which may be impossible to detect in the recipient country.
- The distribution plan often ignores normal administrative procedures. For example, the distribution system may bypass the central government stores or otherwise conflict with the plan of the national authorities.
- Donated pharmaceuticals may have a high declared value reflective of the market value in the donor country rather than the world market price. This valuation may result in high import taxes and overheads for storage and distribution in the recipient country, and the inflated value of the donation may be deducted from the recipient government's pharmaceutical budget.
- Pharmaceuticals may be donated in the wrong quantities or be otherwise unusable, and some stocks may have to be destroyed. Disposing of pharmaceuticals is not only wasteful; it is expensive for the recipient to safely destroy pharmaceutical stock.

There are several underlying causes for these problems. The most prominent cause is probably the common but mistaken belief that any type of pharmaceutical is better than nothing at all or, similarly, that expired pharmaceuticals are good enough for people in need. Second, pharmaceutical donations are often made despite the lack of a stated need or prior clearance by the recipient. Third, in many donor countries, donated pharmaceuticals are tax-deductible (at full market price). This last factor is why so many donated pharmaceuticals arrive close to or past their expiry date and why such products are typically not high-use, high-volume items. Pharmaceutical donations initiated by pharmaceutical manufacturers in exchange for tax breaks are likely to consist of medicines and supplies that are not commonly viewed as essential.

Inappropriate pharmaceutical donations create logistical problems because the donated products must be sorted, stored, and distributed, sometimes using precious human

resources and transport volume in disaster areas or war zones. Or they may pose an environmental threat if they have to be destroyed. Often, the total transport costs are higher than the value of the pharmaceuticals. Stockpiling of unused pharmaceuticals can encourage pilfering and black-market sales.

Even donations that are appropriate in every other way can cause problems when they far surpass the quantities that are needed. For example, a World Bank analysis of pharmaceutical donations during emergencies indicated that in Gujarat, India, after an earthquake in 2001, 95 percent of the donations received were deemed appropriate, but exceeded what was needed by 1,178 tons (Autier et al. 2002).

Pharmaceutical donations as part of development aid

Most of the problems noted above may also apply to large pharmaceutical donations between governments given as part of development (commodity) aid. The situation is usually better than with emergency aid, however, as there is more time to plan for the donations. Generally, the recipient is more involved in specifying what is needed.

The ideal situation occurs when the recipient country can indicate specific medicines and quantities needed, without any restriction on the selection and country of origin of the pharmaceuticals. Unfortunately, these conditions seldom apply. The choice is often restricted to manufacturers or suppliers in the donor country. Even if the medicines are listed generically on the national list of essential medicines in the recipient country, the donated items are often brand-name products or different formulations that may not be registered in the recipient country. The donation may then interfere with the implementation of national registration, quality assurance, and inspection schemes. If the selection of medicines is restricted by the donor, the donation may not be in accordance with national programs promoting standard treatment guidelines and rational medicine use.

Donations of returned pharmaceuticals

Many nongovernmental groups in developed countries collect unused medicines (returned medicines or free samples) and send these products in emergency situations or, on a regular basis, to institutions in developing countries. At the receiving end, such donations can frustrate all efforts to manage and administer pharmaceutical stocks in a rational way. Donating returned medicines is a clear example of double standards: in no developed country would the use of such products be permitted. In addition, these medicines are a problem for doctor and patient. The prescriber is forced to use countless different medicines and brands in ever-changing dosages; patients on long-term treatment suffer because the same medicines may not be consistently available. For

Country Study 15-1 Multicountry experiences with pharmaceutical donations

Bosnia and Herzegovina, 1997. During the war in Bosnia and Herzegovina, many areas became dependent on foreign donations of medicines and medical supplies. An estimated 27,800 to 34,800 metric tons of medical materials were brought into the area between 1992 and mid-1996. Three types of donations were identified, each inappropriate to some degree. The first type of donation conformed to WHO's interagency guidelines for pharmaceutical donations, but approximately 5 percent of the 13,200 metric tons of this donation were considered inappropriate, because it consisted of prepackaged kits that were not fully applicable to local health needs. The second type of donation consisted of small amounts of miscellaneous medicines that were largely delivered unsorted, unidentifiable, or expired, and were frequently items not useful for the local health problems. The third type of donation comprised large quantities of useless or unusable medicines—what is known as drug dumping. In total, 50 to 60 percent of all the medical supplies donated to Bosnia and Herzegovina were deemed inappropriate (Berckmans and Autier 1997).

Croatia, 1991. Starting in 1991, war and political instability affected countries that were part of the former Yugoslavia, prompting large amounts of pharmaceutical donations from the international community. In Croatia, 2,700 tons of inappropriate donations of foreign origin classified as “pharmaceutical wastes” were stored in 250 warehouses. USD 4 million was budgeted to ensure its safe disposal (World Bank 1999; Stritof and Vrhovac 1997, cited in Autier et al. 2002).

East Timor, 1999. When East Timor declared independence from Indonesian rule, a militia-led campaign of destruction ensued. Seventy-five percent of the population of 850,000 was displaced, and almost 70 percent of the country's infrastructure was destroyed. Assessments estimated that inappropriate donations to East Timor comprised about 10 percent (by volume) of the total donations received during the emergency phase, and less than 5 percent of donations after March 2000. Although the pharmaceutical donations in East Timor had some problems, several reasons why the donations were generally acceptable included—

- Direct connections by air or water to the island are difficult, so supplies went through Australia, which facilitated surveillance.
- The United Nations coordinated significant donations, which came in the form of New Emergency Health Kits, which helped limit ad hoc donations.

- Media coverage was scant.
- Pharmaceutical companies were willing to make donations that complied with WHO's donation guidelines.

The East Timor experience suggests that the WHO donation guidelines can positively affect pharmaceutical donations in emergency and postemergency situations (Autier et al. 2002).

El Salvador, 2001. Two earthquakes hit El Salvador in 2001, affecting at least 25 percent of the total population and up to 75 percent of the population in specific areas. Immediately following the disasters, pharmaceutical donations began to arrive in the country. Although a government-led coordination body managed the donations, the effectiveness of the system was diminished because of a lack of coordination with the agencies sending out the medicines, and lack of classification skills within the country for medicine sorting. Total pharmaceutical donations approximated 882 tons. Approximately 37 percent of the total volume of donated medicines was defined as inappropriate, and an additional 12.9 percent was defined as “mixed unusable drugs giving rise to suspicion of dumping” (Autier et al. 2002).

Eritrea, 1993. During the war for independence, despite careful wording of appeals, much time and energy had to be spent sorting pharmaceutical consignments. Examples of inappropriate donations included seven truckloads of expired aspirin tablets that took six months to burn, a whole container of unsolicited cardiovascular-related medicines with two months to expiry, and 30,000 half-liter bottles of expired amino-acid infusion that could not be disposed of anywhere near a settlement because of the smell.

Gujarat State (India), 2001. A major earthquake occurred in the state of Gujarat in 2001 in an area that was already experiencing a severe drought. India has an established natural disaster management system with a defined chain of command from the central to peripheral level. Officers were stationed at checkpoints to facilitate arrival and movement of supplies and donated goods, and the government had a coordination committee to synchronize the activities of various donors. The result was that the majority of pharmaceutical donations to the area appeared to be appropriate and clearly labeled, and had expiry dates that were at least one year from the time of arrival in India (Autier et al. 2002).

Haiti, 2010. A 7.0 earthquake struck Haiti on January 12, 2010. From January 16–21 alone, approximately 530 tons of pharmaceutical supplies arrived at the Port-au-Prince airport (PAHO/WHO 2010b), and another 810 tons of medical supplies were donated before February 6 (PAHO/WHO 2010a). PROMESS (the Program on Essential Medicine and Supplies), Haiti's central pharmaceutical store, was responsible for organizing the donations. With the assistance of the Pan American Health Organization and the U.S. government, PROMESS staff worked with medical personnel to help receive, sort, and check the expiration dates of the pharmaceutical donations, so that the items could be shelved. They also dealt with the challenges of providing security for the donations and the PROMESS facility. The Ministry of Public Health and Population waived any fees for essential medicines until four months after the disaster to assure maximum access to medicines.

Lebanon, 2006. During a Middle East humanitarian crisis, more than a quarter of the Lebanese population was displaced, and 50 to 70 percent of health facilities were partially or completely destroyed in the affected border regions. In addition, the supply of fuel, medicines, and medical supplies was disrupted. WHO posted a list of needed medicines and supplies—mostly for chronic diseases and surgical interventions—to guide donations. The local WHO coordinator said, “Lebanon needs medicines, but it needs the right kind. Every box of medicines or other supplies donated has to be checked, sorted, stored, and shipped to the right places.” Reports indicated that most of the donations that came in were exactly what the country needed (WHO 2006b).

Lithuania, 1993. Eleven women in Lithuania temporarily lost their eyesight after using a medicine that had been provided through pharmaceutical donations. The medicine, closantel, was an anthelmintic that should be used only in veterinary medicine but was mistakenly given for the treatment of endometritis. The donation had been received without product information or package inserts,

and doctors had tried to identify the product by matching the name on the box with the names on leaflets of other products.

Mozambique, 2000. In 2000, Mozambique was hit by the worst floods ever recorded in the country, resulting in 700 deaths and displacing more than 500,000 people. As news of the disaster spread, a huge volume of aid cargo was sent, but delivery was chaotic. One person involved reported that “[a]t least 71 shipments arrived during 45 days, most without warning, many with no documentation or packing list” (Christie and Hanlon 2001). Overall, the international community donated 514 tons of medicines, but only 130 tons, or 25 percent, corresponded to requests issued by the ministry of health; three-quarters were considered inappropriate (Autier et al. 2002).

Rwanda, 1994. At the peak of the refugee crisis, a large international pharmaceutical company donated six million units of Ceclor CD, a sophisticated antibiotic. The refugee workers had no experience with this medicine, so it was not used. Part of this donation was returned to the donor, and the remainder expired and had to be destroyed (Purvis 1996 in Autier et al. 2002).

Sudan, 1990. A large consignment of pharmaceuticals was sent from France to war-devastated southern Sudan. Each box contained a collection of small packets of medications, some partly used. All were labeled in French, a language not spoken in Sudan. Most were inappropriate; some could be dangerous. Items included contact lens solution, appetite stimulants, monoamine oxidase inhibitors (dangerous in Sudan), X-ray solutions, drugs against hypercholesterolemia, and expired antibiotics. Of fifty boxes, twelve contained products that could be of use. It would have been much better to have used the money spent on transport to purchase penicillin and other essential medicines in Kenya, which could then have been sent to Sudan.

Source: WHO/DAP 1999 unless otherwise noted.

these reasons, this type of donation is generally discouraged and even forbidden in some countries. The immense effort required to sort such donations is largely wasted because most of the products are unusable.

Disposal of unwanted pharmaceuticals

The best way to avoid having to dispose of unwanted pharmaceutical donations is to stop inappropriate donations from occurring; unfortunately, however, even with

increased recognition of problematic donations in the face of large-scale disasters, such as the 2004 South Asian tsunami, disposal remains an important issue. The same international coalition that developed the WHO Drug Donation Guidelines has collaborated on guidelines for the safe disposal of pharmaceuticals. These guidelines were based on experiences during the war in Bosnia and Herzegovina, where an estimated 1,000 to 17,000 metric tons of unused medicines were stockpiled, requiring disposal at a quoted cost of USD 2.20–4.10 per kilogram (WHO 1999). There

have been calls for donors to take responsibility for paying for disposal of unused donations (Ciment 1999).

The need for guidelines

The examples of inappropriate donations discussed above illustrate the need for international guidelines for pharmaceutical donations. In summary, guidelines are needed because—

- Donor and recipient do not communicate on equal terms; recipients, therefore, need assistance in specifying how they want to be helped.
- Many donors mean well but do not realize the difficulties at the receiving end and need guidance.
- Pharmaceutical needs vary by country and situation. Donations should be based on an analysis of actual needs, and selection and distribution must fit within pharmaceutical policies and administrative systems. Inappropriate donations frustrate the implementation of national pharmaceutical policies and programs to promote rational medicine use.
- Medicines are different from other donated items. Medicines can be harmful, they require labels and written information, they need special storage conditions and adequately trained personnel to be used effectively, they may expire, and they may have to be destroyed in a particular way.

15.3 Chronology of existing guidelines for pharmaceutical donations

In 1988, the Christian Medical Commission (CMC) of the World Council of Churches in Geneva was the first organization to issue guidelines for pharmaceutical donations. This carefully worded document was specifically intended to make more rational the many donations that are made to individual church-related hospitals by well-intentioned but ignorant groups or individuals.

In 1990, the WHO Action Programme on Essential Drugs, in collaboration with major international emergency aid agencies, issued a set of guidelines for donors that was included in *The New Emergency Health Kit*, which was updated in 1998, and again in 2006 (WHO 2006a). As with those of the CMC, these guidelines stress that donations should be based on a specific request by the recipient and should, in all cases, be cleared before dispatch. Minimum labeling and outside packaging information standards are also specified.

In 1994, the WHO office in Zagreb issued detailed guidelines for humanitarian assistance for the former Yugoslavia, where WHO acts as a clearinghouse for all donations of medicines and medical supplies (WHO 1994). The guide-

lines are specific for the situation, listing criteria for the acceptance of donations and for necessary documentation, labeling, and packaging.

In 1996, WHO concluded a worldwide consultative process with more than 100 participants to develop *Guidelines for Drug Donations*, in close collaboration with the United Nations High Commissioner for Refugees (UNHCR), United Nations Children's Fund (UNICEF), the Red Cross, and nongovernmental organizations. The Partnership for Quality Medical Donations, which is a coalition of industry and relief groups, also supports the guidelines.

15.4 Guidelines for pharmaceutical donations

WHO carried out an assessment of first-year experiences with the 1996 guidelines (WHO 2000a) and published revised guidelines in 1999. Although the assessment was positive for the most part, concerns were expressed about the clarity of the specific guideline on the shelf life of donated medicines, which was revised in the new edition (WHO/DAP 1999). The new guideline allows for direct donations of pharmaceuticals with a remaining shelf life of less than one year to specific health facilities, provided assurance can be given that the pharmaceuticals can be used prior to expiration. This requirement addresses the concern that legitimate donations were being delayed because of confusion in the original clause related to expiry.

The many problematic donations received during the aftermath of the 2004 tsunami in South Asia, as outlined in [Country Study 15-2](#), indicate, unfortunately, that many donors are not heeding the guidelines.

Core principles

The first and paramount principle is that a donation should be intended only to assist the recipient, and all efforts should be made to maximize its positive effect. This principle implies that all donations should be based on an expressed need by the recipient and that unsolicited donations are to be discouraged. The second principle is that a donation should be given with full respect for the authority of the recipient and be supportive of existing government policies and administrative arrangements. The third principle is that no double standards should be applied: if the quality of an item is unacceptable in the donor country, it is also unacceptable as a donation. The fourth principle is that effective communication must be maintained between the donor and the recipient; donations should be based on expressed need and should not be sent unannounced.

If these core principles are adhered to, donations will usually be helpful rather than harmful, providing the specific guidelines on medicines selection, quality, presentation, packaging, and labeling in [Box 15-1](#) are followed.

Country Study 15-2 Tsunami-related donations of medicines and supplies

On December 26, 2004, a massive earthquake measuring 9.3 on the Richter scale triggered a tsunami that devastated eleven countries in South Asia. International donors were quick to respond with aid; however, as with previous humanitarian crises, the lack of coordination and knowledge about the actual needs of the population decreased the effectiveness of emergency aid and generated additional challenges to public health efforts rather than easing what might have been the biggest crisis the area had ever experienced.

In Indonesia, pharmaceutical donations seemed to cause more problems for government authorities than they helped the population. Although the government asked for no medicines, more than 4,000 tons of pharmaceuticals were received for a population of 2 million, according to an assessment conducted by *Pharmaciens Sans Frontières Comité International*. Of these donations, most were deemed inappropriate: 60 percent of the medicines were not on the Indonesian national list of essential medicines; 70 percent were labeled in a foreign language; and 25 percent had an inadequate expiry date. Of the medicines that were appropriate, some arrived in extremely large quantities that would not be used before they expired. Approximately 661 tons of the donated medicine needed to be destroyed at an estimated cost of EUR 2.4 million. Countries are often hesitant to refuse

donations because of a fear of offending donors, which only perpetuates the problem.

In Sri Lanka, relief workers requested a donation of intravenous antibiotics to treat infected wounds. Although the pharmaceutical manufacturer shipped the antibiotics quickly to a nonprofit consolidator working in Colombo, the shipment was initially delayed by bureaucratic procedure at the airport, and then it took additional time to get the medicines on their way to those in need. By the time any of the shipment made it into the affected regions, the perceived need had not materialized—perhaps because patients had died already or because of the difficulty in assessing the need in the midst of chaos. Although the Sri Lankan officials were grateful to receive “an antibiotic that can treat horrible infections you can’t treat with normal antibiotics,” concern existed about what would happen when the stockpile expired.

The *Pharmaciens Sans Frontières* assessors in Banda Aceh, Indonesia, concluded that in the years after the first publication of the *Guidelines for Drug Donations*, the quality of pharmaceutical donations in emergency situations had not improved. During disasters where resources and capacity are limited, donations can be not only useless, but even detrimental to the health of peoples affected and the economy of the recipient country.

Special guidelines for pharmaceutical donations in emergency situations

In emergency situations, it may not be practical for potential donors to wait for a specific request from the recipient. In any case, however, all proposed donations should be approved by the recipient before they are sent.

In the acute phase of an emergency, or in the case of refugee populations without any medical care, sending a range of medicines and medical supplies that is specifically designed for the circumstances is preferable. The *Interagency Emergency Health Kit*, which has been widely used since 1990, contains medicines, disposable supplies, and basic equipment for a population of 10,000 for three months. Its contents are based on a consensus among the major international aid agencies (WHO, UNICEF, UNHCR, Red Cross organizations, *Médecins Sans Frontières*, and OXFAM). It is permanently stocked by several major international suppliers (for example, UNICEF and the *International Dispensary Association*) and can be available within forty-eight hours.

From the recipients’ point of view, a donation in cash for the local purchase of essential medicines is usually much more welcome than a donation in kind (assuming the local market is functional). Apart from being supportive of the activities of the local coordinating body, a cash donation is usually more cost-effective and also supports local industry. In addition, local prescribers and patients are usually more familiar with locally available medicines. A donation in cash also avoids the problem of the coordinating body having to prioritize long lists of needs according to what might or might not arrive.

Special guidelines for donations as part of development aid

When pharmaceuticals are donated as part of development aid, more time is usually available to specify needs and to follow guidelines on pharmaceutical donations. Special care should be taken that the medicines and their specifications comply with the national pharmaceutical policy and are

Box 15-1 Guidelines for pharmaceutical donations

These guidelines, developed by WHO and updated from the original 1996 guidelines, reflect consensus among the major international agencies active in humanitarian emergency relief: WHO, Caritas Internationalis, Churches' Action for Health of the World Council of Churches, International Committee of the Red Cross, International Federation of the Red Cross and Red Crescent Societies, International Pharmaceutical Federation, Joint United Nations Program on HIV/AIDS, Médecins Sans Frontières, Office of the United Nations High Commissioner for Refugees, OXFAM, Pharmaciens Sans Frontières, UNICEF, United Nations Development Programme, United Nations Population Fund, and the World Bank.

Many different scenarios exist for pharmaceutical donations. They may take place in acute emergencies or as part of development aid in nonemergency situations. They may be corporate donations (direct or through private voluntary organizations), aid by governments, or donations to single health facilities. And although there are legitimate differences among these scenarios, the basic rules for an appropriate donation apply to all. The guidelines describe this common core of good donation practices.

The guidelines aim to improve the quality of pharmaceutical donations, not to hinder them. They are not international regulations but are intended to serve as a basis for national or institutional guidelines, to be reviewed, adapted, and implemented by governments and organizations dealing with pharmaceutical donations.

Selection of medicines

1. All pharmaceutical donations should be based on an expressed need and be relevant to the disease pattern in the recipient country. Pharmaceuticals should not be sent without prior consent by the recipient.
2. All donated pharmaceuticals or their generic equivalents should be approved for use in the recipient country and appear on the national list of essential medicines, or, if a national list is not available, on the WHO *Model List of Essential Medicines*, unless specifically requested otherwise by the recipient.
3. The presentation, strength, and formulation of donated pharmaceuticals should, as much as possible, be similar to those commonly used in the recipient country.

Quality assurance and shelf life

4. All donated pharmaceuticals should be obtained from a reliable source and comply with quality standards in both donor and recipient country. The WHO Certification Scheme on the Quality of Pharmaceutical Products Moving in International Commerce (WHO 2000c) should be used.
5. No medicines that were issued to patients and then returned to a pharmacy or elsewhere, or that were given to health professionals as free samples, should be donated.
6. Upon their arrival in the recipient country, all donated pharmaceuticals should have a remaining shelf life of at least one year. An exception may be made for direct donations to specific health facilities, provided that the responsible professional at the receiving end acknowledges that he or she is aware of the shelf life, and that the quantity and remaining shelf life allow for proper administration prior to expiration. In all cases, the date of arrival and the expiry date of the medicines should be communicated to the recipient well in advance.

Presentation, packing, and labeling

7. All pharmaceuticals should be labeled in a language that is easily understood by health professionals in the recipient country; the label on each individual container should contain at least the international nonproprietary name (INN, or generic name), batch number, dosage form, strength, name of manufacturer, quantity in the container, storage conditions, and expiry date.
8. As much as possible, donated pharmaceuticals should be presented in larger-quantity units and hospital packs.
9. All pharmaceutical donations should be packed in accordance with international shipping regulations, and be accompanied by a detailed packing list that specifies the contents of each numbered carton by INN, dosage form, quantity, batch number, expiry date, volume, weight, and any special storage conditions. The weight per carton should not exceed 50 kilograms. Pharmaceuticals should not be mixed with other supplies in the same carton.

Information and management

10. Recipients should be informed of all pharmaceutical donations that are being considered, prepared, or actually under way.
11. In the recipient country, the declared value of a pharmaceutical donation should be based upon the wholesale price of its generic equivalent in the recipient country, or, if such information is not available,

on the wholesale world-market price for its generic equivalent.

12. Costs of international and local transport, warehousing, port clearance, and appropriate storage and handling should be paid by the donor agency, unless specifically agreed otherwise with the recipient in advance.

Source: WHO/DAP 1999.

in accordance with national treatment guidelines or common practice in the recipient country. Administratively, the pharmaceuticals should be treated as if they were procured: they must be approved for importation and use by the drug regulatory authority in the country, probably through the same simplified procedure that would apply for government tenders. They should be entered into the inventory and distributed through the existing distribution channels. If cost-sharing procedures exist, the donated pharmaceuticals should not automatically be distributed free of charge, and the donor should not insist on free distribution. A good example of a successful integration of donated pharmaceuticals into the regular pharmaceutical supply system is described in [Country Study 15-3](#).

Special guidelines for donations of medical and laboratory equipment and supplies

The same core principles and general guidelines that apply to donating pharmaceuticals also apply to donating medical and laboratory equipment and supplies. A key factor to consider is whether the recipient truly needs the equipment and has the expertise and the means to operate and maintain it. Generally, capital equipment should not be donated in emergency situations, unless the emergency situation is expected to be prolonged.

A donation implementation plan should include the availability of trained personnel for operation and maintenance as well as support for other resources for operation (manuals, reagents, and supplies) and maintenance (technical documentation and spare parts). In addition, plans must include detailed installation and commissioning procedures. Finally, any special requirements for the equipment should be communicated to the recipient. Such requirements may include air or water cooling; electrical power; water quality; mechanical layout or radiation or acoustic shielding requirements; or specialized software needed to install, operate, or maintain the equipment. Periodic inspection, maintenance, and calibration should be carried out. WHO offers guidelines that cover equipment and supply donations (WHO 2000b).

15.5 Implementation of a policy for pharmaceutical donations

In managing pharmaceutical donations, both recipients and donors need to act to ensure that appropriate donations are received and that good use is made of them.

Management of pharmaceutical donations by the recipient

Recipient governments must play a role in managing donations. No matter how disastrous the situation, failure to be involved may make things worse. National guidelines and administrative procedures need to be defined, and any requirements need to be specified in as much detail as possible.

Define national guidelines for pharmaceutical donations. Recipients find refusing a donation that is already under way notoriously difficult. For this reason, prevention is better than cure. The key point is that recipients should indicate to their (future) donors what kind of assistance they are likely to need and how they would like to receive it. If this information is provided in a rational and professional way, most donors appreciate it and will comply. Therefore, recipients should first formulate their own guidelines for pharmaceutical donations based on the CMC or WHO guidelines or the summary given above. These guidelines should then be officially presented to the donor community. Only after the guidelines have been presented and published can they be enforced. The preparation and implementation of the national donation guidelines should include stakeholders at all levels of the country's pharmaceutical management system to ensure that local officials are informed about the guidelines.

Define administrative procedures for pharmaceutical donations. It is not enough for recipients to adopt and publish general guidelines on the selection, quality, and presentation of donations. Administrative procedures need to be developed by recipients for defining needs, receiving donations, distributing, budgeting, and perhaps refusing or

15.10 FINANCING AND SUSTAINABILITY

destroying some goods. Procedures need to be developed to carry out the following actions—

- Define needs
- Prioritize among requirements
- Coordinate all pharmaceutical donations
- Decide what documentation is needed when a pharmaceutical donation is being proposed, and who should receive these papers
- Establish criteria for accepting or rejecting a donation
- Coordinate reception, storage, and distribution of donated pharmaceuticals
- Agree on whether the donor or the recipient will pay for transportation, warehousing, port clearing, and similar costs before the donation shipment arrives
- Agree on how donations are to be valued in budget and expenditure records
- Agree on charging for donated pharmaceuticals in the context of a public user-fee program
- Deal with donated pharmaceuticals not registered or included in the national essential medicines list in the country
- Supervise the distribution of donated medicines and supplies to prevent them from being diverted for

export, for commercial sale, or to illicit channels

- Dispose of worthless donations

Specify the needs for donated pharmaceuticals. Recipients must also provide donors with as much specific information on medicine needs as possible. This requirement puts the onus on the recipient to prepare requests carefully, indicating quantities required and prioritizing the items. The more information that is given, the better. Openness about donations that are already in the pipeline, or anticipated, is helpful to donors. It is always greatly appreciated and pays off in the long term. Recipients are entitled to the same openness from donors with regard to pharmaceutical donations that are in the pipeline.

Good practices for donors

Donors should always respect the four core principles listed in section 15.4. Donors should also respect the guidelines issued by the recipients and respond to the priority needs they have indicated. Donor-driven donations should always be discouraged, particularly donations that are initiated by international pharmaceutical companies to obtain tax advantages or donations of returned medicines or samples.

Country Study 15-3

Integrating pharmaceutical donations into the Mongolian supply system

After the collapse of the former Soviet Union, Mongolia became one of the countries where a large proportion of medicine consumption is covered by pharmaceutical donations. Such donations are treated as regularly procured pharmaceuticals.

Upon the arrival of a donation, all papers are sent to the Ministry of Health for clearance of the import. If the medicines are accepted, an import price is decided on by a special unit in the ministry. This price is normally equal to the last tender price for the same product or a price taken from Management Sciences for Health's *International Drug Price Indicator Guide*. Many donors are valuing their donations at a much higher price—for example, retail price in the donor country—but this price is not accepted as a reference. If a product that is not on the Mongolian essential medicines list is accepted, it is given a price equivalent to that for a similar medicine on the list, irrespective of the price in the donor country.

The value of the pharmaceutical consignment is entered into the accounts of Mongol Emimpex, the state wholesaler. Then a selling price is set for each medicine by adding a 15 percent markup for the wholesaler and 23

percent for the pharmacist. These markups cover all expenses for control and distribution. The (assigned) import value is kept on a separate account and transferred to a fund controlled by the Ministry of Health for future pharmaceutical procurement.

The main benefit of this system is that it is sustainable and not destructive to the existing pharmaceutical supply system. In many other countries, uncontrolled sales of donated pharmaceuticals are well known to take place, and the money is pocketed by health personnel. In Mongolia, the system is completely transparent. All pharmaceuticals coming into the country are for sale, and the donors are assured that their import value goes back to the revolving fund.

The only drawback of the system is that even the neediest customers—patients or health institutions—have to pay for donated pharmaceuticals, and they may not be able to do so. However, the case would be the same with normal pharmaceutical procurement and has to be solved by health insurance systems or specific government support to the needy.

Source: WHO/DAP 1999.

DONATIONS CAN THEMSELVES BE A DISASTER AREA

The public at large in the donor country is usually not aware of common problems with pharmaceutical donations. The government should therefore make some effort to create more public awareness of donors' responsibilities. The best moment for this publicity is probably at the time of the public appeal through the media, when the government is requesting funds.

At the country level, would-be donors are usually counseled to choose a "lead donor" among themselves to coordinate their actions and sometimes also to act as a central contact point in discussions with the recipient government. Some organizations act as coordinators/consolidators for international pharmaceutical donations. For example, the German association of research-based pharmaceutical companies matches requests from ministries of health and international relief agencies with donations from German pharmaceutical companies to maximize the usefulness and efficiency during emergency situations.

As previously mentioned, the recipient country should supply as much information as possible on requested and approved donations. But the donors themselves should also inform the recipient well in advance and in detail about what donations are coming, and when. This information will greatly assist the coordinating body in the recipient country in planning for the proper reception of the donations and in

identifying the need for additional supplies. Although the landscape of pharmaceutical donations is complex, assessments have shown that, when handled with care, the donation process can help satisfy local medical needs (Reich 1999).

15.6 Donations as part of public-private partnerships

Although the focus of pharmaceutical and medical supply donations is on cases of disaster or other emergency, a number of public-private partnerships are built on using existing products to address specific health conditions. Examples of such programs include the albendazole donation program to fight lymphatic filariasis and the Zithromax program to prevent blindness from trachoma. The Axios Foundation administers such programs for pharmaceutical companies, providing technical assistance to facilities in least-developed countries (see, for example, <http://www.accesstotreatment.org> and <http://www.pmtctdonations.org>). Although pharmaceutical companies generally sponsor donation partnerships to help get a particular medicine to those who need it, the partnerships are also part of the companies' goal to publicize social responsibility through philanthropy.

Pharmaceutical companies have spent millions of dollars on donations, and although countries can certainly benefit from the additional resources for targeted programs, the partnerships are not trouble-free. For example, costs are associated with pharmaceutical donation programs, such as distribution, storage, and training health workers. The public sector may be expected to handle those costs, possibly at the expense of other health programs, including the diversion of human resources. In addition, a partnership that targets only a specific country or commits to a specific time period may be depriving other needy countries or patients who will not have access to the medicines after the partnership commitment is completed. Product-based donation programs are generally difficult to sustain without an open-ended commitment or a commitment to eradicate a containable disease, and such programs often fill only a small part of the actual need.

Merck's Mectizan program operates in all countries where onchocerciasis is endemic and where filariasis is co-endemic and is supplying the medicine until the diseases are eradicated. Because onchocerciasis is limited in geography, has a simple treatment protocol, and can be eradicated, an open-ended donation program is feasible. On the other hand, most disease-specific initiatives target only select countries where the disease is endemic and usually commit to a limited initial time frame (Buse and Walt 2000b).

The Malarone donation program in Kenya is an example of a public-private partnership undermined by dissatisfaction among stakeholders about how well their individual interests were represented. Eventually, the partners clashed over accountability and ownership of the program (Shretta et al. 2001). Furthermore, incorporating the donated Malarone into the public health treatment guidelines and national pharmaceutical policy caused confusion and conflict. Ultimately, there was concern that the failure of the Malarone donation program could discourage other corporate philanthropy and taint the view of public-private partnerships.

When entering into public-private health programs based on pharmaceutical donations, recipient countries must be fully involved with the planning and implementation of the program (Buse and Walt 2000a), and the donor organizations should follow the core principles of donating pharmaceuticals or medical supplies. ■

ASSESSMENT GUIDE

Indicators of policy

- Is there a national policy on donations of pharmaceuticals and medical and laboratory equipment and supplies?
- What are the differences between the national policy and the WHO policy on pharmaceutical donations?
- Is there a set of administrative procedures for managing pharmaceutical donations?
- Do pharmaceutical donations comply with the national list of essential medicines?
- Does the ministry of health have control over which medicines and supplies will be accepted?

Extent of pharmaceutical donations

- What is the value of international aid received for pharmaceuticals (cash and in-kind donations) compared with the value of the public pharmaceutical budget spent?

Implementing pharmaceutical donations

- Who coordinates all pharmaceutical donations?
- Which documents are needed when a donation is planned; who should receive them?
- What are the criteria for accepting or rejecting a donation; who makes the final decision?
- What procedure is used when donations do not follow the guidelines?
- Who coordinates reception, storage, and distribution of the donated pharmaceuticals?
- How are donations valued and entered into the budget/expenditure records?

- How will inappropriate donations be disposed of?

Problems with pharmaceutical donations

- What are the main problems with pharmaceutical donations?

Needs assessment for donors in an emergency

- What is the nature of the event, its effects, expected duration, expected amount of time the population will be displaced or affected?
- What are the demographics and socioeconomic status of affected populations?
- What is the status of the existing health care infrastructure and availability of transportation to existing health care sites?
- Are human resources available to take responsibility for and to appropriately dispense prescription medication?
- What are the recipients' customary modes of treating diseases?
- What are the affected area's location, accessibility, climatic conditions, and security status?
- What are the rules and regulations of local recipient governments?
- Are contacts in place for key ministry of health or other country personnel?
- How receptive are local authorities to foreign humanitarian operations in their country?

SUMMARY

The rationale for selecting a limited number of essential medicines is that it may lead to better supply, more rational use, and lower costs. Essential medicines are those that are deemed to satisfy the health care needs of the majority of the population and that should be available in the appropriate dosage forms and strengths at all times. Because selection of medicines has a considerable impact on quality of care and cost of treatment, it is one of the most cost-effective areas for intervention.

A list of essential medicines may be selected for use in one or more health facilities or for the public sector as a whole. In the latter case, the list usually indicates the level of the health care system where each medicine may be used. It can also be considered a supply list. A formulary system is part of the medicine selection process. The system includes a formulary list, which is ideally based on an essential medicines list, and a formulary manual, which contains summary information on each medication on the formulary list. Standard treatment guidelines are systematically developed statements that assist prescribers in deciding on appropriate treatments for specific clinical problems. Whereas a formulary manual is medicine centered, treatment guidelines are disease centered, presenting treatment alternatives and recommending a treatment of first choice.

The process of selecting essential medicines begins with defining a list of common diseases for each level of health care. The treatment of first choice for each health problem is the basis for the list of essential medicines, the national formulary system, and the treatment guidelines. The supply system should then supply the medicines that have been selected, based on this series of steps.

Essential medicines should be selected on the basis of (1) relevance to the pattern of prevalent diseases, (2) proven efficacy and safety, (3) adequate scientific data and evidence of performance in a variety of settings, (4) adequate quality, (5) favorable cost-benefit ratio, (6) desirable pharmacokinetic properties, (7) possibilities for local manufacture, and (8) availability as single compounds. The drugs should be identified by the International Nonproprietary Name (INN), sometimes referred to as the generic name.

General acceptance of an essential medicines list can be promoted by wide consultation with senior specialists and experts, including professional organizations and academic institutions, on the list's development and use. An open and transparent system of regular updates is an absolute prerequisite for maintaining the authority and acceptance of an essential medicines list or formulary list. The essential medicines concept can be applied in any country, in the public and private sectors, and in rural areas as well as at referral hospitals.

16.1 Introduction

Pharmaceuticals may constitute as much as 40 percent of the health care budget in developing countries, yet large portions of the population may lack access to even the most essential medicines. The limited funds available are frequently spent on ineffective, unnecessary, or even dangerous medications.

As much as 70 percent of pharmaceuticals on the world market are duplicative or nonessential. Many are minor variations of a prototype drug product and offer no therapeutic advantage over other medicines that are already available. Some are medications that show high toxicity relative to their therapeutic benefit. In some cases, new medicines are released without sufficient information on efficacy or toxicity. Finally, new products often are for therapeutic indications not relevant to the basic needs of the population. In all of these cases, the newer medicines are nearly always more expensive than existing medicines.

With so many different pharmaceutical products avail-

able, prescribers often find it impossible to keep their knowledge up-to-date and to compare alternatives. In addition, the variety of available products may contribute to inconsistent prescribing within the same health care system or even in the health facility. With regard to procurement, purchasing power is significantly lessened by the large number of duplicative and nonessential pharmaceutical products on the market.

In short, pharmaceuticals can provide great benefits, but their cost is substantial. The selection of medicines has a considerable impact on the quality of care and the cost of treatment, and it is therefore one of the areas where intervention is most cost-effective.

16.2 Practical implications of the essential medicines concept

The World Health Organization (WHO) has defined essential medicines as those that satisfy the needs of the

majority of the population and therefore should be available at all times. The rationale for the selection and use of a limited number of essential medicines is that it leads to an improved supply of medicines, more rational prescribing, and lower costs; in fact, the appropriate use of essential medicines is one of the most cost-effective strategies a country can enact.

The essential medicines concept is a global concept that can be applied in any country, in the private and public sectors, in referral hospitals as well as primary health care units, and in both urban and rural areas. However, the decision about exactly which medicines should be considered as essential should be a national-level responsibility. By 2007, 86 percent of countries had national essential medicines lists, of which at least 69 percent had been updated in the previous five years. Some have state or provincial lists as well (Kathleen Holloway, personal communication, March 2010).

Under optimal circumstances, the registration of medicines for the private and public sectors should be based on an evaluation of efficacy, safety, and quality. In some countries, cost and need are also criteria for medicine registration. In such cases, the selection of essential medicines takes place during medicine evaluation, approval, and registration and is therefore applicable to both the public and private sectors.

More commonly, the selection and use of essential medicines are limited to public-sector health facilities. However, many private-sector facilities and health insurance systems have limited formulary lists, which can serve the same function. For each level of health care in the public sector, a limited list of essential medicines is prepared as the basis for supplying pharmaceuticals, for prescribing in the public sector, and for training of health workers—which is why such lists should be closely related to standard treatment guidelines for clinical health care practice. This correlation is especially relevant for medical and paramedical training institutions and teaching hospitals, because they have an important influence on the prescribers of the future.

There are many reasons to support the use of a limited essential medicines list. First, fairness dictates that basic health services be accessible to everyone before more expensive services are made available to a small, usually urban proportion of the population.

Second, no public-sector or health insurance system can afford to supply or reimburse all medicines that are available on the market. Therefore, essential medicines lists guide not only the procurement and supply of medicines in the public sector, but also schemes that reimburse medicine costs as well as what medicines it makes sense for local manufacturers to produce. Because the availability of pharmaceuticals in the public sector is erratic in many countries, a regular supply of most products on the essential medicines list would result in a real improvement in public health and would increase the public's confidence in the health care

system. Many international organizations, including the United Nations Children's Fund (UNICEF) and international nonprofit supply agencies, have adopted the essential medicines concept for their supply systems.

Third, when the limited list of essential medicines represents prescribers' consensus on pharmaceutical treatments of first choice, its use may improve the quality of care by ensuring that patients receive the treatment of choice as well as similar treatment from different providers. It also allows prescribers to become more familiar with a smaller number of medicines. This restricted number of possibilities contributes to improved recognition of actual benefits and limitations of specific medicine therapy, as well as to the detection and prevention of adverse drug reactions.

Fourth, improved effectiveness and efficiency in patient treatment reduce health care costs. Therefore, lack of funds in developing countries is not the only reason to limit treatment selection to essential medicines, nor does such a policy necessarily compromise quality of care. In fact, the essential medicines concept is increasingly being accepted as a universal tool to promote both quality of care and cost control.

Fifth, for public-sector supply programs, advantages exist in concentrating procurement and logistics efforts on a limited number of medicines, including reduction in the number of different products that must be stocked, distributed, and monitored. Essential medicines are usually available from multiple suppliers. With increased competition, more favorable prices can be negotiated. In addition, limiting the number of different medicines used to treat a particular clinical problem means larger quantities of the selected medicine will be needed, creating potential opportunities to achieve economies of scale. Ensuring the quality of a small number of pharmaceutical products is easier, which is another reason why many national pharmaceutical programs base their medicine donation policies on the national essential medicines list.

Finally, the selection of a limited number of essential medicines facilitates efforts to provide drug information and education, both of which advance rational prescribing and use. Objective drug information and training materials are so scarce in most developing countries that their provision is considered very beneficial by physicians and other health care workers. Thus, although the number of pharmaceutical products for public health use may be limited by an essential medicines list, the practical availability of medicines and corresponding drug information and training materials may be increased. Patient education and efforts to promote proper use of medicines by patients can also be enhanced by focusing on these medicines.

The potential advantages of using a limited list of essential medicines are summarized in [Table 16-1](#). These advantages do not, however, follow automatically. The essential medicines list is only a starting point, not an end in itself. For

Table 16-1 Advantages of a limited list of essential medicines

Major objective	Challenge
Supply	<ul style="list-style-type: none"> • Easier procurement, storage, and distribution • Lower stocks • Better quality assurance • Easier dispensing
Prescribing	<ul style="list-style-type: none"> • Training more focused and therefore simpler • More experience with fewer medicines • Nonavailability of irrational treatment alternatives • Reduction of antimicrobial resistance • Focused drug information • Better recognition of adverse drug reactions
Cost	<ul style="list-style-type: none"> • Lower prices, more competition
Patient use	<ul style="list-style-type: none"> • Focused education efforts • Reduced confusion and increased adherence to treatment • Improved medicine availability

countries to realize its advantages, the selection of essential medicines must be followed by other actions outlined in this book, including the promotion of the essential medicines list by use of a formulary manual and standard treatment guidelines, improvements in procurement and distribution, and efforts to promote rational medicine use.

With the continuing impact of infectious diseases such as malaria, tuberculosis, and HIV/AIDS, as well as widespread increases in antimicrobial resistance, the application of the essential medicines concept is more appropriate than ever. In developing countries, antimicrobial resistance has resulted in the use of new and far more expensive treatments for malaria and tuberculosis, while the scale-up of treatment for HIV/AIDS is straining limited health care resources. Developed countries, too, have experienced large increases in pharmaceutical expenditures. The use of the essential medicines concept in both developed and developing countries can promote the most efficient use of resources as well as help combat the spread of antimicrobial resistance.

16.3 Selection criteria

Although there are many different settings in which a national list of essential medicines can be used, the criteria for selection are basically the same in each. For a national essential medicines list to be credible and widely accepted, the criteria must be defined and published. The final selection criteria should be based on thorough discussions and acceptance by a multidisciplinary committee of experts. Specialists within the selection committee can interpret data and evaluate the safety of medicines in their areas of expertise.

[Box 16-1](#) summarizes the criteria used by the WHO Expert Committee on the Selection and Use of Essential Medicines, which were the result of extensive deliberation. The WHO criteria are frequently adopted and modified to fit local requirements.

Determining the safety and efficacy of specific pharmaceutical products requires access to relevant, up-to-date, and unbiased information, such as summaries of relevant clinical guidelines, systematic literature reviews, important references, and quality assurance standards. Personal observations should not be used as justification for selecting a medication, nor should selection be based on sales figures or a medicine's popularity in the market. Sources of objective information can include a national drug information center; many useful references are available in the WHO Essential Medicines Library (<http://www.who.int/medicines/publications/en>). See also Section 16.8 and [Chapter 34](#).

The choice of medicines depends on the capacity of health care staff to use them effectively. Consequently, it is important to have thorough knowledge of the extent of staff training and the availability of support facilities for each level of the health care system before deciding where individual medicines will be made available. For example, cancer medicines are expensive, have serious side effects, and require frequent laboratory monitoring. Therefore, such medicines might be limited to a few designated cancer treatment centers. In addition, selection should take into account potential staff confusion and medication errors that could be caused by including sound-alike or look-alike products and various concentrations of liquid preparations for the same drug.

In choosing among medicines of similar safety and efficacy, the total cost of treatment should be considered. Care must be taken, however, in making the comparison. For example, ampicillin may be cheaper than amoxicillin in a tablet-to-tablet comparison but more expensive in a course-of-therapy comparison, because ampicillin must be taken more often. Because pharmaceutical costs vary from country to country, cost comparisons should be country-specific.

Decision making becomes more complicated when more expensive medicines are also more effective, as in the case of certain antibacterial, antitubercular, or antimalarial medicines for resistant organisms. In such cases, the cost of cure may actually be lower for medicines that are more expensive, based on a tablet-to-tablet (dose-to-dose) comparison. [Chapters 10](#) and [17](#) discuss how cost-effectiveness analysis can guide such decisions.

Thus, although all selection criteria may appear reasonable and almost self-evident, considerable room exists for discussion about the relative merits of individual medicines. Before such a discussion occurs, members of the selection committee should review, discuss, and come to a common understanding of the selection criteria and the quality of the evidence to support the choices.

16.4 Use of International Nonproprietary (generic) Names

Each drug product on the market has a chemical name (for example, 6-{D(-)-, a-amino-a-phenylacetamido}-penicillanic acid) and an International Nonproprietary Name, or generic name (ampicillin). The INN is the medicine's official name, regardless of what company or organization manufactures or markets it. A proprietary, commercial, trade, or brand name is chosen by the manufacturer to facilitate recognition and association of the product with a particular firm for marketing purposes. For most common medicines, there are several branded products that all contain the same active ingredient and therefore share the same INN.

INNs are intended for use in pharmacopoeias, labeling, product information, advertising and other promotional material, pharmaceutical regulation, and as a basis for generic product names. INNs are assigned through WHO, following a well-established procedure. Official INN listings are in Latin, English, French, Spanish, and Russian. Their use is normally required by national or, as in the case of the European Union, international legislation. As a result of ongoing collaboration, national names such as British

Approved Names (BAN), Japanese Adopted Names (JAN), and U.S.-Accepted Names (USAN) are usually the same as the INN. WHO offers guidance on the use of INNs (see <http://www.who.int/medicines/services/inn/en>).

The use of generic names for pharmaceutical purchasing as well as prescribing carries considerations of clarity, price, and quality. Proponents of generic drug purchasing and prescribing point out that—

- Generic names are more informative than brand names and facilitate the purchase of products from multiple suppliers, whether as brand-name or generic products.
- Generic drug products are often cheaper than products sold by brand name.
- Generic prescribing facilitates product substitution, whenever appropriate.

With regard to clarity, the generic name helps identify the class of medication. The common stem of the INN usually indicates a “family” of drugs. For example, the names of all benzodiazepines end with -zepam (diazepam, temazepam, nitrazepam), and beta-blockers share the stem -olol

Box 16-1 WHO criteria for selection of essential medicines

Essential medicines are those that satisfy the health care needs of the majority of the population; they should therefore be available at all times in adequate amounts and in the appropriate dosage forms.

The choice of such medicines depends on many factors, such as the pattern of prevalent diseases; treatment facilities; the training and experience of available personnel; financial resources; and genetic, demographic, and environmental factors.

Only medicines for which sound, adequate data on efficacy and safety are available from clinical studies, and for which evidence of performance in general use in a variety of medical settings has been obtained, should be selected.

Each selected medicine must be available in a form in which adequate quality, including bioavailability, can be ensured; its stability under the anticipated conditions of storage and use must be established.

When two or more medicines appear to be similar in the above respects, the choice between them should be made on the basis of a careful evaluation of their relative efficacy, safety, quality, price, and availability.

In cost comparisons between medicines, the cost of the total treatment, not only the unit cost of the medicine, must be considered. The cost-benefit ratio is a major consideration in the choice of some medicines for the list. In some cases, the choice may also be influenced by other factors, such as pharmacokinetic properties, or by local considerations, such as the availability of facilities for manufacture or storage. In 2002, WHO began to view and evaluate affordability as a consequence of a selection rather than as a precondition for selection; for example, antiretroviral medicines for HIV/AIDS are now included in the WHO Model List, although they are expensive. Including these medicines on the list implies that they should become affordable enough for any patient to have them.

Most essential medicines should be formulated as single compounds. Fixed-ratio combination products are acceptable only when the dosage of each ingredient meets the requirements of a defined population group and when the combination has a proven advantage over single compounds administered separately in terms of therapeutic effect, safety, or patient adherence to treatment.

(propranolol, atenolol, metoprolol). In addition, students and prescribers should find learning one generic name rather than a host of different brand names much easier. Nevertheless, many students initially may find memorizing a brand name easier, because such names are usually designed to sound attractive. The confusion comes later, when the students are confronted with many different names for the same medicine.

With regard to price, the patents on many common medicines have expired, allowing various manufacturers to produce and market equivalent products by the medicines' generic names. These generic products are usually sold at a lower price than that of branded equivalents. Therefore, the use of the generic name introduces elements of price competition. If a prescription is written using the generic name of the medicine, the pharmacist may dispense an equivalent product with a price that is more attractive to the consumer but that also meets quality standards. The concept of generic substitution is accepted in an increasing number of countries: even if the prescription is made under a brand name, the pharmacist may substitute a generic equivalent unless the prescriber specifically indicates that this should not be done, by writing "do not substitute" on the prescription. This measure may lead to large savings in pharmaceutical costs.

Opponents to generic prescribing argue that the quality of generic medicines is inferior to that of brand-name products. Quality control and naming of medicines are completely separate issues. Generic medicines from reliable suppliers are as safe, effective, and high quality as medicines

with well-known brand names. At the same time, brand-name medicines from a manufacturer with inadequate procedures for quality control can be of poor quality, despite the brand name. Also, although any medicine can be counterfeited, there are more incentives for counterfeiting brand-name medicines. In countries with strong drug regulatory systems, drug products sold by generic name have the same low rate of recall as brand-name products. Some pharmaceutical companies also sell their branded products under the generic name, for a much lower price.

Bioequivalence is often misused as an argument against the use of generic equivalents. For many medicines, the variation in bioavailability among individual patients is much larger than the variation among products of different manufacturers. In fact, bioavailability is clinically relevant for only a relatively small number of medicines. (Medicine quality and bioequivalence are discussed in [Chapter 19](#).)

16.5 Essential medicines lists in context

An essential medicines list names the medicines considered optimal treatment choices to satisfy the health care needs of a given population. In its simplest form, it is used for one health facility (for example, a hospital) or for a group of health facilities to indicate which medicines should be procured and prescribed. For practical purposes, the lists can be considered supply lists, defining the range of medicines for the different levels of care and indicating dosage form and, sometimes, pack size and other specifications. A sample

page of a list, organized by levels of use, is reproduced in Table 16-2.

Lists of registered medicines

Adoption of a national list of essential medicines, usually limited to the public sector, does not necessarily mean that no other medicines are available in the private sector. In many countries, the marketing of pharmaceutical products requires prior evaluation, approval, and licensing by the national drug regulatory authority. The criteria for approval and licensing include efficacy, safety, and quality, but some countries also consider cost and need. Registration of medicines is discussed in greater detail in Chapter 6. The list of registered medicines includes all drug products that have been licensed.

The number of drug products that are licensed may be many times greater than the number of drug products on the essential medicines list, for two reasons. First, equivalent drug products produced by different manufacturers are registered separately (the product is registered, not the active substance). Second, medicines may not be considered essential for use in the public sector, yet their efficacy, safety, and quality are such that they can be available in the private market. For example, in the United Kingdom, the list of medicines available free of charge through the National Health Service contains several laxatives; if a particular patient wants another brand, it is available for sale but without reimbursement. Figure 16-1 illustrates the relationship between the list of essential medicines and the list of registered medicines.

Formulary manuals

The term *formulary* can be confusing. It is useful to distinguish between the formulary list as a selection tool, the formulary manual as a source of medicine information, and the formulary system as a pharmaceutical management process.

A *formulary list* is a list of pharmaceutical products approved for use in a specific health care setting. It may be a national formulary list, a provincial list, a hospital list, or a list indicating products reimbursed by a health insurance program. In the public sector of most developing countries, the formulary list is synonymous with essential medicines list.

A *formulary manual* contains summary drug information. It is not a full textbook, nor does it usually cover all medicines on the market. Instead, it is a handy reference that contains selected information that is relevant to the prescriber, dispenser, nurse, or other health worker. It commonly includes the generic name of a medicine, indications for use, dosage schedules, contraindications, side effects, and important information that should be given to the patient. A formulary manual is drug centered—it is based

Figure 16-1 The essential medicines target

Notes: S = specialist medicines available to special hospitals and departments in the public sector; CHW = community health worker, who typically has an essential medicines list of 12 to 18 items.

on monographs for individual drugs or therapeutic groups. Formularies may or may not contain evaluative statements or comparisons of medicines. Some national formularies include options for therapeutic substitution; for example, in Panama the official medicines list includes three interchangeable drugs—astemizol, cetirizine hydrochloride, and loratadine—under the category of “nonsedating antihistamines.” Some formularies include comparative price information, which can help guide prescribing decisions.

A *national formulary manual* is based on the national list of essential medicines. The *British National Formulary* includes most of the medicines registered for use in the United Kingdom, and even though medicine selection is not as limited there as in developing countries, the beginning of each section in the manual contains general evaluative statements, and the formulary indicates the medicines whose costs are not reimbursed through the National Health Service. The development of a formulary manual is discussed in Chapter 17.

Finally, the term *formulary system* is used in some settings to encompass the whole system for developing, updating, and promoting the formulary (essential medicines) list. A fully developed formulary system usually includes, in addition to the formulary list and formulary manual, regular newsletters or bulletins, guidelines for the use of non-formulary medicines, and methods for evaluating the need for changes in the formulary list or manual. The formulary system in the hospital setting is discussed in Chapter 45.

Treatment guidelines

Treatment guidelines (standard treatment guidelines [STGs], treatment protocols, clinical guidelines) are systematically developed statements that assist prescribers in deciding on appropriate treatments for specific clinical problems. These guidelines usually reflect the consensus on the optimal treatment options within a health facility or health system. The information is disease centered, emphasizing the common diseases and complaints and the various treatment alternatives. Information on medicines is usually limited to strength, dosage, and duration. Most guidelines indicate a treatment of first choice. Some include diagnostic criteria for starting the treatment or for choosing among treatment alternatives. The development of treatment guidelines is discussed in [Chapter 17](#).

The key difference between a formulary manual and treatment guidelines is that the former is drug centered, concentrating on drug information and usually not providing comparisons of different medicines, whereas the latter are disease centered, listing treatment alternatives and indicating treatments of choice.

16.6 Approaches to developing essential medicines lists, formularies, and treatment guidelines

Essential medicines lists, formularies, and treatment guidelines are interdependent and should be developed in a systematic way (see [Figure 16-2](#)). The most logical approach is based on the needs of patients and on the job descriptions of health workers. The first step is to prepare a list of common health problems. A first-choice treatment for each health problem on the list may be limited to one or more medicines or to various forms of nondrug treatment. This choice of treatment can be the basis for two important documents: the list of essential medicines for the specific level of care, which is a direct result of the selection; and a set of treatment guidelines for that level of care, which requires additional clinical information (diagnostic signs and symptoms and treatment algorithms).

This approach works best for the primary health care level. The number of diseases and conditions may be too many or too complex to be practical for a hospital, although the approach could be applied at the departmental level and is commonly used at the specialist level. An example of the latter is cancer treatment, in which following an STG provides a way of evaluating outcomes and improving treatment.

In practice, some sort of medicines list is already available in most settings and can serve as a starting point. This list is critically reviewed by therapeutic group, and, as in the WHO Model List of Essential Medicines, first-choice medi-

cines and alternative or complementary medicines may be indicated.

The lists of essential medicines for each level of care should be combined into one national list of essential medicines. This list is the basis for developing the national formulary system. This approach ensures that the supply of medicines, which is based on the national list of essential medicines, is consistent with the treatment guidelines in public-sector facilities and training institutions and that summary drug information is available for all medicines supplied in the public sector.

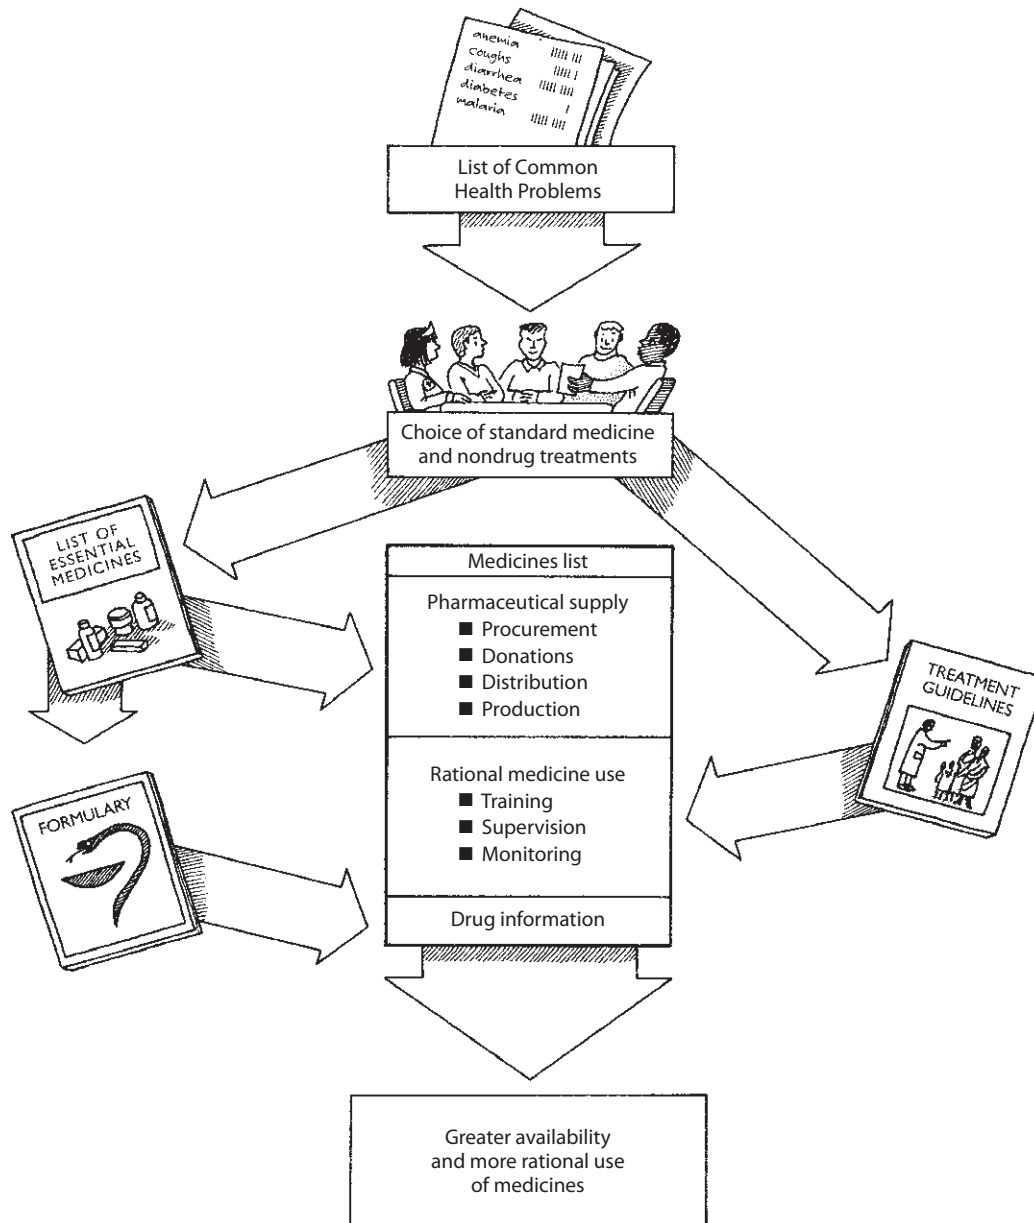

Using another approach, the list of registered medicines can be critically reviewed for selection of a much shorter national list of essential medicines. Using this shortened list, drug and therapeutics committees in individual health facilities can choose a treatment of first choice for that facility or district. Medicine selection at the facility level is especially valuable when the national list of essential medicines is too extensive to be practical for individual facilities. In addition, facility-level medicine selection ensures the maximal involvement, acceptance, and compliance of the prescribers concerned (see [Country Study 16-1](#)).

For most countries, medicine selection by committee is the preferred approach because it minimizes the opportunity for private interests to influence the decision-making process. Furthermore, the judicious selection of committee members with relevant backgrounds, previous experience, and no conflicts of interest can ensure the transparency of the decision-making process and thereby facilitate the rational selection of medicines (see [Country Study 16-2](#)).

At the national level, an officially appointed committee or regional or local officials can select essential medicines for the public sector. One advantage of national-level selection is the potential for improved efficiency and economy of central procurement; regional or local staff members should be included in the committee. In large countries, regional selection and procurement may be more appropriate.

The greatest efficiency is possible when medicine selection is coordinated with other activities in the supply process. This coordination can be achieved, in part, by including representatives from the ministry of health, the purchasing department, and regional and local health facilities, including medical and paramedical prescribers. Technical experts should include one or more clinical pharmacologists, an internist, an infectious diseases specialist, a pediatrician, a surgeon, one or more hospital and district pharmacists, a hospital director, and other specialists as needed. Representatives of disease control programs (such as malaria, tuberculosis, and HIV/AIDS programs) can be co-opted to attend certain meetings. Committee members should serve for several years with staggered terms, so that the committee retains some experienced members each year. Committee members should be known for their integrity, honesty, and dedication; ide-

Figure 16-2 Common health problems guide selection, training, supply, and medicine use

ally, they should not have relationships with any pharmaceutical manufacturer or distributor, or be closely related to any person who does.

The most practical approach to drawing up an essential medicines list for the first time is to have it prepared by one or two experts, preferably using the WHO Model List of Essential Medicines and the WHO criteria for selection (see Box 16-1). The full committee can then review the draft and finalize the list. After first publication of the national list, the committee should meet at least every two years to update it. The committee's decisions should again follow the established criteria. Using a revision form may facilitate rational

additions and deletions (Figure 16-3). It provides a mechanism for prescribers to participate constructively in the selection process, and because the form requires a certain amount of effort on the part of the petitioner, it may reduce requests for items that are not really needed.

The same basic principles apply at the hospital level. The selection of medicines should be made on the basis of the national list of essential medicines, using similar criteria. The list should be made by a hospital drug and therapeutics committee that, ideally, is convened by a clinical pharmacologist, with senior clinicians and the hospital pharmacist as members. This committee may also advise on

prescribing policies and should, from time to time, review the prescribing patterns in the facility through simple prescription surveys (see [Chapter 28](#)). Such committees are now mandatory in several countries. In countries where the numbers of qualified staff members are limited, the first priority is establishing such committees in the teaching hospitals to serve as models for the rest of the country and for future generations of prescribers. [Chapter 45](#) describes in detail medicine management in a hospital setting.

Lists of essential medicines and treatment guidelines should also be drawn up for the lower levels of health care, such as health centers and dispensaries. Paramedical workers and teaching staff such as nurse tutors should be involved in the process, which is usually coordinated at the national level.

16.7 Therapeutic classification systems

Essential medicines lists and national formularies are best organized according to therapeutic category. In addition, analyses of medicine requirements, medicine consumption, or medicine prices are often facilitated by listing medicines according to their therapeutic class. Countless therapeutic classification systems are in use throughout the world. Some, such as the British National Formulary system, are organized by target organ or disease condition (for example, eye infections). Others, such as the American Hospital Formulary Service Drug Information system, are organized by pharmacologic-therapeutic action. The Nordic ATC system combines anatomic, therapeutic, and chemical criteria to classify medicines.

Country Study 16-1

Approaches to updating essential medicines and formulary lists

Ethiopia. The first edition of Ethiopia's national essential drugs list was published in 1980, and with the establishment of the first national drug policy in 1993, the government confirmed its commitment to the essential medicines concept. The fourth edition of the list, which was revised in 2002, includes sublists appropriate for different levels of health care: health centers, which include community health stations; district hospitals; and zonal hospitals (see [Table 16-2](#)). The revised edition was initially prepared by two committees assigned by the oversight agency, Ethiopia's Drug Administration and Control Authority (DACA). The committees presented the original list at a three-day workshop that included stakeholders from many disciplines, such as representatives from academia, professional associations, research institutions, the Ministry of Health, and consumer organizations. The revised version of the list was drawn up by a technical committee designated at the workshop. DACA sees the national medicines list as the product of an ongoing process, subject to continual deletion and addition as new medicines with better risk/benefit ratios replace less effective products.

Organisation of Eastern Caribbean States.

The Organisation of Eastern Caribbean States Pharmaceutical Procurement Service (OECS/PPS) is a group purchasing service for nine small Caribbean countries. Procurement is limited primarily to the OECS/PPS Regional Formulary. Medicines are selected by the OECS/PPS Technical Advisory Subcommittee (TAC), which consists of one member appointed by each participating country (generally, the chief medi-

cal officer or a comparable ministry appointee) and the central stores managers from each country. The OECS/PPS managing director is a nonvoting member of the TAC. The formulary list is subject to continual review; in the sixth edition (2002–05), twenty-nine pharmaceutical products were removed from the list and eighty-nine were added. The sixth edition also includes a new section on managing HIV/AIDS, including the addition of antiretroviral medicines. Changes are based on the evaluation and approval of written requests (see [Figure 16-3](#)).

World Health Organization. Since publication of the first Model List of Essential Drugs in 1977, the list has been updated every two to four years. The list is updated using a systematic approach, similar to that recommended for developing STGs. An expert advisory committee consisting primarily of clinical pharmacologists and physicians evaluates the latest clinical evidence, and decisions are made through a transparent process involving several rounds of external review. A major change that occurred with the 1985 list was the introduction of complementary medicines, which allowed substitution of therapeutic equivalents. In the first fifteen years, the number of medicines on the list increased slightly, but most changes involved replacement of one preparation with a more therapeutically appropriate or cost-effective preparation. For example, amoxicilline replaced ampicillin, and doxycycline replaced tetracycline. Nevertheless, the seventeenth Essential Medicines List, published in 2011, contains more than 350 active ingredients and is divided into a core list and a complementary list.

Country Study 16-2 Updating the National Essential Medicines List of Kenya

Kenya was one of the first African countries to recognize the importance of the essential medicines concept and developed its own essential medicines list in 1981, based on the WHO model. In 1992, the Ministry of Health decided to intensify its efforts to rationalize the pharmaceutical sector. Those efforts included updating the essential medicines list, rigorously implementing the list as the basis for pharmaceutical management in the public sector, and developing clinical treatment guidelines.

It was decided early on that the review of the essential medicines list and the development of clinical guidelines should be done in tandem. Draft treatment guidelines for the most common diseases and conditions had been prepared by the Ministry of Health, in consultation with university teachers and specialists at provincial hospitals, and distributed widely for comments. Review of the essential medicines list was begun by comparing the drugs from the 1981 national list with those mentioned in the draft treatment guidelines, alongside the 1992 WHO Model List of Essential Medicines.

It was decided to hold two national workshops simultaneously at the same location, one for refining the treatment guidelines and the other for revising the list. This process facilitated interaction between the two development committees and ensured that the new essential medicines list was in keeping with national clinical practice.

The participants in the medicines list workshop were mainly government pharmacists from various departments, joined by a professor of clinical pharmacology and a clinical pharmacist from the University of Nairobi, a senior nursing officer, and the head of the Kenya Essential Drugs Programme. The group based its deliberations on the WHO criteria for the selection of essential medicines (see [Box 16-1](#)) and consulted frequently with the clinical guidelines group. Emphasis was placed on medicines required to meet the health care needs of the majority of the population.

The two workshops concluded with a final joint session in which a revised list conforming to WHO criteria was approved. This list included 195 drugs in 256 dosage forms and strengths (fewer than the 1981 version) and was divided into seven levels of care. The process that was

followed resulted in a common base of understanding and commitment toward both the essential medicines list and the treatment guidelines.

The revised essential medicines list was printed in a twenty-eight-page booklet, which included background information, selection criteria, and listings by therapeutic category and level of care, as well as an alphabetical listing with store codes and packing units. This booklet was distributed to all public-sector hospitals, missions, professional associations, and local manufacturers. In the newest edition, published in 2002, the Ministry of Health combined the essential medicines list and the national standard treatment guidelines into one document.

The national drug policy adopted in September 1993 stated that the essential medicines list would be used for (1) public education and information; (2) public-sector procurement, prescribing, and dispensing; (3) paramedical and medical graduate education; (4) in-service training programs for health professionals; (5) preferential import duties and value-added taxes on drugs; (6) selective support for the local pharmaceutical industry; (7) pricing policies; and (8) controlling donations of medicines.

In the late 1980s and 1990s, the government of Kenya turned its focus to managing the HIV/AIDS epidemic. Initially its strategy was centered on behavior change and prevention, but lowered prices and increased access to antiretroviral medicines made treatment a reality for people living with HIV/AIDS in Kenya. The Ministry of Health gathered stakeholders comprising senior clinicians and pharmacists from the government, academic, and private sectors to collaborate on a standard treatment protocol for HIV/AIDS, and clinical guidelines for anti-retroviral treatment were published in 2001; the second edition was published in 2002 (NASCOP 2002).

The process for establishing the most appropriate HIV/AIDS treatment regimens was based on an evaluation of clinical efficacy, cost, and the need for a second line of treatment in case of antimicrobial resistance, adverse effects, or treatment failure. The antiretrovirals established as first- and second-line treatments have been added to the Kenya Essential Medicines List.

Relative contraindications: Hypersensitivity; renal function impairment. Caution: There is limited experience of the effect of concurrent HIV infection on adverse effects profiles. (2)</p> <p>Dosages (Maximum and Minimum): 500 mg as a single dose in adults.</p> <p>References: (1) Ndowa et al, "Efficacy of STD Treatment Regimens in a Genito-Urinary Clinic in Harare." <i>Centr. Afr. J. Med.</i> 3, 1995, pp. 36-40. (2) USP-DI 1994 and manufacturer's product data sheet.</p>	

Existing therapeutic classification systems also differ in their complexity; some systems may have five or six levels of subdivision. The level of complexity should be appropriate to the intended use of the system. In general, public pharmaceutical supply programs should strive for a noncomplex therapeutic classification system that is readily understood by midlevel medical workers and trained supply clerks as well as by pharmacists and physicians.

Increasingly, essential medicines programs are adopting the Anatomical Therapeutic Chemical (ATC) classification scheme used in the WHO Model List of Essential Medicines. In the ATC system, medicines are divided into different groups based on the body organ or system on which they act and their chemical, pharmacological, and therapeutic properties (WHO Collaborating Centre for Drug Statistics Methodology 2009). The searchable website is http://www.whocc.no/atc_ddd_index. This relatively straightforward system has been adopted by UNICEF and by most international nonprofit suppliers of essential medicines. Therefore, national and local programs will find price comparisons and ordering are easier if this system is adopted.

16.8 Sources of information

In most developing countries, the sources of current information available for medicine selection decisions are limited. (Chapter 34 discusses sources of drug information and how to assess them.)

Many academicians prefer to base the selection of essential medicines on information from original research articles, which requires compiling articles from journals for comprehensive review. The randomized controlled trial is becoming the “gold standard” both to establish medicine efficacy and to determine the comparative efficacy of different medicines for the same clinical problem. Results from such studies are not easily obtainable, unfortunately, so selection decisions must usually be made on the basis of the best available evidence.

Many respected reference texts and periodicals, such as drug bulletins, critically assess and synthesize the best available evidence. Of the many valuable resources that may be consulted, *Martindale: The Extra Pharmacopoeia* is particularly useful because it contains summaries on more than 5,300 medicines and information on the composition of 70,000 medicinal preparations. Other publications, such as the *British National Formulary*, contain comparative evaluations of individual drugs or of therapeutic groups. Independent drug bulletins, such as the *Medical Letter on Drugs and Therapeutics* and the *Drug and Therapeutics Bulletin*, regularly prepare comparative reviews of medicines and therapeutics.

The WHO Model List of Essential Medicines is a useful reference, derived from the consensus of recognized international experts and updated every two to four years. In 2007, WHO published the first Model List of Essential Medicines for children, revising it in 2008 and 2011 to include missing medicines for children, using evidence-based

clinical guidelines. The medicines on this list are widely acknowledged to be safe, efficacious, cost-effective, and of acceptable quality. Consulting essential medicines lists from other countries may also be useful. Many drug regulatory authorities post essential medicines lists and formularies on their websites.

Sufficient information on efficacy, safety, and dosages—particularly for risk groups such as children, pregnant women, and the elderly—is often difficult to obtain for newer drug products. Because the relative merits of newly marketed pharmaceuticals are unknown until clinical experience has accumulated or appropriate comparative trials with other medicines are undertaken, it is advisable to delay the inclusion of such medicines until sufficient information is available from reliable independent sources.

16.9 Implementing and updating essential medicines lists

The development and use of lists of essential medicines have enormous implications for pharmaceutical procurement, local production, supply, training, prescribing, and supervision. However, many essential medicines lists, treatment guidelines, and formulary manuals have been developed, printed, and forgotten. There are many reasons for such failures.

Reasons for failure

Probably the most common reason for failure is not involving as wide a group of national experts and policy makers as possible. Lists and guidelines developed by individuals, departments, or institutions operating in isolation are bound to fail, as are those that are not updated regularly. They lack credibility, and other interested parties will not accept them. Another common mistake is a lack of both a purpose and a medicine policy framework. Such weaknesses provide an opportunity for pressure groups to defeat the endeavor. Also, if the whole selection process lacks openness and transparency, or if no procedure exists for incorporating suggestions and additions, the lists and guidelines are likely to fail. Last, failure can result if selections are perceived as unrealistic (for example, listing sophisticated medicines for lower health care levels in resource-poor settings).

Gaining acceptance of essential medicines lists

The development and use of a national list of essential medicines are cornerstones of a national medicine policy. The formulation and acceptance of a national medicine policy are, in most cases, based on the concept of essential medicines and entail the development of a list. An essential medicines list can be developed without a medicine policy, but it

Table 16-3 Key factors in successfully developing and implementing an essential medicines program

Key factor
<ul style="list-style-type: none"> Establish a transparent process for creating and updating the list of essential medicines, providing a voice for key stakeholders but ensuring a scientific, evidence-based process.
<ul style="list-style-type: none"> Link the essential medicines list to clinical guidelines for diagnosis and treatment, involving both specialists and primary care providers.
<ul style="list-style-type: none"> Actively engage support from medical opinion leaders, senior clinicians, training institutions, professional organizations, nongovernmental organizations, and the public.
<ul style="list-style-type: none"> Make the list of essential medicines, formulary manuals, and standard treatment guidelines widely available in all health care facilities and to all health care providers in both printed and electronic versions.
<ul style="list-style-type: none"> Consider launching new or revised lists with the involvement of senior government officials, such as the minister of health or the president, and intensive press coverage.
<ul style="list-style-type: none"> Make clear the specific legal or administrative authority of the essential medicines list for training, procurement, reimbursement, and public information.
<ul style="list-style-type: none"> Consider establishing an administrative or budgetary mechanism to allow the limited supply and use of nonlisted medicines (for example, by certain specialist units).
<ul style="list-style-type: none"> Regularly update the list so that it reflects therapeutic advances and changes in cost, antimicrobial resistance patterns, and public health relevance.

Source: WHO 2002.

cannot be developed without wide agreement on the purpose and use of the list.

In developing a national list of essential medicines, it is important to obtain the support of professional organizations, such as the national medical and pharmaceutical associations. They should be consulted from the start and should be informed about the reasons for developing a list and the selection criteria. The same is true for senior clinicians and teachers from medical and pharmacy schools, who are often leading national figures involved in the process of medicine registration. Arguments in favor of the essential medicines concept and the advantages of a limited list of medicines (see [Table 16-1](#)) should be discussed with those individuals. The acceptance of the list by senior specialists and other health care workers can be further enhanced by their involvement in the development of the list, treatment guidelines, and formulary manual (see [Chapter 17](#)) and by generous acknowledgment of their contributions. The obvious advantages of a consistent set of training and information materials and a corresponding system of pharmaceutical supply offset most professional resistance.

When the list is completed and printed, it is important to give it national prominence and credibility through a launching campaign. This step should involve the highest level of government officials, such as the minister of health

ASSESSMENT GUIDE

Management structure of the National Essential Medicines List (NEML)

- Has an NEML been officially adopted and distributed countrywide?
- Is there an official medicines committee whose duties include updating the NEML?
- Has the NEML been updated and distributed countrywide in the past five years?
- Is there a national medicine policy statement to promote and define the use of the NEML?
- What are the selection criteria for the NEML?

Outcome of the selection process

- What are the total number of medicines on the NEML (in dosage forms and strengths) and the number of medicines per level of health care?
- Is there duplication of therapeutically equivalent products on the NEML?

Use of the NEML (public sector)

- Is procurement in the public sector limited to medicines on the NEML?

- What is the value of medicines from the NEML out of the total value of medicines procured?
- What percentage of health facilities has a copy of the NEML available?
- What is the number of medicines from the NEML out of the total number of medicines prescribed?
- Do pharmaceutical donations comply with the NEML?
- Is the concept of essential medicines part of the curriculum in the basic training of health personnel?

Use of the NEML (private sector)

- Is the NEML used to promote national pharmaceutical production?
- Is there at least one major incentive for selling essential medicines at low cost?
- Are essential medicines sold under INNs in private drug outlets?
- Of the fifty best-selling medicines in the private sector, how many are on the NEML?

or the president, and intensive press coverage. A national conference can emphasize points such as the advantages of the list, the national consensus in defining the health needs of the population at large, and the cost-effective use of limited resources.

Authority of essential medicines lists

Specifying the purpose of the list at an early stage is critical. Will procurement and distribution of medicines in the public sector be limited to products on the list? Is a change in legislation or regulation needed for enforcing the use of a list, or perhaps a decree? Will exceptions to the list be allowed? If so, on what grounds and by which authority?

Pressure will be brought to provide patients with medicines not on the essential medicines list. Exceptions to the official list must be controlled by administrative or budgetary methods. Health services often require a written request for special authorization of nonlisted medicines (for example, the form in [Figure 16-3](#)) and have procedures for evaluating and approving such requests. A budgetary maximum may also be used for such exceptions—a maximum of 5 to 10 percent of the pharmaceutical budget, for example. Such a budget for nonlisted medicines is usually effective in ensuring acceptance of the list by district authorities and clinical specialists; without such a safety valve, many lists are

perceived as too rigid and are likely to be undermined. In addition, if certain nonformulary medicines are commonly ordered, they may be considered for inclusion when the list is revised.

Finally, an open and transparent system of regular updates is an absolute prerequisite to maintain the authority and acceptance of an essential medicines or formulary list. [Table 16-3](#) lists the factors that are important in developing and implementing the elements of an essential medicines program. ■

Glossary

Bioavailability: The rate and extent of availability of an active ingredient from a dosage form as measured by the concentration/time curve in the systemic circulation or its excretion in the urine.

Branded generics: Generic pharmaceutical products marketed under brand names.

Drug: Any substance in a pharmaceutical product that is used to modify or explore physiological systems or pathological states for the benefit of the recipient.

Drug product: A unique combination of drug(s), strength, and dosage form (for example, ampicillin 500 mg capsule).

Efficacy: The ability of a medicine to produce the purported effect, as determined by scientific methods.

Formulary list: A list of medicines approved for use in a specific health care setting.

Formulary manual: A manual containing clinically oriented, summary pharmacological information about a selected number of medicines. The manual may also include administrative and regulatory information pertaining to medication prescribing and dispensing.

Formulary system: The principles, criteria, procedures, and resources for developing, updating, and promoting the formulary (essential medicines) list.

Generic name: The locally approved or nonproprietary name of a drug. It is generally the International Nonproprietary Name given by WHO.

Generic pharmaceutical products: Products marketed by any producer under nonproprietary or locally approved names.

International Nonproprietary Name (INN): A globally recognized name developed by WHO to facilitate the identification of pharmaceutical substances or active pharmaceutical ingredients. A nonproprietary name is also known as a generic name.

Multisource pharmaceutical products: Pharmaceutically equivalent products, available from different manufacturers, that may or may not be therapeutically equivalent.

Pharmaceutical equivalents: Products that contain the same amount of the same active substance(s) in the same dosage form, meet the same or comparable standards, and are intended to be administered by the same route.

Pharmaceutical product: A dosage form containing one or more drugs along with other substances included during the manufacturing process.

Therapeutic equivalents: Pharmaceutically equivalent products whose effects with respect to both safety and efficacy are essentially the same, when administered in the same molar dose, as can be derived from appropriate studies (bioequivalence, pharmacodynamic, clinical, or in vitro studies).

SUMMARY

Treatment guidelines are disease oriented and reflect a consensus on the treatments of first choice for a range of medical conditions. A formulary manual is drug oriented and contains summary drug information on a selected number of medicines, sometimes combined with practical prescribing and dispensing information. They can both be developed for various levels of health care.

The process of developing these publications (the formulary process) is a continual effort, not limited to the one-time production of a set of treatment guidelines or a formulary manual. The process includes gaining acceptance of the concept, preparing a text on the basis of wide consultation and consensus building, implementing an introductory campaign and training activities, and undertaking regular reviews and updates.

Treatment guidelines can be made for one institution, such as a hospital; for one level of care, such as all health centers; or for a region or nation. Treatment guidelines are powerful tools to promote rational prescribing, provided they are based on extensive involvement of the end users. Their development is a good opportunity to

integrate technical advice from various disease programs into an overall training program. Treatment guidelines should be used as the basis for undergraduate medical and paramedical training, for in-service training, for supervision, and for medical audit. The range of medicines included should be limited to those on the national list of essential medicines.

A formulary manual, whether at a national or facility level, should be developed by a formulary subcommittee of the national drug committee or the facility's drug and therapeutics committee. Both committees should ensure the full participation of prominent specialists and health opinion leaders in the process. One or two editors should be commissioned to draft and edit the formulary manual.

To maintain the credibility of the information, a system for regular updates and for incorporation of accepted amendments into the next edition is essential for both formularies and treatment guidelines.

This chapter builds on concepts introduced in [Chapter 16](#), which should be read first.

17.1 Need for local reference manuals

After standard treatment guidelines (STGs) for a country's common conditions and complaints have been agreed upon and adopted, the next step is the development of a national essential medicines list and a formulary manual.

The procedures for developing an essential medicines list, a set of treatment guidelines, and a formulary manual are all similar; together, they can be called the formulary process. Standard treatment guidelines are disease oriented, whereas formulary manuals are very much drug-oriented documents. These two documents are the cornerstone of rational medicine therapy. General information on the selection of medicines and the development and maintenance of a list of essential medicines is given in [Chapter 16](#). In this chapter, the specific aspects of the formulary process are outlined in relation to developing treatment guidelines or a formulary manual.

Treatment guidelines

The terms *standard treatment guidelines*, *treatment protocols*, and *clinical guidelines* are all used to indicate systematically developed statements that help practitioners or prescribers make decisions about appropriate treatments for specific clinical conditions. Treatment guidelines exist for various levels of health care, ranging from general prescribing

guidelines for paramedical workers in rural areas to detailed protocols for tertiary health care centers in wealthy urban areas and teaching hospitals.

Standard guidelines benefit health officials, supply management staff, health care providers, and patients ([Box 17-1](#)). Together with a national list of essential medicines, treatment guidelines are powerful tools in promoting the rational use of medicines, and they are integral in strategies to reduce antimicrobial resistance. They offer an opportunity to ensure that the training of health workers is based both on a logical approach to treatment and on a consensus about the selection of essential medicines. Comprehensive treatment guidelines are a logical starting point for integrated training and an excellent basis for pharmaceutical supply in the public sector. Treatment guidelines should be used for in-service training, supervision, and medical audit. They can also assist in the standardization (and rationalization) of prescribing patterns in countries with large numbers of foreign-trained medical graduates. STGs, when properly developed and implemented, will improve the patient's clinical outcome at a lower total cost (Grimshaw et al. 2004).

Formulary manual

A formulary manual contains summary information on a selected number of medicines. It is drug centered, and the information is usually organized in therapeutic groups. In

Box 17-1**Potential benefits of standard treatment guidelines****For health officials**

- Permits identification of cost-effective treatments for common health problems
- Provides basis for assessing and comparing quality of care
- Identifies most effective therapy in terms of quality and combats antimicrobial resistance
- Provides information for practitioners to give to patients concerning the institution's standards of care
- Is a vehicle for integrating special programs (control of diarrheal disease, acute respiratory infection, tuberculosis, malaria, and so on) at the point of the primary health care provider

For supply management staff

- Identifies which medicines should be available for the most commonly treated problems
- Facilitates prepackaging of course-of-therapy quantities of commonly prescribed items

- Makes medicine demand more predictable, so forecasting is more reliable

For health care providers

- Provides expert consensus on most effective, economical treatment for a specific setting
- Gives providers the opportunity to concentrate on correct diagnosis
- Sets a quality-of-care standard
- Provides a basis for monitoring and supervision

For patients

- Encourages adherence to treatment through consistency among prescribers at all locations within the health care system
- Ensures most cost-effective treatments are provided
- Improves availability of medicines
- Improves treatment and outcomes

most developing countries, the national formulary list is limited to medicines on the national list of essential medicines. A *therapeutic formulary* includes detailed and comprehensive therapeutic information on each of the medicines listed and may also include guidelines on rational prescribing and dispensing; here, the distinction between a formulary and treatment guidelines becomes less clear, as is the case with the *British National Formulary* (BNF).

Although there are several available reference texts that include comprehensive drug information, they may not be appropriate for all settings. A national formulary manual concentrates on medications relevant to a particular country. For example, it would exclude information on medicines that are not available in the country or that are overly expensive. It would also put less emphasis on uncommon, irrelevant, or minor side effects. But it should include information that may be missing in other texts on nationally important medicines, such as those used for tropical conditions or for locally common diseases that may be rare in other countries. It would also include information on specific treatment considerations (for example, G6PD deficiency, sickle cell anemia, HIV infection). Recommended dosage schedules can be adapted to national requirements, special storage guidelines may be added, and specific national problems (such as overuse of injections or polypharmacy) can be addressed.

The World Health Organization (WHO) launched its first model formulary in 2002, with electronic versions

available on its website and on CD-ROM. The *WHO Model Formulary* presents independent information on the more than 300 medicines on the *WHO Model List of Essential Medicines* and is updated periodically, along with the essential medicines list. Each section of the formulary starts with a comparative overview of various therapeutic alternatives, while each medication entry has information on use, dosage, adverse effects, contraindications, and warnings. The formulary is intended to be a model for national governments and institutions to use as a basis for developing their own national formularies. It is particularly relevant for developing countries, where commercial and promotional materials are often the only available source of drug information to health workers, prescribers, and patients.

17.2 Treatment guidelines

In developing standard treatment guidelines, the starting point is a list of common diseases and complaints. Next, the standard treatment of choice is defined for each diagnosis or problem. In terms of selection of health problems to be addressed, formatting standard treatment guidelines can be approached in different ways—

- Individual—Standard treatments are established for only one problem or set of problems, such as only

diarrheal disease, only acute respiratory infection (ARI), or only malaria.

- Selective—Standard treatments are established for a small number of high-priority problems, perhaps six to twelve, for example, a “package” of treatments for diarrheal disease, ARI, antenatal care, immunization screening, malaria, and tuberculosis.
- Comprehensive—Standard treatments are established for 30, 50, 100, or an even greater number of common health problems. When published, such standard treatment guidelines become more like textbooks than basic references.

Technical advice from various vertical disease-oriented programs (malaria, diarrheal diseases, schistosomiasis, tuberculosis, sexually transmitted infections, HIV/AIDS, and many others) can be integrated into one set of national treatment guidelines; however, separate funding sources for vertical programs can result in the independent publication of disease-specific STGs, which may be appropriate for facilities that function primarily to treat one condition (for example, HIV/AIDS).

The number of treatment guidelines developed should be appropriate to the specific situation. But developing individual treatment guidelines one by one may result in a missed opportunity to use the process to integrate several special programs. At the other extreme, comprehensive standard treatment guidelines risk overwhelming health workers with new information, thus reducing the chance that *any* of the standard treatments—even those for common, high-priority problems—will be followed. There may be situations where it is appropriate to target different levels of the health system with manuals containing differing amounts of information.

Information on local disease patterns should also be considered. Seldom do primary care clinics have access to clinical laboratories. But results from surveys using available district, regional, or national laboratory facilities can be used to make scientifically based selections of preferred medicines for certain types of diarrhea, ARI, malaria, tuberculosis, and other infectious diseases. Dynamic standard treatment guidelines are periodically updated to reflect changes in treatment patterns.

Any treatment guideline should include only medicines on the national list of essential medicines. This limitation ensures that the supply system, based on the list of essential medicines, supports the treatment guidelines. Ideally, a formulary list should be developed after the appropriate treatment guidelines for common diseases have been identified or developed.

Unlike the drug information in a national formulary manual, which tends to be noncontroversial, treatment guidelines may generate considerable differences of opinion among prescribers. Reaching consensus is much more

difficult, and the developmental process takes much more time. To the extent possible, treatment selection should be evidence based and take into account the local economic situation. Wide consultation is a key condition for acceptance and impact.

The process of developing treatment guidelines is similar to that of developing an essential medicines list or formulary manual (see [Country Study 17-1](#)), and only those aspects specific to treatment guidelines are discussed here (see [Table 17-1](#) for an overview of the process).

Establishment of a guideline development committee

For national treatment guidelines, the guideline development committee can be a subcommittee of the national drug and therapeutics committee and is likely to differ from the national formulary committee. The committee should include one or two leaders who have final responsibility for the guidelines and who can lead the group through the process; clinical specialists in the fields under study; other experts as needed, such as a nutritionist or a health economist; several end users (general practitioners, medical assistants, nurses); patient/caregiver advocates; and other stakeholders who should have input. Sometimes focus groups are used to provide patient and caregiver feedback. Not all medical specialties need to be represented on the committee, but they can be co-opted to prepare or review the relevant chapters. The group should also have technical and administrative support.

Before starting the work, and especially before inviting other experts to write chapters or sections, the guideline development committee must make several important decisions on target groups, choice of authors, and editing and reviewing of the manuscript.

Targeting different levels of care. The length and format of the publication depend on the target group and the level of detail. A key question is: should all information for all levels of health workers be presented in one publication, or should different publications be issued for different levels of care? One publication for all levels can serve as a complete reference for all recommended treatments. It also allows practitioners at the lower levels to read about treatments that are recommended at the higher levels, which may be an advantage in emergency cases and is, at the least, educational. In addition, the production process is easier, and the publishing costs are reduced.

In contrast, separate guidelines for different levels of health care can recommend treatments focused on medicines supplied to that level, so that no unavailable medicines are recommended. Several developing countries with large proportions of paramedical prescribers have produced separate national treatment guidelines for general practitioners and for paramedical prescribers (such as clinical officers, medical assistants, and nurses). The former are pocket-size

Country Study 17-1 Production and use of treatment guidelines

Australia. Started as a hospital-based initiative, the Antibiotic Guidelines were first issued in Victoria in the late 1970s. They were used as a teaching document for medical students and interns and, more important, as an audit standard against which prescribing patterns in the wards could be compared. More and more hospitals became involved, and subsequent editions of the guidelines booklet were increasingly used in other regions of the country. New editions were introduced with marketing campaigns that were professional and inventive, using posters, advertisements, drug use studies, and face-to-face education. These campaigns, together with the widening range of professionals involved in subsequent editions, greatly improved the acceptance of the guidelines.

As the administrative requirements of producing, promoting, and evaluating a comprehensive set of therapeutic guidelines increased, the series was turned over to a nonprofit organization, Therapeutic Guidelines Limited, which expanded the range of titles and converted them to electronic format. The guidelines now cover ten areas, including analgesic, antibiotic, cardiovascular, gastrointestinal, psychotropic, and respiratory medicines, and provide up-to-date therapeutic information for a range of diseases. The guidelines are developed by expert writing groups composed of about twelve people, including a chair, an editor, experts in relevant medical specialties, a general practitioner, and a pharmacist. Although the text is drafted by individual members of the writing groups, all group members devote many days to meetings and workshops to discuss and reach agreement on the final guidelines. At that point, the manuscript is reviewed by ten to twenty outside experts. The time taken to produce each book, from the first writing group meeting to publication, is twelve to fourteen months. Each booklet is updated every two to three years. Although the guidelines are used primarily in Australia, several other countries, including Japan and China, have adapted and translated individual guidelines for use locally.

Nicaragua. A series of therapeutic guidelines existed in Nicaragua; however, although they were technically sound, their presentation was unattractive and the language was more appropriate for doctors than for paramedical workers. In addition, the material was spread

over several booklets, and many health facilities did not have a complete set.

Development of new guidelines for rural health workers included a three-day workshop attended by health workers who were stationed alone in ten “sentinel” health posts as well as nurses, physicians, and pharmacists from the surrounding areas. The group identified the most common diseases treated in the health posts and drew up a corresponding list of essential medicines. The resulting draft booklet was widely field-tested. It was then decided to revise and expand the handbook for the national level with a bottom-up approach, again calling on the experience of end users. The national-level draft was also reviewed by a multidisciplinary group of specialists at the regional, provincial, and university levels. The product was an extensive, illustrated, 440-page learning and action guide for local health workers, *Buscando remedio* (“Seeking a Remedy”). The sixth edition was published in 2010.

Ghana. In 2004, Ghana’s National Drugs Program published the fifth edition of the Standard Treatment Guidelines (STGs) and Essential Medicines List (EML). The STG 2004 is an update of the 2000 version. The fifth edition is based on the best-available medical evidence and includes ratings of the quality of evidence associated with each recommendation. The new STG lists 530 drug products, a number that reflects eighty-three deletions and forty-eight additions since the 2000 edition. Changes to the list of medicines are partly the result of changes in the *WHO Model List of Essential Medicines* and the addition of antiretroviral medicines for HIV/AIDS. In addition, the British Approved Names used in the previous edition have been replaced with the recommended International Nonproprietary Names.

Ghana’s publication of the updated STG and EML 2004 coincided with the nationwide implementation of the National Health Insurance Scheme (NHIS). The STG and EML 2004 govern the standards of care under the NHIS, and the NHIS list of medicines for reimbursement is based on the national EML. The introduction of the new health insurance scheme gives Ghana the opportunity to make the STG 2004 widely available and facilitates adherence monitoring.

Table 17-1 Summary of the standard treatment guideline development process

Key action	Tasks
Recruit guideline development group chair	<ul style="list-style-type: none"> • Advertise • Interview • Train

Source: Adapted from NICE 2009.

books with treatment guidelines in a condensed format; the latter use simpler language, are extensively illustrated, and recommend only medicines that are available at rural health facilities. One set of guidelines is usually sufficient in countries where primary health care is delivered mainly by physicians.

Identifying and assessing the clinical evidence. The first step in identifying the evidence is for the group to formulate the clinical questions to answer. The PICO guide (NICE 2009) provides a framework based on patients, intervention, comparison, and outcome—

Patients/population: Which patients or population of patients are we interested in? How can they be best described? Are there subgroups that need to be considered?

Intervention: Which intervention, treatment, or approach should be used?

Comparison: What is/are the main alternative/s to compare with the intervention?

Outcome: What is really important for the patient? Which outcomes should be considered: intermediate or short-term measures; mortality; morbidity and treatment complications; rates of relapse; late morbidity and readmission; return to work, physical and social functioning and other measures such as quality of life; general health status; costs?

A systematic review of the evidence involves identifying and evaluating information to answer the questions based on the best available evidence in the relevant area. This process should be transparent and involves four major steps: selecting relevant studies; assessing their quality; synthesizing the results; and grading the evidence. The evidence may include primary scientific papers, systematic reviews from the Cochrane Collaboration, reviews published in well-

known journals, and guidelines developed by other credible organizations.

Many resources exist on how to assess clinical information (see, for example, NICE 2009, Shekelle et al. 1999, and SIGN 2008). [Chapter 34](#) includes more detail on evaluating pharmaceutical information.

Drafting the guidelines. The most practical approach is to invite a number of authors to draft first texts of separate chapters. The authors should be recruited from the level of prescribers for which the guidelines are intended. For example, inviting a university specialist to write treatment guidelines for dispensing nurses may not be practical; a nurse-tutor would be better equipped for that task, although the author can consult relevant specialists and have them review the draft text. Several production issues—for example, the specifications for text and presentation (see Section 17-4)—should be addressed early in the process. A key to the successful acceptance of treatment guidelines is involving well-respected opinion leaders in the development process.

Reviewing and editing the draft. The editors of the guidelines should unify the draft chapters into one consistent document before sending the draft text out for review by a large number of stakeholders. As mentioned, reaching consensus on a treatment of first choice is usually more difficult than agreeing on the factual drug information that is included in a national formulary manual. In addition, more opposition is bound to arise after the guidelines have been published. Several rounds of consultation, involving an increasing number of experts, professional associations, patient/caregiver advocates, and other stakeholders can do a great deal to resolve objections. If consensus cannot be reached, the guidelines should indicate it.

Adapting existing guidelines. Many health care organizations and some ministries of health do not have the resources necessary to develop treatment guidelines from scratch. In this case, existing guidelines can be adapted for local use. Policy makers should focus on the guidelines that are most important, based on local disease patterns. It may be difficult to identify appropriate guidelines to evaluate, as they may not be easily accessible; however, some organizations post their guidelines on the Internet (see References and Further Readings). Other resources may be leveraged through partnerships and collaboration with other stakeholders.

Once a guideline development group identifies existing guidelines that correspond with their treatment priorities, they must still use as rigorous an evaluation method as possible, given the resources available. The task of the group that adapts existing guidelines, then, is not to identify and analyze the available literature, but rather to ensure that the adaptation and its recommendations are locally relevant and likely to be adopted by health care providers. A guideline assessment tool can be used to evaluate its usability and

validity. The Joint United Nations Programme on HIV/AIDS includes such a tool in its publication on developing treatment guidelines (UNAIDS 1999).

Information in treatment guidelines

Treatment guidelines are disease oriented (in contrast to formularies, which are drug oriented). This focus means that the treatment of choice is presented for each common health problem, together with basic information needed by the prescriber. Any appropriate nondrug treatments should always be included. Alternative treatments may be listed, with an indication of when they should be used. Comparisons of the costs of various treatments may also be included in the analysis, with the “best” treatment dependent on circumstances (such as antimicrobial resistance) or selection criteria ([Box 17-2](#)).

Some STGs, for example, those of Ghana, also include a section on the level of evidence for the recommended treatment. The evidence is rated as supported by either (A) randomized controlled trials; (B) well-conducted clinical studies; or (C) expert committee recommendations.

Treatment guidelines necessarily repeat some information that is also presented in the national formulary manual. It is not necessary, however, to include all drug information—only that which is needed to make rational treatment decisions.

Diagnostic criteria. Diagnostic criteria are especially important when a disease may present in different stages of severity (for example, dehydration). They must indicate when treatment is needed and when it is not, such as in the treatment of fever or cough. Required investigations may be included.

Treatment of first choice. The section on the first-choice treatment (drug or nondrug) contains the most information for the prescriber. It should include the choice of medicine, its usual dosage schedule, and, when needed, adapted dosage schedules for children, for patients with concurrent liver or renal diseases, for pregnant patients, for the elderly, and for other high-risk groups.

Cost of treatment. Information on the cost of treatment is useful if alternatives are proposed. However, including such information means that the guidelines must be updated regularly. The information can also be presented as price ranges, such as “cheap,” “moderate,” and “expensive”; these types of categories are unlikely to change substantially.

Important contraindications and side effects. The section on contraindications and side effects should list both relative and absolute contraindications; groups at special risk (the elderly, and patients who are pregnant, breastfeeding, or have liver or renal disease) must be highlighted. Side effects should be broken down into reactions that are self-limiting and those that may require a change in therapy.

Box 17-2**Cost-effectiveness analysis for choosing standard treatments**

Even when funds are limited, the cheapest treatment for a specific health problem may not be the best treatment. A cost-effectiveness analysis (CEA, see [Chapter 10](#)) may help to organize cost and effectiveness information to guide decisions about first- and second-line treatments. Including indirect costs beyond the price of the medicine in the analysis provides a clearer picture. Indirect costs might include program costs, such as health staff, program administration, laboratory reagents, hospitalization costs, and vehicle costs. A CEA may be particularly helpful when higher-cost treatments are also more effective, such as for certain antibacterial, antitubercular, or antimalarial drugs for which drug resistance is high. A CEA can also be useful in establishing standard treatment guidelines for chronic diseases, such as hypertension, and for antibiotic prophylaxis for surgery.

Below is a real-life example of how two different kinds of thrombolytic agents for the treatment of myocardial infarction were compared from the point of view of effi-

cacy and cost-effectiveness in Australia. The usual treatment of myocardial infarction was compared with usual treatment plus the use of either streptokinase or tissue plasminogen activator.

Comparison was done in terms of (a) total treatment costs, (b) death rates, and (c) cost per life saved (or death averted). The treatment costs included all the direct and indirect costs.

A CEA may be carried out using only information on cure rates and medicine costs. However, a truer picture may emerge if broader measures of effectiveness are used (morbidity, including disability, as well as mortality) and if all costs are included. For example, in an area of moderate resistance, a more effective second-line antimalarial may not be more cost-effective when only medicine costs are considered, but it may prove more cost-effective when additional costs are considered, such as hospitalization of patients who fail to respond to first-line treatment.

Economic analysis of two thrombolytics in acute myocardial infarction in Australia

A review of the literature was conducted in Australia to determine the cost-effectiveness of different thrombolytics to treat myocardial infarction (MI). The evaluation included the cost of the treatments and the mortality rate following MI.

Cost of treatment and mortality rates

Usual care (UC) of MI: 3.5 million Australian dollars (AUD)/1,000 cases, 120 die
 UC of MI + streptokinase (SK): AUD 3.7 million/1,000 cases, 90 die
 UC of MI + tissue plasminogen activator (tPA): AUD 5.5 million/1,000 cases, 80 die

Comparison of the different treatments

Difference between SK and UC of MI:

Cost of treatment = AUD 3.7–3.5 million/1,000 cases = AUD 0.2 million/1,000 cases = AUD 200 per case
 Number of deaths that will be prevented = 120–90 = 30 deaths/1,000 cases treated
 Cost-effectiveness of SK = AUD 0.2 million/30 lives = AUD 6,700 per life saved

Difference between tPA and usual care of MI

Cost of treatment = AUD 5.5–3.5 million/1,000 cases = AUD 2.0 million/1,000 cases = AUD 2,000 per case
 Number of deaths that will be prevented = 120–80 = 40 deaths/1,000 cases treated
 Cost-effectiveness of tPA = AUD 2.0 million/40 lives = AUD 50,000 per life saved

Difference between tPA and SK treatments for MI

Cost of treatment = AUD 2.0–0.2 million/1,000 cases = 1.8 million/1,000 cases = AUD 1,800 per case
 Number of deaths that will be prevented = 90–80 = 10 deaths/1,000 cases treated
 Increased cost-effectiveness of tPA over SK = AUD 1.8 million/10 lives = AUD 180,000 per life saved

If one has a budget of only AUD 500,000, which medicine should one use?

For SK: number of cases that can be treated = 500,000/200 = 2,500 cases
 Number of lives that can be saved = (30/1000) × 2500 = 75 lives
 For tPA: number of cases that can be treated = 500,000/2000 = 250 cases
 Number of lives that can be saved = (40/1000) × 250 = 10 lives

Conclusion

This study concluded that although tPA had slightly better efficacy and saved marginally more lives, when cost was taken into account, more patients could be treated and more lives saved using SK. In other words, the extra cost-effectiveness of tPA over SK was so high (AUD 180,000 per life saved) that fewer people could be treated, and fewer lives saved, using tPA as compared to SK, with the limited budget available.

Source: Aylward 1996, cited in RPM Plus/WHO 2007a.

Important drug information, warnings, and precautions. This section highlights the information that the patient should be given by both the prescriber and the dispenser.

Referral criteria. These criteria describe when to refer the patient to a higher level of care. For example: If the patient's condition does not improve within four hours, refer the patient to a hospital.

Index. Although treatment guidelines are usually disease centered, many prescribers also use them to check on specific drugs or dosage schedules. For this reason, an index with both drug names and health problems makes the manual more useful.

Use of treatment guidelines

Treatment guidelines should be used for basic training of health workers, in-service training, supervision, reference, and medical audit. They are potentially valuable in promoting the rational use of medicines, because many prescribers recognize them as useful references. Because they are related to the list of essential medicines, they should also serve as the basis for the supply of essential medicines.

It was originally hoped that the availability of guidelines would change irrational prescribing patterns. However, it has become apparent that sending treatment guidelines to all prescribers is not enough to bring about an improvement in prescribing practices. To be effective, guidelines must be properly introduced to the prescribers, and their use should be monitored (see [Country Study 17-2](#)).

All relevant health workers should have their own copies of the guidelines, and training courses should be organized to introduce the guidelines and teach health workers how to use them. Treatment guidelines for paramedical prescribers are usually well received and are common in developing countries, as is also true of national treatment guidelines for general doctors. National guidelines for tertiary care are rare, but general care guidelines are often used in tertiary institutions. In South Africa, three separate STGs exist: one each for adult and pediatric patients in the hospital setting and a combined version for primary health care, which also includes the national essential medicines list. In developed countries, treatment protocols are usually drawn up for specific diseases (hypertension, diabetes, certain types of

Country Study 17-2 Improving compliance with standard treatment guidelines in Indonesia

Acute respiratory infection (ARI) is the leading cause of morbidity and mortality of children under five years old in Indonesia. Despite the widespread availability of standard treatment guidelines in health centers, evidence suggested that health professionals did not always comply with the STGs and that the use of nonstandard medicines for ARI, such as antibiotics, antihistamines, corticosteroids, and phenobarbital, was common. An intervention study was carried out in twenty-four health centers with the aim of reducing the use of nonstandard medicines for under-five ARI patients.

Twenty-four health centers from two districts were randomly assigned to receive the intervention (Group A) or act as controls (Group B). The intervention consisted of a two-hour small group discussion about ARI STGs, followed by two self-assessment discussions (after one month and two months) to discuss prescribing habits. Finally, both the intervention and control groups participated in a feedback seminar where the results of the study were presented. The level of compliance with the STGs was measured by analyzing thirty prescriptions a month from each health center that had ARI as a single diagnosis, and looking at the number and costs of prescriptions and how many prescriptions included antibiotics, antihistamines, or corticosteroids.

Outcome measures	Baseline/4 weeks postintervention	
	Group A (n = 12)	Group B (n = 12)
Medicines prescribed per encounter	4.0/3.1	3.8/4.0
Percentage antibiotics	63/22	67/67
Percentage antihistamines	79/23	75/64
Percentage corticosteroids	21/6	22/24
Average prescription costs (rupiahs)	1,123/750	1,296/1,151

As the results in the table show, in Indonesia, small-group interactive seminars followed by two self-assessment meetings were effective in improving health center staff compliance with STGs for ARI. In addition, after presentation of the study results to both groups, the control health centers experienced significant improvements on all outcome measures. So, even though these centers did not experience the entire intervention, a low level of feedback was instructive.

Source: Hidayati and Munawaroh 2004.

Box 17-3**Using monitoring systems to evaluate the appropriateness of standard treatment guidelines**

Integral to the success of instituting and promoting the use of standard treatment guidelines is establishing a monitoring and evaluation system to guide updates and revisions. Monitoring programs can focus specifically on the issue of treatment failure, and reports of high rates of clinical failure should prompt a thorough investigation and evaluation. For example, are there problems in the treatment guidelines themselves or in the implementation of the treatment guidelines? Are quality medications available and used properly by patients? Investigations should document clinical failure rates, physician compliance with STGs, patient compliance with prescriptions, drug quality, and antimicrobial resistance estimates. If the evaluation finds high rates of clinical failure despite compliance with STGs, a review of the official recommendations is essential.

In several countries, monitoring programs for formal treatment failure have been established for certain conditions, such as malaria and tuberculosis, and results have been used to modify existing treatment guidelines. Many malaria-endemic countries have changed their national malaria treatment policy after antimicrobial resistance monitoring indicated that chloroquine or sulfadoxine-pyrimethamine was no longer effective in the country. For most infectious diseases, however, formal monitoring systems are not usually in place. Yet, mechanisms should exist for health care providers to report their experiences in using national STGs, and in turn, national authorities should have a procedure in place for responding to concerns by conducting studies or investigations.

Source: APUA 2003.

cancer) or for single hospital departments (prescribing policies in the pediatrics department of a teaching hospital, for example).

Treatment guidelines have the strongest long-term impact if they are frequently updated, widely distributed, integrated into the basic curriculum of medical and paramedical teaching institutions, and used for audit—especially when the turnover and transfer of field staff is so frequent that the effect of in-service training is quickly diluted. The first edition of guidelines should be reviewed and updated after one year to rectify errors and ambiguities; after that, revisions should occur every two to three years, or as indicated by new evidence to support changes (see [Box 17-3](#)).

17.3 Formulary manuals

As noted in [Chapter 16](#), the term *formulary* can be applied to a simple formulary list, the formulary manual (the subject of this discussion), or a fully developed formulary system. A formulary system develops from the essential medicines or formulary list and the formulary manual. It includes drug information and other resources to support good pharmaceutical management and the rational use of medicines. Formulary manuals provide on-the-spot information with a particular scope of use in mind—for example, national versus facility-specific—as well as a focus on a particular level of health care practice. As with treatment guidelines, the production of a formulary manual is one step in an ongoing process, and formulary manuals should periodically be reviewed and updated.

Information in a formulary manual

The information is usually presented in the form of drug information sheets or drug monographs. Such sheets can also be used as the basis for developing drug package inserts for locally manufactured drugs targeted at either prescribers or patients.

In most developing countries, the medicines included in the national formulary list are limited to those on the national list of essential medicines. However, a formulary manual may also include some information on commonly used medicines whose use is not recommended, stating exactly why these medicines are not recommended and discouraging their use.

[Box 17-4](#) outlines information that may be included in a formulary manual. Acknowledgments should list all persons or agencies that contributed to the formulary; this background enhances its authority and credibility. The introduction should briefly describe the development process and the manual's intended use.

Basic information for each medication should be easy to read and complete but concise. The format and wording should be carefully chosen so that the information can be easily understood.

If cost information is included, the formulary manual must be updated regularly. Price information may be presented as treatment cost per day or as cost per course of treatment. This information may be presented in tables or bar charts. If the manual includes information that prescribers or dispensers should give to patients to ensure the correct use of the drug, this information should be specific.

Box 17-4 Information in a formulary manual

Introductory information

- Acknowledgments (individuals and agencies that contributed, explanation of how drug information is presented in manual)
- List of approved abbreviations
- Introduction (development of manual, intended uses)
- Formulary policies and procedures

Basic information for each drug

- Generic name, common synonyms, or brand names
- Dosage form(s) and strength(s)
- Main indications (diseases and conditions for which a drug is given)
- Pharmacology (may include pharmacokinetic data)
- Contraindications (reasons not to give the drug)
- Precautions (such as pregnancy, breast-feeding, certain health conditions)
- Side effects (major and minor, with estimated frequency)
- Dosage schedule (dosage form, frequency, duration, pediatric dosage, dosage adjustments for the elderly and for those with renal or liver disease)
- Instructions and warnings
- Drug, food, lab interactions (most common or severe)

Supplementary information on each drug

- Price
- Level-of-use code
- Regulatory category (prescription only, over-the-counter, controlled narcotic drugs)
- Storage guidelines
- Patient counseling information
- Labeling information

- National essential medicines list reference number
- Stores catalog number

Prescribing and dispensing guidelines

- Rational prescribing
- Principles of prescription writing
- Use of placebos
- Special requirements for inpatient prescriptions
- Guidelines on quantities to be supplied
- Special requirements for controlled drug prescriptions
- Prevention and reporting of adverse drug reactions
- Dispensing guidelines (correct dispensing practices, patient counseling)
- List of cautionary and advisory labels
- Table of drug interactions (highlighting most common and most severe)

General drug use advice (optional)

- Use of intravenous (IV) additives (general guidance, table with recommended quantities)
- Prescribing in special situations (pregnancy, breast-feeding, renal or liver disease, the elderly, children, terminal care)
- Poisoning (general information, antidotes for common poisons, telephone for poison center if one exists)
- Treatment of snakebites, insect stings

Other components

- Metric conversion scales and tables
- Adverse drug reaction reporting form
- Formulary revision form
- Indexes (by generic name, brand name, therapeutic category)
- Abbreviations

Cautionary and advisory labels may be mentioned as a letter code (for example, A: Do not use alcohol).

A section on prescribing and dispensing guidelines can help promote rational medicine use. For example, general points to consider before writing a prescription include the use of International Nonproprietary (generic) Names, the importance of nondrug treatment and simple advice, suggestions for dealing with patients' demands for injections and other expensive dosage forms, and the limited usefulness of combination drugs (see [Box 35-3](#) on safe medication practices, in [Chapter 35](#)). Dispensing guidelines may include correct dispensing practices and types of information to be

given in counseling patients (see [Chapters 30](#) and [33](#)). A list of cautionary and advisory labels can be included. Each of these can be numbered and cross-referenced in the drug sheets.

A comprehensive index of all drug groups and drug names (including brand names in italics, where appropriate) should be provided at the end of the publication. A good index greatly enhances the usefulness of the formulary manual and the accessibility of its information.

The first edition of the formulary manual will generate many comments. It is worthwhile to invite and structure such comments by including a formulary revision form, containing a request for supporting references.

Developing a formulary manual

The production and maintenance of a formulary manual are major tasks requiring discussion and planning. A clear, systematic process for the development, printing, and distribution of the manual should be agreed upon, with sufficient time, personnel, and resources allocated.

Many aspects of the formulary process have already been described, in discussions of essential medicines lists (Chapter 16) and standard treatment guidelines (in this chapter). The process for developing a formulary manual or national formulary list is not very different, and only some specific aspects are discussed here. WHO has published a practical guide on how to develop a national formulary based on the *WHO Model Formulary* (WHO 2004).

Establish a national formulary committee. The formulary committee could be the national drug committee itself or a smaller subcommittee of it. Ideally, the formulary committee should include a clinical pharmacist or pharmacologist, a physician, and additional prominent medical specialists, as required, to prepare or review sections related to their areas of expertise for accuracy and completeness.

Secure agreement on the content, structure, and format of the formulary. The formulary committee should propose the content, structure, general arrangement of the information, and layout for approval by the national drug committee. The committee should use models such as the *WHO Model Formulary* to save time and effort. Specific issues to be addressed regarding the nature, content, and format of the formulary manual are summarized in the next section.

Appoint an editor. One person (or a maximum of two coeditors) should be appointed to draft the text of the formulary manual. The editor should have an understanding of the pharmaceutical, pharmacological, and clinical aspects of the information required and of the level of language appropriate for the target audience.

Review the draft. When the first draft has been produced, it should be presented to the formulary committee for review. The committee should call upon other experts to resolve issues in dispute or to assist in the review of sections on specialized drugs or topics. Future users of the manual, such as doctors, nurses, pharmacists, and other health care workers, can comment on local practices and customs that may affect how the formulary is accepted. The accepted amendments are then incorporated into the text. This second draft should be widely circulated among the members of the national drug committee and any other invited reviewers for further comment.

A special national meeting involving committee members and stakeholders, including future users of the formulary manual, should then be called to discuss any outstanding issues and gain final approval of the form and content of the document. It is important for the credibility and accept-

ability of the formulary manual that all relevant opinions be considered and that key health policy makers be included in the process, even when their expected contributions may be minimal. With this approach, all participants will consider the formulary as partly their own creation and thus will be more committed to ensuring its acceptance and widespread use. Finally, it is important to keep the process ethical. The formulary system must not tolerate influence or pressure from pharmaceutical manufacturers or suppliers concerning any product being considered for addition to or deletion from the formulary.

Revise and produce new editions. As therapeutic practices change and amendments are made to the national list of essential medicines, these must be reflected in the formulary manual, along with proposed revisions submitted by users. When a sufficient number of revisions has been received and accepted, the development process must be repeated to produce a new edition. Producing new editions regularly is important for maintaining the usefulness and credibility of the formulary.

Between editions, new information can be disseminated through circulars or drug bulletins. Prior to the production of a second edition, readers' opinions on the general usefulness, design, and layout of the manual may be sought through a survey.

Practical issues in formulary manual development

In developing a formulary manual, consideration needs to be given to such issues as sequencing, presentation of the information, which information to include, ease of use, inclusion of brand-name drugs (see Figure 17-1), and pricing choices.

Sequence of drug monographs. Structuring drug information by therapeutic class is often preferred to alphabetical order. This format places each medicine in its therapeutic context and helps minimize duplicate listing of medicines. The therapeutic classification of the national list of essential medicines (Chapter 16) should be used. If the manual is organized by therapeutic class, each new section (by therapeutic class) could begin with applicable STGs (for example, guidelines for antiretroviral therapy at the beginning of the listings for the antiretroviral therapeutic class).

Presentation of drug information. Information on drugs can be presented in text or tables. Tables are useful if the information is brief and aid comparisons among medicines. When information is relatively extensive, however, text is more appropriate.

Information on medicines not on the national list of essential medicines. Should information be included on medicines that are not recommended but are used in some settings or that complement medicines on the list? Alternatively, information on these medicines can be provided through a drug information circular or drug bulletin,

Figure 17-1 Sample page from *WHO Model Formulary, 2008*

2. Analgesics, antipyretics, NSAIDs, DMARDs
Codeine
<i>Tablet: 30 mg (phosphate)</i>
Drug subject to international control under the Single Convention on Narcotic Drugs (1961).
Uses: mild to moderate pain; diarrhea (section 17.5.3).
Contraindications: respiratory depression, obstructive airways disease, acute asthma attack; where risk of paralytic ileus.
Precautions: renal impairment (Appendix 4) and hepatic impairment (Appendix 5); dependence; pregnancy (Appendix 2) and breastfeeding (Appendix 3); overdose: section 4.2; interactions: Appendix 1.
Dose: Mild to moderate pain, by mouth, ADULT, 30–60 mg every 4 hours when necessary; maximum, 240 mg daily; CHILD, 1–12 years, 0.5–1 mg/kg every 4–6 hours when needed; maximum, 240 mg daily.
Adverse effects: constipation particularly troublesome in long-term use; dizziness, nausea, vomiting; difficulty with micturition; ureteric or biliary spasm; dry mouth, headaches, sweating, facial flushing; in therapeutic doses, codeine is much less liable than morphine to produce tolerance, dependence, euphoria, sedation, or other adverse effects.

NSAIDs = nonsteroidal anti-inflammatory medicines; DMARDs = disease-modifying antirheumatic drugs.

as well as through training of prescribers. Including private-sector medicines that are not on the national list of essential medicines makes the formulary manual more comprehensive and of interest to a wider audience. However, inclusion of these medicines means that many more monographs must be prepared, making the publication much larger and not easily produced in portable form. And including information that is not relevant to the public sector may induce an unwanted demand for items that are not on the national list of essential medicines.

Size of the publication. A formulary manual may be pocket size for day-to-day use or a larger, desktop reference for occasional use. If used daily, durability is a key consideration. Size is determined primarily by intended use. If the focus is on individual drugs, the formulary is probably most useful as a desktop reference. If the focus is more comparative and evaluative, with information on indications, dosages, and cost—including medicines of first choice—it should probably be pocket size. A loose-leaf edition is not recommended, because with this format, pages tend to disappear and updates are not always properly inserted.

Ease of use. Consideration should be given to promote fast and easy access to the information in the manual, for example by using color-coded pages for each section, edge indexes, and headers. A quick reference listing of commonly used topics can be included on the back cover.

Inclusion of brand-name drugs. Although the drug monographs should always appear under the generic name of the drug, listing common brand names may be useful. If these names are included, they should appear in italics, both in the main text and in the index, so that they are easily identifiable. This method enables prescribers who are

not yet familiar with generic names to locate the required monograph easily. Cross-references are helpful.

Provision of national formularies free of charge. The production of a formulary manual is time-consuming and costly, and recovering some of these costs may be necessary. It may be possible to provide the formulary free to public-sector health workers and students and to charge the full price to users in the private sector. Ideally, the formulary manual should be distributed without charge to everyone in the target audience.

Hospital formularies

In many countries, especially those with highly developed health systems, hospitals develop their own formulary manuals. The advantage is that the formulary can be tailored to fit the particular requirements of the hospital and to reflect departmental consensus on first-choice treatments from the national list of essential medicines. In many countries, national STGs are in place, which can be used as a starting point when developing a hospital formulary list or local STGs.

The process is similar to that previously discussed. A hospital formulary committee is given responsibility for producing and subsequently revising the formulary list and manual. Additional information presented in hospital formulary manuals may include details of recommended hospital procedures, hospital antibiotic policy, and guidelines for laboratory investigations and patient management. Hospital formularies usually reflect consensus on the treatment of first choice and thus are not always distinct from treatment guidelines.

17.4 Production and distribution issues

Production issues for treatment guidelines and formulary manuals are similar. In addition to the information in Section 17-3, the following practical advice is useful for producing local reference manuals. The Malawi Essential Drugs Programme documented its experience in a WHO document that includes useful tips and descriptions of how problems were solved (WHO/DAP 1994).

It is important to define a standard style for chapters, tables, and monographs before requesting outside experts to write sections of a publication (treatment guidelines or formulary manual). If standards are not set, large differences in approach, level of detail, and style (for example, for headings, abbreviations, and use of bullets) can be expected. Correcting those differences at a later stage is cumbersome, time-consuming, and expensive. It is a good idea to include one or two examples and a few sample pages along with instructions to the writers. When the manual is ready to be printed, the page proofs should be checked very carefully. A typographical error in a dosage, for example, could be fatal.

The manual can be designed using an in-house computer and word-processing program or contracted out to a graphic designer and printing company. In estimating the number of copies required, consider whether the target audience is likely to increase in the time between editions. The number of copies required is commonly underestimated. Because increasing the number of copies is usually relatively cheap, including an extra margin of at least 10 to 20 percent is recommended.

A clear, systematic, and realistic distribution plan should be drawn up before the manual is printed. Apart from government mail, distribution may be carried out through workshops, professional associations, or sales, or by adding the manuals to regular pharmaceutical supply deliveries. The use of advanced technology in developing countries will affect how health care providers access information such as STGs and formularies (see [Chapter 50](#)). More and more formularies and guidelines are being made available online, especially those related to HIV/AIDS (for example, in Brazil, India, Namibia, Nepal). In addition, personal digital assistants (PDAs) and smart phones, which are gaining popularity in developed and developing countries, are another platform for medicine information; the *British National Formulary* is available in PDA format, and the *WHO Model Formulary* will also be PDA-accessible. The U.S. Guideline Clearinghouse has a list of guidelines that are downloadable to a PDA (www.guideline.gov). Whatever distribution method is chosen, the introduction and distribution costs should be included in the budget. A procedure should be set up to monitor distribution and to handle requests for additional printed copies.

17.5 Implementing and maintaining treatment guidelines and formulary manuals

The most common failure in implementing treatment guidelines and national formularies is a lack of credibility and acceptance, caused by failure to involve a wide range of national experts and established training institutions in their production. The greater stakeholders' involvement in the development process, the more likely they are to accept, use, and defend the outcome. Therefore, it is important to involve health workers at various levels, including rural health care and training institutions, in both the development and the review process. A broad range of opinions on the proposed content and format of a first edition and subsequent revisions should be solicited.

After the treatment guidelines manual or formulary manual has been developed and distributed, work is still required to ensure its acceptance and widespread use. Which interventions are the most effective to maximize usage in the health care community will vary depending on the local environment; however, studies show that all interventions should include paper-based or computerized reminders (Grimshaw et al. 2004). The quality of the materials also contributes to their acceptance. A common mistake with treatment guidelines is the selection of medications that are too sophisticated, too expensive, or not generally available at the relevant level of health care. However, acceptance can be improved by ensuring that medicine availability matches the guidelines, by using the materials for teaching and examination at all levels of training, and by using the manual to set standards for drug utilization review. If possible, free copies should be made available to all health workers and all types of students (nursing, pharmacy, paramedical, and medical) and the material should be officially adopted in training institutions. Finally, treatment guidelines and formulary manuals need to be publicized, so health care professionals know they are available (see [Country Study 17-3](#)).

The following are important elements for a plan to implement standard treatments—

- Printed reference materials
- Official launch
- Initial training
- Reinforcement training
- Monitoring
- Supervision

Printed reference materials may include manuals, posters, and training materials. Depending on the number of treatments involved, printed references may be in the form of wall charts, pocket handbooks, or larger, “shelf-size” reference books.

Country Study 17-3**Availability and knowledge of HIV/AIDS-related treatment guidelines in Rwanda**

The Rwandan government has developed standard treatment guidelines for a number of illnesses, including HIV/AIDS, tuberculosis, and malaria. However, health providers at different levels of care do not necessarily have copies of the guidelines on hand—and indeed may not even know they exist. A 2003 survey focused on the availability of various Rwandan HIV/AIDS guidelines, including those for antiretroviral therapy (ART), opportunistic infections (OIs), sexually transmitted infections (STIs), and voluntary counseling and testing (VCT). Of the forty-nine public and mission facilities surveyed, staff at less than one-third knew that these documents existed,

with awareness being highest at referral facilities and lowest at district pharmacies (see table below).

Despite the government's efforts to develop a variety of guidelines to help health care providers mitigate the effects of the HIV/AIDS epidemic, stronger efforts are needed to improve awareness, demand, and distribution of STGs throughout the health care sector. To support correct usage of the HIV/AIDS guidelines, the survey authors' recommendation was that all staff involved in HIV/AIDS patient management, including pharmacists and pharmacy staff, receive training.

Availability of HIV/AIDS-related documents in public and mission health facilities

Document	All facilities (n = 49)	Level of care			
		Referral hospital	District pharmacy	District hospital	Health center
Awareness of existence of documents	27%	67%	21%	29%	23%
Guidelines for ART, adult and child	10%	67%	0%	6%	15%
Guidelines for ART and monitoring	18%	100%	0%	12%	31%
Guidelines for prescription of ARV drugs	16%	67%	0%	24%	15%
Guidelines for clinical management of HIV/AIDS patients	11%	100%	0%	6%	15%
Guidelines for medical management of HIV/AIDS, including OI	24%	67%	7%	24%	38%
Standard operating procedure for OIs	27%	67%	7%	29%	38%
Guidelines for STIs	57%	67%	29%	65%	85%
Correct manual for corresponding level of care	8%	33%	7%	0%	15%
Guidelines for VCT	39%	67%	7%	59%	46%
Guidelines for home-based care of HIV/AIDS	4%	33%	0%	0%	8%

Source: Lijdsman et al. 2004.

After the materials are distributed, a careful introduction campaign is needed to promote their general acceptance and use. This campaign may include the official launch of the publication by an upper-level official, press reviews, introductory workshops in key educational institutions, articles in drug information circulars and drug bulletins, or a competition for the design of the cover or formulary logo. The cost of such a campaign should be included in the planning.

To maintain formularies and STGs, regularly scheduled meetings must be established and attended by expert committee members who are responsible for updates. The committee reviews and evaluates the latest evidence regarding treatment of diseases and conditions as well as therapeutic drug classes, and considers which medicines should be added to or deleted from the formulary list. A monitoring and evaluation system that tracks treatment failure can

also inform this updating process (see [Box 17-2](#)). Any new medicines offering an advantage over the current selections should be considered for addition, and medicines that are no longer used or for which there is insufficient evidence of efficacy, safety, or quality should be recommended for deletion. Although the task of regularly maintaining STGs and formularies is time-consuming, it is critical.

As with the list of essential medicines ([Chapter 16](#)), the credibility and acceptability of the treatment guidelines and formulary manual can be maintained only if a transparent process for reviewing and updating them is in place. Especially for treatment guidelines, a second edition will be needed soon after the first. Mistakes will undoubtedly have occurred that need correction, and comments and proposals for change are bound to be received from people who may not have taken the trouble to comment on the first draft. ■

ASSESSMENT GUIDE

Management structure

- Is there a national committee responsible for managing the formulary process?
- Are there drugs and therapeutics committees in major hospitals?

Outcome of the formulary process

- Is there a national therapeutic guide with standardized treatments? When was the last update?
- Is there a national formulary manual with basic drug information? When was the last update?
- Are the treatment guidelines and formulary manual consistent with the national list of essential medicines?
- Do the treatment guidelines cover common problems such as acute respiratory tract infections, diarrheal diseases, sexually transmitted infections, tuberculosis, leprosy, hypertension, diabetes, and epilepsy?

Use of treatment guidelines and formulary manual

- Is there a national drug policy statement to encourage the use of the treatment guidelines and formulary manual?
- Are the treatment guidelines and formulary manual used for basic and in-service training of health personnel?
- What percentage of public-sector health facilities has a copy of the treatment guidelines and/or formulary manual?
- What percentage of prescriptions in public-sector health facilities complies with the treatment guidelines?
- Is a process in place to ensure that treatment guidelines and formulary manuals are periodically evaluated and updated?

SUMMARY

This chapter focuses primarily on best practices for health systems that manage procurement in-house. An effective procurement process seeks to ensure the availability of the right medicines in the right quantities, at reasonable prices, and at recognized standards of quality. Pharmaceuticals may be acquired through purchase, donation, or manufacture.

The procurement cycle involves the following steps—

- Mobilize procurement team and key players
- Review medicine selections
- Specify quality standards
- Determine quantities needed
- Reconcile needs and funds
- Choose procurement method
- Locate and select suppliers
- Specify contract terms
- Monitor order status
- Receive and check medicines
- Make payment
- Distribute medicines
- Collect consumption information

The major procurement methods used by health systems are open tender, restricted tender, competitive negotiation, and direct procurement, which vary with respect to their effect on price, delivery times, and workload of the procurement office. In recent years, some public-sector procurement systems (particularly in Latin America) have introduced e-procurement (Internet tendering) and more specifically the “reverse auction” approach, although these methods have not been widely used to procure pharmaceuticals. Funding sources (governments and donors) often dictate which procurement method to use. Finally, some developing-country health systems purchase medicines and health commodities directly from international procurement agents, many of which are based in Europe.

Key principles of good pharmaceutical procurement for health systems include—

- Reliable payment and good financial management
- Procurement by generic name
- Clear specification of a recognized pharmaceutical quality standard

- Limitation of procurement to the essential medicines list
- Increasing procurement volume by aggregating demand
- Formal supplier qualification and monitoring
- Competitive procurement
- Monopsony commitment
- Order quantities based on reliable estimate of forecasted actual need
- Transparency and written procedures
- Separation of key functions
- Product quality assurance program
- Annual audit with published results
- Regular reporting of procurement performance indicators

As described in [Chapter 8](#), different systems for managing supply chains for public health systems include the central stores system, autonomous supply agency system, direct delivery system, primary distributor system, private pharmacy system, or often a mix of these systems. All involve pharmaceutical procurement.

Procurement may proceed under different purchasing models—annual purchasing, scheduled purchasing, or perpetual purchasing. Different combinations of these models may be used at different levels of the system or for different medicines.

Effective procurement is a mechanism for managing the buyer-seller relationship to ensure transparent and ethical transactions that result in the buyer receiving the correct goods and the seller receiving timely payment. A collaborative process is needed between the procurement office, with requirements for trained staff and appropriate management systems, and technical and policy committees, which may make final decisions as to which medicines to buy, in what quantities, and from which suppliers.

Key considerations for financial sustainability include reliable access to funds for pharmaceutical purchase and support of the procurement office, access to foreign currency exchange for international procurement, and reliable payment mechanisms.

18.1 Introduction

The pharmaceutical procurement system is a major determinant of pharmaceutical availability and total pharmaceutical costs. In most developing countries, pharmaceutical purchases represent the single largest health expenditure after personnel costs. Pharmaceuticals also consume the major share of health-related foreign currency exchange.

An effective procurement process should—

- Seek to manage the buyer-seller relationship in a transparent and ethical manner
- Procure the right medicines in the right quantities
- Obtain the lowest practical purchase price
- Ensure that all pharmaceuticals procured meet recognized standards of quality
- Arrange timely delivery to avoid shortages and stock-outs
- Ensure supplier reliability with respect to service and quality
- Set the purchasing schedule, formulas for order quantities, and safety stock levels to achieve the lowest total cost of purchasing at each level of the system
- Achieve these objectives in the most efficient manner possible

Given the impact of procurement activities on the operation and effectiveness of health services, it is essential that these activities be performed by competent staff using sound procedures, working in adequate offices with good communications, and with access to reliable inventory and consumption information. Good procurement management also demands medical, pharmaceutical, managerial, financial, and often political expertise.

Some developing countries have relatively successful public-sector procurement programs, but in many countries, pharmaceutical procurement continues to be less successful, in spite of extensive reform efforts and substantial financial assistance from aid agencies.

When a health system sets up a centrally managed pharmaceutical procurement program, it is, in effect, developing a form of a pooled procurement system serving health regions, districts, and individual health facilities. The purchases may be financed centrally through government allocations or donor contributions, in a decentralized way through medicines fees, or through some combination of financing alternatives. Procurement may be managed through any of several organizational arrangements described in [Chapter 8](#) and discussed later in this chapter.

Over the last twenty years, formal pooled procurement programs have become common in some industrialized countries (known in the United States as group purchasing organizations), and the factors that make them successful are known. Regional approaches to multicountry pooled

procurement have had mixed results, although there are some long-standing regional programs that have achieved some successes. At the global level, United Nations agencies such as UNICEF, United Nations Population Fund, and United Nations Development Programme have long functioned as pooled procurement systems serving their country programs. In recent years, a number of new global procurement mechanisms have emerged, such as the Stop TB Global Drug Facility, the U.S. President's Plan for Emergency AIDS Relief (PEPFAR)–funded Supply Chain Management System (SCMS), and the Global Fund to Fight AIDS, Tuberculosis and Malaria's voluntary pooled procurement system.

Although the procurement chapters in this manual are written primarily with public-sector procurement programs in mind, the principles and procedures can be applied to either public or private procurement at any level, from a rural aid post to a national health program. The details of procurement at various levels may be slightly different, but the basic steps are the same.

18.2 The procurement cycle

The procurement cycle includes most of the decisions and actions that determine the specific medicine quantities obtained, prices paid, and quality of medicines received.

Procurement is defined here as the process of purchasing supplies directly from national or multinational private or public suppliers; purchasing through global agencies and procurement mechanisms or regional procurement systems; or purchasing from international procurement agents. These sources may be used individually or in combination to meet the entire range of pharmaceutical needs.

Steps in the procurement cycle are illustrated in [Figure 18-1](#) and discussed in [Chapters 9–15](#) and [18–21](#).

18.3 Factors influencing pharmaceutical prices and total costs

Given the limited budgets of virtually all health programs, pharmaceutical procurement costs must be a concern of all policy makers, senior officials, essential medicines program managers, and procurement staff. Pharmaceutical procurement costs include several different components; some costs are obvious and some are not.

Unit prices

What determines the tender price of a container of 1,000 amoxicilline tablets or ten ampoules of adrenaline? There are many considerations involved in pharmaceutical pricing by manufacturers and distributors, and many factors that

Figure 18-1 Procurement cycle

cause prices to vary from country to country. A fundamental principle is that increasing competition among suppliers and products usually decreases pharmaceutical prices.

Several factors influence competition and pricing in any pharmaceutical market. One issue is how many different drug products and different generic versions of the same product are on the market. The “rule of five” in pharmaceutical pricing says that in general the lowest competitive prices are available when five or more generic alternatives for a particular product are available or when, in a tender, there are at least five bids per item (WHO 1999).

These factors can be influenced by government policies on registration, licensing for manufacturing and distribution, authority to prescribe and dispense, generic substitution, and price control. In some markets, even sole-source suppliers may offer discount pricing to the public sector that is not necessarily related to purchase volume to establish or maintain market share or to negotiate with international development entities. As discussed in Section 18.4, the type of procurement method used greatly influences how much competition there is among potential suppliers. The strategies and issues discussed in Section 18.5 also directly or indirectly influence the degree of competition and the degree of discount pricing available to the health system.

Reorder frequency and the total cost of purchasing

Pharmaceutical acquisition prices are only one part of the total cost of pharmaceutical purchasing; the other important components are the costs associated with holding inventory, the costs of operating the purchasing system, and the extra costs incurred when stockouts occur (shortage costs).

Although procurement offices typically concern themselves mainly with pharmaceutical acquisition costs, the other cost components may increase the total purchasing cost by 50 percent or more of the acquisition costs. For each country’s situation, total purchasing costs can be minimized by choosing the optimal reorder frequency model, as defined by the—

- Interval between orders—options include annual (one order per year), scheduled (periodic orders, for example, every three months), and perpetual (orders placed whenever stock falls to a specified level)
- Safety stock targets, which vary according to supplier lead times, patterns of consumption, and service-level objectives
- Formula used for calculating the order quantity, which may be a fixed or variable quantity

The choice of reorder frequency models is discussed in [Chapter 23](#); these are not always simple decisions. Systems minimize costs by striking the right balance between the various elements—less frequent ordering decreases pro-

urement process costs, but increases stock-holding costs. The reorder frequency model may differ from one level of the supply system to another or from one type or class of drug product to another. For example, consider a supply system with a central medical store (CMS) and several regional warehouses that serve hospitals and major health centers, which then distribute to primary care facilities. The CMS might purchase most items through annual tender; however, most countries can achieve lower total costs by purchasing at least some items more frequently. The regional stores might order from the CMS on a quarterly basis for most items. The health centers and hospitals might order most items monthly, with a weekly supplemental order, and so forth.

The reorder frequency influences the types of procurement methods and purchasing contracts that can be used (see Section 18.4). However, this works both ways; individual country circumstances (typically storage conditions and space availability) or laws and funding regulations, especially from donors, may dictate one sort of procurement method or contract, which then limits the options for choosing the reorder frequency. For example, if only fixed-quantity tenders are allowable under local laws, implementing a perpetual purchasing model will be difficult. If all pharmaceuticals are imported and average lead times are six to nine months, avoiding an annual purchasing system for most items will be a challenge.

The systems and formulas used to estimate needs and define order quantities vary with the purchasing model and with the availability of information on past consumption. The procedures for estimating annual procurement needs are discussed in [Chapter 20](#); with scheduled or perpetual purchasing, order quantity can usually be determined by one of the formulas from [Chapter 23](#). However, some situations may require the use of a procedure such as morbidity-based forecasting to estimate needs for procurement ([Chapter 20](#)).

[Chapter 40](#) presents total cost analysis as a method for compiling and analyzing the total costs of inventory management: pharmaceutical acquisition, inventory holding, purchasing operations, and shortage costs. Total cost analysis examines stable and variable costs for potential savings and helps managers evaluate potential changes in supply chain structure, and in procurement and distribution policy and procedure, in terms of the likely impact on total operating costs.

Visible and hidden costs

As discussed above, the total procurement cost has four components—pharmaceutical acquisition prices, inventory-holding costs, purchasing operations costs, and shortage costs. Some of these costs are easily visible to managers—the total expenditures for pharmaceutical acquisition or the

salaries of procurement staff. However, the costs associated with shortages and poor supplier performance are not so obvious; hidden costs associated with poor performance by the supplier or the procurement office include—

- Increased acquisition costs due to emergency procurement, such as when a vital medicine is ordered too late or usage exceeds estimates or the supplier fails to deliver on time
- Replacement costs when goods are lost or must be discarded because of poor packaging, improper shipping conditions, rapid spoilage, or short shelf life
- Replacement costs for short shipments, incorrect concentrations of liquid preparations, wrong dosage forms, and so on
- Storage, port charges, and administrative expenses due to inefficient clearing procedures or lack of funds or proper documentation
- Health and economic costs of stockouts resulting from delay or default on delivery

The potential impact of hidden costs on the total cost is illustrated in [Figure 18-2](#). In this example, supplier A has quoted a lower price, but additional expenses resulting from poor performance ultimately raise the total cost above that quoted by supplier B. In a competitive tender, a large number of suppliers with varying technical and commercial backgrounds may submit bids, and their quoted prices will vary considerably. Because no cost adjustments for performance are permitted to be considered during the tender assessment process, once tender bidding has begun, the prequalification of suppliers based on past performance can help minimize the impact of hidden costs.

Many of the hidden costs mentioned above can be minimized through careful procurement practices, such as avoiding last-minute orders due to a lack of planning; however, other hidden costs are imposed or regulated by the government, which may be more difficult for the procurement office to work around. [Country Study 18-1](#) shows examples of hidden costs of medicines that are controlled through national pharmaceutical policy. See also [Chapter 9](#) on pharmaceutical pricing.

18.4 Overview of procurement methods

There are numerous mechanisms by which governments, nongovernmental organizations (NGOs), and other organizations manage their in-house procurement of pharmaceuticals. Pharmaceutical procurement methods, at any level of a health system, generally fall into a few basic categories: open tender; restricted tender; competitive negotiation, including international or local shopping; and direct procurement. Each of these methods can be used with any of the standard

Figure 18-2 Impact of hidden cost on total cost

reorder frequency models—annual, scheduled, or perpetual review—given the right sort of procurement contract.

Open tender: Open tendering is a formal procedure by which quotes are invited from any supplier's representative on a local or worldwide basis, subject to the terms and conditions specified in the tender invitation. International competitive bidding, as specified in World Bank (2000; 2004b) guidelines, is a tender open to all interested international manufacturers from World Bank member countries.

Restricted tender: In a restricted tender, interested suppliers must be approved in advance, often through a formal prequalification process that considers adherence to good manufacturing practices, past supply performance, financial viability, and related factors. The prequalification process is often open to any supplier that wishes to apply.

E-procurement and reverse auction: E-procurement is Internet-based tendering. In the reverse auction approach (which is a variation of restricted tenders), qualified bidders submit an initial offer; the lowest offer received is posted publicly without naming the bidder after the first round; and then qualified bidders are invited to offer lower prices than that posted low price. The process continues round-by-round until no more prices are submitted; then the lowest posted bid wins the contract. This approach has rarely been used for pharmaceutical procurement (with most experience in Latin America); however, it may gain traction as global Internet capacity and use increase. Pharmaceutical qual-

ity assurance requirements and related factors may limit the use of this model, at least in its current form.

Competitive negotiation: In competitive negotiation, the buyer approaches a limited number of selected suppliers (typically at least three) for price quotations. Buyers may also bargain with these suppliers to achieve specific price or service arrangements. This procurement method is used primarily in the private sector, because public-sector procurement organizations are generally forbidden from negotiating or bargaining with suppliers. For example, global organizations such as UNICEF, the Clinton Foundation, and SCMS have successfully negotiated reduced prices of antiretroviral (ARV) medicines with manufacturers.

International or local shopping: As with competitive negotiation, in international or local shopping, the buyer obtains at least three quotes from suppliers; however, bargaining or negotiation of any kind are generally not permitted.

Direct procurement: The simplest, but usually most expensive, method of procurement is direct purchase from a single supplier, either at the quoted list price or at a negotiated standard discount off the list price. For single-source medicines (generally those under patent

with no licensing agreements that allow other firms to manufacture the medicine), the buyer basically has three choices—negotiated procurement, direct procurement, or selection of an alternative drug product.

International open tenders usually attract the largest number of competitive offers and potentially the lowest prices. International tenders for pharmaceuticals are limited to primary manufacturers and commercial suppliers or to international procurement agencies.

Virtually all professionally managed pharmaceutical procurement offices (that is, international procurement agencies and successful government pharmaceutical procurement units) purchase most large-volume items by either restricted tender or competitive negotiation from a limited list of reliable suppliers, such as private companies and global procurement mechanisms such as SCMS, the Global Fund's voluntary pooled procurement, or UNICEF.

Some procurement offices use a combination of methods: open or restricted tender for large-volume items, and competitive negotiation or direct procurement for lower-volume or emergency supplies.

In many country situations it may not be feasible or cost-effective to satisfy demand for medicines and obtain

Country Study 18-1

Hidden costs in the procurement process: Examples from nine countries

Understanding the many component costs related to procuring medicines is an important step in reducing overall costs. Improving procurement practices can help decrease hidden costs, but many costs result from government policies. In a study of the hidden costs of essential medicines, information on such government-

influenced tariffs and charges was collected from the literature and through personal communication. The table below shows the extensive variation and potential impact that these types of costs can have on prices of essential medicines—which may be passed along to patients.

Source: Adapted from Levison and Laing 2003.

Hidden cost	Percentage added to prices of essential medicines								
	Sri Lanka	Kenya	Tanzania	South Africa	Brazil	Armenia	Kosovo	Nepal	Mauritius
Import tariff	0	0	10		11.7	0	1	4	5
Port charges	4	8	1				4		
Clearance and freight		1	2					1.5	5
Preshipment inspection		2.75	1.2						
Pharmacy board fee			2						
Importer's margins	25						15	10

Retail	16.25	20	50	50	22	25	25	16	27
Total markup	63.97	54.22	74.3	74.05	82.38	87.5	73.64	48.08	59.26

Country Study 18-2**Pooled procurement through the Organisation of Eastern Caribbean States/ Pharmaceutical Procurement Service**

The Pharmaceutical Procurement Service (PPS) (originally known as the Eastern Caribbean Drug Service) was established in 1986, with U.S. Agency for International Development (USAID) support, to manage the procurement process on behalf of member countries of the Organisation of Eastern Caribbean States (OECS).

Before the OECS/PPS, the pharmaceutical supply systems of OECS member countries were beset with problems: disorganized procurement and management functions and poorly trained staff contributed to chronic medicine shortages in health facilities. Because of fiscal constraints, countries were slow to make payments to suppliers and incurred large surcharges. The pharmaceutical prices paid by OECS states ranged 30 percent or more above those paid by other countries of the Caribbean, such as Barbados.

Design of the OECS/PPS procurement program incorporated a number of key features—

Selective list: Procurement under OECS/PPS is based on the *Eastern Caribbean Regional Drug Formulary and Therapeutics Manual*, compiled from individual country medicine lists representing large-volume items for which demand is consistently high. The OECS/PPS procures approximately 80 percent of public-sector pharmaceuticals and medical supplies. Country-level purchasing officers may purchase nontender items independently.

Pooled quantities: Each year, the nine participating countries project their expected purchases of formulary items and forward these estimates to OECS/PPS, where management and technical staff review them. The individual projections are then aggregated into a single tender list.

Competitive bidding: Suppliers are prequalified for the OECS/PPS restricted tenders. Prequalification is based on submission of a vendor registration form and reference checks with international agencies and procurement agencies that are listed as references. A single contract award is made for each tendered product to a primary and a secondary supplier. Unless quality or performance issues are a concern, the lowest tender price receives the primary award. Tenders are not split.

Supplier monitoring and quality assurance: The performance of all contract suppliers (lead times, partial shipments, quality problems) is monitored and reviewed annually to determine which suppliers should continue as registered participants. OECS/PPS solicits oral and written reports from member countries concerning potential product problems and follows up with testing at the Caribbean Regional Drug Testing Laboratory.

Variable purchase quantities by group members: OECS/PPS estimates of purchase volume are not binding on individual countries or on OECS/PPS, and no

competitive pricing entirely through locally managed procurement. There are global as well as some regional procurement sources that can be accessed to augment, or if needed, to replace locally managed procurement for a selected set of products.

At the global level, United Nations agencies such as UNICEF have long operated pooled procurement systems primarily serving their own country programs. In recent years, several other global pooled procurement mechanisms have emerged along with the large increase in funding for procurement through financing mechanisms such as the Global Fund, UNITAID, and PEPFAR. Moreover, a number of nonprofit procurement agencies serve as suppliers to public and NGO health systems in developing countries; while these are not pooled procurement mechanisms per se, they do offer relatively small-scale purchasers access to “global” pricing.

Generally, three types of these global procurement mechanisms exist—

Integrated “local-to-global” supply chain systems: These mechanisms work directly with countries to coordinate demand and manage tenders and competitive negotiations to establish best prices; manage global freight and logistics systems to coordinate distribution; and operate in-house product quality assurance programs. The best known such mechanism is probably the UNICEF system. In addition, SCMS now provides HIV-related commodities and services to countries that receive PEPFAR funding.

Donor-supported global procurement agencies: Examples include the Stop TB/WHO Global Drug Facility, which purchases and distributes both first-line and second-line TB medicines, and the Global Fund’s voluntary pooled procurement mechanism, which purchases and delivers medicines and other health commodities to Global Fund principal recipients.

Nonprofit procurement agencies: These agencies purchase and distribute medicines and other health commodities

fixed procurement quantity or delivery schedule exists. All OECS member states are charged the same contract price, regardless of volume, for the duration of the contract period. All tender prices are CIF (cost, insurance, and freight) direct to the member country.

Monopsony commitment: Member countries are required to purchase items listed in OECS/PPS contracts solely through the PPS system, from contracted suppliers. OECS/PPS monitors this requirement annually.

Reliable payment mechanism: Payments to suppliers are managed by the Eastern Caribbean Central Bank (ECCB), where each participating country maintains a special revolving drug account. Suppliers are paid directly by the ECCB from the purchasing country's drug account, and the individual countries reimburse their accounts when they receive their shipments. An important element in PPS's initial success in pooling procurement was its ability to pay suppliers promptly in foreign exchange within sixty days of receipt in country. However, in recent years, some OECS countries have been slow to reimburse their country drug accounts, resulting in suppliers withholding shipments to both the late and the on-time payers. An additional consequence has been the dwindling number of suppliers competing in the tendering process, which can discourage the lowest prices in competitive bidding.

Thirteen-percent fee to group members: With each order, an administrative fee of 13 percent of the payment amount is made by ECCB to the PPS account. (The fee was originally 15 percent.) This fee covers all PPS operating expenses; no additional budget allocations have been required. OECS/PPS became financially self-supporting in 1989.

The results of the OECS/PPS procurement program have been extremely positive. After initial success with pharmaceuticals, the PPS has expanded its list of tendered products to include medical supplies, contraceptives, and x-ray consumables. It includes 700 items—about 70 percent of them pharmaceuticals. Participating countries benefited from an average 44 percent reduction in acquisition price for tender products in the first OECS/PPS tender cycle (1987–88) and an average of 37 percent between 1998 and 2002. Between 1997 and 2006, the value of annual purchases increased by more than 100 percent.

The main challenges include late payments by member countries, the opposition and influence of suppliers, countries making purchases outside of the cartel, managing donations, poor forecasting, and small purchase orders.

Sources: Burnett 2003; WHO 2007.

to public sector and NGO health systems in developing countries. Such agencies are often, but not always donor financed. Examples include Action Medeor, IDA Foundation, MissionPharma, and Trimed.

Regional multicountry pooled procurement has been attempted over the years in different parts of the world, but has rarely proven sustainable. However, some regional systems have achieved successes over time, including the Pooled Procurement Service (PPS) of the Organisation of Eastern Caribbean States (OECS), the Gulf Cooperation Council group purchasing program, and the Pan American Health Organization (PAHO) regional programs for purchasing vaccines and ARVs.

Undoubtedly, the primary consideration in developing a pooled procurement system is political commitment; without it, the system will never succeed. But even with political commitment, several aspects of procurement need to be harmonized for successful implementation of multicountry pooled procurement mechanisms. They include laws, regulations, and operational processes related to—

- Medicines regulation and registration of products
- Procurement processes and local preference issues

- Financial mechanisms and payment to vendors
- Standard currency

The difficulty in harmonizing these processes should not be discounted, and some issues also affect global pooled procurement mechanisms. For example, the lack of harmonization among national registration requirements often limits the capacity of a global pooled procurement system to establish supply contracts that will serve all target countries, because the best-value supplier may not have registered its products in all of the countries. Over the years, regional groups, such as the Association of Southeast Asian Nations and the Pan American Network for Drug Regulatory Harmonization have worked to formalize pharmaceutical harmonization initiatives, often focused on pharmaceutical registration, and sometimes on procurement policies and regulations (see [Country Study 18-2](#)).

Four models of procurement collaboration include informed buying, coordinated informed buying, group contracting, and central contracting and purchasing (MSH/CPM 2002). Regional pooled procurement does not have to start with a full-fledged pooled procurement system. The first step might be simple information sharing between national or subnational procurement agencies. If

Country Study 18-3**Assessing regional collaboration of procurement activities to increase access to HIV/AIDS medicines and commodities in sub-Saharan Africa**

Sub-Saharan Africa faces challenges in increasing access to high-quality, affordable pharmaceuticals for treating people living with HIV/AIDS. Even when antiretroviral treatment is available, its effectiveness is undermined by lack of access to a constant and uninterrupted supply of antiretroviral medicines. Groups of countries in different parts of the developing world have had success in pooling their resources to more efficiently procure essential medicines and supplies. Regional collaboration for the procurement of HIV/AIDS-related pharmaceuticals and commodities was proposed as a way to increase access to these products in the fourteen countries belonging to the Commonwealth Regional Health Community (CRHC) of East, Central, and Southern Africa.

Regional collaboration for procurement

Collaborative procurement covers a range of options, from simple information sharing to pooling of resources, combined with contracting and purchasing by an agency acting on behalf of a group of facilities, health systems, or countries. The four models of collaboration assessed are informed buying, coordinated informed buying, group contracting, and central contracting.

Information sharing		Pooled procurement	
Informed buying	Coordinated informed buying	Group contracting	Central contracting and purchasing
Member countries share information about prices and suppliers.	Member countries undertake joint market research, share supplier performance information, and monitor prices.	Member countries jointly negotiate prices and select suppliers. Member countries agree to purchase from selected suppliers.	Member countries jointly conduct tenders and awards contracts through an organization acting on their behalf.
Countries conduct procurement individually.	Countries conduct procurement individually.	Countries conduct purchasing individually.	Central buying unit manages the purchase on behalf of countries.

all the requirements to sustain an effective and efficient formal pooled procurement system can be met, the group can progress to pooling resources combined with joint contracting and purchasing carried out by an agency acting on behalf of a group of facilities, health systems, or countries. [Country Study 18-3](#) summarizes an assessment of countries in sub-Saharan Africa that was done to determine if a regional collaboration model for procurement was feasible.

In many countries, laws and government regulations or the funding sources (that is, donors) dictate the procurement method to be used, often based on the value of the goods being purchased. [Chapter 21](#) focuses on the tender process and compares the most common procurement methods.

18.5 Good pharmaceutical procurement practices

Pharmaceutical procurement practices vary widely from country to country. However, decades of experience with essential medicines programs and many more years of experience with large government-run pharmaceutical supply

services in a number of countries, as well as with regional and global pooled procurement schemes, have suggested a number of key principles, which [Box 18-1](#) summarizes. These practices are applicable to individual procurement agencies as well as to pooled procurement systems serving multiple health systems.

Reliable payment and good financial management

Prompt, reliable payment of suppliers has the single greatest influence on bringing down pharmaceutical prices and keeping those prices as low as possible (see [Country Study 18-2](#)), but this area often receives inadequate attention. Given greater needs and limited resources, donors and funding agencies are increasingly disbursing funds more readily to health programs with a history of strong financial management, and in some cases, *only* to countries that have strong financial management records.

Financial mechanisms such as decentralized, dedicated pharmaceutical purchasing accounts may allow the procurement cycle to operate independently from the treasury cycle. Revolving pharmaceutical funds can help achieve this separation by establishing their own bank accounts and their own working capital.

Assessment

The Rational Pharmaceutical Management (RPM) Plus Program of Management Sciences for Health administered a questionnaire to assess the structure of public-sector pharmaceutical management to support pooled procurement in eleven CRHC member states: Kenya, Lesotho, Malawi, Mauritius, Mozambique, Seychelles, Swaziland, Tanzania, Uganda, Zambia, and Zimbabwe. Before this study, no standardized approach had been used to guide groups of countries in selecting the best model for collaboration. The methodology identifies favorable conditions that point a group of countries toward a particular model, based on the group's characteristics.

Assessment results

The assessment results showed that three countries—Lesotho, Tanzania, and Zimbabwe—representing 27 percent of countries studied, appeared ready to initiate coordinated informed buying. This method of collabo-

ration for procurement requires dedicated human resources and a budget to conduct market research on pharmaceutical suppliers. A number of countries do not currently have the needed resources, resulting in the small proportion of countries ready to start this mode of collaboration.

Coordinated informed buying strategy

- Creating a mechanism for the collection, analysis, storage, and dissemination of information on HIV/AIDS-related pharmaceuticals and commodities
- Creating awareness of coordinated informed buying among decision makers and other relevant bodies
- Developing capacity within member states to conduct informed buying-related market research
- Setting up and operating a coordinated informed buying system within the CRHC member states
- Monitoring program execution

Source: MSH/RPM Plus 2004.

Readiness of countries to undertake coordinated informed buying

Efficient financial management systems are especially important if funds are limited and procurement priorities must be closely managed. Being able to order pharmaceuticals when needed and to pay for them on time reduces both prices and stockouts.

Procurement by generic name (International Nonproprietary Name)

Procurement by generic name—formally known as the International Nonproprietary Name (INN)—has become the standard for purchasing pharmaceuticals that are available from multiple companies. Brand-name suppliers may compete, but their bids should be by generic name; they may offer lower prices for certain medicines than generic competitors, because they wish to keep their public-sector market share. Perhaps the most impressive achievement in recent years is the dramatic reduction in worldwide prices of ARVs, which has led to a surge in patients who can receive

life-saving treatment. This price reduction has largely been driven by procurement of generics, which has been well documented (Holmes et al. 2010). All pharmaceuticals supplied to the health system should be labeled with the INN featured prominently, in addition to any brand name that may be on the label. For more information on INNs see <http://www.who.int/medicines/services/inn/en>.

Procurement limited to essential medicines list or formulary list

Virtually no health program can afford to purchase all pharmaceuticals available on the market. A limited medicine list or formulary, defining which medicines will be purchased, is one of the most effective ways to control procurement costs. It simplifies other supply management activities and reduces inventory-holding costs as well (see [Chapter 23](#)).

The first step is to avoid generic duplication; after this, two main options exist for reducing the procurement list. The

Box 18-1**Good pharmaceutical procurement principles****Reliable payment and good financial management**

- Develop mechanisms for prompt, reliable payment, which might bring down pharmaceutical prices more than bulk discounts.
- Establish financial mechanisms with separate pharmaceutical accounts (for example, revolving drug funds) to allow the procurement cycle to operate on a separate schedule from the treasury cycle.

Procurement by generic name

- Use generic names (International Nonproprietary Names) for fair competition.
- Specify quality standards, not specific brands, for medicines with bioavailability problems.

Procurement limited to essential medicines list or formulary list

- Select safe, effective, cost-effective medicines.
- Use formal approval procedures for procurement of nonlisted medicines.

Procurement in large volume

- Concentrate purchases on limited list to increase quantities, reduce price.
- Specify divided deliveries

Formal supplier qualification and monitoring

- Use formal supplier qualification based on pharmaceutical quality, service reliability, and financial viability.
- Approve suppliers before tendering (prequalification) or after (postqualification).
- Use a formal monitoring system to ensure continued supplier qualification.

Competitive procurement

- Use competitive bidding on all but very small or emergency purchases to obtain the best prices.
- Allow only prequalified suppliers to compete in restrictive tenders.
- Evaluate suppliers after submission of bids in open tenders.

Monopsony commitment

- Procure all contracted pharmaceuticals from winning supplier.

- Enter into no separate deals with noncontracted suppliers.

Order quantities based on reliable estimate of actual need

- Develop reliable consumption records and morbidity data.
- Adjust systematically for past surpluses, shortages, stockouts.
- Adjust for expected program growth and changing disease patterns.

Transparency and written procedures

- Develop and follow written procedures for all procurement actions.
- Make information on the tender process and results public to the maximum extent possible.

Separation of key functions

- Separate key functions that require different expertise.
- Functions that involve different committees, units, or individuals may include selection, quantification, approval of suppliers, and award of contracts.

Product quality assurance program

- Establish and maintain a formal system for product quality assurance.
- Include quality assurance product certification, inspection of shipments, targeted laboratory testing, and reporting of suspect products.

Annual financial audit with published results

- Conduct an annual financial audit to assess compliance with procurement procedures, promptness of payment, and related factors.
- Present results to the appropriate public supervising body.

Regular reporting on procurement performance

- Report key procurement performance indicators against targets at least annually.
- Use key indicators such as ratio of prices to world market prices, supplier lead times, percentage of purchases made through competitive tendering, and planned versus actual purchases.

first combines the standard formulary process (Chapter 16) with therapeutic category analysis (Chapter 40). For example, a program that regularly purchases cimetidine, famotidine, and ranitidine (all therapeutically similar anti-ulcer medicines) might save substantial sums by restricting the formulary to one of these medicines and combining the estimated purchase volume into a single, much larger quantity of the selected medicine.

The second approach takes formulary selection and therapeutic category analysis one step further through competitive tender within a selected therapeutic subcategory (Chapter 40). The medicine selection committee determines which subcategories are appropriate for category-based tendering and which medicines in those subcategories are acceptable equivalents. The tender request specifies only the therapeutic category rather than individual drug products. This strategy has been used for several years in some purchasing groups in the United States and in the OECS and is similar to strategies used in Europe for establishing reimbursement prices.

Any change from one therapeutically similar product to another should be carefully considered, particularly for medicines used in chronic treatment; patients using these medicines need to be monitored during the changeover, which can generate significant costs for care and treatment.

Efforts to limit the medicine list by reducing therapeutic duplications will meet resistance both from pharmaceutical suppliers whose products are removed from the procurement list and from some doctors and some patients who prefer a wider range of choices. Suppliers may issue dire public warnings of adverse impact on public health and patient care if their pharmaceuticals are not purchased. The health system needs to be prepared to counter these claims with carefully designed information campaigns.

Resistance from doctors can often be overcome by documenting the cost savings possible with the restricted procurement list and pointing out the benefits of year-round access to the limited list rather than sporadic access to a larger list of medicines.

Increasing procurement volume by aggregating demand

One of the essential characteristics of pooled procurement is pooling the relatively small demand for a product from each health unit to create a single larger procurement volume for that product. Increasing the total procurement volume for any product increases the likelihood of favorable prices and contract terms as long as there is sufficient competition in the market. Moreover, increasing procurement volume typically increases the number of potentially interested suppliers who wish to win the business, and increases the loyalty and responsiveness of suppliers who win contracts. When the market is tight for a particular product or set of prod-

ucts and available supplies are not adequate to meet global demand, the larger purchasers typically get first preference from suppliers.

However, simply increasing procurement volume may not necessarily assure low prices; one recent analysis of global pricing of ARVs did not correlate volume and price for nineteen of twenty-four dosage forms (Waning et al. 2009), and a study of e-procurement reverse auctions (although not pharmaceutical procurement) also could not link product volume with reduced pricing (Shalev and Asbjornsen 2010). However, in most circumstances, when procuring generically available medications with multiple suppliers, greater procurement volume will attract more competitive offers.

At the national or subnational levels, pooling procurement volume from many facilities or from several states or countries, restricting the medicine list, and eliminating duplication within therapeutic categories lead to higher volumes for single items. In addition, the commitment to awarding a single contract for the entire volume of each item raises suppliers' interest in bidding and provides an incentive for them to offer their most competitive prices.

A contract award to a single supplier does not mean that the entire volume must be shipped at once. Many procurement services specify divided deliveries over the period of the contract as part of the contract terms, sometimes to multiple delivery points. As discussed in Chapter 21, many supply systems use estimated quantity tenders, with orders placed throughout the contract period as needed, using either a scheduled or perpetual purchasing model (see Chapter 23). These strategies allow optimal use of available storage and transport capacity, reduce inventory-holding costs, and ease cash flow constraints.

The potential pricing benefits from a single-supplier award must be compared to the risks to commodity security in the event of unforeseen events (supplier failure, war/civil unrest, industrial disruption, weather events, and other instances of force majeure). In some cases, especially for critical medicines, a risk analysis calls for a secondary supply source. Moreover, when the volume of procurement for individual items represents a significant percentage of the total market for those items, it may be wiser to split contract awards or negotiated contracts among multiple suppliers to preserve future competition and to assure the availability of reliable supply sources if the primary contractor is unable to perform.

Formal supplier qualification and monitoring

All suppliers should be qualified through a process that considers product quality, service reliability and delivery time, and financial viability. The process for evaluating new suppliers can include formal registration, reference checks with past clients and international agencies, test purchases

in small quantities, and informal local information gathering (see [Chapter 21](#)). The global procurement mechanisms such as SCMS and Global Fund voluntary pooled procurement may insist that suppliers and their products either be registered by a “stringent regulatory authority” or approved by the WHO prequalification system ([Chapter 19](#)).

Although both prequalification (qualifying suppliers before the tender process) and postqualification (qualifying suppliers after bids have been received) have been used in international pharmaceutical procurement, increasingly, health systems and the donors that finance procurement prefer prequalification. In a postqualification system, the procurement office evaluates the suppliers after it receives the bids. Once the tenders are opened, the time window to evaluate and award a contract is limited, which can lead to rushing through the postqualification process. Qualifying suppliers before the tender submission allows enough time for a thorough evaluation. And by first eliminating substandard suppliers from the tender process, prequalification results in a more efficient process by automatically qualifying the lowest-priced bidder.

No matter which supplier qualification model the health system uses, the procurement office needs to make vigorous efforts to assure that purchases come only from suppliers that are known to provide quality products.

Successful procurement operations ensure continued good performance by suppliers through a formal monitoring system that tracks lead time, compliance with contract-pricing terms, partial shipments, remaining shelf life, compliance with packaging and labeling instructions, and compliance with other contract terms. A data file for each supplier, which may be electronic or manual or a combination, should have copies of registration papers, references, special correspondence, complaints, and other anecdotal information. The information system should track the number and value of tender contracts awarded chronologically and the value of total purchases from the supplier by year.

Procurement programs using restricted tenders should make special efforts to seek out potential new suppliers at least every two to three years to maintain competitive pressure on established suppliers.

Competitive procurement

As discussed in Section 18.4, the main methods for purchasing pharmaceuticals are restricted and open tenders, competitive negotiations, and direct purchase from a single-source supplier. Supplier competition is key to favorable pricing, and most modern procurement regulations require competitive procurement in the public sector; therefore, if the needed products have multiple suppliers, then public-sector programs should use competitive bidding for all but very small or emergency purchases. This would not be required when purchasing through a regional or global

pooled procurement mechanism because the global or regional procurement office would manage competition.

Monopsony and pooled procurement

A monopsony refers to a situation involving one buyer with many sellers. This is the cornerstone of a pooled procurement system—the group members act as one buyer.

Maintenance of the procurement monopsony will be most feasible when there is strong political will or when all members of the procurement group are voluntarily and enthusiastically participating. Perhaps the single most important factor in the twenty-five-year survival of the multicountry pooled procurement system serving the OECS has been political will and commitment of member governments, although maintaining the monopsony remains a challenge that they must address constantly (see [Country Study 18-2](#)).

A review of the two other successful regional pooled procurement programs—the Gulf Cooperation Council and PAHO’s vaccine and ARV programs—identified voluntary commitment as a critical factor of their success (DeRoeck et al. 2006). Each program has some flexibility. In the PAHO system, countries choose to participate or not on a yearly basis, and in the Gulf Cooperation Council system, countries are allowed to purchase up to 40 percent of their vaccines outside of the system. But the major point is that once members have committed to purchase a certain percentage or quantity, they are expected to honor that commitment.

On the other hand, the lack of political will to sustain the monopsony commitment is one reason the CARICOM (Caribbean Community) purchasing program for the public sector was unsuccessful in the early 1980s, and it was a major factor in the failure of the FORMED system, which was tried in Central America in the 1990s.

The monopsony commitment should be monitored and enforced. Frequently, local, regional, or multinational suppliers will offer low prices on a short-term basis to individual group members in an attempt to break the purchasing group. A transitory small benefit to one critical group member will adversely affect all other group members, so they must resist these offers; otherwise, suppliers will lose interest in the pooled procurement tenders, the group will fail, and prices overall will rise. Decentralization in some countries has complicated the procurement issue by providing budget funds to lower levels of the health system, to procure their own pharmaceuticals, in addition to the centrally allocated procurement budget. This leads health facilities to purchase from more expensive, but in some cases, more reliable private-sector sources, which leaves the central procurement system with a severe financial shortage because of lost procurement volume (MOH Uganda 2008).

Order quantities based on reliable estimate of actual need

Accurate estimates of procurement volume are needed to avoid stockouts of some pharmaceuticals and overstocks of others in the case of guaranteed quantity contracts. In addition, suppliers are most apt to compete for an estimated-quantity supply contract if they believe that the quantities specified are reasonably accurate.

The most reliable way to quantify future pharmaceutical demand is to start with accurate past-consumption data from all units being supplied, assuming the supply pipeline has been consistently full. These data should be tempered by known or expected changes in morbidity patterns, seasonal factors, service levels, formulary changes or changes to prescribing patterns, and patient attendance. Unfortunately, in many countries, past consumption data are incomplete or do not reflect real need because the supply pipeline has never been full. In such cases, the morbidity-based and adjusted consumption techniques discussed in [Chapter 20](#) may be needed to estimate procurement demand.

Expert technical assistance in quantification may be useful in initial phases of the procurement program, with local officials participating to gain an understanding of the methodology, particularly when applying the morbidity or adjusted consumption methods.

When funds are not available to purchase all the pharmaceuticals listed in estimates, reducing the list according to health system resources is required. The following three tools, discussed in more detail in [Chapter 40](#), can help with prioritization—

VEN (vital, essential, nonessential) analysis classifies medicines in two or three categories, according to how critical the medicines are for treating commonly encountered diseases. Priority is given to vital medicines.

Therapeutic category analysis applies economic analysis of therapeutic choices to help select the best medicines for treating common diseases while minimizing overall cost to the health system.

ABC analysis assembles data from recent or projected procurements to determine where procurement money has actually been spent, allowing managers to focus first on high-cost and high-use items when considering ways to reduce procurement costs.

Transparency and written procedures

The appearance and reality of open and fair competition are essential to attract the best suppliers and the best prices. Fair competition can be achieved by maintaining transparent tender procedures: formal written procedures should be strictly followed throughout the tender, and formal, explicit criteria should be used to make procurement decisions.

Broad-based committees should have the sole authority to make contract awards. Information on the tender process and results should be public, to the extent permitted by law and regulation. At a minimum, both bidders and health units should have access to information on the suppliers and the prices for all winning contracts.

When the pharmaceutical tender process is secretive, it tends to be perceived as corrupt or unfair. There may be charges of cronyism. Whether true or not, such charges are damaging in that suppliers, health care providers, and patients lose confidence in the system. Unsuccessful suppliers may feel that they have no chance to win and consequently withdraw from future tenders or submit only token bids. As the pool of potential suppliers decreases to a small set, price competition decreases and procurement prices will be much higher than necessary.

Advocates for increasing the use of e-procurement systems, and particularly e-procurement-mediated reverse auctions, cite transparency and the potential for reduced tender management costs as primary benefits; however, as noted, their effectiveness in widespread application for pooled procurement of pharmaceuticals remains to be seen. One study of public e-procurement in Chile (including all products, not just pharmaceuticals) did not try to compare relative transparency of e-procurement compared with other methods, but it did show a minimal decrease of less than a half of 1 percent in administrative costs when compared with standard methods and less than 3 percent savings through overall price reductions (Singer et al. 2009).

Separation of key functions

There are several key procurement functions, which typically require different expertise. In general, these functions should be handled by different individuals, units, committees, or subcommittees. Such functions include—

- Selection of medicines
- Quantification of pharmaceutical requirements
- Preparation of product specifications and quality standards
- Approval of suppliers (prequalification or post-qualification)
- Adjudication
- Award of tender

Without appropriate separation of functions, the procurement process is much more susceptible to influence by special interests. Suppliers or procurement personnel may be able to bias medicine selection, manipulate orders to increase the quantities of certain medicines, prejudice supplier qualification decisions, manipulate the final award of tender, and slant product specifications to limit competition, for example, by selecting less common dosage forms.

Separation of key functions contributes to professionalism and accountability. Section 18.6 describes ways in which a procurement system can be organized to separate these functions.

Product quality assurance program

An effective procurement program must ensure that the medicines purchased and distributed are of the specified quality, according to specified standards, which are clear and recognized. [Chapter 19](#) discusses three categories of procedures to establish an effective quality assurance system—

- Ensuring that only medicine products that meet current standards for quality are bought
- Verifying that shipped goods meet the specifications
- Monitoring and maintaining the quality of pharmaceuticals from the moment they are received until the medicine is finally consumed by the patient

When managing pharmaceutical procurement by generic name and introducing new suppliers whose products are not familiar in the country, the procurement program must be particularly alert to product quality issues.

Some products vary substantially in formulation and bio-availability from supplier to supplier. When this difference is therapeutically significant, purchasers should be cautious about making changes in supplier from year to year, and particularly in accepting unknown suppliers.

Even when new products are completely equivalent in content and effect, changes in dosage form can be problematic, requiring patient and provider re-education. For medicines used primarily in chronic therapy, changes should only be made to effect a significant cost savings.

Annual audit with published results

At least once a year, the procurement unit should undergo a financial and procurement audit, which is a formal examination and verification of books and records by accountants who specialize in financial audit procedures. *Internal audits* are conducted by auditors from within the government (for the public sector) or the organization managing the health system (for the nonpublic sector). *External audits* are conducted by auditors from outside the managing organization and are generally considered less potentially biased and therefore more credible, even if the process and findings are the same.

The annual external or statutory audit, conducted by a registered or licensed auditor, should include tests to ensure that the organization's assets are safeguarded and accounted for, that the systems of internal controls and procedures are adequate to account for all the organization's income and expenditures, and that the organization is complying with its constitution, rules and regulations, and management.

This includes compliance with procurement procedures, promptness of payment, and inventory control.

The auditor should issue a statutory audit report in accordance with legal regulations of the jurisdiction and, in addition, should issue a detailed letter of comment to the management of the organization and to the appropriate public supervisory body.

Regular reporting on procurement performance

Using standard *indicators* to monitor performance and program implementation (see [Chapters 36](#) and [48](#)) significantly improves pharmaceutical management. Standard indicators allow comparison of actual performance with targets, over time and among countries. Some indicators use a standard list of ten to twenty *indicator medicines*, which are also called tracer medicines or a market basket of medicines ([Chapter 48](#)).

The procurement office should be required to report on key procurement performance indicators at least annually. The Assessment Guide at the end of this chapter suggests some procurement indicators. Indicators such as average supplier lead time and percentage of key medicines in stock should be used to assess performance on a continuing basis. These indicators should not be limited to the public sector but can be used by all organizations including faith-based pharmaceutical services, NGOs, and private health institutions seeking to control their pharmaceutical costs and improve their performance. [Figure 18-3](#) provides actual indicator data from several countries.

18.6 Organization and management of the procurement and distribution functions

One important policy issue facing senior managers is how to structure the procurement program and supply chain system and how to divide the responsibilities. [Chapter 8](#) describes five different supply chain systems currently being used by governments to supply pharmaceuticals to their health services—

Central stores system: Conventional CMS approach, in which pharmaceuticals are procured and distributed by a centralized government unit.

Autonomous supply agency system: Bulk procurement, storage, and distribution managed by an autonomous or semi-autonomous supply agency, *not* directly managed by the government (although government is often part of the agency's governing board).

Direct delivery system: A “non-CMS” approach, in which tenders establish prices and suppliers for each essential medicine, which is delivered directly by suppliers to individual districts and major facilities.

Figure 18-3 Comparison of two procurement indicator results for six countries

Sources: CPM 2003a, 2003b, 2003c, 2003d, 2003e, 2003f.

Primary distributor system (also known as prime vendor system): contract for pharmaceutical pricing is negotiated with suppliers, and a separate contract is negotiated with one or more primary distributors, who warehouse and distribute pharmaceuticals to districts and major health facilities.

Primarily private supply: Public-sector patients obtain pharmaceutical services from private pharmacies. Government may or may not reimburse the cost of those services, and may also set maximum reimbursable prices including a dispensing fee, minus any co-payments. Reimbursement may go directly to the pharmacy-based on claims submitted, or to the patient (meaning that the patient pays the pharmacy and submits a reimbursement claim).

The important point to a public health system in adapting these alternative supply chain models is to retain the advantages of pooled procurement to the extent feasible. Generally, two common variations exist on managing the

purchasing transactions in pooled procurement programs. In both, a single agency manages tenders and contract negotiations on behalf of the group. Then, in a centralized purchasing model the central office also manages the purchasing transactions on behalf of group members, while in a decentralized purchasing model the group members purchase individually from the suppliers who hold the contracts that were centrally negotiated. (See [Country Studies 18-2](#) and [18-3](#) for examples of group purchasing systems.)

Centralized management of both the purchasing and contracting functions offers some potential advantages—

- Economies of scale reduce the cost of managing procurement offices.
- Sustaining an effective program is easier with only one procurement unit to staff and manage.
- A single procurement list for a large group of facilities increases volume, promotes reduced prices, and improves market presence, which leads to better supply security and quality.

18.18 PROCUREMENT

- Better-managed systems of finance and payment may encourage suppliers to compete for contracts and to perform well.

A centralized purchasing system also has potential drawbacks—

- If it does not function well, all group members suffer: although the prices may be theoretically better than with individual members doing the purchasing, the system may not be as responsive and may not provide the medicines needed in time to provide continuous care to patients.
- Without significant input from the participating facilities, centralized purchasing services will likely not meet users' needs very well.
- If the central agency has substantial corruption, the program will never function effectively.

Pharmaceutical purchasing and distribution systems have traditionally been heavily centralized in many developing countries, with little management input from lower levels. Many of these countries are now decentralizing procurement to the regional, state, or even local facility level, either by choice or because the central system has collapsed.

However, decentralized procurement management has proved challenging in many countries. Problems encountered include significantly higher prices (if the decentralized managers select their own suppliers), potential product quality issues, irrational purchasing patterns based on the whims of prescribers or local procurement offices, and overall erratic supply because of local inefficiencies, lack of access to funds, or poor management.

Supervision by senior management

Without political commitment to efficiency and active supervision by senior management, the procurement system will not function efficiently, regardless of its organization. The lack of modern financial management, accounting systems, and supervisory responsibility has doomed many pharmaceutical systems to chronic failure.

To manage the pharmaceutical supply chain, senior managers should demand and use regular reports from procurement and distribution agencies and from health facilities on expenditures, purchases, stock levels, order status, lead times, and budget status. If a system lacks the capacity to produce these reports in a timely manner, introduction of the tools to provide them should be top priority. Senior managers should also maintain regular communications with facilities and staff; systems do not work very well if the senior managers have never visited any facilities outside the capital.

Many operations-level procurement managers have not had formal management training and may fail to appreciate the importance of setting such realistic and quantifiable procurement objectives as—

- Acquiring quality supplies at the best possible price
- Ensuring prompt and dependable delivery
- Following procedures that are transparent and not influenced by special interests
- Maintaining a procurement pattern that produces an even workload and constant supply to clients
- Achieving efficiency through use of appropriate systems and procedures
- Limiting total procurement operating costs
- Ensuring that revenue is adequate to support the office, and that finances are managed effectively
- Filling key positions with well-trained and motivated staff
- Maintaining effective working relationships with senior management and with clients

Senior management is responsible for assuring that these considerations are properly addressed and particularly for enforcing transparency and equity in the purchasing process.

Responsibilities in the procurement process

Effective procurement is a collaborative process between the procurement office, which manages many of the steps, and technical and policy committees, which should usually make the decisions about which medicines to buy, in what quantities, and from which suppliers. In a complex setting such as a procurement program at the national level, the following division of responsibilities may be appropriate.

Procurement office. The procurement office, which may be part of the government or independent, collates information on medicine needs, develops a proposed procurement list based on clients' requirements, manages the tendering process, manages and arranges supply contracts unless there is a separate tender board, and monitors performance of suppliers and of clients.

Staff of the procurement office should not have the sole deciding voice in determining which products are purchased and which suppliers receive contracts; these decisions should be made by committees that include representatives from other administrative sections or stakeholders, including client facilities. This separation of powers helps ensure broad ownership of the system and avoids conflicts of interest. If the procurement office is independently operated, it is important that its operations be supervised by a board of directors that includes senior health-policy makers.

Tender board. In many countries, tendering and contract negotiation are done according to law by a government tender board, which either reports to the finance ministry or is independent of any ministry. In such situations, the procurement office prepares the list of requirements, and the tender board may monitor the tender process. The prime task of the tender board is to make the award decision; in some cases, this will be an absolute decision, while in others, the tender board will make recommendations to health officials. Whichever system is followed, it is essential that the health system provide technical input into the contract award decision.

Medicine selection committee. Often the same as the formulary committee or pharmacy and therapeutics committee, the medicine selection committee should comprise knowledgeable practitioners and other health professionals who evaluate competing drug products in various therapeutic categories and select products that are most essential to the health system. A senior physician frequently chairs the committee, and a pharmacist generally serves as organizing secretary. The committee reviews requests for additions to the procurement list, compares the cost effectiveness of medicines on the list, and recommends which medicines to purchase, and when necessary, which medicines to delete. The committee also determines which therapeutic categories, if any, are suitable for open tender by therapeutic class. The committee needs access to current, unbiased drug information and members who can synthesize such information to make appropriate selection decisions.

Procurement/tender committee. Whether or not a government tender board is in charge of tendering, the health system should establish a procurement committee to make final decisions or to make the recommendations for such decisions to the tender board on medicine selection, procurement quantity, and supplier selection, and approve the exact specifications for product description, packaging and labeling, and quality assurance standards. The committee should base those decisions on recommendations from technical committees and subcommittees. It reviews information on suppliers and determines which should participate in tenders, if a restricted tender is used, and which suppliers should receive contracts, unless such decisions are made by a separate tender board. The procurement committee should include senior officials from the highest level of government served by the procurement system as well as officials from user facilities. For example, a federal government program that serves teaching hospitals and regional health systems might include two or three representatives of the ministry of health, two or three regional representatives, and one or two teaching hospital representatives.

In some countries, separate subcommittees develop product specifications and investigate suppliers' qualification for participation in tenders.

Procurement office staffing and management systems

The structure of the procurement office depends on the scope of the program, the availability of funds, and whether the office is managed as a government entity or as an independent agency.

Staffing requirements. In general, the procurement office needs a director, an assistant director, and experienced technical staff members, with at least one pharmacist or physician to provide sound technical input for the development and refinement of procurement lists.

Accounting and finance officers are needed to manage the accounts and in some systems manage payment to suppliers. Automated offices need data processors and at least one information technology professional. Also needed are one or more clerical managers, one or more secretaries or clerks, a receptionist or telephone operator, maintenance staff, and, in some systems, a driver and security staff.

Staff in key procurement and distribution positions must be well trained and highly motivated, with the capability to manage the procurement process effectively. Unfortunately, in many countries, people are transferred just as they become competent in a position, and a new cycle of training and time lag between appointment and competence must begin again.

Salaries for procurement staff. When procurement office salaries are too low to support an individual or a family, or much lower than for equivalent work in the private sector, corrupt practices and neglect of duties are much more likely to occur. These kinds of problems increase funding requirements to replace the resulting theft and waste. Paying reasonable salaries in the first place and implementing tough controls is more cost-effective.

In some countries, restructuring the procurement office as an independent parastatal or privatized unit may be the only way to pay adequate salaries to staff.

Communications and market information. To succeed in the international market, procurement programs need two sorts of critical information: comparative price and availability data on products in the national and international pharmaceutical market and information about suppliers' capacity, reliability, and quality. Health system procurement agencies without access to price information or to the performance record of international suppliers operate in a vacuum and are essentially at the mercy of the marketplace.

Access to information depends on communications capacity. An Internet and e-mail connection and

GOOD COMMUNICATION IS ESSENTIAL TO THE PROCUREMENT PROCESS

external telephone line are essential in modern procurement, even if all procurement is done through local suppliers. For international procurement, direct access to an overseas line is mandatory. Countries have sources of comparative price information including the *International Drug Price Indicator Guide* (MSH, published annually), the annual source and price guide for HIV/AIDS medicines and commodities (WHO/UNICEF/UNAIDS/MSF 2005), the Global Fund's price and quality reporting tool (<http://www.theglobalfund.org/en/procurement/pqr/>), and other national and multicountry resources that WHO makes available on its website (<http://www.who.int/medicines/areas/access/ecofin/en/index.html>) and through its Procurement & Supply Management Toolbox (<http://www.psmtoolbox.org>). Chapter 21 discusses options for obtaining and evaluating information about pharmaceutical suppliers. A central repository of international information on worldwide supplier performance and tender pricing would be useful but has not yet proved feasible.

Tracking performance of the procurement system. A reliable management information system (MIS) is one of

the most important elements in procurement. Lack of a functioning MIS or the inability to use it appropriately is a primary cause of program failure.

The MIS must be used to track all orders placed, the number and status of shipments and receipts, compliance with contract pricing, lead time of each order, payments made by the office or by group members, performance bond status, and the results of any investigations related to product quality.

The information system should also track the performance of health system units, number of orders placed, payments made, quantities actually purchased compared with estimates, purchases from all contract suppliers, and if possible, pharmaceutical purchases from noncontract suppliers. In all but the smallest procurement systems, the MIS should be computerized.

Computerized procurement information systems depend on appropriate software (Chapter 50). Key staff must be familiar with the software, and competent data entry personnel must be available.

Procurement manuals and technical assistance. Achieving and sustaining an efficiently functioning procurement

system are complex and demanding jobs. Using written policies and procedures that spell out how the procurement process should be managed and how the procurement system should operate is critical. A comprehensive procedures manual can be time-consuming to develop, but worthwhile if actively used to orient and manage staff.

The Global Fund to Fight AIDS, Tuberculosis and Malaria publishes policy guidelines for procurement through its program (Global Fund 2009). For purchasing through World Bank–financed loans, the World Bank's *Standard Bidding Documents for Procurement of Health Sector Goods* (World Bank 2004b) and *Procurement of Health Sector Goods Technical Note* (World Bank 2000) are essential references. A recently developed procurement system assessment tool, funded by the World Bank, includes transparency indicators in its evaluation (see Country Study 36-3).

When starting a new procurement system or revamping a poorly functioning system, outside technical assistance may help local managers in design and implementation. A number of organizations offer materials and technical support to help procure pharmaceuticals and commodities; for example, WHO has procurement assistance programs specifically for medicines and supplies related to HIV/AIDS, malaria, and tuberculosis (AIDS Medicines and Diagnostics Service, Roll Back Malaria's Commodity Services, and Global TB Drug Facility). WHO also provides other types of technical assistance on procurement issues in addition to its supplier prequalification program. The U.S. Agency for International Development funds several global and local programs that provide assistance to country-level pharmaceutical procurement programs. Other bilateral agencies, such as the U.K. Department for International Development, the Danish International Development Agency, and others, fund support to focus countries and regions, and major development banks and United Nations agencies such as UNICEF and the United Nations Development Programme provide procurement support in some countries (see the Glossary and References and Further Readings sections for more information).

18.7 Financial sustainability

Procurement programs cannot function effectively when funds are chronically inadequate. Traditionally, many countries have relied totally on the public budget to support pharmaceutical procurement, with medicines provided free to both inpatients and outpatients. In some countries, pharmaceutical purchases have consumed 20 to 40 percent of the total public health budget. The reality is that few countries

have sufficient budget capability to purchase enough medicines to cover the needs of all patients, without supplementing the budget with some sort of cost recovery or donor support.

An epic occurrence in international health and development was the advent in the 2000s of global financing mechanisms such as the Global Fund, PEPFAR, and UNITAID, discussed in Chapter 14. These initiatives provide large-scale financing for countries to procure medicines and essential commodities, and in some cases, support global procurement mechanisms that make a limited range of commodities directly available to countries, such as the SCMS and Global Fund voluntary pooled procurement programs described earlier. Despite the increasing scope of these initiatives, financing issues still require the attention of health systems managers.

Sources of funds for pharmaceutical procurement

Primary sources of funds for pharmaceuticals include government financing, user fees, health insurance, community cofinancing, and donor financing. Chapter 11 describes these options in terms of their efficiency, equity, feasibility, and sustainability.

The most important considerations for procurement are regular access to and availability of funds and adequate access to foreign exchange. Government and donor funds are sometimes released irregularly throughout the financial year, and regulations often specify that funds must be spent in the year in which they are allocated or be returned to the treasury. Together, these factors may make it difficult to operate proper procurement systems and to obtain the best prices.

Strategies such as decentralized financial management and various types of revolving drug funds have been used to separate pharmaceutical procurement from the annual treasury cycle. This separation also often requires some form of cost recovery, which the decentralized mechanism manages.

Uncoupling the procurement cycle from the treasury cycle has substantial management advantages. Inventory management improves when medicines can be ordered when needed rather than at an arbitrary point in the government fiscal year. When suppliers know that orders will be placed promptly after tendering and that payment will be made according to contract terms, prices will be much more competitive.

Pharmaceutical financing issues that affect the procurement system are discussed in Chapters 9–14. These issues include the actual revenue potential of user-fee programs, equity aspects of user fees, management and accountability requirements for successful user-fee programs, the role of health insurance and other social financing mechanisms, the role of donor financing, and related issues. For donor financing, grants and loans should be clearly distinguished:

loans may be necessary to finance the start-up capital for a revolving drug fund or for a major emergency, but are an undesirable mechanism for financing the recurrent costs of supplying medicines.

Access to foreign currency exchange

Pharmaceutical procurement almost always requires the health system's largest outlay of foreign currency exchange. Shortage of foreign exchange can constrain international procurement and be a country's rationale for seeking donor support for pharmaceutical purchases. In situations where foreign exchange is constrained, procurement and pharmaceutical management systems should be as efficient as possible, so that they make the best use of local supply sources of products meeting established quality standards and obtain the best possible prices in international procurement. Sound documentation of actual needs and of economical use of funds may help justify increases in foreign currency exchange allocation from the ministry of finance or central bank. For example, in the Organisation of Eastern Caribbean States' Pharmaceutical Procurement Service, the Eastern Caribbean Central Bank handles the program's currency exchange from Eastern Caribbean dollars and pays suppliers in U.S. dollars at no charge to participating countries (Burnett 2003).

Reliable payment mechanism

As discussed earlier, sustained low pharmaceutical prices are possible only when a procurement program can guarantee prompt payment in full according to contract terms.

One example of sustainable financing is the revolving drug fund described in [Country Study 18-2](#). However, revolving drug funds work only if the political will and financial capacity exist to replenish deposits in the fund each time purchases are made. Otherwise, the fund will soon vanish. Examples are numerous: one cautionary tale comes from Central America, where a European donor provided capital for revolving funds in several countries. Within a few years, all but one of the funds were totally decapitalized. That one country continued with the program for an additional year, but it experienced periodic problems with replenishing the account after purchases were made, resulting in delays in procurement and stockouts in health facilities; eventually the system ended.

Financial support for the procurement office

Procurement services may be part of the warehouse and distribution operation or be set up as a separate procurement office. In either case, salaries and operational costs of the procurement function must be covered. For typical public procurement systems, the only existing funding source for

the procurement office is support through the government budget.

For pooled procurement programs that have a centralized procurement office that is not a formal government office, options may include—

- A periodic percentage payment to the office from group members, based on the invoice value of shipments
- A percentage payment from group members at the beginning of the procurement cycle, based on the projected value of the total procurement, or at the end of the cycle, based on the actual value of total shipments
- Payment from group members in the form of a flat annual fee, based on total expenses divided by the total number of areas and independent institutions served

The proper choice depends on the situation. The risk in tying a procurement office's reimbursement to the value of purchases by user facilities is the possible incentive for the procurement office to increase, rather than decrease, prices and total purchases. Therefore, if this approach is used, checks and balances must be put in place, such as using budget price volume instead of actual buy price or requiring that user representatives make all major procurement decisions. ■

Glossary

ABC value analysis: Method by which medicines are divided, according to their annual usage (unit cost times annual consumption), into Class A items (the 10 to 20 percent of items that account for 75 to 80 percent of the funds spent), Class B items (with intermediate usage rates), and Class C items (the vast majority of items with low individual usage, the total of which accounts for 5 to 10 percent of the funds spent). ABC analysis can be used to give priority to Class A items in procurement, inventory control, and port clearing.

Active pharmaceutical ingredient (API): That portion of a drug product that has therapeutic properties.

AIDS Medicines and Diagnostics Service (AMDS): A WHO-sponsored network to provide resources and technical assistance to countries buying pharmaceuticals and diagnostics for HIV/AIDS programs (<http://www.who.int/hiv/amds/en>).

Annual purchasing: A periodic inventory control system in which pharmaceutical requirements are determined and orders are placed once a year.

Back order: An order for a product that is currently out of stock. Back orders are filled when a new supply of the product becomes available.

Basic unit: The smallest unit in which a medicine can be conveniently dispensed or administered. It is used in quantification, reorder formulas, and comparison of prices of different-sized bottles or vials. Typical basic units are tablet or capsule, mL (for liquids), and g (for ointments and creams).

ASSESSMENT GUIDE

Procurement performance indicators

- Percentage by value of ministry of health (MOH) medicines purchased through a central procurement system
- Percentage of average international price paid for last regular procurement (indicator medicines)
- Percentage by value of MOH pharmaceutical purchases that are on the essential medicines list or national medicines formulary
- Percentage by value of MOH medicines purchased through competitive tender
- Percentage by value of medicines purchased from local manufacturers
- Average lead time for a sample of orders (calculated separately for all suppliers, local manufacturers, foreign suppliers)
- Average time for payment for a sample of orders (calculated separately for all suppliers, local manufacturers, foreign suppliers)
- Percentage of pharmaceuticals (batches) subjected to quality-control testing compared with target percentage to be tested
- Percentage of pharmaceuticals (batches) that failed quality-control testing

Procurement system procedures

- What type of system is used to supply medicines to public facilities (CMS, autonomous agency, direct delivery, primary distributor, private pharmacies)?
- What type(s) of purchasing models are used at each level of the supply system (annual, scheduled, or perpetual)?
- How are order and tender quantities determined at each level of the system?
- How are suppliers selected for tender or negotiation—does a formal qualification process exist?
- Is procurement done using generic names, brand names, or a mix?
- Are therapeutic equivalent medicines purchased through therapeutic subcategory tendering?
- How are lead times factored into ordering formulas and safety stock requirements?

- Are purchases limited to items on the formulary or essential medicines list?
- What constraints limit successful procurement in the public-sector pharmaceutical supply system?

Procurement system responsibilities

- Which agency or office is responsible for procurement of medicines and, if different, vaccines, contraceptives, diagnostics, and medical supplies?
- How are procurement responsibilities divided for medicine selection, needs estimation, tender management, and contract awards?
- Are written procedures for tenders and contract awards in place and regularly followed? Is the tender process transparent?
- What type of procurement management information system is used, and what kinds of reports are produced?
- How does the purchasing office obtain information on comparative prices and new supplier performance?
- What kinds of computers and computer applications are used to manage procurement?
- Is information available to carry out ABC, VEN, or total variable cost analyses?
- What procedures are used for monitoring supplier performance and enforcing procurement contracts?

Procurement finance

- What are the usual payment terms, payment lead times, and current debts owed to local and international suppliers?
- Does a problem exist with currency-exchange status in the public sector? If so, what impact does this situation have on pharmaceutical procurement?
- Are funds available as needed or is a fixed schedule used for the release of funds (and what approvals are needed)?
- Do cost recovery or drug revolving funds contribute significantly to procurement financing?
- To what degree is procurement financed by donors or by loans from development banks?

Batch: The quantity of a pharmaceutical produced in one production run.

Bid bond: A form of financial guarantee provided when a bid is submitted. The bond is forfeited if the successful bidder withdraws the offer or refuses to agree to the announced contract requirements.

Bulk purchasing: Procurement of pharmaceuticals in large quantities

in order to obtain lower unit prices. Generally done in a bid system in which all medicines are identified by their generic (INN) name.

Call for offers: A publicized invitation to bid. Used in tender or bid purchasing. Includes product specifications, required delivery date, closing date for submitting offers, and other requirements of participation.

- Certificate of manufacture:** A document accompanying a commercial invoice that is presented to the buyer's bank—usually one of the requirements of a letter of credit—certifying that the products have been manufactured, are ready for shipment, and are in safekeeping.
- CIF (cost, insurance, freight):** When a seller quotes CIF, the costs of goods, marine insurance, and transportation to the named destination point are included.
- Competitive negotiation:** A procurement method by which the buyer approaches a small number of selected potential sellers and bargains with them directly to achieve specific price or service arrangements (used primarily in the private sector).
- Compound:** To mix together the ingredients of a prescription or pharmaceutical formula. Generally refers to a manual process performed for individual orders by a dispenser or pharmacist.
- Consumption:** The rate at which items are issued to clients or patients. This is also called demand (which is, in strict terms, the rate of requests or orders). Consumption is usually measured in terms of units consumed within a specific period.
- Consumption-based estimate:** Prediction of future pharmaceutical requirements on the basis of historical information on pharmaceutical consumption.
- Direct procurement:** The simplest but usually most expensive method of procurement, in which an item is purchased from a single supplier at its quoted price.
- Disintegration:** The breaking up of a tablet or capsule into granules or aggregates in an aqueous fluid.
- Dissolution:** The breaking down of fine particles into molecules or ions homogeneously dispersed in an aqueous fluid.
- Estimated-quantity contract:** A supply contract for a fixed period that stipulates an estimated total quantity, with the actual total quantity determined by orders placed as needed at the contract price during the contract period.
- Excipient:** An inert substance used to give a pharmaceutical preparation a suitable form or consistency.
- Expiry date:** The date appearing on a drug product and established by the manufacturer beyond which the manufacturer will not guarantee the potency, purity, uniformity, or bioavailability of the product.
- External packaging:** The case, crate, carton, or other container in which individual packages are placed.
- FAS (free alongside ship):** Used to indicate only the cost of transporting the goods to a ship are included by the seller. Carriage and freight are specifically excluded.
- Financial guarantees:** Deposits in the form of earnest money, bid bonds, performance bonds, or retention money required of suppliers to guarantee their participation once they have submitted bids or to ensure the complete fulfillment of contractual obligations by the supplier that wins the bid.
- FOB (free on board):** Used to indicate only the cost of transporting the goods to and on board a ship are included by the seller. Carriage and freight are specifically excluded.
- Freight:** The fee charged for carrying goods. The term is also applied to the items to be carried although the correct term for them is *cargo*.
- GDF (Global Drug Facility):** An organization that currently both supplies and acts as a procurement agent for anti-tuberculosis drugs for developing countries (<http://www.stoptb.org/GDF/default.asp>).
- Global Fund to Fight AIDS, Tuberculosis and Malaria:** An international, independent public-private partnership designed to attract and manage significant funding to finance the fight against AIDS, tuberculosis, and malaria (<http://www.theglobalfund.org>).
- GMPs (good manufacturing practices):** Performance standards for pharmaceutical manufacturers established by WHO and many national governments; they include criteria for personnel, facilities, equipment, materials, manufacturing operations, labeling, packaging, quality control, and, in most cases, stability testing.
- GPP (good procurement practice):** The internationally recognized concept of using best-practice principles in procurement, marked by openness and transparency.
- Group purchasing:** Purchasing done by one procurement office on behalf of a group of facilities, health systems, or countries. Group members agree to purchase certain medicines exclusively through the group.
- Hidden costs:** Costs in addition to the contract price that are not paid to the supplier but are real costs to the supply system. These include costs associated with poor quality, late deliveries, defaults on deliveries, short packing, and other factors.
- Identity:** Presence of the correct active ingredient in a drug product.
- Immediate container (package):** The individual jar, bottle, box, blister pack, or other container in which a single group of items is packed.
- International procurement services:** Organizations such as UNICEF, IDA Foundation, SCMS, and other groups that supply medicines on a nonprofit basis.
- Inventory:** The sum of all items held in stock.
- Inventory-holding cost:** Also known as *carrying cost*. The cost of holding one unit of an item in stock for a year. It may be expressed as a monetary amount or a percentage of purchase cost. This includes capital costs, costs associated with storage space, utilities, handling costs, losses due to waste and theft, and storehouse administrative costs. These costs may be 20 to 40 percent of the purchase price for a year.
- Inventory value:** The sum of the number of units of each item on hand or in storage in the system multiplied by the current unit price of each item.
- IQC (Indefinite quantity contract):** A contract that provides for an indefinite quantity, within stated limits, of specific supplies or services to be furnished during a fixed period with deliveries to be scheduled by placing orders with the contractor.
- Issue unit:** The quantity or size of each item counted in the stock records. For example, in some supply systems, the unit for tetracycline capsules might be one bottle of 100 capsules, and in others it might be one capsule. This is not necessarily the same as the basic unit or comparison unit, although they may be the same (see [Chapter 50](#) for a discussion of units).
- Item:** A unique product for inventory purposes. In pharmaceutical supply, an important issue is whether generic equivalent items are treated as the same item or whether different brands of the same generic product are treated as different items. The item is sometimes called a stock-keeping unit (SKU), which is *not* the same as an *issue unit*.
- Lead time:** The time interval needed to complete the procurement cycle. It begins at the time the need for new stock is recognized and ends when that stock is received and available for issue.

Lead-time analysis: A systematic study of the components of lead time, aimed at discovering areas in which lead time can be reduced.

Line item: A product listed on an order or invoice. Each separate product on the document is one line item, no matter what quantity of the product is listed.

Make or buy: A management decision that involves the analysis of the cost and potential benefits of manufacturing a product rather than buying it on the open market.

Monopsony: A monopsony is a market with only one buyer. The buyer's-side analogy is a monopoly, in which there is only one seller in a market.

Open tender: The formal procedure by which quotations for the supply of pharmaceuticals under their generic names are invited from any local or international manufacturer or representative, subject to the terms and conditions specified in the tender invitation.

Opportunity cost of inventory: The cost of monies tied up in inventory. If average inventories increase, then capital invested in inventory increases proportionally. Since these funds invested in inventory could be used for other expenditures, they should be valued at current bank interest rates.

Order quantity: The amount of stock to be ordered (or that has already been ordered) via requisition or purchase order from a supplier or supply point.

Order status: The position of an order with respect to the specific tasks that must be performed for the order to be delivered to the buyer.

Payment terms: The conditions arranged between a buyer and a seller regarding the method of reimbursement. Letters of credit and commercial or deferred terms are the most common.

Performance bond: A form of financial guarantee that the supplier deposits when accepting the contract. This amount is forfeited if the supplier defaults on the contract.

Perpetual purchasing: A procurement model in which stock levels are reviewed continually, and orders are placed whenever stock levels fall below designated or calculated reorder points.

Pooled procurement: Another name for group purchasing.

Population-based estimate: Prediction of future pharmaceutical requirements based on the demographic composition of the population, disease patterns, and norms for treatment.

Port clearing: The process of locating items in port, obtaining the proper import documentation, paying the necessary fees, and inspecting the pharmaceuticals for damage during transit.

Potency: The extent to which a medicine contains the specified amount of the active ingredient.

Procurement: The process of acquiring supplies, including those obtained by purchase, donation, and manufacture.

Procurement period: The period of time between an order to a supplier and the next scheduled order.

Product file: A card or ledger file that records the technical specifications and performance of suppliers for each product.

Purchasing costs: All costs involved in placing and monitoring an order, including communication costs, the cost of preparing an order or tender and of subsequent negotiations, the staff time involved in routine checking of inventory levels, costs of receiving goods, any related special fees, and administrative costs. In practice, the cost of each order is estimated by dividing the total

annual direct and indirect costs of the purchasing department by the number of orders placed in the year.

Purity: The extent to which medicines are free from potentially harmful contaminants, significant quantities of other medicines, bacteria, or other microorganisms.

Quality assurance: The management activities required to ensure that the medicine that reaches the patient is safe, effective, and acceptable to the patient.

Quality control: The testing of medicine samples against specific standards of quality.

Quantification: Estimation of the quantities of specific medicines needed. Financial requirements for purchasing the quantities are also calculated.

Restricted tender: Procurement procedure in which participation in bidding is limited to suppliers that meet certain prerequisites or have previously registered as suppliers.

Retention money: See **Performance bond**.

Roll Back Malaria Partnership's Commodity Services: A unit to support the procurement and supply management efforts for nets, insecticides, medicines, and diagnostics. The commodity service does not procure products itself, but it publishes market data, distributes forecast information, and fosters collaboration to address bottlenecks. (<http://www.rollbackmalaria.org/psm/index.html>)

Scheduled purchasing: Procurement model in which stock levels are reviewed periodically at set times during the year and orders are placed as necessary.

Secondary manufacture: The processing of medicinal substances, usually together with excipients, to produce a pharmaceutical dose form.

Shelf life: The length of time a material may be stored without affecting its usability, safety, purity, or potency.

Shortage cost: If emergency supplies are purchased to address a stockout, any increment in purchase price is a shortage cost. This cost is more difficult to quantify than holding cost but may still be significant. Loss of customers, decreased goodwill, and decreased sales are also real shortage costs if pharmaceutical sales are involved.

Specifications: A precise description of an item to be procured, including any special requirements.

Stock: The items stored in a warehouse or facility (or health system). There are several types of stock:

Pipeline stock: Stock that is in transit at various stages of the purchasing and distribution cycles.

Quarantine stock: Stock that has been physically received in the storage facility but is held separately and not available for issue. There may be a need to confirm product quality or compliance with the contract, or the transfer to working stock might be delayed pending completion of necessary documents.

Safety stock: The buffer or minimum stock that is kept on hand to protect against stockouts. If there is no safety stock, stockouts will occur when deliveries are delayed or when there is an unexpected increase in demand. In theory, the safety stock is separate from the working stock, but in practice there is no separation of the two, and safety stock sometimes must be issued.

Seasonal stock: Stock that is acquired with the expectation that it will be needed to satisfy seasonal demand—for example, cough and cold medications in the winter. This stock is also part of the working stock once it is in the warehouse.

Vertical program stock: Stock that is not available on open request but is held for sole use by a vertical program, such as family planning or the Expanded Programme on Immunization (EPI). This stock may also be separated into working stock and safety stock.

Working stock: Stock that is on hand in the warehouse or store-room and is shipped to requesting operating units. Working stock fluctuates as orders are filled and new stock arrives.

Other stock: Stock that is not usually issued but may be needed for purposes such as shipping or repackaging. May include items such as shipping tape, boxes, and labels.

Supplier: Any individual or company that agrees to provide medications, regardless of whether that party is the manufacturer.

Supplier file: A record kept for each supplier indicating when orders were placed, when they were received, what kind of service the supplier provided, and the quality of the product provided.

Supplier reliability: The past performance of a supplier in terms of medicine and packaging quality, timeliness of delivery, and level of service provided.

Supply Chain Management System (SCMS): A U.S. government initiative to procure and distribute HIV/AIDS-related pharmaceuticals and other commodities in countries supported by PEPFAR (www.pfscm.org).

Tendering: The procedure by which competing bids are entered for a particular contract.

Trade terms: A set of standard terms to describe the buyer's and seller's responsibilities in international trade—a list is found in [Chapter 39](#).

VEN system: A system of setting priorities for purchasing pharmaceuticals and keeping stocks in which medicines are divided according to their health impact into vital, essential, and non-essential categories.

Wholesaler: A dealer who purchases supplies from a manufacturer and resells them to the ultimate buyers.

SUMMARY

The purpose of quality assurance in pharmaceutical supply systems is to help ensure that each medicine reaching a patient is safe, effective, and of acceptable quality. A comprehensive quality assurance program includes both technical and managerial activities, spanning the entire supply process from pharmaceutical selection to patient use.

Established quality standards are published periodically in pharmacopoeias and in some government publications. For the purposes of primary health care, the most important characteristics of a pharmaceutical product are identity, purity, strength, potency, uniformity of dosage form, bioavailability, and stability.

Pharmaceutical quality is affected by starting materials, manufacturing process, packaging, transportation and storage conditions, and other factors; these influences may be cumulative.

If a pharmaceutical does not meet established quality standards, passes its expiration date, or has been degraded by storage conditions, the possible consequences are—

- Lack of therapeutic effect, leading to prolonged illness or death
- Toxic and adverse reactions
- Waste of limited financial resources
- Loss of credibility of the health care delivery system

A comprehensive quality assurance program must ensure the following—

- Pharmaceuticals selected have been shown to be safe and efficacious for their intended use, are presented in an appropriate dosage form, and have the longest possible shelf life.
- Suppliers with acceptable quality standards are selected.
- Pharmaceuticals received from commercial suppliers and donors meet specified quality standards at the time of delivery.
- Packaging meets contract and usage requirements.
- Repackaging activities and dispensing practices maintain quality.
- Storage and transportation conditions do not compromise product quality.
- Product quality concerns reported by prescribers, dispensers, and consumers are properly cataloged and addressed.
- Product recall procedures are implemented to remove defective products.

A quality assurance program should include training and supervision of staff members at all levels of the supply process and a suitable information system. Often, public officials must balance the costs of establishing and maintaining quality assurance systems against the benefits of having safe and effective medicines.

19.1 Pharmaceutical quality

As in most manufacturing processes, the quality of a final pharmaceutical product is determined by the starting materials, equipment, and technical know-how that go into producing and packaging it. Unlike a steel bolt or a tailored suit, however, a medicine is a dynamic product whose color, consistency, weight, and even chemical identity can change between manufacture and ultimate consumption. A medicine that passes all laboratory tests upon receipt may be useless within a few months if the packaging, storage, and transportation conditions are not maintained properly.

The purpose of quality assurance in pharmaceutical supply systems is to help ensure that each medicine reaching a patient is safe, effective, and of appropriate quality. The quality of pharmaceutical products is ensured by the technical and managerial activities of the quality system, which includes evaluating pharmaceutical product documentation, performing or reviewing quality-control laboratory

tests, and monitoring product performance. Managerial activities include selecting reliable suppliers, preparing contract terms, monitoring supplier performance, and performing inspection procedures throughout the distribution network (Figure 19-1).

Note that quality assurance in pharmaceutical supply is not the same as quality control in manufacturing.

Pharmaceutical quality assurance framework

The following five elements are critical to achieving the expected treatment outcome. Using a pharmaceutical product to treat a patient presumes that the—

1. Active pharmaceutical ingredient (API) has been shown to be safe and effective for this treatment
2. Product is of suitable quality to provide an effective outcome
3. Prescriber has accurately identified the need for the treatment

Figure 19-1 Quality assurance framework

Source: CPM/MSH 2011.

4. Prescriber or dispenser has properly instructed the patient on how to use the product
5. Patient complies with the prescribed regimen correctly

The first two items are product-specific issues, which are the most easily addressed technically, whereas items three and four are practitioner-specific and depend on the practitioners' education, knowledge, and skill as well as the rigorous enforcement of performance standards. Item five is a patient-specific issue that depends on the patient's knowledge and commitment and the patient's access to services.

The safety and effectiveness of an API may be established either through a review of historical usage, such as in the case of digoxin's evolution from the foxglove plant (*digitalis purpurea*), or through complex procedures established for new chemical entities, such as those described by the International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use (ICH).

After the safety and effectiveness of an API has been approved for marketing in an ICH market region, other regions of the world follow with little or no additional assessment. The ICH economic zones (European Union, Japan, United States) perform almost 100 percent of the pharmaceutical research and consume over 85 percent (by value) of the pharmaceutical products in the world. These regions allocate large amounts of resources to ensure the safety and effectiveness of APIs granted market authorization in their zones. Once the safety and efficacy have been established through these procedures, other regions do not have to expend the same level of resources to establish these attributes. However, other product-quality issues, including bioavailability and bioequivalence, content uniformity, impurities and degradation, and medicine safety (pharmacovigilance), should be monitored on an ongoing basis in all market zones.

The complexity of globalized pharmaceutical markets and the difficulty in ensuring quality of imported products,

including API, have been illustrated in headlines about deaths caused by adulterated products such as cough syrup in Peru and heparin in the United States—both tied to ingredients from China. As a result, the U.S. Food and Drug Administration (FDA) seeks to increase its global presence to make monitoring foreign manufacturers easier and to strengthen its involvement with harmonization of pharmaceutical standards (FDA 2010). In addition, the FDA wants to help build regulatory capacity in foreign counterparts. As part of that international effort, the agency has opened permanent offices in a number of cities around the world and has entered into dozens of agreements with other drug regulatory authorities (DRAs) to share inspection reports and other private information that can help improve the quality of pharmaceutical products worldwide.

The pharmaceutical regulatory and quality assurance processes that should be addressed by a country's DRA include (WHO 2004b)—

- Product registration: assessing and authorizing products for market entry and monitoring their safety and effectiveness after entry
- Regulation of manufacturing, importation, and distribution
 - Quality of manufacturing (good manufacturing practices)
 - Procurement integrity (assuring the qualifications of suppliers)
 - Quality of medicines in the distribution system (including product and premises inspection and product screening and testing)
- Regulation of medicine promotion and information: including postmarketing pharmacovigilance and consumer education

Of course, a country's quality assurance system is only as effective as its ability to monitor and enforce regulations. A country should address all issues at some level as part of a basic pharmaceutical quality assurance infrastructure;

however, in a resource-constrained setting, the risks to patients for each process must be assessed so resources can be allocated to focus on the most significant health threats.

Defining and assessing pharmaceutical quality

Pharmaceutical quality can be defined and tested in many ways. Quality standards are published periodically in pharmacopoeias and in some government publications, which provide detailed descriptions of pharmaceutical characteristics and analytical techniques. Standards may vary slightly from one pharmacopoeia to another, so a particular pharmaceutical may meet the standards of one pharmacopoeia and not those of another. When public standards have not been established, as is generally the case for newly marketed pharmaceuticals, analytical methods developed by the manufacturer and submitted as a part of the tender or marketing authorization requirements are usually applied.

The major pharmaceutical manufacturing and exporting countries publish their own pharmacopoeias, and on a regional basis, the *European Pharmacopoeia* establishes standards that are enforced by the governments of the European Union and others that adopt them. The *International Pharmacopoeia*, published by the World Health Organization (WHO), the *U.S. Pharmacopoeia*, and the *British Pharmacopoeia* are used frequently by public-sector pharmaceutical supply programs in developing countries.

One important limitation of the *European Pharmacopoeia* is that it provides few specifications for individual dosage forms. The WHO *International Pharmacopoeia* (WHO 2008a) includes monographs on finished dosage forms, including antiretrovirals and newly developed antimalarial medicines. Analytical procedures in the *U.S. Pharmacopoeia* tend to use complex and expensive technology, which may be beyond the reach of many developing countries. The European, Japanese, and U.S. pharmacopoeias are engaged in ongoing efforts to harmonize some of their standards, but progress is slow. Until common standards are finally achieved, purchasers must specify which dosage form standards are acceptable.

For pharmaceutical procurement organizations, pharmaceutical quality is assessed as the product's compliance with specifications concerning identity, purity, strength, potency, and other characteristics. Uniformity of the dosage form, bioavailability, and stability are important characteristics that are also considered in the specifications.

Identity. The identity test should confirm the existence of the active ingredient(s) indicated on the label. This characteristic is generally the easiest to check.

Purity. In addition to the API, most pharmaceuticals are made with ingredients added for bulk, consistency, or color that should not contain potentially harmful contaminants or microorganisms. The product should not have significant quantities of other products from cross-contamination.

Strength or potency. The medicine should contain the declared amount of API. Harmful by-products of degradation must be absent or should be below defined limits. Most pharmacopoeias specify an average content range, such as 90 to 110 percent of the amount written on the label, rather than an exact amount. To ensure a long shelf life, manufacturers often produce pharmaceuticals with the maximum allowable amount (for example, 110 mg rather than 95 mg), which provides a margin of safety for slight losses in strength or potency over time.

Uniformity of dosage form. The consistency, color, shape, and size of tablets, capsules, creams, and liquids should not vary from one dose to the next. Any lack of uniformity may suggest problems with other quality parameters such as identity, purity, or strength or potency. Lack of dosage uniformity may not influence the safety or effectiveness of a medicine, but it does reflect a lack of good manufacturing practices, which could influence the acceptability of a product to pharmacists, medical practitioners, and patients.

Bioavailability. *Bioavailability* refers to the speed and completeness with which a pharmaceutical administered in a specific form (tablet, capsule, intramuscular injection, subcutaneous injection) enters the bloodstream. The bioavailability of a product may depend on the other ingredients used in the formulation, such as solvents, binders, coloring agents, and coatings, or how ingredients are combined.

The comparative bioavailability of two pharmaceuticals is particularly important when a product that is usually purchased from one manufacturer is replaced with a product containing the same drug substance in the same dosage form, and in the same amount, but manufactured by a different firm. Even though the products both contain the correct amount of the API, the preparations may not give the expected therapeutic result if the API is released too quickly, too slowly, or incompletely when they are compared. Two pharmaceuticals are said to be *bioequivalent* and may be used interchangeably if both are absorbed into the bloodstream at the same rate and to the same extent.

Human bioequivalence studies are required for a number of medicines. [Box 19-1](#) lists some medicines documented to have problems in bioavailability that require studies to determine the bioequivalence of products. Guidelines are available for the study of bioavailability, as well as specific bioavailability protocols for a small number of medicines (WHO/EURO 1988; USP 2007).

If purchasing is done through established and reliable suppliers, the bioavailability of most brand-name and generic medicines used in primary health care is sufficient to ensure that the patient receives the intended effect. Deciding which pharmaceuticals have a potential bioavailability problem is important, because manufacturers cannot supply clinical studies for all products, and government procurement programs generally cannot perform bioequivalence test-

Box 19-1**Some substances exhibiting potential bioavailability problems in conventional oral forms****API**

- Aminophylline
- Ampicillin
- Carbamazepine
- Chloramphenicol
- Chloroquine
- Chlorpromazine
- Digitoxin
- Digoxin
- Dihydroergotamine
- Ergotamine
- Erythromycin
- Estrogens, conjugated or esterified
- Furosemide
- Glibenclamide
- Glyceryl trinitrate
- Griseofulvin
- Hydrochlorothiazide
- Iron sulfate
- Isosorbide dinitrate
- Levodopa
- L-thyroxine
- Methotrexate
- Methyldopa
- Nitrofurantoin
- Phenytoin
- Prednisolone
- Prednisone
- Quinidine
- Rifampicin
- Spironolactone
- Theophylline
- Warfarin

ing. The Biopharmaceutical Classification System can help identify potential bioavailability problem products (Kasim et al. 2004). Where pharmaceutical registration systems exist, manufacturers or suppliers should be required to supply data on clinical studies whenever needed. Procurement agencies should also work with country DRAs and use their information in making decisions.

Stability. To be useful, a pharmaceutical must retain its properties within specified limits, such as particular storage conditions. The manufacturer and, in some cases, a country's DRA establish the time that a pharmaceutical's stability is under warranty, which ends with the expiration date. A product's stability depends on the active ingredient, which can be affected by its formulation and packaging. Improper storage and distribution can lead to physical deterioration and chemical decomposition, reduced potency, and occasionally, formation of toxic by-products of degradation. These effects are more likely to occur under tropical conditions of high temperature and humidity.

WHO has published a list of pharmaceutical substances that are less stable and therefore require particular attention (WHO 1990). However, few data are available on the stability of medicines under true field conditions. The ICH,

whose members comprise experts from the major pharmaceutical manufacturing countries, has established guidelines on quality testing and storage in tropical regions (ICH 2003). WHO has been updating its stability guidelines with input from member country DRAs and in cooperation with ICH (WHO 2010d, 2009b). Several studies have examined the stability of a small number of essential medicines under tropical conditions of excessive temperature (over 40°C), high humidity, and inappropriate storage conditions (Gammon et al. 2008; Hogerzeil et al. 1991; Hogerzeil, Walker, and de Goeje 1993). [Table 19-1](#) lists the medicines that have been found to have problems under tropical and high-temperature conditions.

Consequences of poor pharmaceutical quality

A poor-quality medicine is one that does not meet specifications. The use of poor-quality products may have undesirable clinical and economic effects, as well as affect the credibility of the health delivery system. Clinical effects can include prolonged illness or death or adverse reactions. On the economic side, limited financial resources may be wasted on poor-quality medicines.

Table 19-1 Medicines found to have stability problems under tropical or high-temperature conditions

Oral solids (tablets)	Oral liquids (syrups)	Inhalation	Injections/injectables
Acetylsalicylic acid	Paracetamol	Ipratropium	Ergometrine
Amoxicilline			Lidocaine
Ampicillin			Methylethergometrine
Diltiazem			Succinylcholine
Lopinavir/ritonavir			Naloxone
Penicillin V			
Retinol

Figure 19-2 Determinants of pharmaceutical quality

Lack of therapeutic effect may lead to prolonged illness or death. Poor pharmaceutical quality can sometimes lead to serious health consequences and death—for example, the use of poor-quality cardiac medicines and medicines for seizures and asthma. With others, such as cold remedies and minor painkillers, a reduction of up to 50 percent in the content of the active ingredient may not have serious consequences apart from ineffectiveness, although the best procurement policy requires all products to meet specifications.

Poor-quality pharmaceuticals may induce toxic or adverse reactions. When some products expire or are exposed to adverse climatic conditions (for example, excessive heat and humidity), they may undergo physical or chemical changes that can result in the formation of possibly toxic degradation products. Although fear of toxic pharmaceutical degradation in tropical climates is prevalent, tetracycline is the only common medicine in which it is known to occur. Excessive active ingredients may also lead to toxic or adverse reactions.

A much more frequent problem is contamination with microorganisms, usually bacteria or fungi. The consequences of this lack of sterility can be quite severe, particularly in the case of injectable medicines or in patients who are immunocompromised. Contamination of creams, syrups, and other medicines in jars and tubes is especially common in tropical environments, but the consequences vary, depending on the type of organism and the pharmaceutical involved. Errors in formulation and product contamination are uncommon with manufacturers who strictly comply with internationally accepted procedures and good manufacturing practices (GMPs). In practice, however, adherence to GMPs may vary from country to country, from manufacturer to manufacturer, or even between production runs at the same manufacturer. When contaminants are highly toxic or when toxic substances are inadvertently included in the product, the result can be catastrophic.

Poor pharmaceutical quality wastes money. Ineffective care or the need to treat adverse drug reactions resulting from poor product quality leads to more costly treatments. Poor pharmaceutical packaging casts doubts on product quality, leading to rejection by health personnel and patients. These products will then expire on the medical stores' shelves, wasting limited financial resources.

Poor pharmaceutical quality may seriously affect health system credibility. Patients and providers may suspect the quality of medicines when therapeutic failure or adverse drug reactions occur. Changes in product appearance, such as discoloration, crumbling of tablets, and hardening of oral suspensions, or changes in taste and smell rightly influence patients' perceptions of product quality. Patients may be discouraged from using health facilities, and worker morale may be affected, particularly if medicine shortages are also common.

Determinants of pharmaceutical quality

The quality of a medicine product coming off the production line is determined by the start-up materials, plant environment, manufacturing equipment, and technical know-how invested in developing and manufacturing the pharmaceutical. The medicine that ultimately reaches the patient, however, is further affected by packaging and by transportation and storage conditions.

These influences, especially factors in the manufacturing process, can be cumulative. For example, the excipient substances used to give tablets bulk and consistency may not affect the color, texture, or chemical quality of a pharmaceutical until the immediate container is opened in a hot, humid environment. Then, depending on the ingredients, the tablet may remain firm and dry or become moist and crumble within a matter of days. Factory humidity during packaging may also affect quality. If oral rehydration sachets are not packaged in a very low-humidity environment, moisture enters the sachet and may result in chemical or physical changes in the mixture that make it difficult to use. Similarly, the amount of grinding, thoroughness of mixing, choice of packaging, maintenance of packaging equipment, and other factors can have an effect that may not appear until the medicine reaches the point of consumption. [Figure 19-2](#) summarizes these influences.

The dynamic nature of pharmaceuticals and the cumulative effects of the production process, right through to packaging, handling, transport, and storage conditions, require quality assurance at all levels in the pharmaceutical supply system (see *A Model Quality Assurance System for Procurement Agencies* [WHO/UNICEF/UNDP/UNFP/World Bank 2007]).

Prevalence of poor-quality pharmaceuticals

Data summarized in [Table 19-2](#) indicate the extent of the pharmaceutical quality problem, as detected by pharmaceutical quality testing in the public, private, and nongovernmental organization (NGO) sectors of six countries.

In recent years, national and international authorities have recognized the emergence of counterfeit medicines as a serious problem. In most industrialized countries with effective regulatory systems and market control, the incidence of counterfeit medicines is an estimated 1 percent of market value (WHO 2010b). Therefore, most counterfeiting cases occur in developing countries—especially in Asia, where many of the counterfeit medicines are produced, and in Africa, where poverty and loose regulatory oversight make marketing of counterfeit products easier (see [Box 19-2](#)). However, counterfeiting is an increasing problem in all countries, including developed countries, where Internet purchases are popular. Over half of Internet medicine purchases from illegal websites are counterfeit (WHO 2010b).

Table 19-2 Percentage of tracer medicines that failed quality testing in the public, private, and NGO sectors

Country	Number of medicines	Number of samples	Public facilities	Private facilities	NGO facilities
Brazil (Minas Gerais)	8	64	13.6	9.1	10.0
Cambodia	14	132	13.0	9.6	7.7
El Salvador	10	87	50.0	28.6	27.3
Tanzania	10	110	12.9	13.0	0
Ghana	7	103	6.3	2.9	0
India (Rajasthan)	9	125	6.0	12.7	0

Global quality-monitoring options

Currently, no global pharmaceutical quality standards exist, even for the APIs used in worldwide pharmaceutical product formulation, which are produced by only a few countries. However, the ICH processes to establish GMPs for APIs were more inclusive than any of the previous processes; for example, besides the usual ICH parties, representatives from the generics industry, the self-medication industry, and the Pharmaceutical Inspection Convention and Pharmaceutical Inspection Co-operation Scheme were included in the deliberations (ICH 2000).

These GMP standards are the world's first harmonized standards and have been adopted by the ICH regions and the Pharmaceutical Inspection Convention and Pharmaceutical Inspection Co-operation Scheme, in addition to WHO and many other countries. This harmonization implies that any DRA could perform an inspection of an API manufacturer and expect it to conform to these consensus GMPs. However, because almost all sovereign nations or market zones protect their local production of pharmaceutical products through selective tariffs and other mechanisms, no incentive exists for the development of a worldwide quality standard for APIs (Chapter 7). Some pharmacopoeias, including the *European Pharmacopoeia* and WHO's *International Pharmacopoeia*, have regional quality standards for many APIs; however, these pharmacopoeial standards have not been harmonized, resulting in varying specifications for APIs among regions (see Chapter 6 for more information on pharmacopoeias).

Because of the lack of harmonized standards, no basis exists for a pharmaceutical product common market with universal recognition of quality standards. The dearth of internationally recognized specifications leaves each market zone to establish its own specifications. Among the major pharmacopoeias, only the *British Pharmacopoeia* and the *U.S. Pharmacopoeia* have standards for a significant number of products, and even they have essentially no specifications for products under patent protection in their markets.

19.2 Practical approaches to quality assurance

The procedures to establish a comprehensive quality assurance program can be divided into three categories—

1. Procedures to ensure that only medicine products that meet current standards for quality are bought. These include—
 - Careful product selection
 - Careful supplier selection
 - Certificate of analysis for each batch of product
 - Certification of good manufacturing practices
 - Batch certification (WHO-type certificate of a pharmaceutical product)
 - Inclusion of detailed product-quality specifications in the contract
2. Procedures to verify that shipped goods meet the specifications. These include—
 - Pre- and postshipment inspection
 - Analytical pharmaceutical testing
3. Procedures to monitor and maintain the quality of pharmaceuticals from the moment they are received until the medicine is finally consumed by the patient. These involve—
 - Proper storage and distribution procedures
 - Appropriate dispensing
 - Instructions to the patient on proper use of medications
 - Product defect and pharmacovigilance reporting programs

Few pharmaceutical management programs can effectively manage all the possible quality assurance activities for all the medicines that are procured. Consequently, realistic goals must be set to identify the combination of managerial and technical quality assurance activities that will be most effective under existing conditions. The critical elements in quality assurance for pharmaceutical procurement are listed in Figure 19-3, and Country Study 19-1 discusses how the Tanzania Food and Drugs Authority

Box 19-2 Counterfeits and diversion from legal channels

Recent examples of dangerous counterfeit medicines in the marketplace in countries worldwide include—

Southeast Asia: Of 391 samples of artesunate, 50 percent had little or no active ingredient and a wide range of wrong ingredients, including banned pharmaceuticals (Newton et al. 2008).

Madagascar, Senegal, and Uganda: Of 197 anti-malarial samples from the public and private sectors that underwent full laboratory quality-control testing, the failure rates from Senegal, Madagascar, and Uganda were 44 percent, 30 percent, and 26 percent, respectively (USP and USAID 2009).

United States: The FDA warned consumers about 24 websites selling counterfeit medicines (FDA 2007).

Democratic Republic of Congo: The antidepressant fluvoxamine and the muscle relaxant cyclobenzaprine HCl had been labeled and sold as commonly prescribed antiretrovirals for HIV/AIDS treatment (Ahmad 2004).

Niger: Up to 2,500 people reportedly died after being given a fake meningitis vaccine (WHO 2003).

WHO defines counterfeit medicines as those that are “deliberately and fraudulently mislabeled with respect to identity and/or source” (WHO 2010c). Within this broad definition, it is useful to consider different categories of counterfeiting activities—

- Professional counterfeit organizations have modern production facilities capable of manufacturing products and labeling strikingly similar to the authentic products. They operate in the most lucrative markets—mostly developed countries.
- Mediocre counterfeit organizations produce poorly made look-alike products that in a side-by-side comparison can be discerned from legitimate products.

- Minor relabelers distribute to only a few outlets in an attempt to preserve the value of their outdated inventory by relabeling expired products with valid expiration dates and the same product name.
- More advanced or major petty relabelers deal in a secondary pharmaceutical market for outdated products primarily obtained from legitimate sources in developing and developed countries but distributed mostly in developing countries.
- Substitution counterfeiters place lower-priced finished dosage forms into more expensive packaging for marketing at higher prices. These relabeled outdated products may be distributed in developing or developed countries.

Formulating counterfeiters generally do not include the active pharmaceutical ingredient in the formulation. Substitution counterfeiters generally use the wrong medicine, whereas the relabelers generally have the right API present in about the right amount. Therefore, relabelers are the most difficult to detect, if their labeling is well done. Generally, most counterfeits have flawed labels that can help identify them as substandard. If the pharmaceutical product is provided without its original label, however, this feature may not always be helpful in identifying counterfeit products. Local or within-country counterfeit marketing depends on astute practitioners and consumers for detection and a good internal communication system to support prompt legal action.

The different characteristics of counterfeiters can be roughly summarized as follows in the table below.

In 2006, WHO launched the International Medical Products Anti-Counterfeiting Taskforce, which is WHO’s primary channel for anti-counterfeit activities.

Category	API ^a	Distribution scale	Product quality ^b	Label quality ^c	Detection
Professional	No	Large; frequently international	Very good	Excellent	Testing, side-by-side comparisons
Hack	No	Generally within a country or a limited region of a country	Poor	Good	Testing, physical examination
Minor petty	Yes?	Generally a few privately held stores	Very good	Good	Label examination
Major petty	Yes?	Generally a limited market segment in a given country	Excellent	Good	Label examination
Substitution	No	Generally a few privately held stores	Good	Good	Testing, examination

^a In general, only the relabelers may have the correct product.

^b Physical appearance, uniformity.

^c Print quality, color.

Figure 19-3 Critical elements in quality assurance for pharmaceutical procurement

1. Product selection

- products with longer shelf life (for example, powders for reconstitution rather than oral suspensions)
- avoidance of products with bioavailability problems, when possible

2. Product certification

- supplier prequalification
- recent GMP inspection reports from national drug authorities
- formal supplier-monitoring system
- limitation of purchases from new suppliers to noncritical products

3. Product certification

- GMP certificate from drug regulatory authority (prequalification)
- certificate of pharmaceutical products (WHO-type) for all new products, new suppliers
- batch certificate (WHO-type) for problem drugs only

4. Contract specifications

- acceptable pharmacopeial standards
- language, labeling requirements
- minimum shelf life
- packaging standards

5. Inspection of shipments

- physical inspection of all shipments
- sampling for analysis of suspect products

6. Targeted laboratory testing

- therapeutically critical drugs
- drugs with known bioavailability problems
- new suppliers
- suppliers with quality difficulties in the past

7. Product problem reporting system

- system for reporting suspect or problem products

approached the design of its pharmaceutical quality assurance program.

Because resources are limited, countries should target priorities for quality assurance activities. The VEN (vital, essential, nonessential) method (Chapter 40) helps identify a small group of medicines that have the greatest health impact. Vital lifesaving medicines (antibiotics, cardiac medications, and intravenous solutions) warrant greater attention than other important but not lifesaving medications, such as analgesics. ABC analysis (Chapter 40) can be used to identify those medicines that have the greatest budgetary effect if their quality is unacceptable. The choice of medicines to monitor closely is based on the following criteria—

- Medicines with a narrow therapeutic window
- Medicines with inherent bioavailability problems
- Modified-release preparations
- Products from new suppliers and suppliers with problems in the past
- Medicines that require stable dosage forms and appearance

19.3 Obtaining good-quality pharmaceuticals

Obtaining medicines of good quality involves careful selection of suppliers and products, compliance with GMPs, reliance on appropriate pharmaceutical product or batch certificates, and detailed contract specifications.

Careful product selection

In many systems, therapeutic medicine formulary committees first assess the safety and efficacy of selected medicines on the basis of evidence from clinical trials (Chapter 16). Specific product selection involves assessing the technical documentation provided by the supplier on the pharmaceutical characteristics of the dosage form. Dosage forms that may offer longer shelf life include—

- Powders for reconstitution instead of injectable liquids
- Powders for reconstitution instead of oral suspensions
- Tablets instead of capsules

When appropriate, request and review product-specific stability studies from the manufacturer. For a few medicines, such as certain heart, asthma, and seizure medicines, studies that demonstrate bioequivalence among different manufacturers' products may also be necessary.

Select products with packaging that can withstand rough transport and extreme climatic conditions. Plastic containers may be better than glass bottles for intravenous solutions, oral liquids, and disinfectants. Avoid metal tins that will rust. In some countries, unit-of-use packages (blister

packs) and containers with smaller quantities (for example, 100 tablets rather than 1,000 tablets) may be cost-effective. These measures aim to avoid quality loss after the containers are opened or as a result of frequent handling. The increased costs should be weighed against the wastage and contamination that may occur with bulk containers, plus the costs of any repackaging.

Careful supplier selection

This step may be the most critical in quality assurance (see [Chapter 21](#)). Suppliers can be selected competitively by restricted tender with prequalification, through open ten-

der with postaward qualification, or in some cases, through less formal procedures (see [Chapters 18](#) and [21](#)). Standard procedures should include requiring certifications, gathering information on supplier reliability and product quality, inspecting product samples, and if necessary, conducting laboratory testing of pharmaceuticals with high potential for bioavailability or stability problems. Country procurement offices obtained a major resource for helping assure quality pharmaceutical purchases when WHO launched its medicine prequalification program in 2001. [Box 19-3](#) has more information on the program.

Contacts with DRAs and purchasing groups (for example, the United Nations Children's Fund and IDA Foundation)

Country Study 19-1

Building quality assessment infrastructure in Tanzania

Substandard pharmaceuticals circulating in the market are a problem in many countries. As part of a 2001 assessment, the Strategies for Enhancing Access to Medicines (SEAM) program took 110 samples of ten different medicines and found that 12.9 percent of the samples from public facilities and 13 percent from private pharmacies were substandard. A further measure of the quality of medicines in the marketplace is the percentage registered with the Tanzanian Food and Drugs Authority (TFDA). Only 26 percent of the medicines surveyed in the thirty-nine *duka la dawa baridi*, which are private drug shops, were registered, while a further 24 percent were notified. The quality of notified and unregistered medicines cannot be assured, since they have not passed through the registration process, which would include almost three-quarters of medicines sampled at the *duka la dawa baridi*.

SEAM collaborated with the TFDA to establish a comprehensive national quality assurance program that can ensure that both imported and locally manufactured pharmaceutical products meet approved quality standards. The main focus of the intervention was on product examination and testing at ports of entry and surveillance and testing of products circulating in the market. Market surveillance requires routine inspection of facilities and sampling of products in the marketplace, including distributors and retail outlets. This strategy required enhancing inspection and pharmaceutical testing capacity within the TFDA, which involved developing and incorporating a number of tools and activities, among them the following—

- Flow charts and standard operating procedures for structured inspection activities at ports of entry and facilities, such as warehouses, hospital dispensaries,

retail pharmacies, and over-the-counter drug shops. The flow charts and procedures have been compiled into a *Level One Drug Inspectors' Handbook*.

- A thin-layer-chromatography-based program to screen pharmaceutical products (initially targeted at antimalarial medicines, then selected antibiotics and antiretrovirals).
- Quality assurance protocols and training materials based on a combination of visual inspection and non-laboratory-based testing (using thin-layer-chromatography Minilab). School of Pharmacy faculty at the Muhimbili University College for Health Sciences collaborated on the development and oversight of the inspectors' training.
- Support for TFDA inspectors' training, and monitoring and evaluation.
- Personal digital assistants to standardize the inspection process and allow computer downloads of inspection results for management review.

Working closely with stakeholders and sensitizing them to quality requirements helped get the quality assurance program established in 2002. Since then, improved efficiencies have resulted in a doubling of the number of pharmaceutical products screened and a quadrupling of the number of premises inspected—all with relatively few inspectors. The new quality assurance program has resulted in many product confiscations and importation refusals, in addition to closures of premises and improvements in standards. In summary, the quality assurance activities were conducted with relatively modest resources yet increased the presence of the TFDA in the marketplace, providing a significant deterrent to the marketing of substandard and counterfeit products.

Source: SEAM 2007.

Box 19-3 WHO's prequalification of medicines program

In 2001, WHO, in partnership with the United Nations Joint Programme on HIV/AIDS, the United Nations Children's Fund, and the United Nations Population Fund, and with support from the World Bank, launched its prequalification of medicines program to assess and approve manufacturers of medicines to treat HIV/AIDS, malaria, and tuberculosis. Since then, the program has added medicines and commodities related to reproductive health, and it also prequalifies quality-control laboratories. The program evaluates data on medicine safety, efficacy, and quality and inspects facilities for compliance with GMPs. Inspection activities have expanded to include manufacturers of selected APIs as well as clinical sites and contract research organizations. In addition, the program offers training workshops on how to meet prequalification requirements, assess multisource interchangeable medicines, and conduct and assess stability studies.

In 2009, the program prequalified 44 products, for a total of 237 products manufactured in sixteen countries (WHO 2010c). The program also prequalified three new quality-control laboratories to bring the total to eleven.

Originally intended for United Nations procurement agencies, the program has become a valuable resource for any purchaser, including countries themselves.

More information on the prequalification program is on WHO's website at <http://apps.who.int/prequal/>. The website lists all product and manufacturing site requirements, standards used in evaluating the product, and the profile of the inspection teams. It also includes the list of prequalified medicines and their manufacturers.

Source: WHO 2010c.

and product-quality testing laboratories can help with reference checks and exchanges of information on problem products. Publications by medicine information services and professional organizations, such as the U.S. Pharmacopeia, the FDA, and the American Society of Health-System Pharmacists, provide information on the bioequivalence of pharmaceuticals as well as on pharmaceutical recalls (see [Annex 19-1](#)).

A procurement office or agency needs to analyze information on suppliers' performance and develop and apply operational definitions and criteria to assess the reliability of suppliers and avoid subjectivity. Lack of explicit definitions and criteria provides rejected suppliers with the opportunity to question the integrity of the procurement process.

For products from new suppliers, visual inspection of samples of the product, packaging, and labeling is important. Some programs send samples for laboratory testing on a routine basis; others do so only when concerns arise about specific products. Although prepurchase testing may detect defective products, bear in mind that the samples are provided by the supplier, which will make every effort to ensure that the samples meet the standards. The samples may not, however, be representative of what is actually delivered.

[Chapter 21](#) discusses the need for an information system that provides the procurement office and tender committee with feedback on suppliers' compliance with contracts. Keeping a record of condition of received goods, compliance with contract terms, and timeliness of delivery is essential.

This information, and that from the adverse drug reaction and product-quality reporting system, should be considered when assessing offers and awarding supply contracts.

Product certification

WHO has established GMPs for pharmaceutical products, similar to those enforced by the national pharmaceutical control agencies in industrialized countries. They include criteria for personnel, facilities, equipment, materials, manufacturing operations, labeling, packaging, quality control, and in most cases, stability testing.

In countries with effective pharmaceutical control agencies, adherence to GMPs is enforced by a system of inspections and regulatory controls, often specific to individual medicine dosage forms. A manufacturer may have acceptable standards for solid dosage forms but not for sterile injectable preparations. Recent reports of GMP inspections and pharmaceutical recall histories can be obtained by writing to national pharmaceutical control agencies. Often, a supplier must approve or at least expedite requests for performance reports from national pharmaceutical control agencies, and failure to obtain such reports for the buyer makes past performance suspect.

Buyers with pharmaceutical staff trained in GMP inspection may perform their own inspections of local manufacturers that are potential suppliers, if funds are available to do so.

Countries that participate in the scheme agree to certify that pharmaceuticals are registered in the exporting country

and that manufacturers' facilities have been inspected and comply with GMPs. However, a WHO study (1995) showed that very few importing countries actually request pharmaceutical product certificates for registration or procurement purposes.

This certification scheme provides some assurance, based on inspection of the manufacturing facilities for GMPs by the competent authority of the exporting country. For the procurement office, it is an inexpensive means to help ensure the quality of purchased products. Through the certification scheme, the procurement office should be able to obtain the following information—

- Whether a product is legally marketed in the exporting country, and if not, the reasons why
- Whether the supplier manufactures the dosage forms, packages, and/or labels a finished dosage form manufactured by an independent company, or is involved in none of these activities
- Whether the manufacturer of the product has been inspected and the periodicity of inspection
- Whether the certificate is provisional, pending technical review
- Whether the information submitted by the supplier satisfies the certifying authority on all aspects of manufacture of the product undertaken by another party

The reliability of the pharmaceutical product certificates issued under the WHO scheme and access to them depend largely on the—

- Reliability and responsiveness of the exporting country's authority
- Capability of the exporting country's authority to make adequate GMP inspections
- Capability of the importing country's authority to assess the authenticity or validity of the certificate of a pharmaceutical product submitted, especially when it is submitted through the manufacturer or importing agent

Therefore, product certification under the WHO scheme is only as reliable as the agency performing it, and WHO estimates that only about 20 percent of member countries have a national drug regulatory system that can ensure the quality of medicines circulating in their national markets (WHO 2008b). For this reason, certificates should be accepted with caution unless the national DRA's competence to fulfill the scheme is known. In addition, although national pharmaceutical-control agencies in the major pharmaceutical-exporting countries are generally conscientious in their assessments, receiving reports may take some time. Agencies in some countries have been found to be less reliable and responsive.

WHO recognizes that today's pharmaceutical manufacturing sector looks much different from when the scheme was formulated decades ago under the assumption that a pharmaceutical product would be sold directly from the country of manufacture to the country of final destination. Pharmaceutical manufacturing and trade have become far more globalized in that different stages of manufacturing take place in different countries before the product reaches the final destination. Because of this evolution and other identified problems, WHO has proposed revising the scheme (WHO 2008b).

Product pedigrees

The purpose of a pharmaceutical pedigree is to establish a chain of custody from the manufacturer to the dispenser by documenting all parties that have handled a particular unit of a pharmaceutical as it travels through each step in the supply chain. Pharmaceutical wholesalers who provide fraudulent or no product pedigrees may help divert counterfeits into legitimate distribution systems. Failure to comply with the pedigree requirements is against the law in the United States.

Implementing a pharmaceutical pedigree process can be done with paper or electronic records. For example, affixing radio frequency identification (RFID) or bar codes to packaging would help maintain supply chain integrity and improve inventory control (see Section 19.4). Although electronic tracking is likely more efficient and secure, it requires expensive technology and training. Paper-based systems may be executed quickly but in the long run may be more time-consuming and more susceptible to forgery.

Batch certificates

Reliable pharmaceutical manufacturers may comply with GMPs by routinely conducting batch analyses. Local manufacturers that do not have their own quality-control laboratories may contract quality-control testing services from other manufacturers, private testing facilities, or national reference laboratories.

Some pharmaceutical procurement offices request other certificates, such as the certificate of free sale, the certificate of origin, or the certificate of licensing status (see [Table 19-3](#)). These certificates do not provide important information regarding compliance with GMPs, or results of laboratory testing of samples from individual batches. For this reason, the WHO-type certificate of a pharmaceutical product and batch certificate are preferred.

DRAs and the procurement market today

In many countries, DRAs and procurement offices do not work together effectively, nor are integrated information

Table 19-3 Comparison of certificates used in pharmaceutical procurement

Type of certificate	Uses	Limitations
WHO-type certificates		
<i>Certificate of pharmaceutical product</i>		
<ul style="list-style-type: none"> • Issued by DRA in exporting country • Provides licensure status of product • Provides inspection status of manufacturer 	<ul style="list-style-type: none"> • Essential for product licensure • Ideally required for all new products • Prequalification of suppliers • Screening of new suppliers 	<ul style="list-style-type: none"> • Is only as reliable as issuing DRA • Does not provide batch-specific information
<i>Statement of licensing status</i>		
<ul style="list-style-type: none"> • Issued by DRA in exporting country • States that product is licensed 	<ul style="list-style-type: none"> • Prequalification of suppliers • Screening of new suppliers 	<ul style="list-style-type: none"> • Does not provide batch-specific information
<i>Batch certificate</i>		
<ul style="list-style-type: none"> • Issued by manufacturer or DRA in exporting country • Confirms that individual batches conform to specifications • Linked to certificate of pharmaceutical product 	<ul style="list-style-type: none"> • Usually requested for antibiotics • May be required for problem medicines 	<ul style="list-style-type: none"> • Issued by few DRAs • Easily falsified • Many require additional expense
Non-WHO-type certificates		
<i>Free-sale certificate</i>		
<ul style="list-style-type: none"> • Issued by DRA in exporting country • Confirms product is sold in the country of origin 	<ul style="list-style-type: none"> • Commonly used for licensure 	<ul style="list-style-type: none"> • No indication that product has been evaluated for safety and efficacy • No indication that product is registered for use in country of origin
<i>GMP certificate</i>		
<ul style="list-style-type: none"> • Issued by DRA in exporting country 	<ul style="list-style-type: none"> • Prequalification of suppliers 	<ul style="list-style-type: none"> • Only as reliable as issuing DRA
<i>Analytic batch certificate</i>		
<ul style="list-style-type: none"> • Issued by manufacturer • Contains results of analytical tests • Not linked to certificate of pharmaceutical product 	<ul style="list-style-type: none"> • Postqualification of suppliers 	<ul style="list-style-type: none"> • Manufacturers' certificates may be falsified • Does not necessarily conform to specifications approved at time of product licensure

systems in place. Ideally, when a DRA exists and the medicine registration system is operational, procurement by government agencies should be limited to medicines registered by the DRA. Procurement offices should seek information from the DRA and strive for closer cooperation with the authority. To facilitate registration of generic medicines, the evaluation and approval process should not be complicated. Clinical trial data, except for bioequivalence data, are not normally required, allowing the submission of an abbreviated application by the manufacturer or distributor. WHO recommends that all medicines on the public or private market in a country, whether they are imported or locally manufactured, be subject to the same standard of control, including medicine registration.

The standard of control varies from country to country. In some exporting countries, medicines are registered and freely sold but not rigorously evaluated for efficacy. In other countries, which do evaluate efficacy, certain medicines may have been registered before evidence of efficacy was legally required. Moreover, in some countries, manufacturers may produce exclusively for export; the exporting coun-

try's DRA may not closely scrutinize these manufacturing plants. Procurement offices still need to request certificates from the DRA of the exporting country, as recommended by WHO.

Contract specifications

Detailed specifications to help ensure that high-quality products are bought and received include the following—

- Analytical methods and source of reference materials or documented evidence of suitability for the material used to assess product-quality attributes and certificate of analysis.
- Portions of manufacturers' reference materials to be used in product-quality assessments. For these reference materials, the manufacturers will supply either the API used in the manufacture of the product or a purified portion of the API. Because the reference material is used to assign qualitative and quantitative properties, its identity must be assured and its

purity must be suitable to perform the assessments at an appropriate confidence level for the intended use of the material. The identity of a reference material is generally assessed by infrared spectral comparisons and quantitative assessments performed by ultraviolet-visible spectral measures, either directly or in conjunction with chromatographic procedures. However, for most pharmaceutical measurements, the identity and quality of solid materials can be assessed by melting point/mixed melting point measurements, while liquids can be assessed by refractive index measurements.

- Language for the product label and package insert, which should be the language or languages common to the country.
- Minimum information required on the label (generic or International Nonproprietary Name, dosage form, strength, quantity, expiration date, manufacturer, batch number).
- Additional information, such as the product registration number and date of manufacture.
- Standards for packaging that will withstand the specific storage and transport conditions (for example, corrugated boxes with specifications for dividers, maximum size, and maximum weight).

To reduce theft and resale, some programs may require labeling and logos to indicate that the product is solely for distribution within a particular health care program (for example, ministry of health, social security fund).

Contract specifications are discussed in detail in [Chapter 39](#).

19.4 Verifying the quality of shipped products

The quality of products received should be verified as soon as possible by physically inspecting each shipment and testing selected products in the laboratory as required by regulation. In addition, more advanced product-tracking technologies have been introduced to help ensure the integrity of the pharmaceutical supply chain.

Product identification technology

The traditional approach to assuring product integrity is labeling with batch number and expiration date. Unfortunately, this labeling is easily duplicated. To make fraud more difficult, several approaches are available that use overt or covert systems. *Overt technologies* are visible to the eye, and *covert technologies* require devices for detection. Because each step up in identification technology costs more, the most advanced technologies are used on high-value products or in large-quantity inventory control.

Bar coding: The simplest and least expensive technology for product tracking is the bar code, which has been adopted widely in many industries. Its uses range from tracking shipping containers to individual dosage units. The airline industry makes extensive use of this technology to track and direct baggage, and the retail industry has made bar coding the standard to track inventory and sales. Because of their widespread use and simplicity, bar-code detecting devices are relatively inexpensive.

Radiofrequency identification: The RFID tag is a radio-frequency transponder chip with a permanent unique identification code and the ability to be programmed with product information, such as batch number and expiration date. The combination of product information and identification code provides a high level of security against counterfeiting. RFID can be used overtly or covertly—either visible on the product or hidden in the packaging. Another advantage of the RFID technology is the ability to detect several different items at the same time, unlike visual bar-code readers, which must have each tag visible and separate for reading. However, until this RFID technology matures and becomes more widespread, it will remain much more expensive than the traditional bar-code technology.

Holograms: Hologram technology provides visual authentication that can be very difficult to counterfeit or remove (although instances of fake holograms have been found on counterfeit antimalarial products in Southeast Asia). However, the technology is not easily automated and optimally requires an authentic label or accurate image for visual comparison.

Other technologies that have been developed for product authentication include color-shifting inks, ultraviolet printing, and embedded chemical markers and infrared tags. As the technologies mature, several will likely be used to assure different aspects of the supply chain. The continuing adoption of these authentication technologies will make product counterfeiting more difficult and expensive, but unfortunately will not likely eliminate it.

Inspection of shipments

Regardless of other quality assurance procedures in use, each pharmaceutical shipment should be physically inspected. This means verifying adherence to contract specifications and order completeness as well as inspecting samples of all items to spot any major problems. Training competent receiving staff can be an economical means of ensuring pharmaceutical quality and reducing losses from supplier negligence or fraud.

Inspection in the exporting country before shipment can be arranged through an independent agency (for

example, the Société Générale de Surveillance), for early detection of noncompliance with contract terms or defective products.

Tiered pharmaceutical quality assessments

As mentioned earlier in the chapter, the safety and efficacy of an API is the most critical attribute of a pharmaceutical product. The safety and efficacy of new APIs in the European Union, Japan, and the United States are determined in accordance with exhaustive ICH consensus guidelines that have been incorporated into the laws and regulations of those sovereign areas.

When the safety and efficacy of an API have been established, the dosage regimen is set so the minimum therapeutic level is attained without exceeding the maximum tolerated dose. That level of efficacy is called the “therapeutic window” (see [Box 19-4](#)). Pharmaceutical quality assessments may include bioavailability testing to ensure that the API falls within the therapeutic window.

Three tiers of product-quality assessment differ by cost and levels of precision, accuracy, and sensitivity—

1. *Minilab® screening assessments*: The Global Pharma Health Fund developed the Minilab to rapidly assess whether products are grossly substandard and to

detect counterfeit products with no API or the wrong ingredients (see <http://www.gphf.org/web/en/minilab> for more information). The Minilab uses a thin-layer-chromatography method that does not require standard laboratory resources, so it can be used in the field, such as at ports of entry, while providing a good level of quality assurance. The Minilab has methods available for more than fifty pharmaceutical products and is regularly incorporating more.

2. *Validated laboratory assessments or legal reference method assessments*: These methods are used to assess assays, content uniformity, known impurities, and API dosage release. For medicines with a narrow therapeutic index, such as warfarin sodium, or for pharmaceuticals that fail the first-tier screening assessment, more accurate laboratory assessment technologies are required to support litigation concerning quality standards violations. Legal reference methods are methods of analysis that have been adopted into law and are suitable for use in litigation; however, Minilab screening and validated assessments are generally quicker, less labor intensive, and less expensive than legal reference methods, which are the gold standard.
3. *Specialized instruments*: Methods such as high-performance liquid chromatography coupled with

Box 19-4 Therapeutic window

Fortunately, the overwhelming majority of pharmaceutical products have a large therapeutic window, which is a great advantage for manufacturers and consumers. A wide therapeutic window allows the production of fewer dosage levels, which reduces production, supply, and inventory costs and allows consumers to more easily take a dose of a medicine that is efficacious and well tolerated. Products with a narrow therapeutic window require strict monitoring of the patient's therapeutic response; for example, patients taking the anticoagulant warfarin sodium must have their individual coagulation times strictly monitored to determine the ideal dose. A further indicator of the critical dosing requirement for this product is the large number of tablets available containing 1, 2, 2.5, 3, 4, 5, 6, 7.5, or 10 mg. These dosing levels contrast markedly with those of acetaminophen (paracetamol), which has a wide therapeutic window. In the United States, acetaminophen is often marketed as a 325-mg dosage unit, whereas in Europe the dosage unit generally is 500 mg. The dosing instructions for both products instruct the user to take one or two units up to four times per day.

mass spectrometry may be used to determine unknown impurities and metabolites. Generally, these technologies are expensive and require highly trained individuals to operate them and interpret the data.

In summary, wide-therapeutic-index products may be screened rapidly to assess their quality clearance with minimal risk of compromising their safety and efficacy. Narrow-therapeutic-index products and those that fail the rapid screening technologies should be assessed by validated technologies that are fast and efficient. Products that fail the validated technologies may require further assessments by the legal reference methods of the sovereign state to support litigation or with specialized instrumentation to litigate untoward or unexpected contamination.

Laboratory testing

Upon arrival after shipment, batch samples may be laboratory tested routinely or “by exception.” Most programs test selected samples from only some of the batches. Testing by exception means that analyses are done only when a supplier or a particular product is suspect.

Laboratory testing is costly in terms of technical human resources, equipment, and reagents. Guidelines should target sampling to products that (a) have the greatest potential for bioavailability and stability problems, (b) are from new or questionable suppliers, and (c) have been the source of complaints. With new suppliers, a probationary testing period—for example, testing the first three shipments, then shifting to intermittent sampling—is useful. Suppliers whose failure rates are unacceptable are dropped from future tenders. Sampling from well-established suppliers is done much less frequently, often only for at-risk products.

Programs that require routine testing of samples for all products prior to distribution to health facilities often produce significant delays in product availability at the health-facility level. The need for laboratory testing of products reported to have problems should be carefully assessed; many problems with quality are detectable on visual inspection and do not require laboratory testing. For example, verified observations of tablets that crumble before their expiry date, oral suspensions that harden, or injectable solutions that contain particles are enough to justify recalling the product without testing.

The tests that should be performed depend on the pharmaceutical and the reason for testing. Basic chemical analyses are done to verify the identity of the medicine and under extenuating circumstances to look for degradation, chemical contamination, or adulteration. WHO advocates a system of economical, less technically demanding basic tests for commonly used medicines (WHO 1998) that can be done in simple laboratories. A complete analysis of tab-

let and capsule forms includes tests for identity, strength or potency, uniformity, impurities, disintegration, and dissolution.

Biological testing is more specialized and can be performed only in established facilities with staff trained to use microbiological and pharmacological methods. Microbiological tests include sterility tests for injectable medicines and eye preparations and microbiological assays of antibiotics and vitamins. Pharmacological tests include the pyrogen test; toxicity tests; hormone assays, such as for insulin and pituitary derivatives; and tests to determine the bioavailability of selected pharmaceuticals.

Construction of a quality-control laboratory where one does not already exist should be considered with caution. It may not be cost-effective for some countries to establish a sophisticated national pharmaceutical control laboratory for a number of reasons, including—

- Low projected volume of work
- Insufficient financial resources for land purchase, facility construction, testing equipment, furniture, supplies, equipment maintenance, salaries, training, and other operating costs
- Lack of trained personnel, such as microbiologists, pharmacologists, laboratory technicians, and animal caretakers
- Lack of local capacity for maintenance and repair of equipment, difficulty in obtaining spare parts, irregular and unstable power supply

In some countries, a college of pharmacy or an independent laboratory may have some of the required testing facilities. Also, many international quality-control laboratories provide pharmaceutical analyses at a relatively reasonable price. If analyses are performed by foreign laboratories, foreign exchange and billing problems may be reduced by requiring the suppliers to pay the laboratory directly, with the arrangement clearly described in the purchase contract. In addition, chain-of-custody and legal standing of the testing laboratory in the importing country may be at issue.

19.5 Maintaining pharmaceutical quality

Maintaining medicine quality requires careful attention to storage conditions and transport, as well as to dispensing practices and use.

Appropriate storage and transport

Procedures to help maintain pharmaceutical quality begin with proper storage conditions at the port and prompt release. Storage activities are discussed in [Chapters 42, 44,](#)

and 46, and proper transport conditions are addressed in [Chapter 25](#).

Appropriate dispensing and use

Inappropriate dispensing procedures contribute to pharmaceutical product deterioration and contamination or medication errors. The following procedures help maintain the quality of pharmaceutical products—

- Use only proper dispensing containers (for example, airtight containers, light-resistant bags or vials); the paper envelopes often used for end-user dispensing do not protect tablets and capsules.
- Require clear labeling of dispensed medicines, and enforce procedures to label products with the patient's name, the medicine's name, its strength, its expiration date, and instructions for its use and storage.
- Write information and instructions in the local language, avoiding the use of abbreviations, or use symbolic instructions.

The prescriber and the dispenser should counsel the patient on the proper use of medications, explaining *what* the medicine is, *why* the patient needs it, *how* to take it, and *where* and *how* to store it until treatment is completed, in addition to possible contraindications and adverse reactions (see [Chapter 30](#)).

Pharmaceutical product presentations: treatment kits, co-packaging, and fixed-dose combinations

Medicines can be packaged according to therapeutic regimens or for delivery to dispensing sites or individual patients to facilitate and reduce the costs of inventory management and distribution systems. For example, a tuberculosis treatment kit could include enough antimicrobial products for a particular number of patients. Broader-based treatment kits for poorly served areas may include a selection of essential medicines that supplements the national supply system (see [Chapter 26](#) for more information).

Co-packaging or co-blistering is a method commonly used to deliver multiple medicines for a specific treatment regimen such as tuberculosis. These packages are prepared from individual pharmaceutical products, so their quality assessments should be based on each product's individual standards, including stability testing.

Fixed-dose combination (FDC) products have more than one active ingredient formulated into one product—for example, the anti-tuberculosis medicines isoniazid and rifampin are available as single products or as an FDC in one pill. FDCs simplify the prescription of

medicines and the management of pharmaceutical supply, improve patient adherence, and may also limit the risk of treatment-resistant infections caused by inappropriate medicine selection and monotherapy, as is the case with artemisinin-based combination therapies. WHO recommends FDCs be developed for antiretroviral pharmaceutical products to simplify HIV/AIDS treatment regimens and to improve patient adherence. From a regulatory standpoint, FDCs are treated as new pharmaceutical entities in which the individual APIs must be shown to be stable and bioavailable in this composite product (WHO 2003).

19.6 Monitoring pharmaceutical quality

Despite every effort, defective products occasionally slip through, and the quality of even the best-manufactured product may deteriorate. Furthermore, health care personnel and patients alike may have erroneous perceptions that only brand-name products from innovator firms are of good product quality, especially when generic products are not well known and accepted.

Product problem reporting system

Establishing a national product problem reporting system is important so that health workers can report suspected or confirmed problems with specific pharmaceutical products. Product problem reporting should be part of an overall pharmacovigilance system, which also includes monitoring and reporting adverse drug events and medication errors. [Chapter 35](#) covers those areas of pharmacovigilance in detail.

[Figure 19-4](#) is a sample medicine and supplier evaluation form that pharmacy staff and health care providers at all levels can use to report suspected lapses in pharmaceutical or packaging quality. Standard procedures for product problem reporting should specify—

- Who should report the perceived product quality problem
- How to fill in the reporting form
- Where and to whom the reporting form should be sent
- What additional measures need to be taken, such as sending samples or information concerning the quantities involved
- What follow-up information should be provided to the person or facility that reported the problem

Quality assurance program staff should carefully analyze all reports, using laboratory testing as required, and take appropriate actions. The reporter should be informed about the results and the actions taken, even if products are

MEDICINE AND SUPPLIER EVALUATION FORM

Submitted by: _____ Date: _____

Country: _____

Sample Location:

CMS

Other _____ (specify)

Address communications to:

ECDS
PO Box 3093
La Clery
Castries
St. Lucia

Telephone: (809-45) 25058/25895

Medicine Description: Generic Name, Strength, Form,	Brand Name	Medicine or Supplier	Lot Number or Batch Number	Expiration Date	Comments

Suggested criteria for medicine evaluation:

1. Physical characteristics
 - e.g., hardness, color, mixing ease for reconstitution
2. Packaging
 - expiry date, lot or batch number, package insert
3. Labeling
 - language (English vs. French), legibility (especially ampoules)
4. Patient acceptability
 - taste, color, size of tablet, etc.
5. Health care provider acceptability
 - e.g., is the ampoule easy to break?

Guidelines for medicine sampling:

1. Take samples from previously unopened containers.
2. Minimum sample size: tablets/capsules—200; injections—40 ampoules; liquids—40 mL.
3. Tablets/capsules must be tightly packed in plastic/glass vial (DO NOT USE PAPER OR PLASTIC ENVELOPES).
4. Enclose COMPLETE LABEL (generic name, strength, quantity, manufacturer and supplier names, lot/batch number, expiry date, date of manufacture).
5. Print label legibly, and double check lot number for accuracy.

not defective, to encourage continued participation in the program. Product problem reports and results should be recorded to provide information for future procurement.

Product recalls

Pharmaceutical products found to be defective should be recalled quickly. The quality assurance unit in the country's DRA should develop standard procedures for carrying out the recall. Rapid action helps avoid unnecessary exposure once the problem has been detected. The central distributor's inventory control system should include information on all batches that have been received. Because tracking individual batches to the health facility is often either impractical or fraught with uncertainty, recall notices have to be sent to all health facilities that received any of the products in question to check their shelves and return the products to the central distribution point.

Recalls may be classified according to the degree of risk to the consumer: (a) serious illness or death, (b) temporary or mild illness, or (c) no adverse clinical effect. The level of recall is determined by both the degree of risk and the extent of distribution of the product and may be directed at the patient, the health facility, or the medical stores level.

After issuing a recall, the quality assurance program should monitor its progress to ensure complete compliance. The supplier should be notified and required to replace defective products. The procurement office should pursue other remedies specified in the contract, such as withholding payment or obtaining reimbursement for or replacement of the defective products.

19.7 Personnel and training in the supply system

Central to the operation of most well-run pharmaceutical supply systems is at least one qualified pharmacist with some training or experience in industrial pharmacy and procurement. Such an individual can be invaluable in establishing and overseeing quality-control practices suited to local requirements. This person should participate in—

- Selecting medicines
- Setting technical specifications for pharmaceutical contracts
- Reviewing supply offers and selecting suppliers
- Reviewing storage and transportation facilities
- Coordinating any pharmaceutical quality testing and helping to train the inspectors who check pharmaceutical shipments

In some government systems, qualified pharmacists are employed at all levels, including the district hospitals, and they are expected to oversee local storage and transportation conditions. In addition, they report problems or questions concerning individual medicines to the main office. In other countries, locally trained dispensers are responsible for much of the day-to-day work and must be trained to detect and report quality problems. Some countries must rely on staff that has not received any technical training in pharmaceutical management.

In addition to pharmacists and pharmaceutical assistants, other staff members involved in quality assurance need training and supervision as a part of quality assurance efforts.

- Physicians, health administrators, and health system officials must know about the factors that influence pharmaceutical quality to make informed decisions about supply sources and to monitor and promote quality assurance in their facilities.
- Port-clearing personnel should be trained to identify the categories of pharmaceuticals requiring special storage and transport conditions.
- Clerks responsible for inspecting pharmaceutical shipments should receive formal training in inspection procedures.
- Pharmaceutical inspectors must be familiar enough with pharmaceutical labeling and packaging materials to determine whether contract conditions regarding pharmaceutical dosage, packaging, and labeling have been met.
- Staff involved with local repackaging should be trained to ensure pharmaceutical quality and to follow good practices, especially regarding label control.
- Physicians, nurses, and paramedical personnel handling pharmaceuticals throughout the health system need to know about the factors that influence pharmaceutical quality and what they can do to ensure that the medicines dispensed to patients are safe and effective.

Quality assurance is a widely shared responsibility. Within a supply system, the organizational structure needs to establish the responsibilities for the review and preservation of pharmaceutical quality at all levels. If a pharmaceutical becomes ineffective or unsafe by the time it reaches the patient, then all the other activities of the supply system have been in vain. ■

ASSESSMENT GUIDE

Quality assurance structures

- Are there stated policies and practices aimed at ensuring pharmaceutical quality?
- Who is responsible for monitoring pharmaceutical quality?
- In what laboratories is quality-control testing done?
- Does a formal system exist for reporting product quality complaints?

Quality assurance procedures

- Is the WHO Certification Scheme on the Quality of Pharmaceutical Products Moving in International Commerce used systematically?
- Are favorable GMP inspections required for all suppliers, including local manufacturers?
- Is a physical inspection made of all pharmaceuticals received?
- Are all pertinent documents and labeling, including patient inserts, reviewed for accuracy and compliance with standards?
- How many laboratory analyses were performed during the past year of the total number of products or batches procured?
- To whom are results of analyses of suspected or confirmed defective products communicated?

- Are the test results of substandard medicines recorded for use in future procurement assessments?
- Is information on pharmaceutical stability and problem pharmaceuticals used in evaluating suppliers and pharmaceutical products?
- Are storage conditions periodically evaluated at the ports of entry? At the central warehouse? At district and regional stores? In hospital pharmacies? At health centers and rural health posts?
- Are transport conditions maintained to ensure product quality?
- Are good dispensing practices followed in the health facilities or pharmacies?
- Are the various levels of health workers adequately trained to carry out their respective roles in quality assurance?

Outcome of quality assurance

- In the previous year, how many reports were submitted on pharmaceutical product problems?
- What number of pharmaceuticals or batches failed quality-control testing of the total number of pharmaceuticals or batches tested in the previous year?

SUMMARY

Quantification is the first step in the procurement process (see [Chapter 18](#)). In general terms, quantification is the process used to determine how much of a product is required for the purpose of procurement. But more specifically, quantification involves estimating not only the quantities needed of a specific item, but also the financial means required for purchasing the item. Needs are estimated for a given context, and the analysis must include contextual factors, such as available funds, human resources capacity, storage space capacity, and capacity to deliver services.

The methods and strategies described in this chapter can be used as tools to—

- Prepare and justify a pharmaceutical budget
- Plan for new and expanding programs
- Optimize pharmaceutical budgets based on priority health problems to be treated and the most cost-effective treatment approaches
- Calculate emergency needs for disaster relief and epidemics
- Resupply an existing supply network that has become depleted of products
- Compare current medicine consumption/demand with public health priorities and usage in other health systems

The quantification method must be chosen in light of the resources and information available.

The consumption method, which uses data on medicine consumption, gives in many instances the most accurate prediction of future needs. Large, well-established pharmaceutical supply systems rely primarily on the consumption method. To be reliable, the consumption data must come from a stable supply system with a relatively uninterrupted supply and a full supply pipeline. Consumption data may or may not reflect rational prescribing and use of medicines or actual demand for medicines.

The morbidity method quantifies the theoretical quantity needed for the treatment of specific diseases. This method requires reliable data on morbidity and patient attendances (visits to health facilities) and uses standard

treatment guidelines to project medicine needs. This method is the most complex and time-consuming, and it can produce major discrepancies between projections and subsequent use. Nevertheless, this method is often useful for new and expanding programs and may be the most convincing approach for justifying a budget request.

If no reliable information is available on past consumption or morbidity, use can be extrapolated from data for other facilities, regions, or countries. The proxy consumption method is flexible enough to apply to various situations and can be either population or service based. Service-level quantification of budget requirements can be applied when only budget requirements, and not specific medicine quantities, are needed. It provides a clear, logical, one-page justification of pharmaceutical financing requirements.

Several critical issues are common to all methods. The medicines list is the central component and must be produced in a format suitable to the type of quantification. In a new supply system, or one in which shortages have been widespread, quantification estimates must be adjusted because the supply pipeline must be filled. The lead time has a major effect on quantities required for safety stocks. In virtually all supply systems, adjustment is necessary for losses caused by wastage and theft.

Quantification estimates can be cross-checked by combining different methods. No matter which method is used, a gap may exist between the initial estimates of medicine needs and the allocated budget. The quantification process itself may help justify an increase in the budget, but often the quantification estimates must be adjusted and reconciled to match available funds. The choice between manual and computerized quantification may be dictated by circumstances, but the process is much easier with computer assistance. Quantification can be centralized, or it can be decentralized to staff of peripheral warehouses and health facilities. The personnel and time requirements depend on the quality and accessibility of source data and on the type and scope of quantification.

20.1 Methods of quantification

Quantification is the first step in the procurement process (see Chapter 18). In general terms, quantification is the process used to determine how much of a product is required for the purpose of procurement. But more specifically, quantification involves estimating not only the quantities needed of a specific item but also the financial means required for purchasing the item. Needs are estimated for a given context, so the analysis must include contextual factors, such as available funds, human resources capacity, storage space capacity, and capacity to deliver services. Often, the terms *quantification* and *forecasting* are used interchangeably. For purposes of this chapter, forecasting refers to the projection of future needs beyond the next purchase order.

Medicine needs can be quantified by using one or a combination of four standard methods. Quantification involves estimating the quantities of specific medicines or supply items needed for a procurement. Most quantification exercises also estimate the financial requirements to purchase the medicines. The quantification methods described in this chapter are normally used to quantify needs for an annual or semiannual procurement. They are not usually used to calculate routine order quantities in an established supply system that uses scheduled purchasing (periodic orders) or perpetual purchasing (orders placed whenever need arises). In such situations, one of the reorder formulas presented in Chapter 23 is used to calculate the optimal order quantity

and order interval for each item. The goal is to maintain the most cost-effective balance between service levels and inventory costs.

Major options for quantification

The four general methods discussed in this chapter are—

1. Consumption method
2. Morbidity method
3. Proxy consumption method
4. Service-level projection of budget requirements

The *consumption method* uses records of past consumption of individual medicines (adjusted for stockouts and projected changes in medicine use) to project future need (see Section 20.4).

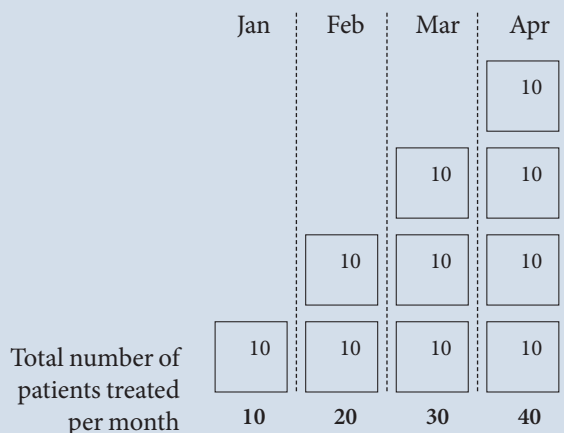

The *morbidity method* estimates the need for specific medicines based on the expected number of attendances, the incidence of common diseases, and standard treatment patterns for the diseases considered (see Section 20.5). [Box 20-1](#) describes the morbidity method used when a program is scaling up.

The *proxy consumption method* uses data on disease incidence, medicine consumption, demand, or use, and/or pharmaceutical expenditures from a “standard” supply system and extrapolates the consumption or use rates to the target supply system, based on population coverage or service level to be provided (see Section 20.6).

Box 20-1

Estimating for programs that are scaling up care for patients requiring continuous treatment

In the following example, the program is scaling up with ten new patients per month requiring continuous treatment. The number of patient-months of medicines that can be expected to be consumed from January to April is $10 + 20 + 30 + 40 = 100$ patient-months.

A formula used to determine number of patient-months is—

$$P \left(\frac{n(n+1)}{2} \right)$$

P = average number of patients added each month
 n = number of months covered

For the preceding example the calculation would be—

$$10 \left(\frac{4(5)}{2} \right) = 100 \text{ patient-months for the period of January to April}$$

Service-level projection of budget requirements uses the average medicine cost per attendance or bed-day in different types of health facilities in a standard system to project medicine costs in similar types of facilities in the target system (see Section 20.7). This method does not estimate quantities of individual medicines.

Relative predictive accuracy of quantification methods

Quantification of pharmaceutical requirements is inherently imprecise because of the many variables involved. Useful results depend as much on “art,” or human judgment, as on science.

In many instances, the most precise method for quantifying pharmaceutical usage is the consumption-based approach, provided the source data are complete, accurate, and properly adjusted for stockout periods and anticipated changes in demand and use. This method does not normally address the appropriateness of past consumption patterns, which may or may not correspond with public health priorities and needs. Thus, irrational medicine use may be perpetuated by total reliance on the consumption method. If stockouts have been widespread for long periods, applying this method accurately may be impossible, which is why capturing actual demand is the most accurate approach.

Morbidity-based quantification is the most complex and time-consuming method. In many countries, assembling valid morbidity data on more than a defined set of diseases is very difficult; therefore, some needs will be overlooked in the quantification. Data on patient attendance are often incomplete and inaccurate, and predicting what percentage of prescribers will actually follow the standard treatment regimens used for quantification is difficult. Despite these constraints, this method may remain the best alternative for planning for procurement or for estimating budget needs in a supply system or facility in which a limited range of health problems accounts for virtually all medicine consumption, such as a small primary care system; a special-purpose hospital; a new program with no previous consumption history, such as HIV/AIDS programs rolling out antiretroviral therapy (ART); or changes in standard treatment guidelines.

Proxy consumption is the method generally used if neither the consumption-based nor the morbidity-based method is feasible. This method is most likely to yield accurate projections when used to extrapolate from one set of facilities to another set that serves the same type of population in the same type of geographic and climatic environment. If the method is applied by drawing standard data from another country, the results will be only a rough estimate of need. Even when target and standard facilities are closely matched, quantification estimates are suspect, because it is a big leap to assume that disease incidence, utilization pat-

terns, and prescribing habits will be essentially the same in both settings. Still, this method may be the best alternative in the absence of suitable data required for the consumption- or morbidity-based method. The proxy consumption method is also useful for cross-checking projections made with other methods.

Service-level projection of budget requirements produces a rough estimate of financial needs for pharmaceutical procurement and not the quantity of products. The method relies on two assumptions: (1) that the “standard” system (used for comparison) and the target system are comparable in terms of patient attendance and bed-days per type of facility, and (2) that the patterns of medicine use are roughly the same in both systems. Despite its limitations, this method can be useful in predicting medicine costs in a new system or in a system in which no data are readily available. [Table 20.1](#) summarizes the applications and limitations of the four major quantification methods.

20.2 Applications of quantification

Quantification is normally applied for—

Calculating order quantities for procurement: Formal quantification may be necessary before each scheduled procurement. These estimates need to be accurate to avoid stockouts, emergency purchases, and overstocks and to maximize the effect of procurement funds. The consumption method is the first choice, cross-checked to assess the appropriateness of usage and demand patterns. When consumption data are unreliable or unavailable, such as in new programs, the morbidity method, the proxy consumption method, or both, may need to be applied for an initial quantification, switching to the consumption method when reliable data can be compiled or the program has stabilized.

Estimating budget requirements: In many countries, the annual pharmaceutical procurement budget is determined by adding a fixed percentage to the previous year’s request or allocation to allow room for contingencies, such as expected cuts by the ministry of finance, population growth, or expansion of services. Both budget requests and cuts are frequently prepared without reliable estimates of actual needs. This cycle can be broken with rational, well-documented quantification. Although consumption-based quantification is the best guide to probable expenditures, the morbidity-based method may be the most convincing documentation for a budget request. Proxy consumption is useful for checking and justifying either consumption or morbidity methods. When budget requirements do not need to be justified by specifying order quantities, the service-level method can be used as an alternative.

Table 20-1 Comparison of quantification methods

Method	Uses	Essential data	Limitations
Consumption	<ul style="list-style-type: none"> • First choice for procurement quantifications, given reliable data • Most reliable predictor of future consumption 	<ul style="list-style-type: none"> • Reliable inventory records • Records of supplier lead time • Projected pharmaceutical costs 	<ul style="list-style-type: none"> • Must have accurate consumption data • Can perpetuate irrational use
Morbidity	<ul style="list-style-type: none"> • Estimating need in new and scaling-up programs or disaster assistance • Comparing use with theoretical needs • Developing and justifying budgets 	<ul style="list-style-type: none"> • Population and patient attendances • Actual or projected incidence of health problems • Standard treatments (ideal, actual) • Records of supplier lead time • Projected pharmaceutical costs 	<ul style="list-style-type: none"> • Morbidity data not available for all diseases • Standard treatments may not really be used • Accurate attendance difficult to predict
Proxy consumption	<ul style="list-style-type: none"> • Procurement quantification when other methods are unreliable • Comparing use with other supply systems 	<ul style="list-style-type: none"> • Comparison area or system with good per capita data on consumption, patient attendance, service levels, and morbidity • Number of local health facilities by category • Estimates of local user population broken down by age 	<ul style="list-style-type: none"> • Questionable comparability of patient populations, morbidity, and treatment practices
Service-level projection of budget requirements	<ul style="list-style-type: none"> • Estimating budget needs 	<ul style="list-style-type: none"> • Use by service levels and facility type • Average medicine cost per attendance 	<ul style="list-style-type: none"> • Variable facility use, attendance, treatment patterns, supply system efficiency

Developing procurement quantities for new programs: When medicines are needed for launching a new full-service health system or vertical program (such as HIV/AIDS programs or DOTS), quantification serves two purposes: to establish funding requirements for procurement and to develop the initial procurement list. In most situations, the consumption-based method is not feasible, and some combination of morbidity-based and proxy consumption methods must be used for the initial quantification.

Developing procurement quantities for scaling-up programs: *Scaling up* is the term used to describe an incremental increase or growth in the number of patients being treated over a period of time. Patient-months can be used to estimate needs for scaling up, where one “patient-month” is the quantity of a product needed to treat one patient for one month. The total number of patients treated over an incremental period of time in patient-months is often used in this situation for estimating needs for chronic conditions. For example, programs may not be able to serve all the patients needing ART at the start of an HIV/AIDS program but are able to scale up slowly as they receive additional donor funds, human resources, and training and address other access barriers (see [Box 20-1](#) for an example of a scaling-up calculation).

Quantifying for assistance projects: A donor organization may undertake ad hoc quantification studies to plan procurement needs in the context of a development project. When local consumption data are not sufficiently reliable for quantification, the morbidity or proxy consumption method should be used, either singly or in combination.

Estimating pharmaceutical requirements for emergency relief situations: In emergencies such as floods or earthquakes, the first step is to provide emergency kits quickly ([Chapter 26](#)). As local health problems become clear, a morbidity-based method can be used to project requirements in the short and medium term, until the regular supply system can resume services. [Country Study 20-1](#) describes quantification for a cholera epidemic.

Comparing actual medicine consumption with theoretical need: In most functional supply systems, the regular procurement quantification is based on past consumption. However, periodic comparison of consumption with theoretical demand based on public health priorities is a useful practice. The morbidity-based method provides the most informative comparison, but simply comparing consumption data from different systems is worthwhile because significant differences in medicine use can help identify irrational prescribing patterns or persistent inventory problems.

20.3 Issues to consider in quantification

Several issues must be addressed in any quantification process—

- Preparing an action plan for quantification
- Using centralized or decentralized quantification
- Using manual or computerized methods for quantification

- Estimating the time required
- Developing and organizing the medicines list
- Filling the supply pipeline
- Estimating the procurement period
- Considering the effect of lead time
- Estimating safety stock
- Adjusting for losses and other changes
- Cross-checking the results of quantification
- Estimating total procurement costs
- Adjusting and reconciling final quantities
- Preparing for possible program expansion (scaling up)

Preparing an action plan for quantification

Perhaps the most critical step in any large-scale quantification is preparing and then following a sound action plan through each step of the quantification. [Country Study 20-2](#) shows the Dominican Republic’s quantification experience when scaling up its national TB program. Essential points in planning for quantification include—

- Naming the official or office that will manage the process and define roles and responsibilities

Country Study 20-1
The morbidity method and a cholera epidemic in a Latin American country

A cholera epidemic in Latin America spread rapidly to most regions of one country within six months. A quantification was carried out to determine pharmaceutical supply needs to treat cholera patients.

Target coverage. All cholera patients requiring treatment through hospitals, clinics, and community health workers were to be covered.

Medicines list. The medicines to be included were not clear, because average treatment practices were not known and standard treatment guidelines had not yet been developed. A team collected data from sample patient charts and focused surveys to determine current treatment practices.

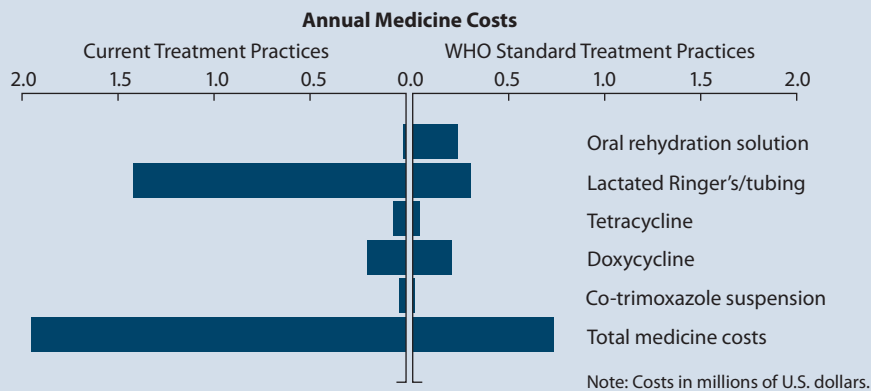

Source of supply. Products were to be purchased from both local and international suppliers. All cost estimates were converted to U.S. dollars for purposes of consistency.

Data. Because demand had increased dramatically for medicines used to treat cholera, stockouts were common and consumption data were not reliable. Fairly accurate morbidity data were readily available, reported weekly by fax to the central level.

Resources for quantification. A team of local and international specialists collected and analyzed data on disease incidence and current treatments and developed a computer spreadsheet for quantification.

Quantification. The morbidity method was used to calculate supply needs based on current epidemiological data, with two alternatives for treatment: current average treatment practices, and WHO treatment guidelines. The accompanying graph illustrates the projected annual supply costs for both calculations. Note the huge difference in total costs of the alternative treatment regimens. Total medicine costs were more than two times higher with current treatment practices, with the excess almost exclusively caused by overuse of lactated Ringer’s IV solution when oral rehydration solution (ORS) could be safely substituted.

Results and follow-up. The results of calculations were presented to the national cholera committee, which agreed to a switch to WHO guidelines. Policy makers used the comparative cost information in educational activities to improve prescribing practices.

- Forming a working group to coordinate activities of the offices, departments, and facilities involved
- Defining the objectives and coverage of the quantification
- Examining the availability of data and choosing the best quantification method according to objectives and available data and resources (personnel, funding, computer capacity)
- Developing medicines lists and data collection forms
- Determining standard treatments used in quantification
- Training staff members in the applicable quantification method and in data collection and analysis
- Developing a workplan and timeline for quantification, with realistic deadlines for each phase
- Managing quantification according to plan (adjusting for inevitable delays and unexpected constraints)
- Communicating results to relevant committees or

Country Study 20-2

Using consumption data to quantify medicines for the national TB program in the Dominican Republic

The morbidity method is usually recommended for quantifying tuberculosis (TB) medicines and supplies. The advantage of this method is that the necessary information, either the number of cases in previous years or the expected number of respiratory symptomatic cases (expected RS), is usually available in most TB programs. Since implementing the DOTS strategy in 2002, the Dominican Republic has used the expected RS–morbidity method to estimate the needs of TB medicines and commodities. However, as in most countries in the initial phases of implementing DOTS, the Dominican Republic National TB Program (DR-NTP) identified many fewer cases than expected. So in the program's initial years, the quantifications were overestimated, and deficiencies in the inventory reporting systems prevented corrections, leading to large surplus stocks. When a national financial crisis in 2004–05 slowed the public procurement process, the surplus TB medicine was used as safety stock.

In 2004, the DR-NTP pilot-tested a pharmaceutical information system based on consumption. The data showed a progressive depletion of the safety stocks in the health facilities in the pilot areas and overstocks of some medicines in certain other health facilities. Based on this information, the DR-NTP redistributed medicines from health facilities with overstocks to those with limited safety stocks to reduce the risk of interrupting or delaying the start of DOTS treatment. Furthermore, because of devaluation of the local currency, resources to procure TB medicines were insufficient to meet demand. Using data generated by the system, RPM Plus showed that the cost of a course of treatment for a new patient had increased from USD 32 in 2004 to USD 155 in 2005. RPM Plus presented the price analysis to Ministry of Health and TB program authorities and recommended they procure lower-priced, quality medicines through international agencies. As a result, a ministerial decree was pro-

mulgated that required TB medicines to be procured through the Global Drug Facility (GDF). The annual savings were estimated at about USD 775,000.

Although the information system was running in just two pilot areas, the data proved valuable for decision making. The staff endorsed the new system because the time it took to fill out the forms was less than the time it took to take physical counts of the medicines. Staff members also appreciated having an updated register of the availability of medicines in health facilities and warehouses at any given time. In addition, the daily consumption form provides an overview of medicine use in the health facilities, showing data on the start of new treatments, the completion of treatments, and treatment defaulters.

The consumption-based information system relies on four basic forms—

- A daily consumption form filled out in health facilities
- A quarterly report on consumption and availability (which is a requisition form, as well) filled out in health facilities and sent to the provincial authorities
- A quarterly report on distribution and availability (which is a requisition form, as well) filled out by the provinces and sent to the national authorities
- A quarterly national summary that is prepared at the national level

By 2010, the scaled-up information system was generating data routinely on stock levels at facilities. In addition to allowing program managers to respond promptly to the stock crisis, the information on prices paid allowed the national TB program to make important decisions about procurement methods to maximize the efficient and effective use of public resources.

managers to determine final assumptions and quantities

- Adjusting estimated quantities as needed
- Evaluating the quantification process and planning improvements to resolve problems encountered

The WHO manual *Estimating Drug Requirements* (WHO/DAP 1988) discusses how to develop a good action plan and manage the quantification process.

Countries that are faced with the major challenge of rapidly scaling up ART programs have special quantification issues to address. [Country Study 20-3](#) describes how some

African countries have worked to improve the quantification process for their ART programs.

Using centralized or decentralized quantification

Most supply systems have traditionally managed quantification at the central level. The increasing trend toward decentralizing this responsibility adds significantly to ownership of the results at health facilities and, if managed properly, can improve the accuracy of the results. However, a centralized approach is generally more efficient when the supply system is in equilibrium, with adequate supply to all levels.

Country Study 20-3

Quantification challenges in sub-Saharan countries scaling up antiretroviral therapy

An increase in funding from global initiatives such as the Global Fund to Fight AIDS, Tuberculosis and Malaria and the U.S. President's Emergency Plan for AIDS Relief has resulted not only in greater access to antiretrovirals (ARVs) in developing countries, but also in political pressures to increase the number of patients receiving ART. Previous methods used for quantifying pharmaceuticals clearly were not effective in the context of the unprecedented level of scale-up of HIV/AIDS programs, and new methods and tools were required to help countries and facilities determine their ARV needs.

Besides the scope and speed of the scale-up efforts, a key difference to address was the chronic nature of ART—lasting for the lifetime of a patient. A concern that continues to vex HIV/AIDS programs is quantification for pediatric ART. Issues include inappropriate pack sizes, the lack of fixed-dose combination products that are suitable for children, and the need to accommodate a child's growth patterns when calculating dose and consumption. (See [Chapter 2](#) discussion of HIV/AIDS, tuberculosis, and malaria.)

Management Sciences for Health's Rational Pharmaceutical Management (RPM) Plus Program worked with a number of countries in sub-Saharan Africa in developing effective ways to quantify their needs for scaling up ART programs—

Data collection. Often, data collected at the clinics do not meet the needs of pharmacy staff for quantification; for example, data may not represent patients who actually collect their medicines from the dispensary. Mechanisms and tools, such as the Electronic Dispensing Tool (MSH/SPS n.d.), were put into place to collect data at the dispensary. The tool has been

used in Côte d'Ivoire, Kenya, Namibia, Rwanda, Tanzania, and Zambia. The data collection activities were developed in collaboration with the facility staff members who collect and use the data themselves, resulting in more consistent collection and better quality data. Good quality data at the facility level is forwarded to the national program to use for national quantification purposes and results in more accurate forecasts and assumptions.

Quantification tools and related training. Facility-level tools were developed to determine quantification needs for ARVs. A manual and electronic version of the tool is used by facility staff to determine order quantities from the central medical stores. Quantimed, a quantification tool for larger programs, includes the capability to perform quantification for programs that are scaling up. Training for staff at central medical stores and ministries of health focuses on how to use Quantimed to estimate the amount of pharmaceuticals needed for procurement purposes and also to plan budgets and reports to donors. More information on Quantimed can be found in [Box 20-2](#).

Coordination mechanisms. Kenya, Namibia, and Rwanda established committees under their national AIDS control programs to regularly discuss procurement and quantification activities for HIV/AIDS programs. The committees include representatives from donors, central medical stores, and ministries of health as well as ART providers. The committees track growth trends, monitor data collection, and evaluate the assumptions used in national quantifications on a quarterly basis. The committees' key role is to identify problems in the quantification process and make recommendations to remedy them.

A common approach in decentralizing quantification is to have each responsible office or facility compile its own estimates, based on a common list of approved medicines. The list can be sent directly to the procurement office, which compares the list with past consumption, clarifies any questions directly with the client, and compiles the master list for procurement. Reviews at the district and provincial levels before submission to the procurement office may increase the validity and ownership of estimates, at the cost of adding time to the process.

It is important to make sure that consumption is not double counted: that is, if all medicines come to facilities

through a central warehouse, and a needs estimate is submitted by both the central warehouse and the client facilities that order from the warehouse, the total estimate for each medicine should be either the total of all facility estimates (plus central warehouse safety stock) or the central warehouse estimate, whichever is deemed more accurate.

Using manual or computerized methods for quantification

Conducting an accurate pharmaceutical quantification without computerization is possible; however, computers

Box 20-2

Quantimed: Pharmaceutical quantification and cost estimation tool

Quantimed is a Microsoft Access–based tool, developed by Management Sciences for Health, that facilitates the calculation of pharmaceutical needs using one of three primary quantification methods—past consumption, morbidity (including scaling-up patterns), and proxy consumption—or any combination of these. With appropriate data, Quantimed determines needs for a single health facility, a national public health program, or a group of geographic or administrative areas.

Quantifying needs for HIV/AIDS-related medicines and other commodities is particularly challenging in rapidly expanding prevention of mother-to-child transmission (PMTCT) and antiretroviral therapy (ART) programs that do not have data history to drive conventional model estimates. Quantimed’s scaling-up function facilitates calculations of pharmaceutical requirements and costs for programs that are expanding, and allows comparisons of different scaling-up scenarios.

The primary users of the Quantimed tool are program managers of public or private programs and government planners, all of whom can gain information useful for strategic and program planning, pharmaceutical rationalization, and financial planning.

Quantimed is designed to—

- Quantify requirements and calculate estimated cost of pharmaceuticals needed for a short course of treatment or long-term treatment for chronic conditions, such as HIV/AIDS
- Develop caseload estimates for each type of health service or intervention for a given target population, using morbidity-based, consumption-based, and/or proxy consumption-based methods

- Determine pharmaceutical requirements for a new or expanding public health program
- Compare the costs of alternative treatment regimens and pharmaceutical products
- Compare alternative expansion models to enable the user to determine the possible extent and speed for scaling up a program with given resources
- Calculate percentages of the patient population receiving various therapies for a program with limited treatment data
- Calculate the estimated total cost of medicines, medical supplies, laboratory supplies, and reagents needed to provide services for a given target population, or for an estimated number of patients
- Calculate order quantity, based on the best estimate of requirements for each pharmaceutical, according to user-defined procurement and inventory factors
- Assist program managers in comparing medicine and other health commodity prices from local and international suppliers
- Provide cost estimates in local currency and international currencies, as well as conversions between currencies

Users should be aware that Quantimed is only a tool; it cannot reason for itself. All results must be analyzed and interpreted using human judgment. Quantimed cannot be used to distinguish between accurate and erroneous data, or for distinguishing between rational and irrational therapy, determining which pharmaceuticals should be ordered, or making management decisions. A user’s guide is available (MSH/RPM Plus 2006).

For more information on Quantimed, see <http://www.msh.org/projects/sps/Resources/Software-Tools/Quantimed.cfm>.

using spreadsheet or database software make the process much easier. The examples of quantification tables in this chapter were constructed with a standard spreadsheet. One database software tool developed to ease the process of quantification is called Quantimed. For more information on Quantimed, see [Box 20-2](#).

Computerized quantification has three major advantages: speed, accuracy, and flexibility. The process is much faster because the formulas can be programmed into the software, and after the data for basic assumptions are entered, the calculations are done automatically. The computer itself will not make errors in computation; if the data are entered correctly and the formulas are correct, the calculated answer will be correct. Speed and accuracy are especially useful for very complicated calculations such as those used to determine the number of patient-months of treatment for programs that are scaling up.

Finally, it is much easier to do “what if” analysis, where the user makes changes in quantities of various items to see what happens to the total procurement costs. Tables constructed manually need to be retyped or rewritten, and all sums need to be recalculated each time a change is made. With a computer, the recalculation and reprinting are done at the touch of a key. When a computerized medicines list and quantification model have been developed, they can be reused repeatedly.

Estimating the time required

Quantification is time-consuming, and a realistic time frame must be established for all the steps in the quantification plan. The time frame depends largely on how many levels of the supply system are involved and on the quality and type of data available. In multilevel systems in which data are incomplete, several months will almost certainly be required to produce a useful quantification.

Developing and organizing the medicines list

The medicines list is the central component of any quantification process. The quantities needed cannot be calculated until it is known which products are needed. Specifications for each medicine on the list should include the following elements—

- Medicine description, generic name, or International Nonproprietary Name (INN)
- Dosage form, such as tablet, suppository, ampoule for injection
- Strength/concentration—for example, 250 mg, 95 percent, 10 mg/mL
- Basic unit, such as tablet, tube, milliliter, bottle
- Package size in basic units
- Projected purchase price per basic unit or per package

In computerized quantification, data management is easiest when a separate field is provided for each of these specifications (see [Chapter 50](#)).

The medicines on the list need to be sorted according to the type of quantification and the type of facilities and personnel that will be recording data. The list must be provided in a form useful for retrieving information quickly and correctly. For example, if medicines are stored and records are arranged by dosage form (all tablets and capsules together, all injections together), the list should be organized by dosage form. If items are stored by therapeutic class, the list should be organized by therapeutic class, and so on. If the process involves decentralized data collection, the list should be distributed on data collection forms to each level and facility responsible for quantification at least three months before the estimates are needed for procurement.

For decentralized quantification, all facilities should submit estimates directly on the list (by hard copy or electronically). This procedure allows the compilation of one master list in a reasonable time, comparison of estimated quantities among facilities, and verification of estimates and adjustment if necessary. Dosage forms and strengths should match those included in the appropriate standard treatment guidelines and those available from likely sources of supply. For example, if 500 mg tablets are quantified but suppliers offer only 300 mg tablets, making a conversion will be difficult.

Medicines lists for quantification are often derived from past procurement or formulary or essential medicines lists. Procurement lists from previous purchases may contain specifications and the last prices paid, but they may not represent rational medicine selection or comply with the formulary or essential medicines list. Essential medicines lists or medicine formulary lists that have been regularly updated should be the basis for the quantification list, because they reflect medicines needed for current morbidity patterns (see [Chapters 16 and 17](#)).

Filling the supply pipeline

The supply pipeline refers to stock levels within the supply system and the number of supply points at each level, as discussed in [Chapter 23](#). The number of levels, the frequency of requisition and delivery, and the amount of safety stock at each level all influence the amount of pharmaceuticals needed to fill the pipeline and, hence, the amount that must be procured when a program is started or expanded. Underestimation of stock in the pipeline is a common cause of program failure, particularly when a revolving drug fund has been planned. Quantification for a depleted pipeline should include the safety stock levels required at each level of distribution, not just the central level.

Estimating the procurement period

The procurement period covers the time from one order until the next regular order will be placed. In a scheduled system, this period might be multiples of one month; in a perpetual system, it could be counted in days or weeks for the purposes of quantifying. Note that the quantity ordered plus the safety stock must cover the time until the next order is received, which is the procurement period plus the lead time (see below). Procurement periods are influenced by funding and storage space availability as well as by expiry and stability of the stock being ordered.

Considering the effect of lead time

The procurement order quantity should be sufficient to last until the next procurement cycle is completed. The steps of the procurement process needed to place an order may take several months. In addition, after an order is placed, several more months are often required for the pharmaceuticals to arrive in the country, clear customs, and reach the central warehouse. The waiting period from the time an order is prepared until it arrives in the country is the lead time (Chapter 23). The lead time can vary for each product and/or supplier. When lead times are underestimated, the likely results are shortages and more expensive emergency purchases.

When quantifying for a program that is scaling up, the quantity required to cover the lead time will also need to be scaled up.

Estimating safety stock

Safety stock is the amount of stock that is kept in reserve in case an item is unavailable from the supplier or for a sudden increase in demand.

$$\text{Safety stock} = C_A \times \text{LT}$$

C_A = Average monthly consumption, adjusted for stock-outs (see Section 20.4)

LT = Average lead time (for projected supplier or worst case), in months

Any length of time can be used for the lead time in the preceding equation, but the period should be at least as long as the lead time period, while taking financial resources and storage space into consideration.

When a lead time is unreliable, safety stock should be increased. With a variable lead time, use the following formula—

$$DD_E = DD_p + (\text{OD} \times \text{OD}\%)$$

DD_E = expected delivery date

DD_p = promised delivery date

OD = average overdue period in days

OD% = percentage of orders overdue

When quantifying for a program that is scaling up, the quantity required for safety stock will also need to be scaled up.

Adjusting for losses and other changes

Inevitably, some medicines will be lost because of damage, spoilage, expiration, and theft. If such losses are not considered in quantification and procurement, stockouts are likely to result. To prevent shortages, a percentage can be added to allow for losses when quantifying requirements. Many systems need to allow at least 10 percent for losses.

Not all medicines are equally at risk for loss—for example, some are more attractive to thieves than others, such as valuable antiretrovirals and artemisinin-based anti-malarials. The medicines that are most at risk may vary from country to country. If they can be identified, adjusting the quantities for those items by a higher percentage may be feasible, rather than applying the same adjustment to all items. One strategy is to allow a loss percentage only for vital items, accepting the risk of stockouts for other items. If losses have already been accounted for as part of a consumption-method quantification, there is no need to make a loss adjustment.

Clearly, the best interests of the health system are served by making every effort to control loss and wastage. Options for controlling theft are discussed in Chapter 43; Chapter 40 offers tips for analyzing expiry dates in a large pharmaceutical inventory; and Chapters 45 and 46 provide suggestions for managing stock to avoid wastage.

In a supply system in which patient use or the number of facilities is growing, assuming that medicine consumption will increase is reasonable. In such situations, estimated quantities can be increased by a percentage corresponding to the rate of growth.

Cross-checking the results of quantification

Because there will be some imprecision in the estimates no matter how rigorously the appropriate quantification methods are followed, checking the estimates with a different quantification method is always useful. Ideally, the estimates would produce very similar results, but in practice this rarely happens. The two sets of data can then be evaluated to see which appears to be more realistic, considering the reliability of source data used for the two estimates. Box 20-3 provides guidelines for how to evaluate and compare consumption-based versus morbidity-based estimates. These quantities will likely need to be adjusted to fit

Box 20-3**Comparing morbidity- and consumption-based estimate results**

The following scenarios include suggested actions to take based on the results of each method and depending on confidence in the data used. For the consumption method, the pharmaceutical management information system should accurately and reliably maintain data on *consumption* (not on stock movement, which may include losses and expired stock). A crucial factor to consider in any analysis of results is the possible irrational use of medicines in the system.

Consumption-based estimate greater than morbidity-based estimate

If the consumption-based estimate is 50 percent greater than the morbidity-based estimate, conduct a more detailed investigation of the data before proceeding with the quantification. Were the data entry and transcription done correctly? Was the correct population and morbidity information obtained? Is there a possibility of large-scale leakage and/or diversion of supplies? When the data have been verified, or for discrepancies less than 50 percent, proceed as follows—

If **not confident in the quality of either** the consumption or morbidity data—

- Consider an overall system assessment, then strengthening of the health management information system and pharmaceutical management information system.
- Seek comparative facilities, regions, or countries with reliable information systems and use their data as proxy data.
- Try to estimate the percentage of confidence in the accuracy, completeness, or reliability of the data and adjust the results accordingly.

If **more confident in the consumption data** than the morbidity data—

- Examine the morbidity data for underestimation of disease incidence.
- Make sure the population data are current. Ask whether any large movement of population into the area has occurred, such as refugees, seasonal workers, or employees of new industries.
- Determine whether standard treatment guidelines are followed.
- Investigate whether pharmaceuticals are used in other programs or for other purposes.

If **more confident in the morbidity data** than the consumption data—

- Consider whether pilferage, expiration, or stock leakage is high.
- Investigate whether pharmaceuticals are used in other programs or for other purposes.
- Ask whether stockouts of related pharmaceuticals caused higher consumption of this item.

If **confident in the quality of both** the consumption and morbidity data—

- Use the consumption-based estimate to avoid the problem of ordering too few pharmaceuticals and supplies.

Morbidity-based estimate greater than consumption-based estimate

If **not confident in the quality of either** the consumption or morbidity data—

- Consider an overall system assessment, then strengthening of health management information system and pharmaceutical management information system.
- Seek comparative facilities, regions, or countries with reliable information systems and use their data as proxy data.
- Try to estimate the percentage of confidence in the accuracy, completeness, or reliability of the data and adjust the results accordingly.

If **more confident in the consumption** data than the morbidity data—

- Examine the morbidity data for overestimation of disease incidence.
- Ask whether a change in population has occurred as a result of exodus caused by war, unrest, drought, famine, migration of seasonal workers, or departure of refugees.
- Determine whether standard treatment guidelines are followed.
- Investigate whether pharmaceuticals are used for other programs or for other purposes.
- Consider whether program coverage is low and/or support services or diagnostics for health conditions are inadequate.

If **more confident in the morbidity** data than the consumption data—

- Consider whether the management information system is poor.
- Ask whether the budget has been sufficient to meet the full needs of the population or if a proportion has gone untreated.
- Consider whether program coverage is low and/or support services or diagnostics for health conditions are inadequate, and whether access to these services

has been limited by unrest, strikes, or transport problems.

- Determine whether medicines are being supplied from multiple sources not included in the quantification.

If **confident in the quality of both** consumption and morbidity data—

- Use the morbidity-based estimate to avoid ordering too few pharmaceuticals and supplies.

the budget as well. [Table 20-2](#) illustrates how three different quantification methods produced different estimates for the same supply system in a Latin American country.

Cross-checking is a fundamental step in reconciling procurement quantities with available funds. It is also useful to cross-check consumption with theoretical demand to get an idea of the rationality of pharmaceutical therapy in the system. If the supply system usually bases purchases on past consumption, cross-checking for high-volume, high-cost medicines using another method may reveal targets for interventions to promote more rational medicine use. For example, in one quantification conducted for intrauterine devices (IUDs), the quality of the issues data (quantities distributed from a storage point) were considered good, and indeed they were an accurate record of the stocks given out. However, enough IUDs had been issued for every man, woman, and child in the province. A comparison of the population and morbidity data highlighted the problem of leakage and/or resale of the IUDs outside the country. This comparison produced a more accurate quantification for next year's supply.

Estimating total procurement costs

When estimating the cost of medicines on a quantified list, the critical issue is determining the next purchase prices. Using the last purchase prices is not adequate, because in most cases, doing so results in an underestimate of the actual next purchase prices, leading to insufficient funds when the time comes to place orders.

Two basic ways exist to estimate the next purchase price of a medicine; both are usually needed to estimate the cost for the full list of medicines.

The first option is obtaining data on current medicine prices in the market where the medicines will be purchased. As discussed in [Chapter 21](#), sources for price data include local suppliers, international procurement agencies, and references such as Management Sciences for Health's *International Drug Price Indicator Guide*, which is updated annually.

Table 20-2 Comparison of quantification results in a Latin American country

Medicine	Consumption estimate	Morbidity estimate	Proxy consumption estimate
ORS 1 L package	11,290,000	18,650,000	14,850,000
Chloroquine 300 mg tablet	1,230,000	2,233,000	2,005,000
Paracetamol 500 mg tablet	20,960,000	14,010,000	22,320,000

The other option for estimating next purchase price is to adjust the last purchase price for factors such as—

- International inflation for products bought internationally
- Devaluation of local currency for products purchased internationally (if relevant)—this percentage is added to the price for medicines purchased on the international market
- Local inflation for products purchased on the local market, adding the appropriate percentage based on the current local situation

After price estimates are obtained, percentages for shipping and insurance of pharmaceuticals obtained from international sources (usually 15 to 20 percent) and any known fees, such as those paid to a tender board or for local customs duties, must be added.

Adjusting and reconciling final quantities

Difficult decisions must often be made to reduce the number of medicines or the quantities of medicines or both until the estimated quantities and costs correspond with the available budget. These reductions may require policy decisions regarding priority diseases, priority age groups, priority facilities to be supplied, selection of less expensive

SUCCESSFUL PHARMACEUTICAL QUANTIFICATION REQUIRES A TEAM EFFORT AND A MIX OF METHODS

therapeutic alternatives, and changes to standard treatment guidelines. [Chapter 40](#) discusses several approaches for making reductions rationally, using specific tools such as VEN (vital, essential, nonessential) categories, ABC analysis, and therapeutic category analysis. Another way of providing a foundation for reduction is to cross-check the quantification with another method to find out where the quantified estimate is much higher than necessary based on known morbidity and attendance data or much higher than that in a comparable health system.

Eliminating adjustments for expected losses may be a tempting first step in reducing quantities, but it is a false economy unless losses will in fact be eliminated. If the losses are likely to occur, they must be incorporated into the final quantification, or stockouts will almost certainly result. Cutting the overall percentage allowed for losses may be possible by targeting the allowance to those items most at risk and/or eliminating the adjustment for nonvital medicines, with the expectation that some stockouts will result for medicines that are not covered.

20.4 Consumption method

In the consumption method, a list is prepared of all medicines eligible for procurement, and the most accurate inventory records of past consumption are used to calculate the quantities needed for each medicine.

Consumption during a recent period of six to twelve months is adjusted for stockouts to obtain the average monthly consumption. A percentage for increase in projected use is added to the projected monthly consumption. Then the average monthly consumption is multiplied by the number of months to be covered by the procurement. Safety stock and lead time levels (in months) are also multiplied by the projected monthly consumption. These three figures are added to obtain the gross needs during the period, subtracting the usable stock on hand and any stock on order from the gross estimate, to derive the quantity to purchase. This quantification formula is the same as the consumption-based reorder formula described in [Chapter 23](#). An adjustment is then made for losses.

The anticipated unit cost for each medicine (not the last unit cost) is multiplied by the number of units to be purchased to obtain the expected purchase value for the entire quantity. All purchase values for individual medicines are added to obtain the total expected procurement cost. If this cost is greater than the budget, adjustments are made, as described in the previous section.

Example

[Table 20-3](#) shows a sample consumption-based quantification from an eastern Caribbean country. This sample is

not the complete quantification list, but it illustrates the estimates for nineteen medicines. [Box 20-4](#) provides a summary of calculations used in consumption-based quantification.

Steps in the quantification

Step 1. Prepare a list of medicines to be quantified. The medicines list should be prepared as described in Section 20.3, sorted into the order that will best facilitate data collection, and distributed to those officials and facilities that will enter consumption data.

Step 2. Determine the period of time to be reviewed for consumption. If the procurement is to cover a twelve-month period, the consumption data for the past twelve months should be reviewed (if a full year's useful data are available). A twelve-month review may also be used for a procurement covering six months, but if seasonal variations are significant, such as with malaria, using the same six-month period from the preceding year may be preferable. A short review period, such as three months, is inadequate to plan a procurement to cover twelve months, unless the three months reviewed reflect a steady state of consumption for the entire year.

Step 3. Enter consumption data for each medicine. For each medicine on the list, enter—

- The total quantity used during the review period, in basic units
- The number of days in the review period that the medicine was out of stock (if the number of days out of stock cannot be determined with accuracy, the estimated number of months out of stock during the period can be entered)
- The lead time for the last procurement (or the average from the last several procurements)

Using the most accurate and current records available is important. The likely sources for data on consumption and lead time are—

- Stock records and distribution reports from a central distribution point
- Stock records and reports from regional or district warehouses
- Invoices from suppliers
- Dispensing records from health facilities

If projected pricing data are available at this stage, entering prices while entering consumption data (see step 10) may save time.

Step 4. Calculate the average monthly consumption. The average monthly consumption is a key variable in the quantification formula and should be as accurate as

Table 20-3 Consumption-based quantification for an eastern Caribbean country

Medicine	Strength	BU	C _T		D _{OS}	C _A		C _P	S _L	S _O	SS	O _O	Q _A		Value of proposed order (USD)
			Pack size	Total consumption in period (BU)		Adjusted average monthly consumption (BU)	Projected average monthly consumption (BU)						Stock on hand (BU)	Stock on order (BU)

Dextrose in saline (IV) 1,000 mL	5%/0.9%	Bottle	1	1,525	32	308	323	0	2,288	969	1,588	1,747	1,747	1.35	2,358.45
													Total order cost:	27,097.16	

Note: BU = basic unit; USD = U.S. dollars; MU = mega-unit; consumption period = 6 months; lead time = 3 months; procurement period = 6 months; use adjustment for 6 months = 5%; loss adjustment = 10%.

Box 20-4 Consumption-based calculations

Formula number	Objective of formula	Calculations
1	Adjusted average monthly consumption (preferred)	$C_A = C_T \div [R_M - (D_{OS} \div 30.5)]$
2	Adjusted average monthly consumption (alternative)	$C_A = C_T \div (R_M - M_{OS})$
3	Projected average monthly consumption	$C_P = C_A + (C_A \times A_U)$
4	Basic safety stock requirements	$C_A \times LT$
5	Quantity to order	$Q_O = C_A \times (LT + PP) + SS - (S_I + S_O)$
6	Quantity to order adjusted for losses	$Q_A = Q_O + (Q_O \times A_L)$

C_A = Average monthly consumption, adjusted for stockouts	SS = Quantity needed for safety stock
C_T = Total consumption during review period, in basic units	LT = Average lead time (for projected supplier or worst case), in months
R_M = Total consumption review period, in months	Q_O = Quantity to order in basic units, before adjustment for losses or program change
D_{OS} = Number of days an item was out of stock during the review period	PP = Procurement period (number of months to be covered by order)
M_{OS} = Estimated number of months an item was out of stock during the review period	S_I = Stock now in inventory, in basic units
C_P = Projected average monthly consumption	S_O = Stock now on order, in basic units
A_U = Use adjustment	Q_A = Quantity to order adjusted for losses or program change
	A_L = Loss adjustment

possible. The simple approach is to divide total consumption by the number of months reviewed. If stockouts occurred during that period, the average must be adjusted to include the consumption that would have occurred if stock had been available.

Two ways exist of accounting for stockouts when computing average monthly consumption. The recommended method is illustrated in [Box 20-4](#) as formula number 1. Enter the total consumption and divide this number by the number of months in the review period minus (the total number of days out of stock in the same period divided by 30.5 to convert to months). For example, see the entry for ampicillin 250 mg capsules in [Table 20-3](#), which shows consumption-based quantification for a Caribbean country. Total consumption for a six-month review period was 89,000 capsules. The medicine was out of stock for thirty-four days in the six-month period. Therefore, the average monthly consumption is—

$$C_A = 89,000 \div [6 - (34 \div 30.5)],$$

$$\text{or } 89,000 \div 4.8852 = 18,218$$

An alternative method, which is simpler but less precise, is shown as formula number 2 in [Box 20-4](#). It uses the estimated number of months out of stock for adjusting consumption, omitting the step of converting days to months. Using the same medicine from [Table 20-3](#), the medicine was in stock for about five of the six months, leaving about one month out of stock. Therefore, the average monthly consumption is—

$$C_A = 89,000 \div (6 - 1) = 89,000 \div 5 = 17,800$$

Step 5. Calculate projected average monthly consumption for expected changes in consumption pattern.

When using the example of ampicillin 250 mg capsules in [Table 20-3](#), if use is expected to increase by 5 percent in the coming year, adjusting the average monthly consumption by 5 percent would be reasonable, which would raise the expected monthly need by 911 capsules, bringing the total to 19,129 capsules.

Some changes in consumption may be independent of trends in overall patient use. One example is predictable seasonal variation in the consumption of cough and cold remedies. A potential spike in an unpredictable epidemic disease such as cholera is another example. If such variation is anticipated or is part of the consumption data, increasing or decreasing estimates for medicines such as oral rehydration solution, parenteral solutions, and some antibiotics would be sensible; however, this variation does not mean that the need for all medicines will increase or decrease by the same factor.

If a new formulary medicine is known to be replacing an older medicine in the formulary, the estimate for the older medicine should be reduced. If an initiative is being launched to alter prescribing patterns, anticipating at least some success by reducing the expected need for targeted medicines by a small percentage would be reasonable. When a turnover occurs in prescribing staff members, the new prescribers may have different ways of treating common conditions that could substantially affect medicine needs in some therapeutic categories. If such changes can be anticipated, adjusting the forecasts would be wise to avoid spending resources on medicines that will not be as popular as in the past.

Step 6. Calculate the safety stock needed for each medicine. Safety (buffer) stock is needed to prevent stockouts, although high levels of safety stock increase inventory holding costs and should be avoided (see [Chapter 23](#)). In some supply systems, the safety stock is set for each item at a fixed quantity or a fixed number of months' worth of consumption. However, the preferred method is to calculate the safety stock based on the projected average consumption and the expected lead time (see formula number 3 in [Box 20-4](#)). The projected average consumption from step 5 is multiplied by the average lead time. This safety stock level should avoid stockouts, assuming that the item is reordered when only the safety stock remains, the supplier delivers within the projected lead time, and consumption is no greater than average. Using formula number 3 in [Box 20-4](#), the safety stock for ampicillin 250 mg capsules in the example is $19,129 \times 3 \text{ months} = 57,387$.

For vital items identified from a VEN analysis (see [Chapter 40](#)), adjusting the safety stock may be necessary to cover variations in consumption or lead time. Several options can be used for adjusting safety stock levels (see [Chapter 23](#)). The simplest method multiplies the basic safety stock by an adjustment factor. For example, an adjustment factor of 1.5, or 50 percent, would increase the safety stock of ampicillin 250 mg capsules in [Table 20-3](#) to 86,081 capsules. If this sort of adjustment is done for all items, the cost of safety stock will increase substantially; therefore, adjustments should be made only when true uncertainty exists about the lead time or consumption.

Step 7. Calculate the quantity of each medicine required in the next procurement period. The suggested formula for calculating the quantity to order is shown as formula number 5 in [Box 20-4](#). The calculation is done in three main steps. First, the projected average consumption is multiplied by the sum of the lead time and the procurement period, yielding the total needs before considering safety stock, stock on hand, or stock on order. The second step is to add the quantity needed for safety stock. Finally, the quantity of usable stock on hand and the stock on order are added together, and then subtracted from the previous total. Using the example of ampicillin 250 mg capsules from [Table 20-3](#), the quantity to order is—

$$Q_o = 19,129 \times (3 + 6) + 57,387 - (81,000 + 58,000) = 90,548$$

Because the ampicillin capsules are purchased in bottles of 1,000, ninety-one bottles should be ordered.

Step 8. Adjust for losses. To avoid stockouts, one should adjust quantification estimates to allow for losses, as discussed in Section 20.3. If the supply system from [Table 20-3](#) averaged 10 percent per year in losses, and this percentage was applied to ampicillin 250 mg capsules, the allowance would add 9,055 capsules to the estimate from step 7, bring-

ing the total purchase quantity to 99,603, or 100 bottles of 1,000 capsules.

Step 9. Compile decentralized quantifications (if applicable). In a decentralized quantification, staff members at each facility or storage point enter their own consumption quantities and stockout information following the preceding steps, and the estimates of the individual facilities are totaled and compiled on the master quantification list.

Step 10. Estimate costs for each medicine and total costs. In order to estimate procurement costs, multiply the quantities estimated for each medicine by the most accurate prediction of the expected next purchase price (not the last one), as discussed in Section 20.3.

After the expected price has been entered for each medicine, multiply the price by the estimated quantity needed to obtain the total procurement value for each medicine. [Table 20-3](#) uses the package price as the basis for making these projections, but in many cases using the unit price is preferable, because combining information from different sources to arrive at an average allows more flexibility. The basic unit price is also preferable if the package sizes that will be ordered are not known or if projections are based on average international prices from a source such as the annual *International Drug Price Indicator Guide*.

After the estimated procurement value has been calculated for each medicine, the final step in the basic quantification process is to add the estimated procurement values for all medicines to obtain the total expected cost for the procurement.

Step 11. Compare total costs with budget and make adjustments. If the total expected procurement cost exceeds the available budget, only two choices exist: either obtain more funds or reduce the number of medicines and/or the quantities ordered. Section 20.3 discusses rational ways to adjust the estimates.

20.5 Morbidity method

The morbidity method uses data on patient use (attendances at health facilities) and morbidity (the frequency of common health problems) to project the need for medicines based on assumptions about how the problems will be treated. Readers who plan to undertake a morbidity-based quantification can refer to the WHO manual *Estimating Drug Requirements* (WHO/DAP 1988), which provides a more detailed discussion of the steps in this type of quantification.

The morbidity method requires a list of common health problems, an essential medicines list that includes therapy for the problems, and a set of standard treatments for quantification purposes (based on either average current practices or "ideal" treatment guidelines). For most health problems, at least two alternative treatments exist, and a percentage must be assigned based on how frequently each regimen is

used. Then, the expected incidence (number of treatment episodes) of each health problem must be estimated. The incidence of a health problem can be estimated from total patient contacts or from a subgroup, for example, “number of HIV-infected patients” or “number of women attending antenatal clinic services.”

The quantification formula involves multiplying the quantity of each medicine included in standard treatments for each health problem by the number of treatment episodes expected for the health problem. The expected total need for each medicine is the sum of the estimates from all treatment regimens in which the medicine is included. Then the estimates are adjusted to fill the supply pipeline, allowing for losses caused by theft and wastage. Finally, the expected cost is calculated on the basis of the expected purchase price of each medicine, and estimates are reconciled with available funds.

Because of the limited data likely to be available on morbidity patterns and the difficulty in defining standard treatments that are meaningful for quantification, applying this method to every health problem is difficult. This difficulty limits the method’s utility for a complex health system with many types of health problems and several levels of health facilities. In general, the morbidity method is most useful in estimating for a relatively small number of different health problems, for example, in primary care and special-purpose facilities and programs.

Because a limited number of health problems are likely to be addressed in most morbidity-based quantification procedures, the resulting estimates for each medicine must be adjusted to cover health problems not considered in the quantification, usually using some variant of proxy consumption (see Section 20.6). Adjustments may also be required to fill the supply pipeline, to account for losses, and, in most cases, to reconcile the quantities needed with the funds available.

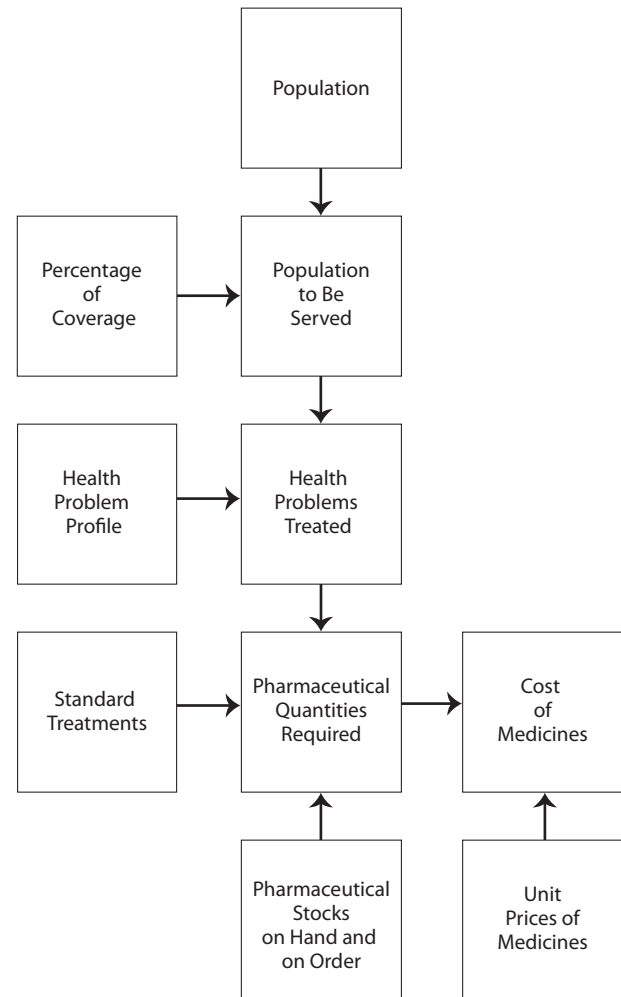

In a simple quantification exercise for one health problem, such as cholera (see [Country Study 20-1](#)), or for a small group of health problems and medicines, the process can be done manually (although it is easier with a computer). A spreadsheet program or specialized quantification software, such as Quantimed, is virtually required to conduct a complicated morbidity-based quantification covering a large number of health problems and medicines (see [Box 20-2](#)).

[Figure 20-1](#) is a flow diagram that illustrates how the data inputs on population, percentage of coverage, health problems, standard treatments, and unit costs are used to calculate the quantities needed and projected procurement costs.

Example

[Table 20-4](#) is an example of morbidity-based quantification. The table shows a number of health problems for which medicines are to be procured, morbidity estimates for a

Figure 20-1 Morbidity method

one-year period, and sample standard treatment regimens expected to be prescribed for the health problems. The medicine needs for the health problems are calculated in basic units. All this information, together with projections for losses, adjustments made to reflect available funds, and quantities required to fill the supply pipeline, is used to produce a procurement list. [Table 20-4](#) follows steps 1–6 in the next section. [Box 20-5](#) provides a summary of calculations used in morbidity-based quantification.

Steps in the quantification

Step 1. Specify the list of problems. List the major specific health problems encountered (see [Table 20-4](#)). If an existing information system reports on diseases, those disease codes should be used; if no coding system exists, the International Classification of Diseases (ICD) system can be used. (See <http://www.who.int/classifications/icd/en> for more information.)

Table 20-4 Pharmaceutical needs based on morbidity

Problem	Severity	Age group	F		E _T	P _T	Pharmaceutical product	Basic unit	D _{CU}	N _D	L _D	Q _E	Q _T
			Episodes per 1,000 contacts	Expected number of contacts									
Malaria	1	<5	364	3,279,578	1,193,767	100	Artesunate 50 mg	Tablet	1	1	3	3	3,581,301
							Paracetamol solution 120 mg/5 mL	Tablet	1	1	3	3	3,581,301
	>5	278	3,279,578	911,723	80	Artesunate 50 mg	Tablet	4	1	3	12	10,940,676	
						Paracetamol solution 120 mg/5 mL	Tablet	4	1	3	12	10,940,676	
		2	80	3,279,578	213,173	100	Quinine injection 300 mg/mL	mL	0.50	3	1	1.5	319,759
							Quinine 300 mg	Tablet	0.50	3	6	9	1,918,553
Conjunctivitis	—	<5	53	3,279,578	173,818	100	Quinine injection 300 mg/mL	mL	2	3	1	6	1,200,326
							Quinine 300 mg	Tablet	2	3	6	36	7,201,954
	>5	61	3,279,578	200,054	100	Paracetamol solution 120 mg/5 mL	mL	1.50	4	10	60	12,790,356	
						Quinine injection 300 mg/mL	mL	2	3	1	6	1,200,326	
		2	100	3,279,578	347,635	100	Paracetamol solution 120 mg/5 mL	mL	1.50	4	10	60	12,790,356
							Quinine injection 300 mg/mL	mL	2	3	1	6	1,200,326
Otitis media	—	<5	38	3,279,578	124,624	100	Tetracycline 1% eye ointment	5 g tube	1	3	7	1	173,818
							Tetracycline 1% eye ointment	5 g tube	1	3	7	1	124,624
	>5	106	3,279,578	347,635	100	Co-trimoxazole suspension	mL	5	2	10	100	34,763,531	
						Paracetamol solution 120 mg/5 mL	mL	1.50	4	10	60	20,858,119	
		3	80	3,279,578	95,108	100	Pseudoephedrine syrup	mL	2.50	4	5	50	13,905,412
							Co-trimoxazole 800/160 mg	Tablet	1	2	10	20	1,902,155
Acute tonsillitis	—	<5	72	3,279,578	236,130	100	Paracetamol solution 120 mg/5 mL	mL	1.50	4	10	60	20,858,119
							Penicillin VK 125 mg/5 mL liquid	mL	5	4	5	100	23,612,964
	>5	33	3,279,578	108,226	100	Paracetamol solution 120 mg/5 mL	mL	1.50	4	10	60	4,167,779	
						Procaine penicillin 3 MU injection	Vial	1	1	1	1	108,226	
		2	100	3,279,578	36,075	100	Penicillin VK 250 mg	Tablet	1	4	5	20	2,164,522
							Paracetamol 500 mg	Tablet	2	4	5	40	4,329,043
Gastritis, heartburn	—	<5	11	3,279,578	252,528	70	Antacid suspension	mL	5	4	5	100	3,607,536
							Antacid suspension	mL	10	4	5	200	35,353,855
	2	30	3,279,578	108,226	100	Cimetidine 300 mg	Tablet	1	4	5	20	1,515,165	

Note: Based on 3,123,408 contacts in the past year; 5 percent expected rate of increase; MU = mega-unit.

The health problem list should not be broken down into too much detail but should be defined according to the diagnostic capacity and health problems treated at each type of health facility. At the lowest level of the system, only a limited number of problems are recognized and treated; the range of problems diagnosed and treated normally increases at the health center, district hospital, and referral hospital levels.

Because treatments differ markedly for adult and pediatric patients, at least two categories (under five years and over five years) need to be included for most problems. Although it may be tempting to establish several categories (under five, five to twelve, thirteen to sixty-five, and over sixty-five), it is best to avoid overcomplicating the development of treatment guidelines (see below) and the process of compiling data on treatment episodes.

Step 2. Establish the list of medicines to be quantified.

The objective here is a list of essential medicines that covers the major health problems and forms the basis for standard treatment schedules (see Table 20-4). A current and appropriate national or health system formulary or essential medicines list should be used when available. If no official list exists, one needs to be developed (see Chapter 17); it may grow out of the process of developing standard treatments.

The medicines list must be available in two formats—one organized in alphabetical order by generic name (INN) and one by therapeutic categories. The therapeutic category list is most useful in developing standard treatment schedules, and the list organized by generic name is used for the procurement list.

Step 3. Establish standard or average treatments.

Standard or average treatment regimens are required for each health problem to forecast medicine needs, as in Table 20-4. Developing this information is the most complicated part of using the morbidity method. Two basic options exist for developing standard treatments: average actual treatments or ideal standard treatments. The components are the same,

but an important difference exists between the approaches: average regimens are based on observed or reported practices and are more likely to predict what will actually happen, whereas ideal regimens define what should happen if prescribers follow the ideal guidelines. Country Study 20-1 illustrates how different the results can be between average current treatments and standard treatments.

Which should be used? Perhaps both, in a combination approach. For example, if one treatment regimen is viewed as ideal but another is commonly used, include both regimens in the guidelines for quantification and estimate the percentage of treatment episodes that will receive each of the two regimens.

For some health problems, particularly with severely ill patients, the duration of treatment varies significantly between individual patients, depending on their treatment response. Expert advice should be used to help estimate average treatment duration. The same applies for preventive treatment, where adherence to treatment can significantly influence treatment duration.

In most quantification exercises, developing (or modifying) the treatment guidelines is necessary (see Chapter 17). Ideally, standard treatment guidelines should be developed by expert committees (with additional expert assistance, if needed). Unless reliable information is available on medicine use and prescribing patterns, a special study may be needed to determine average actual treatment patterns; this study can be combined with a study to determine morbidity patterns and incidence of health problems (see step 4).

Whichever option is used, the same information must be compiled (see Section 20.3)—

- The percentage of treatment episodes in which the medicine will be prescribed
- The name of each medicine and strength/concentration with separate treatments listed for age (or weight) level, as appropriate

Box 20-5
Morbidity-based calculations

Formula number	Objective of formula	Calculations
1	Quantity of medicines needed per treatment episode	$Q_E = D_{CU} \times N_D \times L_D$
2	Expected total number of contacts (in thousands)	$C_E = C + (C \times A_U)$
3	Expected treatment episodes	$E_T = C_E \times F$
4	Total quantity of medicines needed	$Q_T = E_T \times Q_E \times P_T$

Q_E = Quantity of each medicine needed for each treatment episode
 D_{CU} = Basic units per dose
 N_D = Number of doses per day
 L_D = Length of treatment in days
 C = Past total number of contacts
 A_U = Utilization adjustment

C_E = Expected total number of contacts
 F = Frequency of health problem (per thousand)
 E_T = Expected treatment episodes
 Q_T = Total quantity required
 P_T = Percentage of cases expected to be treated

- The basic unit
- The number of basic units in each average dose for the health problem in question
- The average number of doses of each medicine per day for the problem
- The average number of days of treatment for each medicine per episode

These components are combined to project the quantity of each medicine needed for each treatment episode (Q_E) in each standard treatment regimen. This projection is made by multiplying the basic units per dose (D_{CU}) by the number of doses per day (N_D). This result is multiplied by the length of treatment per episode, in days (L_D). The entire formula is—

$$Q_E = D_{CU} \times N_D \times L_D$$

In the example from [Table 20-4](#), three different medicine products are prescribed for otitis media for both age groups; the medicines are the same, but the dose and dosage form differ. The quantity of co-trimoxazole suspension needed to treat otitis media in patients under five years old is calculated as—

$$Q_E = 5 \text{ mL} \times 2 \text{ doses/day} \times 10 \text{ days} = 100 \text{ mL}$$

Generally, this calculation is done for all medicines in all the standard treatment regimens; however, the formula may not be appropriate for all formulations, such as in pediatric solutions, because patients may receive an entire bottle rather than the exact volume needed for a treatment course. Using the average consumption over the course of treatment (or monthly, for chronic conditions) may be more accurate. Similarly, for conjunctivitis in [Table 20-4](#), the basic unit used in the treatment is one tube of eye ointment, but one dose would not comprise one tube—a tube should last throughout the course of treatment.

If different treatment regimens (perhaps with multiple medicines) are used for the same disease according to its severity, separate standard regimens must be considered and assigned for each. This situation is illustrated by the malaria treatment guidelines in [Table 20-4](#), which include two levels of severity. Patients who are categorized as severity 2 could have started on this regimen directly or have been put on this regimen after first-line treatment failed.

For each regimen, the proportion of patients with each disease who will be treated with each different therapy is estimated. From [Table 20-4](#), in patients over five years old with gastritis, 70 percent are expected to be treated with antacid and 30 percent with cimetidine. In some situations, depending on treatment practices, allocating 70 percent for antacid and 50 for cimetidine (because some patients will receive both medicines) might be appropriate. Thus, the

cumulative percentage may exceed 100 percent for a particular health problem.

If major differences exist in the way that health conditions are treated by different level and/or prescribers, estimating how many (or what percentage of) treatment episodes of each disease will be managed by each category of prescriber may be useful; then specify separate treatment regimens common for each prescriber category.

Practitioners involved in developing standard treatment guidelines for quantification should understand that the guidelines are for quantification only and that a prescriber's freedom will not necessarily be curtailed as a result. In one West African country, a committee was formed to develop standard treatment guidelines for quantification, with the assistance of an outside expert. The committee met but decided that standard treatment guidelines would restrict doctors' freedom to choose a therapy and instead produced a simple therapeutics manual. When the external quantification team arrived in the country, no lists had been produced of common diseases with guidelines for quantification, and the process ultimately failed to produce a useful list for procurement.

Step 4. Collect morbidity data for each health problem treated. This step estimates the expected number of treatment episodes for each health problem from step 1. A treatment episode is “a patient contact for which a standard course of drug treatment is required” (WHO/DAP 1988, Module 6, Section 1). [Table 20-4](#) shows one way of organizing morbidity data for the health problems from step 1 and estimating the number of treatment episodes.

Information from the regular health information system on morbidity patterns and treatment episodes can be used for quantification. In many cases, however, this information is not available, and a special study is needed in sentinel facilities, from which data can then (with caution) be extrapolated. The study can take two forms: a retrospective review of records in selected facilities (if those records are relatively accessible, complete, and accurate), or a prospective study in a sample of health facilities. The study must be completed before actually starting the quantification. Some key issues in conducting these studies include—

- Both the number of contacts and the number of treatment episodes must be obtained in the study of sample facilities. In new programs or during scale-up, treatment episodes could take the form of target treatment figures, rather than historical figures from actual patients.
- Only patient contacts that normally result in pharmaceutical treatment should be counted, separate from those that do not (such as well-child programs).
- The sample data should specify the frequency of each health problem in terms of a common denominator, such as 1,000 inpatients or 1,000 outpatient visits (for

example, number of acute diarrhea cases per 1,000 outpatient contacts). The health problem data can also be presented as a percentage of the population (cases out of 100); for example, 20 percent of child visits are for diarrhea.

- Separate frequencies must be developed for all age groups specified in the standard treatment guidelines. [Table 20-4](#) shows one format for doing so.
- Separating curative from noncurative contacts may not be possible in a retrospective review of records. Even for curative contacts, not all patients who come to facilities with health problems receive pharmaceutical therapy (although the vast majority does if medicines are in stock). If this factor is thought to be important, the proportion of cases that will be treated with pharmaceuticals can be estimated.
- Also, some health problems will require short-term treatment, while others, such as HIV/AIDS, will require lifelong ART, which makes distinguishing between acute and chronic treatments important.
- If discrete types of prescribers (such as doctors compared with paramedical staff) use different treatment regimens, the number of treatment episodes must be compiled separately for each prescriber type.
- The sample data should also specify the number of patient contacts per total population in the area served by the sample facilities. For example, if the total population in the sample area was 3.9 million, and 3,123,408 patient contacts took place per year (as in [Table 20-4](#)), on average 0.8 patient contacts occurred per inhabitant. This average could be used to project the number of contacts in another area, as described in Section 20.6 on the proxy consumption method.

Estimating Drug Requirements (WHO/DAP 1988) provides guidelines for surveying health facility records, doing a prospective study of morbidity, and constructing morbidity projections. [Chapter 28](#) of this manual provides guidance for studying medicine use in health facilities.

Step 5. Calculate the number of treatment episodes for each health problem. Two options exist for calculating the number of treatment episodes. If the number of expected patient contacts (outpatient contacts, inpatient admissions, or both) can be estimated directly in the target facilities, the calculations are done in one step based on the number of contacts. If the information on contacts is not reliable, it must be estimated from the population in the area served and the frequency of contacts per inhabitant in the target population.

First, the number of treatment episodes must be adjusted for expected changes in patient use. In [Table 20-4](#), the 3,123,408 contacts from the previous year are separated into two categories: under five years of age and over five years of age. A 5 percent increase is expected (A_U). Therefore, the

estimated number of treatment episodes for each age group and each health problem is multiplied by 1.05.

$$C_E = C + (C \times A_U)$$

$$C_E = 3,123,408 \times 1.05$$

Next, multiply the expected total number of contacts (C_E) by the expected frequency of the problem (F) to obtain the number of treatment episodes (E_T) based on the previous year's data. The estimated total number of patient contacts for the past year is divided by 1,000, so that the denominators of contacts and treatment frequency are the same. (The frequency of treatment episodes is usually expressed in treatment episodes per 1,000 contacts.) This calculation must be done separately for each discrete age range used in the process. If multiple levels of treatment are used, the number of treatment episodes at each level must also be estimated—

$$E_T = C_E \times F$$

In the [Table 20-4](#) example, there were 3,279,578 expected contacts, and in the past year there were 364 episodes of malaria per 1,000 patients under five years old. Therefore, the calculation is—

$$E_T = 3,279,578 \times 364 \div 1,000$$

Step 6. Calculate the quantity of medicines needed for each health problem. For each health problem, the projected number of treatment episodes from step 5 (E_T) is multiplied by the quantity of basic units (Q_E) specified in the guidelines for each age group (and each level of disease severity from step 3). This result is then multiplied by the percentage of cases that are expected to be treated (P_T). The full formula is—

$$Q_T = E_T \times Q_E \times P_T$$

In [Table 20-4](#), 80 percent of patients under age five with malaria, severity level 1, are expected to be treated with paracetamol solution. Therefore, the calculation is—

$$Q_T = 1,193,767 \times 60 \text{ mL} \times 0.8$$

This calculation yields a total of 57,300,816 mL needed for this treatment regimen.

Step 7. Combine the estimates for each medicine from the various health problems into a master procurement list. This step combines the estimated quantities from different treatment regimens into one master list for procurement. For example, in [Table 20-4](#), paracetamol solution is included in four different treatment guidelines (malaria severity 1 and severity 2, otitis media, and tonsillitis). For the master procurement list, the four separate

estimated quantities must be added to yield the total number of milliliters of paracetamol needed. Master list quantities usually then need to be adjusted to cover factors such as health problems not considered in the basic estimates, shortages in the supply pipeline, and losses caused by theft and wastage.

Step 8. Adjust quantities to cover other health problems. The reliability of morbidity-based quantification increases as the number of health problems addressed increases, but getting reliable data or estimates for all major health problems is rarely feasible. In this situation, the morbidity-based quantification cannot predict total pharmaceutical needs, and medicine needs must be adjusted to cover health problems not addressed in the quantification. Otherwise, stockouts will occur.

Because reliable consumption data from the target system are not available for comparison (or that method would probably have been used for the quantification), the proxy consumption method described in Section 20.6, or “expert opinion,” may be used to estimate what percentage adjustment should be made to the morbidity-based estimates.

If data on medicine use are available from another similar health system, extrapolating requirements for twenty or thirty commonly used medicines might be possible, and then determining the average percentage difference between the estimates produced by each method. For example, if the extrapolated method produces estimates that average 10 percent higher than those produced by the morbidity method, the quantities of all medicines could be increased by 10 percent.

An alternative is surveying local experts to determine what percentage of overall patient contacts have been captured in the list of health problems used for morbidity quantification. For example, if local experts agree that about 90 percent of the medicine needs are covered in the standard treatments, estimated quantities could again be increased by 10 percent.

Step 9. Adjust for filling the pipeline and current stock position. So far, the calculations assume that the supply pipeline (see Section 20.3) is relatively intact and that the procurement is only replacing medicines that are being consumed. If major stockouts have occurred that need to be corrected, additional stock will be necessary to fill the pipeline.

If applicable, make adjustments for stock on hand, stock on order, lead time, and safety stock as described in the consumption method (see Section 20.4, step 6) to finalize the preliminary estimates. Because no average monthly consumption data are available to calculate lead time and safety stock, estimate the projected monthly consumption by dividing the total quantity required by the number of months it is to be used. This estimate could be plugged into the formula used to determine safety stock and lead time in the consumption method.

Step 10. Adjust quantities for expected losses. This procedure is discussed in Section 20.3. In most supply systems, losses are a reality, and unless they are considered in the quantification process, stockouts will be unavoidable.

Step 11. Estimate costs for each medicine and total costs. With adjustments made to cover needs for additional health problems, losses, and filling the pipeline (if necessary), the total estimated quantity can be divided by the purchase pack size to determine the number of packs to be ordered. For example, in [Table 20-4](#), 23,612,964 mL of penicillin VK solution are the estimated need. If this medicine is produced in 100 mL bottles, 236,130 bottles should be ordered.

If the basic unit price is used as the basic estimate of cost, multiply it by the expected package size to determine the expected package price. If the available prices are based on package price, enter it directly.

To calculate the estimated procurement value, multiply the expected pack price by the estimated number of packages to be purchased. The prices used in the estimate should be the expected next purchase price, not the last purchase price (see Section 20.3).

Step 12. Compare total costs with budget and make adjustments. Reduce the estimated quantities or the number of medicines or both to conform to budget realities, if necessary. The morbidity-based method lends itself to considering the relative therapeutic value of pharmaceuticals on the list. In the example illustrated by [Table 20-4](#), one might determine that because pseudoephedrine has not proved to be useful in otitis media, the percentages allotted for this medicine could be reduced. The important point is that when reductions are required, they should be made rationally, with the goal of maximizing the therapeutic benefit of expenditures.

20.6 Proxy consumption method

Many supply systems face a severe information deficit, which limits accurate quantification. When neither consumption nor morbidity methods are feasible, the best option is extrapolating from consumption data from another region or health system. The proxy consumption method uses known consumption data from one system, called the standard, to estimate the medicine needs in a similar or expanded system, known as the target.

This method can be population based, defining medicine use per 1,000 population, or service based, defining medicine use per specified patient case, inpatient admission, or rural health center. A complete quantification may use a combination of the two methods, with different denominators for different products.

Table 20-5 Proxy consumption

Pharmaceutical product	Strength	Basic unit	Standard system consumption: 50,000 inhabitants, 32,500 outpatient contacts				Target system extrapolation: 80,000 inhabitants, unknown outpatient contacts						
			Total usage in 6-month period (BU)	Days out of stock	Adjusted average monthly usage (BU)	Adjusted annual usage (BU)	Usage per 1,000 inhabitants	Usage per 1,000 outpatient contacts	Projected requirements in BUs based on 80,000 inhabitants	Order quantity (packs)	Probable pack price (USD)	Value of proposed order (USD)	
Ampicillin	500 mg	Capsule	59,500	0	9,917	119,000	2,380	3,662	190,400	1,000	191	46.50	8,881.50

Total order cost:											212,147.68		

Note: BU = basic unit; USD = U.S. dollars; MU = mega-unit; IU = international unit.

Example

Table 20-5 illustrates the proxy consumption method of extrapolating consumption of outpatient pharmaceuticals from a standard health system to the target health system. The data in Table 20-5 do not represent any particular country.

Steps in the quantification

Step 1. Select the standard system for comparison and extrapolation. The standard facilities should, if feasible, closely resemble the region or country for which the estimate is made in terms of geography and climate, patient population served, morbidity patterns, prescribing practices, standard treatment guidelines, essential medicines lists, and pharmaceutical supply status. Representative standard facilities should be selected at each level of health care that has a different medicines list, morbidity patterns, or prescribing practices. They should have an adequate and uninterrupted pharmaceutical supply (but not greatly overstocked), fairly rational prescribing practices, and complete and accurate records of patient contacts and pharmaceutical inventory movement. Of course, finding an ideal standard may not be possible, but an effort should be made to select the best standard data available.

Step 2. Develop the medicines list. See Section 20.3 for a discussion of issues.

Step 3. Establish the period to be covered in review. Determine the number of months' worth of data to be reviewed in the standard system. See Section 20.4 for a discussion of these issues.

Step 4. Review records from the standard system to compile contact or population data. Use available reports on patient contacts in the standard system; if reports with suitable data are not already compiled, a survey of standard facilities can be done to determine the number of patient contacts during the period established. A similar survey might be carried out in the target system, but if the target system has had a severe problem with stockouts, the attendance data may not reflect the number of contacts that can be expected when medicines are available.

Step 5. Establish the denominator for extrapolation. The denominator used to extrapolate consumption can be either population in the area served or number of patient contacts, depending on the data obtainable through step 4. Whichever one is used, the denominator is usually thousands of patient contacts or thousands of inhabitants in the region (as in Table 20-5). In very large systems, using tens of thousands or even millions of contacts or inhabitants might be preferable.

Step 6. Determine the consumption rate in the standard system. For each medicine, produce an adjusted aver-

age monthly consumption (see Section 20.4). The average monthly consumption is multiplied by twelve to obtain the adjusted annual consumption (or by the applicable number of months for any other period that was determined in step 3). Then divide the adjusted annual consumption by the number of thousands of contacts or inhabitants to establish the consumption rate.

Step 7. Extrapolate the standard system's consumption rate to the target system. Multiply the standard consumption rate for each medicine by the estimated number of thousands of contacts or inhabitants in the target system to yield the projected requirements in the target system.

Step 8. Adjust for expected losses. Because these estimates are very rough and the percentages of losses that were experienced in the standard system may be unclear, adjusting for losses may not be realistic. However, if known losses exist, add a percentage allowance, at least for vital medicines (see Section 20.3).

Step 9. Estimate costs for each medicine and total costs and make adjustments. Multiply the projected quantities for each medicine by the most accurate prediction of the next procurement cost and reconcile that product with available funds, as discussed in Section 20.3.

20.7 Service-level projection of budget requirements

This method is used to estimate financial requirements, not specific medicine quantities, for pharmaceutical procurement on the basis of costs per patient treated at various levels of the same health system or, with great caution, data from other health systems. It does not forecast needs for specific medicines but provides a clear, logical, one-page justification of pharmaceutical financing requirements. Generalizing from one region in a country to another region in the same country is more reliable than extrapolating data to a different country.

Like the proxy consumption method, this extrapolation method produces rough estimates because significant, but not always apparent, variations may exist between the target health system and the system used as a source of standard data. Possible sources of error include prescribers in the target system using a different mix of medicines from those in the source system, variability in disease frequency and the number of patient attendances per facility, and differences in the effectiveness of procurement and financial management systems in the two settings.

The main requirement for this method is a fairly reliable estimate of average medicine cost per patient attendance and average numbers of patient attendances at various levels of the standard health system. This information may not be readily available, but it can be compiled through a special study in one part of a health system where pharmaceutical

Table 20-6 Service-based budgeting of essential medicines requirements

Type of facility and patient (1)	Number of facilities (2)	Average annual workload per facility (3)	Average cost per attendance or bed-day from sample facilities (USD) (4)	Annual pharmaceutical needs (USD) (5)
Provincial general hospitals	13			
Inpatients		176,000 bed-days	0.55	1,258,400
General outpatients ^a		195,000 attendances	0.55	1,394,250
Prenatal patients		19,500 attendances	0.15	38,025
District hospitals	42			
Inpatients		57,000 bed-days	0.50	1,197,000

Per capita requirement				0.686

Source: Adapted from Ministry of Health, Government of Kenya. 1992. Workload-Based Annual Budget for Pharmaceuticals and Non-Pharmaceuticals.

Note: USD = U.S. dollars. The exchange rate used is Kenya shillings 60 to USD 1. Population equals 27 million (estimate for 1993).

^a This category includes (for all levels) adult and pediatric general outpatients, casualty, and specialty clinics.

supplies are consistent and where treatment practices are considered to be representative. The following data must be compiled—

- The average number of curative and noncurative outpatient attendances and inpatient bed-days and/or other type of patient contact for each type of facility in the source health system
- The average cost per outpatient curative and noncurative attendance and per bed-day and/or other type of patient contact in each type of facility in the source health system

Example

Table 20-6 shows the method applied to estimate financial requirements for pharmaceutical procurement in Kenya.

Steps in the quantification

Step 1. Establish the categories of facilities and determine the number in each category. List each type of facility to be quantified for in the first column. The number of facility categories used depends on the size and scope of the target health system. Table 20-6 shows six significant levels,

ranging from provincial general hospitals to dispensaries (see column 1). The number of facilities in each category is entered in the second column.

Step 2. Determine the patient contact denominators for each type of facility, and compile or estimate the average number of patient contacts of each type at each category of facility. These data can be obtained from centrally available information or from a special-purpose survey to determine the average number of patient contacts for each category of facility. For each category, several different types of patient contact may result in pharmaceutical costs. Minimally, inpatient and outpatient costs and contacts should be separated.

In the example in [Table 20-6](#) (column 3), in all but the lowest-level facility (dispensaries) contacts were separated into three types: inpatient, with bed-days as the common denominator; and general outpatient and prenatal visits, each with attendances as the denominator.

Step 3. Calculate the average cost per contact. The average cost per attendance and/or bed-day is derived by dividing the total pharmaceutical purchases for the sample facility or facilities that are providing the source of data for extrapolation in the class by the total attendances or bed-days. In facilities with both inpatients and outpatients, the fraction of total procurement costs attributable to inpatients, outpatients, and noncurative visits must be estimated. Column 4 in [Table 20-6](#) shows the average cost data based on the source data from the sample facilities.

Step 4. Calculate the total projected pharmaceutical costs. Multiply the average number of patient contacts for each facility (column 3 in [Table 20-6](#)) by the number of facilities (column 2). This result is then multiplied by the average pharmaceutical cost for that type of patient in that type of facility (column 4), which estimates total financial requirements for each type of attendance in each type of facility (column 5). These totals are then summed to produce the total financial requirements. The result is an estimate of the probable pharmaceutical costs, on average, for each type of facility and for the system as a whole. The results are not necessarily applicable to any specific facility. ■

ASSESSMENT GUIDE

Availability of data

- Do the medical stores and health facilities have current and accurate records of medicine usage?
- What data and reports are maintained centrally (or at other levels of the health system) on outpatient attendances, inpatient bed-days, or other counts of patient contacts?
- For how many diseases does reliable information exist on numbers of cases reported or treated annually?
- Are there official standard treatment guidelines for certain diseases? If so, how many diseases are covered, and how is compliance monitored?

Management of quantification

- Do a formal workplan and schedule for quantification exist?
- Does a quantification committee exist with representatives from health facilities (prescribers and pharmacy staff), government (heads of special disease programs and health information systems staff), central medical store (or other group handling pharmaceutical distribution), and donors?
- Is quantification done manually or by computer? If computers are used, which offices have computers, and what software program is used for quantification? Which levels of warehouses and facilities have computerized procurement and inventory records?

- Is quantification decentralized or managed centrally? Which offices and levels of the system are responsible for quantification?
- If quantification is decentralized, what training is or has been provided to responsible staff members at peripheral facilities?
- Are preprinted quantification and/or data-collection forms distributed to the facilities?

Quantification methods

- What quantification methods are used to forecast pharmaceutical and budget needs?
- Are actual procurement quantities and costs compared at the end of each year against the initial quantification estimates?
- Is the supply system pipeline functioning well, or have pharmaceutical shortages been frequent or widespread? If shortages have occurred, do only certain medicines present problems, or do shortages exist for many different medicines?
- What information is used to predict procurement costs? If last year's prices are used, how are they adjusted?
- What standard formulas are used to calculate order quantities?
- Is there an essential medicines list or health system medicine formulary that is used for quantification? Is procurement limited to medicines on the list?
- What techniques are used to adjust initial estimates to conform to budget realities?

SUMMARY

The primary function of a procurement office is to obtain the required items at the right time, in the correct quantities, and at the most favorable prices. The procurement office compiles a list of requirements, identifies potential suppliers, selects the most cost-effective supplier for each product, secures firm supply contracts, and makes sure that the suppliers and the health system comply with contract terms. Competitive tenders are recommended for most pharmaceutical procurement in public-sector pharmaceutical systems, so this chapter addresses the principles of efficient tender management, focusing on the most common tendering models.

To maximize the benefit of pharmaceutical purchases, corruption and favoritism in procurement must be minimized. Equally important is avoiding the appearance of favoritism, so the tender process should be as transparent as possible under national procurement laws.

A formal tender process includes medicine selection, quantification, preparation of tender documents and contracts, notification and invitation to bid, formal bid opening, collation of offers, adjudication and supplier selection,

contract award, performance monitoring of suppliers and clients, and enforcement of contract terms if necessary. Reliable suppliers are the cornerstone of effective procurement, and a prequalification process is recommended; tender adjudication and selection of suppliers is the critical step that determines the costs of medicines and defines the integrity of the procurement process. Adjudication should be based on formal written criteria and must be free from influence by special interests.

Accurate and timely information is critical at each stage of the process, and lack of effective information systems is a main cause of procurement delays and inefficiencies. The information system must be able to—

- Produce information for quantification and tender documents
- Collate offers for adjudication
- Issue notifications of award and purchase orders
- Track order status and compliance with contract terms
- Manage communications with contract suppliers
- Track suppliers' performance for future tenders

21.1 Introduction to tender management

Many of the major policy and management issues relevant to pharmaceutical procurement were covered in [Chapter 18](#). Several types of procurement methods are used for pharmaceuticals, but the procurement method chosen for each medicine should—

- Obtain the lowest possible purchase price for high-quality products
- Ensure suppliers' reliability, in terms of both quality and service
- Maintain transparency in the process and minimize the opportunity for illicit influences on procurement decisions
- Achieve these objectives with the least possible professional and clerical staff time and within the shortest possible lead time

[Table 21-1](#) summarizes the most frequently used methods to purchase pharmaceuticals.

This chapter focuses on the management of competitive tenders. Some global procurement mechanisms, such as the United Nations Children's Fund (UNICEF), the Supply Chain Management System, and the Global Fund's voluntary pooled procurement system, use negotiation as a pri-

mary tactic to establish contracts on high-use and high-cost items; as discussed in [Chapter 18](#), these large procurement systems need to ensure multiple source options to assure steady supply and to be certain that multiple suppliers stay in the particular market. However, most modern laws and regulations covering public-sector procurement require competitive procurement methods. Negotiation can be legitimate when only a few suppliers are available for a particular product, but negotiation is not generally recommended when using public funds.

[Country Study 21-1](#) shows how El Salvador lowered costs by making its tendering process more efficient.

This chapter discusses the best practices in managing the standard tender processes used to purchase pharmaceuticals. Historically, the tender process has been an annual cycle in most public-sector health systems. In some situations, tenders are conducted two or three times per year; however, some procurement offices have begun entering into multiyear framework contracts to reduce the administrative burden of managing frequent tender cycles. Global procurement systems such as UNICEF and USAID's Supply Chain Management System also use these sorts of framework contracts for selected products.

As discussed in [Chapter 18](#), Internet-based approaches, including "e-procurement" with "reverse auctions," have been advocated for public-sector procurement, with the

most experience occurring in Latin America. These methods, however, have not yet been proven for pharmaceutical procurement.

The standard steps in the normal tender cycle are—

1. Determine the tender format and scope.
2. Define requirements—select and quantify medicines and supplies.
3. Select suppliers to participate in the tender.
4. Prepare and send tender documents.
5. Receive and open offers.
6. Collate offers for adjudication.
7. Adjudicate the tender.
8. Issue contracts to winning bidders.
9. Monitor performance and product quality.
10. Enforce contract terms as needed.

Each of these steps requires informed decisions about which of several possible procedures best fits the particular situation. In most countries, options will be limited by procurement laws and regulations, but even in the most restrictive legal settings, the procurement program has several choices to make. The goal of this chapter is to provide

information to help procurement managers make the best choices for their own situations.

21.2 Determining the tender format and scope

Some countries have procurement regulations that specify the tender format for pharmaceutical purchasing. The World Bank and some bilateral donors may mandate specific tender formats for procurement financed by loans or donated funds (see References and Further Readings). However, in many cases, flexibility exists in structuring the tender; in those situations, options include—

- Restricted versus open tender
- Local or international scope
- Estimated or fixed tender quantities
- Split or single tender awards
- Primary/secondary contracts or rebids
- Required or optional use of local agents in international tenders
- Annual or biannual tenders versus multiple tenders during the year

Table 21-1 Comparison of procurement methods

Procurement method	Brief description	Effect on price	Procurement lead time	Workload for procurement office	Need for evaluating suppliers	Conditions favoring use
Open tender	Bidding is open for all interested suppliers	Usually lowest prices	Moderate to long	High	High	<ul style="list-style-type: none"> • When many reputable suppliers are available and likely to be interested • If prequalification is not feasible or not allowed by regulation or donor's provisions
Restricted tender	Participation of suppliers is limited to those who have registered with the government or who have prequalified	Favorable	Moderate to long	High	High	<ul style="list-style-type: none"> • When substantial list of registered suppliers has been developed • When capacity exists to manage prequalification and supplier monitoring
Competitive negotiation	The buyer approaches a small number of potential suppliers and negotiates for specific price or service arrangements	Can be favorable	Short to moderate	Moderate	High	<ul style="list-style-type: none"> • Experienced purchasing office with good access to market intelligence • Low-price or small-volume items • When there are few suppliers • When special terms or specifications are required by the buyer for items not widely available • Emergency purchases to supplement tender
Direct procurement	Purchase is made directly from a single supplier at the quoted price	Usually highest prices	Short to moderate	Low	High	<ul style="list-style-type: none"> • Emergency purchases when negotiation is not possible • Purchase of single-source pharmaceuticals • Low-price or small-volume items

Country Study 21-1 El Salvador: Improving efficiency through joint tendering

In El Salvador, the Strategies for Enhancing Access to Medicines (SEAM) Program's 2001 assessment found that some essential medications were lacking in both public health care facilities and those of nongovernmental organizations (NGOs). At the Ministry of Public Health and Social Welfare (MSPAS, from its initials in Spanish), purchasing had been decentralized, decreasing the ability to negotiate prices for pharmaceuticals in large volumes and providing little management capacity for inventory management. Although the NGO sector was small, these organizations provided services in rural areas that did not have access to MSPAS services. Because they bought small volumes, the NGOs could not negotiate favorable prices for their medicines, which limited the availability of essential medicines.

On the basis of the SEAM assessment and recommendations, MSPAS authorities developed a pharmaceutical procurement system based on joint tendering for medicines from the national Essential Medicines List to select products, their suppliers, and unit prices for the thirty hospitals and 362 public and NGO health units.

From late 2002 to 2005, MSPAS held three joint tender processes. The 2003 purchases resulted in a lower number of tenders, a 45 percent decrease in the median unit prices for the medicines, and greater efficiency in spending on medications and use of the budget appropriation.

The three-year experience showed that a joint bidding program based on the national Essential Medicines List could be implemented, and the following lessons were learned—

- The active participation of hospitals in the program's design contributed to its acceptance and to ensuring transparency in the evaluation of tender bids.
- Joint tendering within the network of public hospitals resulted in greater efficiency in spending on medications, a reduction in the number of tender processes, and improved quality assurance of medicines.
- To optimize the benefits of joint purchasing, an effective logistics system must accompany it.

Restricted or open tender

One of the most important decisions to make is whether the tender will be restricted to suppliers who are prequalified because they have demonstrated reliability, or whether the tender will be open to any supplier who is interested. This decision is required whether the tender is local or international.

A restricted tender with *prequalification* involves developing a list of registered suppliers based on past performance, references from previous clients, and documentation of product quality. Then, only those registered suppliers may participate in tenders. This process avoids the necessity of trying to decide whether the lowest bidder is eligible to be awarded the contract. With prequalification, by definition, the lowest bidder should be qualified for the contract.

When prequalification works well, substandard suppliers are kept out of the tender process entirely. Prequalification is not beneficial, however, if it protects favored suppliers from competition. In some countries, a new supplier finds surviving the prequalification process virtually impossible, no matter how reliable the new supplier may actually be.

Prequalification can be extremely time-consuming, especially if policy requires that suppliers be prequalified separately for each medicine. This problem can be mitigated

through ABC analysis and prequalifying only high-demand, category A medicines while prequalifying low-demand products by lot (see [Chapter 40](#) for details). As noted below, however, proper postqualification requires just as much time. The policy question is where the time should be allocated in the tender process.

To help countries procure quality pharmaceuticals, the World Health Organization (WHO) operates a prequalification program for HIV/AIDS, tuberculosis, and malaria medicines. See [Box 21-1](#) for more information. Many international donors that provide procurement funding accept WHO prequalification or documentation of a supplier's or product's approval by a so-called stringent regulatory authority as evidence that the supplier is eligible for prequalification in a tender (see [Chapter 19](#)).

Although a country's laws may require that a pharmaceutical supplier and its products be registered in the procuring country, procurement managers may wish to follow WHO's international standards for prequalifying potential bidders first and then add a requirement that successful bidders must register their products locally.

An open tender with *postqualification* makes the tender available to all interested bidders. Suppliers' bids and documentation are solicited, received, and reviewed with respect to registration status, product quality, technical and financial capacity, and past performance.

An open tender can arguably increase the pool of prospective suppliers, but complications and delays in postqualification often occur. In addition, a well-managed prequalification process can generate good competition. Pharmaceuticals are unlike some other commodities, in that product quality is both crucial and difficult to ensure. Therefore, the success of open tenders with postqualification depends on the capacity of the procurement program to winnow out unqualified suppliers and poor-quality products after bids have been received, in some cases, from all over the world. The procurement office must go through a process similar to that used in prequalification. The difference is the need to screen many more suppliers and products. Moreover, bids are usually submitted with a time limit on price validity (see Chapter 39). Screening all suppliers and products after bid opening and within the period of price validity may be difficult. In one Indian state, for example, price validity was specified as 180 days, while the contract award typically took twelve to fifteen months (Heltzer et al. 2008). If delays like this occur, prices have to be reconfirmed, and in some cases, rebidding may be needed.

Poorly defined criteria for postqualification can also exclude qualified bidders, especially when the criteria favor developing local industry over assuring medicine quality. Finally, postqualification may be used for fraudulent purposes, if, for example, someone in the procurement agency wants to tilt business toward preferred companies.

Prequalification is generally accepted as an essential procurement practice. The *Interagency Guidelines for Establishing a Model Quality Assurance System* specifically state that prequalification is a key element in ensuring product quality (WHO et al. 2007). Following this lead, many countries have formally incorporated prequalification and restricted tendering into their procurement regulations; for example, Tanzania's Public Procurement and Regulatory Authority has published regulations and bid documents for use in the health sector that explicitly provide for restricted, prequalification-based tendering. Such practices have also been a feature of many successful pharmaceutical procurement programs around the world.

As these arguments make clear, the eventual goal of most procurement programs should be tenders limited to registered, prequalified suppliers. Prequalification avoids wasting time on suppliers that do not perform according to contract and helps minimize the possibility of introducing substandard products. However, aggressively seeking out potential new suppliers that may wish to become registered is important for maintaining competitive pressure on established suppliers.

International versus local procurement

In most developing countries, the national pharmaceutical industry produces only a limited range of products.

Box 21-1 WHO's prequalification program

The World Health Organization set up the Prequalification of Medicines Programme in 2001 to facilitate access to quality medicines for HIV/AIDS, malaria, and tuberculosis. Originally, the program was intended to give UN procurement agencies, such as UNICEF, a range of quality medicine suppliers from which to choose. Over time, the program has become a useful tool for anyone purchasing medicines on a large scale, including countries themselves. For example, the Global Fund to Fight AIDS, Tuberculosis and Malaria disburses money for medicines that have been prequalified through the WHO process.

Manufacturers applying to the program must present extensive information on their product to allow qualified assessment teams to evaluate its quality, safety, and efficacy. The manufacturer must also open its manufacturing sites to an inspection team that assesses working procedures for compliance with WHO good manufacturing practices. The assessment teams work with regulators from the developing countries where the medicines

will be used to make sure that the process is transparent and trusted by the end users. The program also prequalifies quality-control laboratories.

WHO's prequalification process takes a minimum of three months if the product meets all the required standards. When products do not meet the appropriate standards, the process can be longer and ultimately result in no prequalification for a product. WHO also carries out random quality-control testing of prequalified medicines that have been supplied to countries.

Medicines on the prequalification list include both brand-name and generic products. Since 2001, reproductive health products and zinc (for childhood diarrhea) have been added to the program. Also included are fixed-dose combinations, which are assessed based on the same principles used by the European Agency for the Evaluation of Medicinal Products and the U.S. Food and Drug Administration.

Source: WHO 2010b.

Therefore, most products must be procured via international markets. Nevertheless, countries with a local industry often require that public tenders give it some preference, such as following the World Bank example of granting a 15 percent price preference to locally manufactured products. However, greater price preferences make it difficult to achieve value for money—which is critical when national pharmaceutical budgets are limited. In all cases, the quality assurance requirement must be maintained. A strong national drug regulatory authority uses its product registration process to assure quality.

For many items, an international competitive tender, whether open or restricted, almost always results in lower prices than a tender limited to the local market. For some inexpensive items that cost a lot to ship, such as parenteral solutions, purchasing locally may be cheaper if the manufacturing plant meets acceptable quality standards. Facility licensing through a strong, independent drug regulatory authority is crucial.

In countries with a large pharmaceutical industry, such as India, international tendering is largely unnecessary; however, some countries that have an enormous number of companies licensed to manufacture pharmaceuticals may only have a few that meet international production and quality assurance standards. In such circumstances, establishing sufficiently stringent prequalification criteria to assure product quality while supporting national economic development demands is a challenge. Failure in this difficult balancing act can result in substandard products entering the health system.

One common constraint on international procurement is pharmaceutical registration. Countries with pharmaceutical registration systems normally require that all medicines purchased through public tender be registered locally. Both restricted and open tenders can be limited to products registered in the purchasing country. This requirement may limit or eliminate international procurement if the registration process is complicated and time-consuming, but in most countries, some flexibility is available to assure access to essential medicines.

Some countries expedite or even waive registration for new medicines that are considered vital to public health, such as antiretroviral medicines. In many cases where registration is waived, a donor is financing the purchase and helps make the case for a waiver.

Countries in some regions, particularly Latin America, have attempted to move toward regional harmonization of pharmaceutical registration, with virtually automatic registration granted if the product is either registered within the region or originates from a country recognized as having effective pharmaceutical regulatory systems. In an example of such harmonization, Namibia accepted products already registered in International Conference on Harmonization countries or South Africa to streamline its registration of

antiretrovirals. However, regional harmonization generally faces many barriers, including concerns that products from the region's stronger economies could have an unfair advantage.

In sum, much has been debated about regional harmonization, but the discussions have not advanced very far. Time will determine whether meaningful harmonization can be achieved.

Estimated- versus fixed-quantity contract

Two basic options exist for defining purchase quantity: the traditional *fixed-quantity, scheduled-delivery* purchasing contract, and the *estimated-quantity, periodic-order* contract.

The *fixed-quantity contract* specifies guaranteed quantities (with a small variation sometimes allowed) and delivery in either one large shipment or smaller, separate shipments over the life of the contract. The purchaser accepts the risk that quantities for specific items may be too high (resulting in overstocks) or too low (resulting in shortages). If the purchaser actually needs more than the projected quantity (plus permitted variation), the price may be adjusted for additional quantities, depending on the contract.

With the second type of contract—the *estimated-quantity, periodic-order (draw-down) system*—the tender quantity is just an estimate rather than a firm order. A contract price is negotiated for each medicine, and the purchaser or members of the purchasing group order periodically from contract suppliers at the contract price throughout the contract term. In a pooled procurement system, orders can be placed directly by group members or channeled to the supplier through a central procurement office. Purchasers order only the quantities of each item needed, regardless of the quantity stipulated in the original tender estimate.

The supplier delivers to purchasers at the contract price throughout the term of the contract, regardless of the variation between projected and actual total quantity purchased under the contract. The supplier takes the risk that actual quantities will differ from those estimated: if the quantities are higher, it is not a problem (assuming the supplier has the necessary capacity), but if purchases are significantly lower than estimates, the supplier may not participate in future tenders. This system benefits the purchaser, because the purchaser's financial liability is limited to each order, and if demand changes, the purchaser is not burdened with unneeded stock or pressed to cover shortages. However, in the interest of maintaining a mutually beneficial relationship with a supplier, the purchaser must make every effort to reliably estimate demand and should communicate any significant changes—either increases or decreases—in projected order quantities.

Pharmaceutical tenders for most developing countries have been made for many years as fixed-quantity, scheduled-

delivery tenders, and suppliers serving these procurement programs might be expected to resist the change to estimated-quantity contracts. However, many large-scale procurement programs serving developing countries successfully use the estimated-quantity, drawdown contract.

When the draw-down system is used, prices should be guaranteed for the entire period of the contract. If possible, prices should be negotiated as CIF (cost, insurance, and freight) or CIP (carriage and insurance paid), with no extra charges for freight and insurance (see [Chapter 39](#)).

In the 1970s and 1980s, when inflation was a persistent problem around the world, tendering more than once a year or including an escalator clause effective after a certain number of months, based on inflation, was often necessary. Although inflation is no longer a severe problem in most places, circumstances in some countries, such as Yugoslavia in the mid-1990s and Zimbabwe in the 2000s, can warrant adding an inflation factor to tender agreements. In such contexts, a guaranteed-quantity tender or a procurement system policy to make most purchases at the lowest contract price possible (that is, before an escalator clause takes effect) may produce the best results for the health system. Guaranteed access to foreign currency greatly helps to manage procurement in high inflationary situations.

In countries where access to funds and foreign exchange is sporadic and uncertain, tendering on a periodic basis, as funds become available, may be necessary. This procedure almost always requires a fixed-quantity, scheduled-delivery tender format.

Similarly, if most products must be imported and lead times are extremely long, fixed-quantity, scheduled-delivery contracts are best, because the drawdown system requires reasonable access to contract suppliers. This type of contract functions acceptably with lead times of up to four to five months, but it would be difficult to manage where lead times are routinely greater than one year. One option is to limit tender participation to suppliers that can provide shorter lead times (assuming such sources are available). This strategy might produce an overall price increase but could potentially reduce waste. A total cost analysis exercise (described in [Chapter 40](#)) would help model the potential impact of such a change.

In some situations, combining the formats might be best: negotiating fixed-quantity contracts for products that can be purchased most cost-effectively in large single quantities and using estimated-quantity contracts for other products.

Splitting tender awards

Some procurement programs routinely split contract awards among two or three suppliers, with the rationale of maintaining capacity with several suppliers or avoiding dependence on one supplier for a critical medicine. However, any health system procurement program that routinely splits

tenders is almost certainly not getting the best possible pricing, and the opportunity exists for “bid rigging”—suppliers agreeing beforehand what bids will be offered, with the realization that all will benefit from a share of the pie.

Split tenders may be desirable in some circumstances—for example, when a country is making one huge annual purchase of essential medicines, the risk of supplier default is real, and the public health consequences will be severe if default occurs and the medicines are not available. In addition, large global procurement programs may determine that split awards are needed to modulate the global market and maintain competition and assure access to essential products ([Chapter 18](#)).

Primary/secondary contracts versus rebids

When a supplier defaults, delays in receiving medicines have usually already occurred by the time the problem is understood. Rebidding contracts through the entire tender procedure will likely result in stockouts or high-priced emergency purchases, or both. A primary/secondary contract system can avoid rebidding delays by providing an immediate option if the contract winner cannot perform. This sort of system is used by the Organisation of Eastern Caribbean States (OECS) Pharmaceutical Procurement Service and is common to many pharmaceutical purchasing groups.

In a primary/secondary system, two contract awards are made, with the primary award to the bidder offering the lowest price and the secondary award to the second-lowest bidder, provided that the secondary supplier is one that is expected to be able to supply under all conditions. The secondary contract should be used only when the primary supplier is unable to perform.

Primary/secondary awards are useful *only* if two requirements are met: the second-lowest price is reasonably close to the lowest and thus worth locking in, and a reliable secondary supplier is prepared to accept that status and guarantee the price in case the primary supplier defaults. If either condition is not met, a secondary award is not worthwhile.

Some countries have regulations prohibiting these types of contracts, requiring that a new tender be made in the case of default. World Bank international competitive bidding tender procedures call for rebids when a supplier defaults, but some flexibility for local purchasing and local competitive bidding usually exists in such cases.

Use of local agents in international procurement

Multinational manufacturers and exporters are commonly represented by local representatives in developing countries. The decision to require, encourage, or avoid buying through local agents in international tenders affects the range of foreign suppliers, the efficiency of communication between the buyer and the supplier, and the choice of trade and

Box 21-2**Advantages and disadvantages of buying through local agents****Potential advantages**

1. *Speeds and improves communication.* Local agents may be authorized to make decisions without a special contact with the foreign supplier. When necessary, the local agent may be better able to contact the appropriate person at the foreign supplier's office.
2. *Locates least-expensive acceptable supplies.* In competitive tenders, the interest of the local agents lies in locating inexpensive suppliers, including sources that might not otherwise have come to the attention of the purchaser.
3. *Facilitates payment.* Local agents can sometimes accept local currency and allow deferred payment. Currency conversions can be troublesome, and some countries specify that payments be made in local currency to local agents.
4. *Expedites delivery.* Local agents often handle port clearing. For instance, when port-clearing fees require negotiation, local agent knowledge and experience can frequently save money and time.
5. *Speeds receipt of emergency supplies.* Local agents often maintain stocks within the country, which speeds receipt of emergency supplies and may reduce the amount of warehouse space required.
6. *Affords greater legal recourse.* The presence of an in-country agent affords greater opportunity for legal action if the supplier defaults.
7. *Introduces new products.* Occasionally, new products or formulations are introduced that are cost-effective alternatives to existing products. The agent is necessarily biased but may provide scientific articles in support of the product. Other information sources

should be sought to supplement the introductory information provided by the agent.

8. *May offer potential for using primary distributor.* In some countries, government warehousing and distribution costs possibly may be eliminated by implementing a prime vendor contract with a local distributor that will warehouse and distribute medicines directly to public health facilities.

Potential disadvantages

1. *May slow and confuse communication.* If untrained, unmotivated, poorly supervised, or part time, a local agent may lengthen and confuse arrangements with the foreign supplier. In addition, if the purchaser requires specific product information, a local agent may impede communication.
2. *May increase cost.* Local agents may add as much as 15 to 30 percent to the visible cost, even though their commission is often much less. Higher unit prices are also paid for low-volume purchases through local agents, compared to direct purchase.
3. *Serves as a source of black-market pharmaceuticals.* Licensed importers can be a major source of pharmaceuticals for illicit use, and local agents need to be regulated through licensure and regular inspection of records and stocks.
4. *May completely default on an order.* Local agents who are not financially stable may go out of business and disappear. Two or three local suppliers should be kept available as backup for emergency tenders.
5. *Attempts to increase medicine consumption.* Local agents employ detail men or company representatives to visit health system physicians to encourage product use, as well as to request new medicines.

payment terms. Major advantages and disadvantages of buying through local agents are listed in [Box 21-2](#).

[Chapters 8](#) and [39](#) further discuss the potential for contracting with local distributors to provide warehousing and transport services.

Tender frequency and timing

Tender planning must take into account the time required for each step. The time required to develop or revise a tender list, including medicine selection and quantification, varies widely, but may require two to six months in some settings. The time required to select suppliers for tender participa-

tion can also be considerable; in one African country, the first prequalification process took more than one year.

If standard documents are not available, preparing documents for tender can take at least a month after quantification is completed. Some countries, such as Tanzania and Uganda, have overcome this problem by developing standard bidding documents. The time spent waiting for tender offers depends on geographic scope (local versus international) and in some cases on regulations of the government or the funding agency. A reasonable response time for local tenders is likely to be fifteen to twenty days, and for international tenders, forty-five to sixty days. Collating offers is quicker with computerized systems, but at least one month

Figure 21-1 Example of a timetable for an annual tendering system

should be allowed for this process. Some online tendering systems capture supplier bids through the procurement agency's Web portal, which can greatly facilitate collection and collation of bids (note that this is not the same process as in e-tendering with reverse auction). Adjudication and contract award should also be faster in computerized systems, but again, one month should be allowed, and at least two months with manual systems. After contracts are awarded, the lead time between orders to the supplier and initial deliveries may be a month or less with local tenders, but international suppliers' lead times usually range from three months to one year, and on occasion even longer.

Efficient procurement offices spread the tender workload throughout the year, with overlap from one tender cycle to the next; when contracts have been awarded for the first cycle, planning for medicine selection for the next cycle should begin. Frequent communication with clients and with suppliers is needed to make sure that the tender proceeds according to schedule. Many procurement offices use spreadsheets to simplify tender tracking, but all procurement staff members need to use a common spreadsheet format to avoid misunderstandings that can result from different people developing their own. Figure 21-1 illustrates an annual tender cycle of fifteen months, with overlap.

The frequency of tendering should be attuned to the funding cycle, and for international tenders, to the avail-

ability of foreign exchange (particularly if inflation is an issue). Tendering once a year is not appropriate when funds, including foreign exchange, are released in monthly installments, because bids will expire before the funds for the actual awards become available. This can also be a problem where funds are released late from the government treasury but revert back if not spent by the end of the fiscal year.

21.3 Defining needs

As discussed in Chapter 18, restricting the number of pharmaceuticals on a procurement list can increase effective procurement volume for those pharmaceuticals. A central agency will usually be more efficient than a large number of health facilities operating independently when it comes to selecting a restricted list of essential medicines. If selection is totally decentralized, the benefits of group purchasing will be lost. On the other hand, if the health facilities do not have real input into which medicines are selected, they will not feel that their needs are being served and will lose a feeling of ownership, which may result in facilities making direct purchases outside the tender contracts, undermining the integrity of the system. A balance needs to be struck between centralized and decentralized elements of procurement.

Selection of medicines for the tender

The medicine selection committee (see [Chapter 16](#)), which is often known as the formulary committee, should meet before each tender to finalize the list of medicines. If, for example, a tender is scheduled for June and quantification takes three months plus one month for clarification and tender document preparation, the medicine selection committee would meet in January.

Requests for additions or changes to the procurement list should be compiled throughout the year by the procurement agency, the selection committee, or both. Often, provisions are in place to obtain special approval for purchasing items not included on the essential medicines list.

Requests for additions to the list should be made in writing with justification for the addition and (if applicable) the name of the product to be replaced. Members of the technical staff of the procurement agency or medicine selection committee should compile information from the medical literature on the new product (and on the therapeutic category the product represents) for the selection committee. Some procurement programs require that for each addition to the list a similar product be deleted, unless the proposed addition represents a new therapeutic category. Usually, however, the list of products continues to grow, which can present problems in both managing and financing procurement.

Analyses of past procurements using methods such as VEN (vital, essential, nonessential), ABC, and therapeutic category analysis (see [Chapter 40](#)) should be compiled before the meeting of the medicine selection committee to focus deliberations and help in rationally limiting the procurement list.

After the selection committee has met, the procurement office develops a list of the approved medicines for quantification. In computerized procurement agencies, this process may take one or two weeks.

Quantification

As discussed in [Chapter 20](#), the procurement office is responsible for producing a reasonably accurate estimate of pharmaceutical requirements for each tender, but much of this responsibility can be decentralized. Some health systems ask each level with decision-making authority to compile its own list of estimated quantities required for medicines on the procurement list. The central procurement office then compares the lists with past consumption, checks for any known changes affecting demand, clarifies questions directly with the client, and compiles the overall list for procurement.

Quantification can consume considerable time in programs that are decentralized but require multiple layers of review. With four levels of management authority (health

area, regions/districts, provinces, and national) involved in reviewing estimates, developing a list of medicine needs for procurement may take six to nine months. If the quantification process extends to six months or more, a full year may pass by the time the pharmaceuticals are actually received. In that time, needs may change, and money is wasted if the pharmaceuticals purchased no longer match current needs.

Methods for procurement quantification—consumption-based, morbidity-based, and proxy consumption—are discussed in [Chapter 20](#). The choice of method is based largely on the type and reliability of data on medicine usage, patient use, and morbidity patterns.

Countries should avoid making one major effort to quantify medicines and then relying on the same data for several years thereafter. No matter how accurate the original quantification may have been, given changes from year to year, the earlier projections become increasingly unreliable guides to later procurement needs.

When the quantification has been completed, the responsible committee (it may be a tender board or a special procurement committee) should review and approve the list of medicines and the quantities proposed. Having the procurement office estimate the actual cost before the list is sent to the committee for review, and definitely before the actual tendering is executed, is important. If cost estimates are not done, the subsequent evaluation of tender offers may indicate that costs exceed funding.

21.4 Selecting suppliers for tender participation

The selection of suppliers has a profound effect on the quality and cost of pharmaceuticals acquired. Inadequate safeguards in supplier selection may result in the purchase of medicines that are ineffective, unsafe, or even deadly. As discussed in [Chapter 18](#), hidden costs resulting from late deliveries, complete default on confirmed orders, losses caused by poor packaging, or short expiration dates—common problems with unreliable suppliers—may raise the actual medicine cost to several times the original contract cost.

New suppliers are constantly coming into the market, while others are changing to new fields, merging, or going out of business altogether. New companies may have difficulties with quality control and packaging for export during their first years of production but later become reliable, low-cost producers. At the same time, a company long known for high-quality products and prompt service may become seriously deficient as a result of changes in management or regional distributors. A multinational company offering an attractive price may provide excellent service in one country and poor service in a nearby country, solely because of its choice of in-country representatives.

An efficient procurement office must therefore be able to closely monitor supplier performance and consider the relevant information during both prequalification or postqualification.

Types of potential pharmaceutical suppliers

Government pharmaceutical factories, local private manufacturers, and foreign manufacturers are *primary* sources of pharmaceuticals, because these companies do the manufacturing themselves. Donors, international procurement services, independent foreign exporters, and local importers and distributors are *secondary* sources; they obtain pharmaceuticals from manufacturers for resale.

As discussed, both donor financing and national procurement laws and regulations may determine the options for supplier selection.

Pharmaceutical manufacturers. Pharmaceutical manufacturers can be classified as *research-based* and *non-research-based* producers. The well-known multinational pharmaceutical companies are research based in that their reputation and, to a large extent, their profitability depend on new pharmaceuticals developed through research. These pharmaceuticals are patented and vigorously promoted by brand name. Nevertheless, many such firms also produce a line of pharmaceuticals that they sell by generic name at a lower price than their brand-name products. These pharmaceuticals are often made on the same production line and sometimes in the same batch as the brand-name product. Quality standards are identical; only the packaging and appearance of the medicine are different.

Non-research-based firms range from small, one-factory, local companies to large national or multinational generic pharmaceutical manufacturers that frequently market pharmaceuticals only by their nonproprietary names. Although they may have less name recognition, many generic manufacturers produce products equal in quality to those of any brand-name company.

International procurement services. International procurement services are sometimes nonprofit companies or arms of international agencies. Sometimes these services operate as private, for-profit entities. They provide services from one or more warehouses, and they vary with regard to selection of medicines, prices, means of quality assurance, payment terms, restrictions placed on the buyer, and nature and timeliness of service provided. Some well-established international procurement agencies are listed in the annual *International Drug Price Indicator Guide* (MSH). Some procurement agencies, such as Crown Agents, do not maintain inventory but are ad-hoc purchasing agents that must go through the sometimes lengthy process of negotiating prices with individual manufacturers and then arranging shipment from the manufacturer to the purchaser.

These agencies can play a valuable role in international tenders, providing competitive international prices for a range of products and access to small quantities of pharmaceuticals—sales that may not interest primary manufacturers. Their proposals should be evaluated by the same criteria used for other sources of supply, and they should specify the name of the manufacturer and the mechanism for quality assurance, like any commercial distributor.

Independent international wholesale exporters. Independent international wholesale exporters—sometimes known as “jobbers”—purchase pharmaceuticals from a variety of manufacturers for resale. Many of these companies around the world specialize in exports to developing countries. Most exporting countries exercise less strict control over jobbers than over manufacturers, a practice that can open purchasers to risk of procuring poor-quality products. Hence, it is essential to get the name of the primary manufacturer and make sure that the distributor provides bona fide quality assurance documents and certifications from the exporting-country regulatory agency with each registration request, tender offer, and shipment. Forged certification documents have been received in some countries from less reliable foreign exporters. WHO has developed prequalification procedures related specifically to wholesalers. Procurement offices should consider adapting the WHO procedures when qualifying wholesalers as suppliers.

Local importers and distributors. Local importers and distributors—also known as wholesalers—are often major forces in the local pharmaceutical market, both financially and politically. Like foreign distributors, these companies may not closely examine the quality of the products supplied by the manufacturers with which they work. In many countries, these companies have exclusive rights to represent certain manufacturers, and tender offers for these manufacturers’ products come through the local distributor. Again, the procurement office may wish to adapt and apply the WHO wholesaler prequalification criteria when qualifying this type of supplier.

Locating and contacting qualified suppliers

Generally, identifying qualified suppliers should be done through a systematic prequalification process or by advertising an open tender followed by a rigorous postqualification evaluation.

Open public tenders can be publicized through local newspaper notices and Internet tender portals, such as dgMarket (<http://www.dgmarket.com>). Increasingly, procurement agencies are posting tender notices to their own websites (for example, Tamil Nadu Medical Services Corporation and Tanzania’s Medical Stores Department). Notices can be sent to international newspapers, trade directories, and journals with wide circulation. The World Bank

has published guidelines on e-tendering for programs that it finances (World Bank 2009).

Agencies that are required to purchase only from prequalified suppliers may still publicize their intent to purchase through an international notice, in addition to contacting prequalified suppliers directly. This “safeguard” practice informs the prequalified suppliers and may also arouse the interest of new suppliers.

Even when all foreign suppliers in a tender are represented by local agents, notice through international channels may be faster and more reliable than depending on local agents to alert foreign suppliers. Earlier notification allows suppliers more time to prepare offers and thus increases the probability of competitive offers.

Contacts with international agencies. Contacts with international agencies may be an effective way for a procurement office with little international experience to identify potential suppliers. This arrangement may be especially useful in places without central government authority, such as in the early days of East Timor’s independence, when UNICEF procured pharmaceuticals on behalf of the interim government.

The WHO prequalification scheme can guide countries to suppliers that provide quality-assured products, and the Global Fund’s voluntary pooled procurement mechanism also helps countries access quality products at competitive prices. Other global initiatives, such as Stop TB and the Global Drug Facility, Roll Back Malaria and the Affordable Medicines for Malaria program, and WHO’s AIDS Medicines and Diagnostics Service, offer information on suppliers of specialized products, and in some cases, on comparative pricing.

Contacts with other procurement offices. As discussed in [Chapter 18](#), even where a formal, regional multicountry pooled procurement system is not realistic, countries in a region may be able to develop a coordinated information-sharing process among their national procurement offices—sharing information on prices and supplier performance.

Information on international prices. To know whether potential suppliers are offering competitive prices, procurement offices need a point of reference or sufficient experience in the market to make accurate cost estimates. One such reference for international prices for essential medicines, the annual *International Drug Price Indicator Guide*, contains the catalog prices from several international procurement agencies and actual tender prices received by developing-country procurement agencies. The Global Fund’s Global Price Reporting Mechanism is an important source of comparative pricing data from countries that purchase medicines through Global Fund grants. Reference prices can also come from one of the nonprofit international procurement agencies, and most of them provide a price catalog on request. The global initiatives discussed above can provide pricing information related to their specific

mandates. [Chapter 18](#) lists various price-reporting references.

Evaluating new suppliers

When considering contract awards to previously unknown suppliers, establishing how product quality will be assured is essential. If the procurement office does not have a way to test products, it may argue against an award to a foreign supplier whose products are either not approved through the WHO prequalification process or not registered by a stringent regulatory authority. As noted, procurement laws, regulations, or policies may require that national suppliers be given preference (or at least access to the tender), but in many cases, these suppliers do not have international certification. The procurement office is still responsible for excluding substandard suppliers from the tender.

In addition to deciding whether a supplier is generally reliable, which of the supplier’s products are of acceptable quality must be determined. Some suppliers may produce good-quality liquids but not tablets or injections. A supplier may have difficulty producing certain medicines because of a lack of quality raw materials or a lack of certain equipment.

Some procurement programs establish a list of critical medicines for which potential quality issues exist and limit suppliers for those products. Trying to qualify each supplier separately for each medicine on the tender list certainly will add substantial time to the pre- or postqualification process. In a West African country that decided to prequalify suppliers separately for each medicine, the prequalification process for one tender took nearly eighteen months.

Procurement staff must develop a formal system of determining suppliers’ reliability to eliminate suppliers that are substandard. Two aspects are involved: evaluating potential new suppliers (for pre- or postqualification) and rating the performance of current and past suppliers.

Evaluation of new (unknown) suppliers should be approached through formal prequalification and through testing products received when feasible, followed by performance monitoring.

Formal prequalification. As mentioned, prequalification is the process of developing a list of registered suppliers based on past performance, references from previous clients, and documentation of product quality before they are invited to submit bids on tenders. Although establishing an initial list of prequalified suppliers can be time-consuming, it expedites the tender evaluation because every bidder is qualified. A rigorous prequalification process will include references from past clients and inspections of manufacturing sites by quality experts (WHO 1999).

[Annex 21-1](#) lists information one should check when considering a new supplier. Sample registration forms used by the international nonprofit procurement agencies can be requested from the agencies.

Test performance on trial purchases. As part of their monitoring process, procurement programs should, if possible, test samples of products received. Products from new suppliers should be tested more often than products from established, trusted suppliers. Purchasers should generally not procure products that are needed to treat critical illness or that absolutely require timely delivery from completely new suppliers. For example, an unknown supplier might be awarded a contract for vitamin B complex, but not for gentamicin.

Monitoring and evaluating supplier performance

After a contract is awarded, monitoring the supplier's service and quality should provide the basis for decisions regarding future purchases. In many countries, monitoring is done informally and without written records, which makes assembling data for review by procurement committees difficult. Successful purchasing agencies use a formal monitoring system, as described in Section 21.9 on procurement information.

In general, suppliers that have performed poorly should be excluded from the next tender. Some procurement agencies give a probationary re-approval to suppliers that have had problems, such as too many partial shipments or excessive lead times, but offer high-quality products at competitive prices. If problems recur, the nonperforming suppliers are then barred from the next tender. If a supplier's problems are sufficiently grave, it can be barred for a two-year period and then be forced to prequalify again.

Some procurement offices use a point system, assigning values to performance criteria such as those shown in [Annexes 21-1](#) and [21-2](#). The relative weights of each category vary; for example, in some situations, the lead time may be very important and be given a high weight; in other situations, it may be a minor factor. In countries with strong regulatory control of the pharmaceutical market, product quality may be given a low weight, because all registered products are assumed to be of acceptable quality.

Rating systems offer two options for ranking applications: in one, a minimum passing score is used; in the other, suppliers are ranked from top to bottom overall, and contract preference is given to higher-ranked suppliers when prices are equivalent. A supplier with a much higher rank might get the contract despite a competitor's offer of lower prices.

Because ratings of supplier reliability and quality have a tremendous effect on the number and quality of suppliers that participate in a tender, the ratings must be as impartial as possible, with criteria written into the tender adjudication process. Ratings will always be subjective to some extent, so to ensure impartiality, the entire procurement committee, or at least a multiperson team, should be responsible for assigning supplier ratings.

21.5 Preparing and issuing tender documents

After selection, quantification, and preparation of the tender list are completed, bid packages are sent out to suppliers or posted on a website. For restricted tenders, packages are made available to all prequalified bidders; in open tenders, they are made available to all interested bidders. The tender package typically includes the documents discussed below. (See [References and Further Readings](#) for sources of tender documents that can be adapted.)

Invitation to bid. This describes the scope of the procurement, the purchasing group that is soliciting offers, the conditions under which bids will be accepted, the address for submission, the date and time bids are due, and the dates to be covered by the contract.

Instructions to bidders. These cover how to submit documents, including how to state prices; dates of bid validity; what currencies to use; what documents are required in addition to bid forms; bid and performance bonds (if applicable; see [Chapter 39](#)); precautions against undue contact with procurement office staff; format for submitting offers; domestic preference (if any); criteria for bid evaluation; and procedures involved in adjudication, award, and notification. Forms should be appended for performance and bid bonds and for documenting domestic preference and value added, if applicable.

In addition, the procurement manager should indicate in the tender document itself how suppliers' offers will be evaluated. This step shows all suppliers the importance of the various requirements specified in the tender. [Figure 21-2](#) shows an evaluation matrix introduced by Papua New Guinea to assess the potential suppliers for pharmaceutical tenders.

Bidding documents usually include a statement indicating that the procurement committee may reject any or all bids. Rejection of all bids is justified when no effective competition exists or bids are not substantially responsive.

Conditions of contract. These discuss general conditions in the contract that will be signed with successful bidders and any special conditions applicable to the current procurement (see [Chapter 39](#)).

General technical specifications. These provide information on good manufacturing practices (GMP) standards, pharmacopoeial standards, nomenclature and description required for each product, shelf life and expiration date parameters, labeling instructions, packaging instructions, GMP and quality assurance certificates required, and other evidence of product quality to be submitted with the tender and with each shipment.

Specific pharmacopoeial standards should be listed for each product; if any of a range of standards is adequate (*British Pharmacopoeia*, *U.S. Pharmacopoeia*, *European Pharmacopoeia*, or *International Pharmacopoeia*), it

Figure 21-2 Papua New Guinea pharmaceutical tender

TENDER EVALUATION SHEET		
Indicator	Weight	Comment
1. Financial	30%	
1.1 Form of bid	30%	Lowest
2. Performance	30%	
2.1 Delivery	5%	Within specified time—5%
2.2 Years experience supplying Papua New Guinea (PNG)	5%	2 years or more—5%
2.3 Past contracts	5%	PNG—3%; developing countries—2% (within last 5 years)
2.4 Packaging	5%	As specified in tender—5%
2.5 Financial capacity	5%	Acceptable bid bond supplied—5%
2.6 Evidence of financial capacity	5%	Banker's details and financial records—5%
3. Quality	40%	
3.1 Product documentation submitted as per conditions of bid	15%	Documents submitted for all pharmaceutical and medical equipment products—15% > 80% required documentation—10% 60–80% required documentation—7.5% 30–60% required documentation—5% 0–30% required documentation—0%
3.2 Manufacturer's certifications submitted as per form of bid	15%	Manufacturer's certifications received for all pharmaceutical and medical equipment products—15% > 80% required documentation—10% 60–80% required documentation—7.5% 30–60% required documentation—5% 0–30% required documentation—0%
3.3 Manufacturer's labeling submitted as per form of bid	10%	Manufacturer's labeling received for all pharmaceutical and medical equipment products—15% > 80% required documentation—10% 60–80% required documentation—7.5% 30–60% required documentation—5% 0–30% required documentation—0%

should be noted. If special packaging or labeling is required for a subset of products, this requirement should be indicated on the schedule of requirements (see below), but a generic statement of packaging and labeling applied to all products should be included in the general technical specifications. Instructions about labeling (contents and language) and package inserts can be included in the technical specifications, unless specific requirements exist for a subset of products. These should be indicated on the tender list.

If all products are to be shipped to the same destination, on the same delivery schedule, by whatever means is most efficient and cost-effective, this specification can be stated in the conditions of contract. If different instructions apply to certain products, they should be stipulated in the schedule of requirements.

Schedule of requirements, or tender list. This provides a concise description of each product and the quantity required, along with any technical specifications unique to that item. If it can be printed with sufficient space for suppliers to enter offers, having suppliers use this space for bids greatly simplifies the collation of offers. Sufficient space should be provided so that the supplier can enter all relevant information, including the name of the original manufacturer.

The schedule of requirements should include the International Nonproprietary Name (INN), or generic name (for combination products, the name of each generic component), the strength in metric units for each component, the basic unit (tablet, capsule, vial, bottle), the package size, and the number of packages needed. Some tenders list both the total number of packages

and the total number of basic units needed, to avoid misunderstanding and to allow for the possibility that a supplier may offer a different (but acceptable) package size representing the same number of basic units. The tender should specify whether the listed package sizes are the only ones acceptable; some procurement agencies request offers on all package sizes available.

Each unique product should have a separate inventory code number, used only for that product. This code is useful in compiling product catalogs and is essential for computerized information systems. It can also be helpful in making sure that all parties are referring to the same item when clarifying issues with client facilities or with suppliers. For therapeutic category analysis, a supplementary code can be used to assign each drug product to a therapeutic category (see [Chapter 40](#)).

To simplify future procurements and make sure that all staff use the same terminology in procurement and tender functions, compiling all information about each tender product into a procurement catalog is useful. With a computerized system, developing a catalog is simple; updating a product catalog manually is more difficult, but the effort may be worthwhile to save time in compiling future tender lists.

21.6 Adjudicating the tender

The most important aspect of adjudication is that it is an open and transparent process that assures all participants that the tender was conducted fairly. Tender adjudication involves several separate activities and stages—

- Prepare for adjudication during the open period.
- Receive and open bids.
- Collate bids for adjudication.
- Adjudicate offers and award contracts.

Preparing during the open period

The length of the open period (time between the invitation to tender and the closing date) typically varies from four to eight weeks. A longer open period lengthens the total lead time for obtaining pharmaceuticals but may also increase the number of offers received. The procurement agency should prepare for receipt of documents, collation, and adjudication during the open period.

Some suppliers may request clarification about product description, package size, pharmacopoeial standard, labeling, or packaging requirements. If clarification is needed because of a mistake or omission in the tender package, it should be provided to all participating bidders. Similarly, if one supplier is given approval to offer a product or package that is similar to but not the same as that listed in the

schedule of requirements, all bidders should be informed that such an exception is approved.

Receiving and opening tender offers

To ensure confidentiality and to avoid accusations of price fixing or undue influence on decisions, the procurement agency must adhere strictly to the closing date and time. No bids should be opened before the date and time specified. A written record should be kept of all bids received, documenting the date received and the person who received the bid. The unopened bids should be stored in a locked, secure area until the closing date. The date of bid receipt should also be entered into the procurement management information system to track the response to tenders. If due dates are approaching and suppliers—particularly those known to be reliable, low-cost sources—have not responded, the procurement agency can remind *all* suppliers of the approaching deadline by telephone, fax, or e-mail.

At the specified date and time, the bids should be formally opened, with at least one member of the procurement committee and bidder representatives (if they choose to be present) in attendance. Specifics of how the bids are opened and documented vary by country—with some procedures mandated by national regulations. Details such as the bidder's name and address, and required documentation such as bid form and bid security for each opened bid, are often read aloud. If the bid security has not been deposited, an immediate disqualification usually results.

Each opened bid should be logged in a ledger and numbered for future reference. If possible, writing the number of enclosed pages on the outside of the tender envelope may be useful to avoid confusion during adjudication. Often, a note taker documents the meeting proceedings, and at the end of the meeting, attendees sign the draft minutes, which everyone will receive for record-keeping purposes.

Collating offers for adjudication

The first step in collating offers is to determine which offers, if any, are nonresponsive to tender conditions. Suppliers that have not met the basic requirements related to bidder qualification, medicine description, strength, pack size, quality requirements, and delivery date are nonresponsive. If required information has not been provided, the bid is nonresponsive. If the tender documents require the supplier's signed acceptance of contract terms and the supplier has not signed, the bid is nonresponsive.

Information from all responsive bids should be compiled in an adjudication report to allow side-by-side comparison of the offers. Nonresponsive bids should not be entered into the collated adjudication report, but the problems should be documented in writing for review by the procurement committee.

Prices must be converted to a common currency and adjustments made for differences in trade terms (for example, adding freight costs to those bids that do not include freight expenses). If local or domestic preference is considered in the adjudication, the adjudication report should separate offers eligible for the local preference margin, so that they can be fairly compared with offers that are not eligible.

Spreadsheets are now commonly used to simplify the collation of information and the preparation of an adjudication report. In addition, specialized procurement software is available that automates all of the processes related to collecting bids, collating offers, and ranking them according to predetermined criteria (see Section 21.10). [Figure 21-3](#) illustrates an adjudication report prepared by a specialized computer program.

Managing the adjudication process

The authority to adjudicate tenders and award contracts should be confined to the procurement committee (or government tender board). Procurement office staff should assemble information for the tender board or procurement committee and make technical recommendations, but they should not have a vote in the contract decision.

As discussed in [Chapter 18](#), the adjudication process must be free from influence by special interests; it should be open and transparent, with written rules for the process, including evaluation, award, any special criteria, and the appeal period for rejected bidders. Results of adjudication, including the winning bidder and the contract price, should be available to all participating bidders. In countries where pharmaceutical procurement has fallen into disrepute, credibility can be rebuilt by broadening participation in the tender board or procurement committee and making sure that it has final authority for approving all pharmaceutical procurement and for enforcing transparency in the tender process.

Evaluation of offers. For restricted tenders that do not involve split contract requirements, this process can be quick. The procurement committee reviews the collated bid information and normally selects the lowest bidder for each product. Contracts are then developed. Disqualification of low bidders should be documented and become part of the tender record.

For open tenders, supplier evaluation does not begin until bids are received, and adjudication is a two-stage process: a tender evaluation committee is formed for ranking the bids according to standard evaluation criteria, and then beginning the postqualification supplier evaluation process. When the postqualification analysis has been completed, the procurement committee meets to review the recommendations of the tender evaluation committee and determine whether the lowest evaluated bid should receive the contract. If not, the next-lowest evaluated bid is considered, and so forth.

The responsible procurement committee or tender board should carefully consider each item on the tender list and make an award for each item, unless no responsive bids were received. If the primary/secondary supplier system is used, equal care is needed in selecting secondary suppliers, because they will automatically be used if the primary supplier defaults.

Written bid evaluation criteria should be applied rigorously and without exception. Tender contracts should be awarded to the lowest bidder that has the capacity to supply products that meet the standards required (considering local preference, if applicable). This award should be mandatory unless the lowest bidder has not performed in prior procurements.

In local tenders, Incoterms, such as cost, insurance, and freight (CIF) and carriage and insurance paid (CIP), are generally not applicable. Delivered price, which includes landed cost, overheads, and profit margin, is more common and is an adequate standard for comparing costs. Letters of credit are normally not used to pay local suppliers; other mechanisms, such as deferred payment, may be beneficial and should be considered if stated in the evaluation criteria and in instructions to bidders. When the health procurement agency sells its products and receives payment from health facilities, it should try to arrange supplier payment terms that are longer than those provided to health facility customers. For example, if health facilities are given thirty days to pay, then thirty-to-sixty-day payment terms to suppliers can help cash flow.

Local and foreign suppliers may offer different trade terms (CIP to purchaser's warehouse, or CIF to purchaser's main port). To make these two prices comparable, all duties, fees, handling, and transportation costs to the purchaser's warehouse must be added to the CIF price.

Delivery dates should be compared in terms of past suppliers' performance rather than promised delivery date. If the lowest acceptable bidder's expected delivery is beyond the required date, then the effect of a shortage must be considered in light of the cost of alternative treatments or of a special air shipment to cover the interim period.

Special criteria. Special criteria are sometimes applied, such as a local preference margin calculated by adding a percentage to the value of foreign bids, before they are compared with local bids. World Bank–financed international competitive bidding (ICB) procurements allow local preference, to a maximum of 15 percent. Although pricing is the accepted means of granting local preference, some countries have more explicit requirements to grant local companies preference in contract awards to foster industrial development. This approach, however, can put the procurement office at risk of having to accept lower local standards of service or product quality. In any event, all procurement agencies should use supplier performance as the basis for purchasing decisions.

Some programs try to maintain as broad a supplier base as possible to protect against loss of a primary supply source.

In insecure regions, maintaining a geographic and political distribution of suppliers can mitigate supply disruptions due to war, natural disasters, or international political problems.

Appeal period for rejected bidders. Some countries allow an appeal period during which rejected suppliers may request reconsideration by the tender board. The appeal process varies greatly according to national regulations; the time to resolve appeals according to law may be less than a week or many months, but ideally, the appeal period should be no more than one month, to avoid delays in procurement. Ultimately, the other bidders should be notified and given information about the winning bid.

21.7 Issuing contracts to winning bidders

When tender awards are made, contracts must be established with successful bidders (see [Chapter 39](#)).

A list of all contracts awarded, specifying for each item the supplier, price, and total value, should be made available to all responsive bidders; if necessary, the name of the successful bidder can be omitted from the public document.

If winning bidders decline to accept the contract, bid bonds or other types of security (if used) are forfeited. In the primary/secondary system, the secondary supplier is contacted immediately. In other cases, the item must be rebid; depending on the volume, local competitive bidding may be the preferred method.

21.8 Laws governing international agreements

Almost all procurement laws and regulations are based on previous laws developed in and for the country, although some countries, such as Tanzania and Uganda, have based their procurement regulations and laws on World Bank standards. With more people and goods moving from one country to another, questions about which system of law applies often arise. If, for example, the Medical Stores Department of Tanzania signs a contract to buy medicines from France, will the agreement fall under Tanzanian law or French law? The matter becomes particularly important if a disagreement arises. For example, suppose some of the goods arrive damaged, but when the contract was written, no specification of legal jurisdiction was included. Which court should adjudicate the matter?

The legal system in the country of one of the parties signing the agreement is usually chosen, or perhaps the country where the goods currently are or where payment is to be made. National procurement laws and regulations may dictate the choice of “prevailing law,” but otherwise choosing the system that seems most relevant to the situation and to the risks is advisable. If, for example, goods are being

imported and the concern is that the supplier may not deliver, involvement of the courts in the supplier’s country may be the best way of ensuring delivery. Goods transported in boats or trains belonging to a third country are not necessarily well protected, and the laws of that country may not safeguard the goods. This fact does not alter the fact that the seller should be responsible for ensuring that the goods arrive. No guarantee exists that the courts of the country selected will agree to adjudicate any case that arises, but if the choice has been a commonsense one, it will probably be respected.

An alternative is to indicate some other body to settle disputes. In commercial contracts with some countries, the chamber of commerce may be asked to act as arbitrator. Arbitration is often a quicker and less expensive way of settling disputes than court proceedings, which may be costly and take many years. Finding a suitable arbitrator who is fair, sufficiently expert in the field concerned, and trusted by both parties is important.

One word of warning: international disputes are often not effectively settled by the courts, or even by arbitration. An unscrupulous foreign seller of a dangerous or defective product may expect to be able to escape liability because of the time and expense involved in bringing an international action. The supplier can change its name, address, domicile, and legal or corporate form and be out of reach of the courts. The law may be unclear. Even between industrialized countries with a long history of personal-injury litigation, claiming compensation for drug injury from a foreign manufacturer of a bad product remains difficult. Dealing with a firm of good reputation may be worth paying a somewhat higher price.

21.9 Monitoring performance and product quality

The procurement office is responsible for monitoring performance and compliance with contract terms by suppliers and facilities that order pharmaceuticals. The office must actively track suppliers’ lead time, delivery status, compliance with contract pricing and terms, shelf life, and packaging of products. In decentralized procurement systems, central procurement authorities find it difficult to monitor local government procurement activities. Resulting problems can include high prices, poor service and product quality, irrational supplier and product selection, and poor payment practices, all of which undermine patient services. Therefore, monitoring local government and facility procurement performance becomes vitally important. Are they ordering according to schedule, in reasonable quantities, and are they paying for their purchases according to the contract? Are total purchases roughly equal to estimated needs? In some countries, governments have concluded

that recentralizing procurement is the best way to achieve desired procurement outcomes.

Maintaining an active program to ensure product quality before procurement and after receipt and distribution is crucial (see [Chapters 18, 19, and 35](#)). Reports of problems from prescribers, dispensers, consumers, and purchasing managers must be recorded in the product and supplier files and reviewed as part of the monitoring and evaluation of suppliers, and suppliers need to be made aware of any problems related to the quality of the products they supplied.

When testing is available, it is not necessary to test every drug from every supplier, but products that have been reported as suspect should always be tested. Testing should be done periodically for random samples of medicines known to be subject to degradation in questionable storage conditions, medicines that have a low therapeutic index (see [Chapter 19](#)), and pharmaceuticals received from suppliers of questionable or unknown reputation.

[Chapter 39](#) discusses supply contracts and enforcement provisions. Enforcement is the key: there is no point in an elaborate contract unless it will be enforced when necessary. The reality is that unless substantial performance bonds are required as a condition of the contract, there may be limited recourse in the case of problems with foreign suppliers other than canceling outstanding orders and withholding payment.

21.10 The procurement information system

The most important tool in the procurement office is its management information system (MIS). The MIS can be computerized, manual, or a combination; computerized systems make it much easier to develop reports, and they speed up procurement processes such as prequalification and collation of tender offers for adjudication.

Procurement offices can probably get the greatest benefit from specialized computer software programs for procurement. Companies that sell off-the-shelf tender software include ActiveCost, BlooChip, mSupply, and Orica. The development and use of standard bidding documents can drastically decrease the time needed to prepare tender documents and contracts. The skills exist in most countries, if not in the procurement agencies themselves, to develop spreadsheet programs that can effectively accomplish most other tasks. Posting tenders and associated documents on an agency website and other Internet sites, such as dgMarket, can also help manage aspects of the tender process, such as sending out tender documents and related information, although certain tasks still require hard-copy documentation.

This section describes the information that should be tracked and used; the method of storing and retrieving the information is secondary. The information system includes

several different types of records: those on products, tendering and ordering, suppliers, clients, quality assurance, accounts receivable and payable for pharmaceutical orders, and accounting records for the procurement office itself (see [Chapters 41 and 49](#)).

Product records

Product files record the standard technical specifications for a specific item and the performance of past suppliers of the product. Detailed product records are particularly important when quality is critical. A sample product card for a manual system is shown in [Figure 21-4](#). Product records can also be maintained in a special-purpose, procurement software system or a spreadsheet. Producing a catalog of all items that can be used to compile quantification lists, tender lists, adjudication forms, and notices of awards may be useful.

Records related to tendering and ordering

A record of each year's procurement, tracking the total quantity estimated and actually purchased of each item (along with the contract supplier and price), facilitates the estimation of future prices and is essential in assembling future quantifications and checking quantity estimates from clients in decentralized ordering systems.

An ongoing record of the order status and shipments pending can be made using separate folders for orders outstanding, orders received as partial shipments, and orders completed.

Another simple manual system uses a ledger to track each order (the order number, date ordered, date received, dates additional shipments were received, and dates payments were made), organized chronologically or by purchase order number. With systems that do not use purchase order numbers, keeping track of outstanding orders may be difficult.

A computerized information system can provide standard reports on order status, organized by product, purchase order number, or supplier. [Figures 21-5 and 21-6](#) illustrate order status reports available from a typical information system.

Records to monitor supplier and facility performance

Supplier performance monitoring has two parts. First, the system should track lead time, compliance with contract pricing terms, partial shipments, remaining shelf life, compliance with packaging and labeling instructions, and compliance with other contract terms. This record should track the number and value of tender contracts awarded chronologically and the value of total purchases from the supplier by year. Second, a file on each supplier should contain copies of all registration papers, references, special correspondence, complaints, and anecdotal information.

21.20 PROCUREMENT

The facility performance monitoring system tracks total purchases compared with estimated quantities for each procurement cycle, purchases from noncontract suppliers, lead time for payment to suppliers (if that is the facilities' responsibility), compliance with deadlines for quantification, complaints about product quality and supplier service problems, and results of follow-up of complaints and requests for action.

Quality assurance records

A chronological record of all product-quality complaints, with documentation on the results of follow-up, should be

separate but linked to a record that documents all quality assurance tests performed, the reason, and the results. These records should be linked to or entered into both product and supplier records.

Accounts receivable and payable

The procurement office should have a record of each order placed with contract suppliers, the dates payments were made against the outstanding amount, and the total amount still owed. A separate purchase order number for each purchase simplifies record keeping and accounting. By using individual purchase order numbers, records can be

Figure 21-4 Sample product card

Side one / product specifications

Generic name: <i>Paracetamol</i>		Category: <i>Analgesic</i>	
Trade names: <i>Calpol, Panadol, Tylenol</i>			Code number: <i>02-4600</i>
Form: <i>Tablet</i>	Dosage: <i>500 mg</i>		Package size: <i>1,000 tabs</i>
Acceptable pharmacopeial standards: <i>IP / USP / EP / BP</i>			
Additional technical specifications: <i>Standard specifications (Schedule A) plus: (1) Double-scored tablet, imprinted with unique identifiers (our logo) (2) Shrink-wrapped in packaging units of 10 x 1,000</i>			

Side two / supplier history

Purchase order number	Supplier	Quantity	Unit price	Date promised	Date delivered	Comments
<i>085/10</i>	<i>Generix</i>	<i>5,000</i>	<i>20.25</i>	<i>01/11</i>	<i>02/11</i>	
<i>086/10</i>	<i>Novapharm</i>	<i>10,000</i>	<i>21.80</i>	<i>01/11</i>	<i>12/10</i>	
<i>003/11</i>	<i>Generix</i>	<i>5,000</i>	<i>20.25</i>	<i>04/11</i>		<i>Revised date 05/11</i>

Table 21-2 Standard procurement reports

Report name	Contents
Reorder report	Suggested order quantities, sorted by item or supplier
Purchase orders pending	Outstanding orders, by item or supplier
Physical stock status	Summary list of quantities for all items in inventory, by name or code, with nearest expiry date
Stock detail report	List of all items in stock, with quantity by batch (lot number) and expiry date
Expired stock	All expired stock and stock without expiry date
Expiry risk	Stock at risk of expiry—stock quantity, expiry date, average use, and quantity and value of stock at risk
Out of stock	All items out of stock
Stock count form	Stock count list, by name, dosage form, location, or code
Inventory adjustment	List of items for which the stock count and records differ
Inventory variance	Changes made to stock balances outside normal process
Suppliers	List of all suppliers, with contact information
Accounts payable	Aged list of debts to suppliers
Facilities	List of all client facilities, with contact information
Accounts receivable	Aged list of debts from facilities
Summary of warehouse activity	Purchases and sales, year to date and month to date
Tender request	List of items needed, with specifications
Tender offers	Bid details for each tender offer
Tender status	Tender contract status and price amendment history
Adjudication report	Bids received by item, ranked by total cost
Tender award list	List of contracts awarded
Currency exchange history	Report on exchange rates by currency
Financial transactions	Financial transactions, by date and account code
Requisition forms	Purchase requisition form and pending purchase requisitions
Stock transactions	List of all shipments to facilities, by item or facility, with total value
Purchases/receipts	List of all purchases and other receipts, by item or source, with total value
ABC analysis	ABC analysis of warehouse consumption, and analysis for each client facility
Supplier performance	Comparison of stated versus actual lead times, adherence to contracted price and delivery terms

arranged by either purchase order number or supplier. The procurement office should include the relevant purchase order number in every communication to the supplier, including the initial order, the tender contract, and any subsequent communications related to the purchase.

If the procurement office is based in a warehouse that also sells pharmaceuticals to clients, accurate records should be kept of amounts owed by clients and fees charged for procurement services. A separate transaction number assigned to each shipment or charge for services makes tracking easier.

Reporting

As discussed throughout this chapter, the procurement information system will be called upon to issue periodic reports for pharmaceutical and supplier selection, quantification, and tender collation and adjudication, as well as status reports on orders or payments. Standard reports, such as those listed in [Table 21-2](#), are much more easily produced by a computerized information system, but even a manual system should be organized enough to produce the reports fairly regularly. ■

ASSESSMENT GUIDE

For additional indicators and procurement assessment information, see the *Methodology for Assessing Procurement Systems* (OECD/DAC 2010) and procurement system assessments from Tanzania (PPRA 2007) and Uganda (PPDA 2007). See also Country Study 36-3 on developing a procurement system assessment in India.

Quantitative indicators

- Percentage by value of ministry of health (MOH) pharmaceuticals purchased through a central procurement system
- Percentage of average international price paid for last regular procurement (indicator medicines)
- Percentage by value of MOH pharmaceutical purchases that are on the essential medicines list or national drug formulary
- Percentage by value of MOH pharmaceuticals purchased through competitive tender
- Percentage by value of pharmaceuticals purchased from local manufacturers
- Average lead time for a sample of orders (calculated separately for all suppliers, local manufacturers, foreign suppliers)
- Average time period for payment for a sample of orders (calculated separately for all suppliers, local manufacturers, foreign suppliers)

Procurement responsibility

- Is procurement managed centrally, or is authority decentralized?
- How much time is normally required to complete the following steps (and who is responsible for managing the step): selection, quantification, preparation of tender documents, tender adjudication, and contract award?
- Have the persons responsible for procurement been trained in this field?
- Is there a written procurement procedures manual? If so, do practices conform to the written procedures?
- What type of procurement method is normally used?
- Who determines the procurement method for a specific procurement?
- Are the methods based on law or written policies?
- How many different suppliers currently supply medicines to the health system?
- Are suppliers bilateral aid programs, international procurement services, multinational companies, or local import agents?

- Does a single supplier or small group seem to win most of the supply contracts for the system?
- Who is responsible for selecting potential suppliers?
- On what basis are the suppliers selected for tender participation?
- Are suppliers prequalified?
- Is a formal rating system used for evaluating suppliers' suitability?
- Are supplier selection criteria documented and closely adhered to?
- What role do local agents play in locating, selecting, and conducting business with pharmaceutical suppliers?
- Who has the authority to award contracts to suppliers?
- Are there written procedures for committee actions, and are they followed?
- Are written minutes made of procurement committee meetings?
- What kinds of influences are brought to bear on the individuals who select the suppliers and award contracts?

Tender and contract methods

- Do tenders and supply contracts specify a fixed quantity and delivery schedule or an estimated quantity, with orders placed as needed?
- If both systems are used, what is the approximate percentage by value of pharmaceuticals purchased under each system?
- What are the procedures for placing orders to suppliers?
- What is the average time required to get an order approved?
- Who approves the order?
- Is there an effective policy limiting MOH pharmaceutical procurement to drugs on the national drug formulary list or essential medicines list? If so, is it effective?
- Is there an effective policy limiting MOH pharmaceutical procurement to medicines registered with the drug regulatory authority? If so, do procedures exist for granting exemptions?
- For competitive tenders, does the schedule of requirements list medicines by generic name or brand name?
- Are any medicines or groups of medicines tendered by therapeutic group (for example, oral first-generation cephalosporin) instead of by individual medicine in the group?

- Does the tender document specify pharmacopeial standards, WHO certification, specific packaging, specific labeling on packaging, specific labeling on individual dosage form, specific labeling language, delivery or order schedule, limit on back orders or number of partial shipments, minimum shelf life, replacement of goods damaged in shipment, samples submitted with bid?
- Are domestic companies allowed a local preference margin on bids? If so, what percentage?
- Is value added required for local preference? If so, what percentage is required, and how is value added determined?
- What is the usual basis for selecting the contract supplier? Is it the lowest price with no exceptions, the lowest price from a prequalified vendor, the lowest price of products deemed to be of acceptable quality, or some other standard policy?
- If product quality is a factor in tender awards, how is quality determined?
- What circumstances prompt split tender awards, if any?
- Are secondary supplier awards routinely made in case the primary supplier fails to perform? If so, do secondary suppliers normally agree to honor original tender prices?
- What circumstances warrant switching to the secondary supplier?
- Are constraints experienced in the use of secondary suppliers?
- Are bid bonds required? If so, what percentage of procurement value is required?
- Are performance bonds required after contracts are awarded? If so, what are the usual amounts or percentage of procurement value required?
- Is a fee charged to vendors that request tender documents? If so, what is the amount?
- Does the tender contract provide for penalties if the vendor does not perform? If so, are these penalties enforced?
- Are contract terms to which suppliers are expected to adhere clearly specified?
- Do these terms provide sufficient protection from common difficulties, such as late deliveries, inadequate

medication labeling, short shelf life, and poor quality?

- Are trade terms, payment terms, delivery schedules, and payment methods clearly specified?

Payment to suppliers

- Are there problems with timely access to procurement funds or foreign exchange? If so, how do they affect the procurement timetable?
- What are the usual payment terms for international purchases and for domestic purchases?
- What are the usual real lead times for payment for credit purchases (both international and local purchases)?
- What is the total debt owed to domestic vendors and to international vendors for pharmaceuticals and supplies?

Procurement information system

- Is there a systematic method for monitoring the status of outstanding orders and for providing information to other units regarding the status of outstanding orders?
- Do suppliers frequently refuse to supply an item for which they have won the contract, or do they default on an order?
- Are there frequent problems with suppliers' performance?
- What system is used to monitor the performance of suppliers and of health units that order pharmaceuticals?
- What reports are prepared on performance, and how are these reports used?
- Are computers used in the tender management and procurement information system? If so, what kinds of software are used?
- Are the software and hardware suited to the purpose?
- Are personnel who use the computers trained in the use of the software?
- Does the computerized information system produce reliable information on consumption and performance?
- Is a reliable system in place for maintaining and supporting the hardware and software?

Annex 21-1 Prequalifying new suppliers

WHO published guidelines related to pharmaceutical procurement that include a section on prequalifying suppliers (WHO/WPRO 2002). The guidelines note that the primary activities for a prequalification system include—

- Obtaining supplier information through the use of questionnaires
- Using the WHO Certification Scheme
- Seeking information from the drug regulatory authority of the exporting country
- Exchanging information with other drug regulatory authorities
- Evaluating product samples
- Monitoring and recording supplier performance

The WHO procurement guidelines also include a model questionnaire for suppliers. The World Bank (2002) also has a prequalification document for its vendors, which may be a useful resource. In addition, an example of the Organisation of Eastern Caribbean States Pharmaceutical Procurement Service's supplier prequalification form is available (OECS/PPS 2009).

Questions to ask as part of a prequalification process include the following. [Annex 21-2](#) lists questions related to supplier performance monitoring.

Status

- Is the supplier a primary manufacturer or a distributor?
- If a manufacturer, does the supplier manufacture all products in-house?
- If the supplier does not manufacture all products in-house, who is the primary manufacturer for each product offered?

Quality control

- Does the supplier use good manufacturing practices (GMPs)?
- Does the supplier have an on-site quality control laboratory or arrangements with an immediately accessible laboratory?
- What tests—chemical, biological, stability, accelerated stability, or others—are routinely performed during and after the manufacturing process?
- Are special tests performed for stability in tropical environments?

Inspection

- What official government agencies or reputable international organizations have inspected the manufacturing facilities?

- What are the results of the most recent inspections?
- What certification documents are available from the regulatory agency concerning the supplier's status and compliance with GMPs?

Personnel and facilities

- What are the qualifications of key production and quality-control personnel?
- What is the capacity of the supplier's plant(s)?
- Does the supplier have the capacity to supply all the required quantities?
- Will the supplier have to subcontract portions of large awards?

Trade references

- What other local or foreign public procurement programs and hospitals buy from the supplier?
- How long has the supplier served the above groups?
- What is the experience of these customers with regard to the supplier's quality and service?

Financial status

- Is the supplier financially stable?
- Will the supplier remain in existence for the entire contract period?

Corporate associations

- Is the supplier a subsidiary, a parent company, or in some other way formally associated with any known supplier? If so, what is the reliability of the known supplier?
- Is the supplier producing certain products under a supervised licensing agreement with a known supplier?
- How long has the supplier been supplying the goods under consideration?

Local reputation

- How is the supplier regarded by knowledgeable physicians and pharmacists?
- How are products of the supplier regarded by knowledgeable physicians and pharmacists?
- Is any information available from public sources (such as newspapers or trade journals) concerning the supplier's performance in other countries?

Annex 21-2 Criteria for evaluating suppliers

SERVICE**Participation record**

- Has the supplier attempted to alter or withdraw bids after submitting them?
- Has the supplier accepted an award of a bid and subsequently failed to deliver the product?

Response to inquiries

- Has the supplier adequately responded to all inquiries from the purchaser within a reasonable period of time?
- Did the supplier provide regular information regarding the status of outstanding orders?

Delivery time

- What was the supplier's average promised lead time? What was the actual lead time for the last procurement cycle?
- What percentage of shipments was late? How many days (weeks, months) late?
- What additional costs were incurred because of late shipments?

Adherence to delivery instructions

- Did shipments arrive under the proper shipping conditions (for example, cold storage for vaccines)?
- Did shipments arrive at the correct port?
- Did the supplier send full shipments as requested, or were there partial shipments? How many partial shipments on average?

Provision of documents

- Did the supplier provide advance copies of documents according to contract terms?
- Did shipments arrive with all required documents correctly and completely filled out and signed?
- If required documents were omitted, how did the supplier correct the problem?

Packing and labeling

- Did the supplier always ship the correct dosage form, the correct package size, the correct quantity in each package? Were short shipments frequent?
- Was labeling complete and adequate for proper use? Was it in the correct language?

Product shelf life

- Did all products shipped comply with contractual terms for remaining shelf life? If not, how many products were shipped with a shelf life less than that called for in the contract?
- Did the supplier promptly replace any items shipped that did not have an acceptable remaining shelf life or allow the return for credit or exchange of products nearing their expiration date (one standard is within three months of expiration date)?
- Did the supplier analyze samples of products approaching their expiration date to determine whether longer shelf lives can be applied to the products? Was there a charge?

Compliance with contract financial terms

- Did all invoices comply with contract pricing terms? Were any problems promptly rectified?
- Were all shipments correctly insured and shipped according to financial terms in the contract?
- Were there any problems obtaining compensation or reimbursement for lost or damaged goods?

Information available from supplier

- Did the supplier make suggestions concerning ways in which the purchaser could reduce costs (for example, by combining or splitting orders or altering delivery schedules)?
- Did the supplier provide information on purchases and payments for use in reconciling accounts?
- Did the supplier provide information on purchases broken down by products and/or therapeutic categories?

QUALITY**Pharmaceutical product**

- Have complaints been received concerning product quality for this supplier? If so, what were the results of follow-up?
- Have products supplied conformed to specified pharmacopeial standards with regard to identity, purity, potency, physical appearance, dissolution, and other attributes?
- Have any products failed quality assurance testing conducted by the purchaser?
- Did the supplier provide requested batch analyses with each shipment?
- Does the supplier cooperate in making samples available and paying for quality-control tests performed by independent quality assurance agencies?
- Were there documented product problems that the supplier refused to acknowledge and rectify?
- Did the products last throughout the period of their stated shelf life?
- Was any discoloration or disintegration reported?

Packaging materials

- Were there specific examples of loss due to breakage or damage to packaging during shipments? If so, what was the extent or value?
- Did packaging meet standards appropriate to the climate of the purchasing country?
- Was external packaging sufficiently rugged to ensure arrival in the country in good condition?
- Did the external packaging protect the product from damage during transport within the country? For example, were vials sufficiently padded to withstand long trips on extremely rough roads?
- Was the immediate container able to withstand rough in-country transportation, heat, and humidity? For example, did pressure-sealed lids on tins shake loose on rocky roads?

SUMMARY

The primary distribution management goal is to maintain a steady supply of pharmaceuticals and supplies to facilities where they are needed, while ensuring that resources are being used in the most effective way. Distribution costs, which include costs related to storage and transportation, are a significant component of the expense of running a public health supply system. Transportation costs alone can represent a significant percentage of the value of medicines distributed to remote locations. Designing a system for storing and distributing pharmaceuticals, medical supplies, and equipment is complex and important.

Effective pharmaceutical distribution relies on good system design and good management. A well-designed and well-managed distribution system should—

- Maintain a constant supply of medicines
- Keep medicines in good condition throughout the distribution process
- Minimize medicine losses caused by spoilage and expiry
- Maintain accurate inventory records
- Rationalize medicine storage points
- Use available transportation resources as efficiently and effectively as possible
- Reduce theft and fraud
- Provide information for forecasting medicine needs
- Incorporate a quality assurance program

The distribution cycle begins when pharmaceuticals are dispatched by the manufacturer or supplier. It ends when medicine consumption information is reported back to the procurement unit.

The distribution cycle includes the following steps—

- Port clearing (for imported products)
- Receipt and inspection
- Inventory control
- Storage
- Requisition of supplies
- Delivery
- Dispensing to patients
- Reporting consumption

Designing a new distribution system or, as is more likely in practice, evaluating and planning improvements to an existing system, requires systematic cost-effectiveness analysis and operational planning. The basic characteristics of a distribution system include its degree of centralization, the number of levels in the system, and the geographic or population coverage.

A distribution system has four major elements—

1. *System type* (geographic coverage, population coverage, or both; number of levels in the system; push versus pull system; degree of centralization)
2. *Information system* (inventory control, records and forms, consumption reports, information flow)
3. *Storage* (selection of sites, building design, materials-handling systems, order picking, layout)
4. *Delivery* (collection versus delivery, in-house versus third party, dedicated or shared arrangements, choice of transport, vehicle procurement, vehicle maintenance, routing and scheduling of deliveries)

Whenever a new system is designed or an existing one is modified, cost analysis (comparing the total costs of using various options) can help ensure that available storage, transport, and human resources are used effectively. After implementation, a program of performance monitoring should ensure that the distribution system works as intended.

Centralized distribution is one option; some countries procure and distribute medicines regionally, and some use commercial supply systems, which often exist in parallel with public systems. Collaboration between private and public systems may occur at any level.

Operational planning and logistics skills are the key to developing a cost-effective and efficient distribution system. It is therefore important to have a logistics management staff composed of qualified professionals.

The steps in planning a distribution system are as follows—

1. Determine whether distribution operations would be carried out most effectively in the public or private sector, or a combination of both
2. Determine whether a push or pull system is to be used
3. Plan store locations and delivery routes—
 - Map the demand for medicines and estimate future demand based on population growth or program scale-up
 - Locate supply entry points
 - Rationalize primary storage points
 - Plan primary distribution routes and locate new intermediate stores, as necessary
 - Plan secondary distribution routes, if necessary
 - Size the stores
4. Plan delivery schedules and the required transport infrastructure

5. Establish staffing levels
6. Establish information flow

In some countries, private or parastatal distribution companies can provide cost-effective alternatives for the storage and distribution of medicines, especially at the national and regional levels. Contracting out to such a company involves—

- Assessing the cost of the existing system
- Determining what functions to contract out
- Specifying service requirements for the contract
- Preparing tender documents
- Evaluating the tender participants
- Agreeing to and signing a contract
- Monitoring the contractor's performance

22.1 Goals of distribution management

The primary distribution management goal is to maintain a steady supply of pharmaceuticals and supplies to facilities where they are needed while ensuring that resources are used in the most effective way. Distribution costs, including storage and transportation costs, are a significant expense of running a public health supply system, often second only to personnel costs. Transportation costs alone may exceed the value of the medicines distributed to some locations, especially in countries with low population densities that cover large geographical areas. Reducing these costs can mean that more money is available for medicine purchases and clinical care. A good distribution system is a *cost-effective* system that provides an acceptable level of service.

Public health authorities are rarely in a position to create a pharmaceutical distribution system from the ground up; rather, the challenge is to evaluate and improve existing systems.

In many public health systems, senior officials do not consider pharmaceutical distribution a high priority; it is too often placed in the hands of poorly trained and inexperienced staff members who are given responsibility but little authority. Under such circumstances, management tends to react to problems and crises rather than take a long-term, strategic view. For example, to save money, a decision may be made to close an apparently costly warehouse, without considering the potential result of increased costs in other areas, such as transportation.

In planning distribution systems to maximize service while minimizing total cost, it is important not to fall into the trap of improving one part of the system to the detriment of the overall system. In the example above, reducing the number of warehouses will decrease operating and inventory costs. However, with fewer warehouses, transport costs for both the central medical stores and hospitals are likely to increase because of the greater distance to travel to either deliver or collect supplies; therefore, the distribution planner will want to ensure that warehouse and inventory savings are not negated by the increase in transport costs. The effect on customer service will also have to be considered. Inventory costs may be reduced, but if customers must wait longer to receive supplies or if availability deteriorates,

broader health system objectives will be undermined. This concept of trade-offs and searching for overall system improvement is important for distribution system planners to understand and apply.

Ideally, a public sector with inefficiencies in its distribution system would perform a wholesale evaluation of the existing structure to find solutions that would be optimal for the entire supply and broader health system. To do this, however, requires that the government deem the distribution function important and make available sufficient financial and expert human resources to conduct the technically demanding strategic reviews. Whereas in some situations existing management will be able to conduct such reviews, in many cases management will have neither the time nor the required expertise to carry them out; therefore, public health authorities may find it more efficient to appoint specialized consultants.

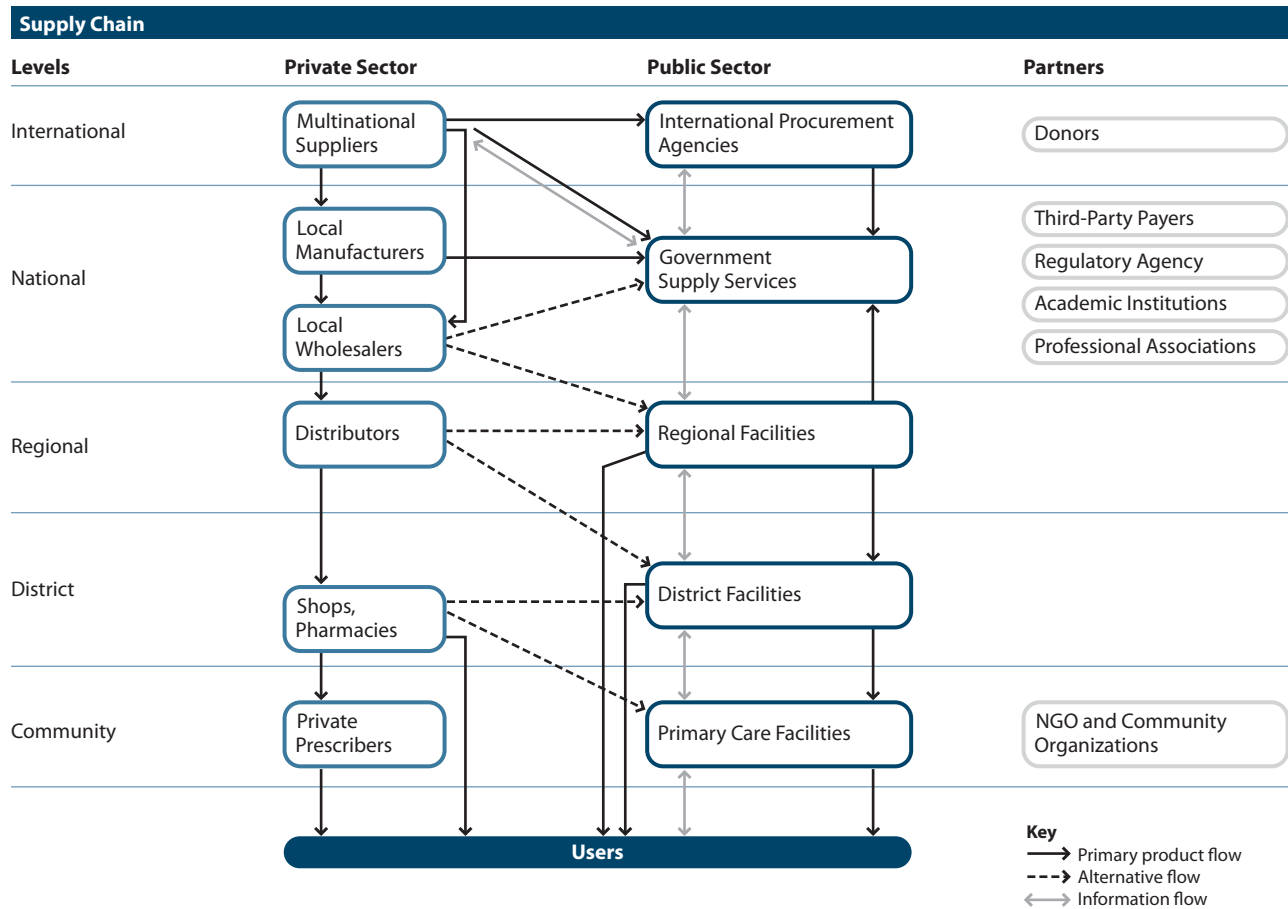

Health programs are frequently managed by well-qualified health personnel who lack logistics experience. *Logistics* is defined here as the “science (and art) of getting the right amounts of the right things to the right places at the right time” (Foster 1990, 207). Warehouse and transport managers, storekeepers, and drivers may possess these skills but may have little influence on decision making. The best way to use their knowledge and skills is to make them part of a logistics team that manages the system design process.

A well-run distribution system should—

- Maintain a constant supply of medicines
- Keep medicines in good condition
- Minimize medicine losses caused by spoilage and expiry
- Rationalize pharmaceutical storage points
- Use available transport as efficiently as possible
- Reduce theft and fraud
- Provide information for forecasting medication needs
- Incorporate a quality assurance program

Senior management should regularly monitor the cost and performance of the distribution system as important indicators of the health care system's operations. Major alterations in the system should be introduced only after careful evaluation and planning, taking into account available human

Figure 22-1 Typical pharmaceutical distribution system

and material resources. A strategic review should begin with evaluating the following factors (which do not, however, comprise an exhaustive list of considerations)—

- Underlying assumptions and strategy of the medical stores organization
- Current and future customer service needs (products, service)
- Basic structure, costs, and performance of logistics system: processes, location and number of warehouses, movement of stock between warehouses
- Product range and sources
- Operating efficiency
 - Space utilization—area, cube, seasonality, pharmaceutical storage requirements
 - Equipment and vehicle use—time, capacity, seasonality
 - Staff performance—throughput per warehouse staff, sales per employee
 - Inventory—stock turn, availability, expiry
 - Order processing—volume of orders, costs, processing time

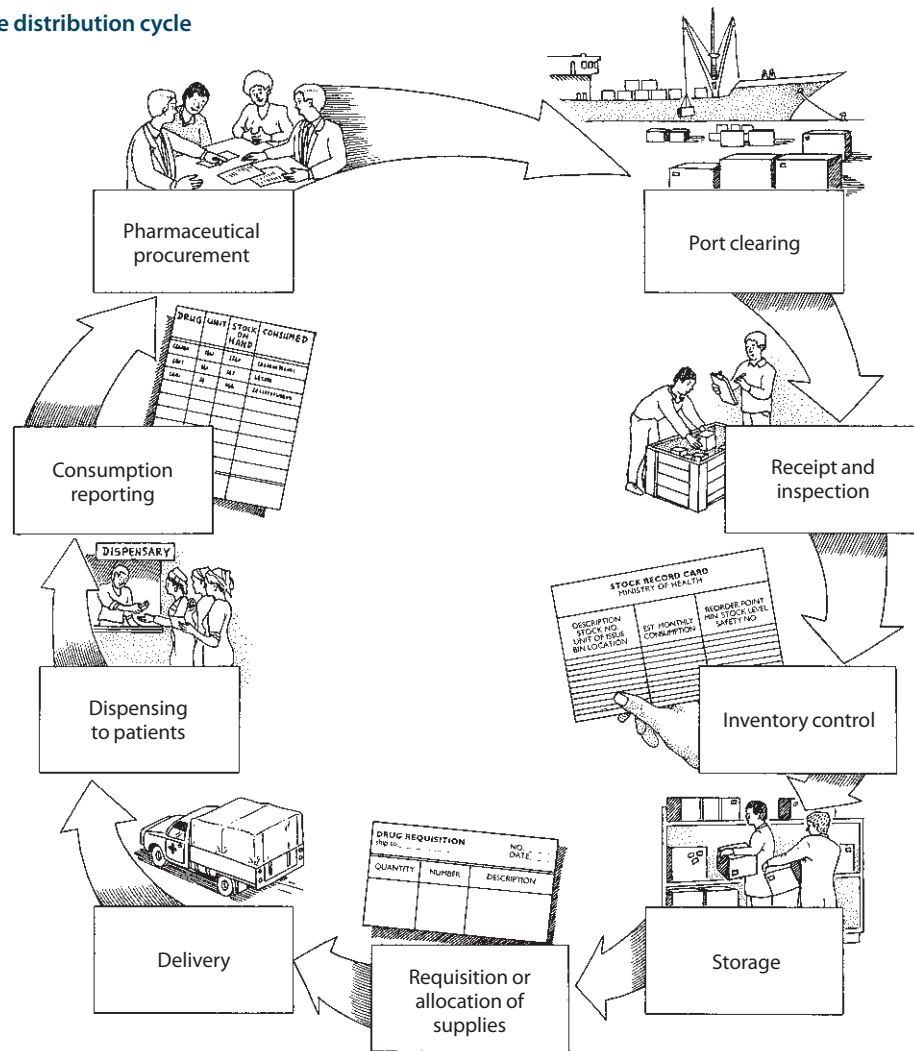

The key to an effective strategic review is exercising rigor in considering all of these areas but not getting mired in precisely analyzing each factor. Appropriate tools to use as part of a strategic review include ABC analysis focusing on order frequency (Chapter 40) and a weighted distribution analysis that identify the most cost-effective distribution strategies using global positioning system (GPS)-based mapping.

Following a review, the alternative options should be evaluated for suitability (main problems are solved, strengths of organization are exploited, option fits with organization and health-sector objectives); feasibility (available funding, skills and operational capacities available, technology available and supportable); and acceptability (preferred solution meets wider expectations and meshes with culture).

22.2 The distribution cycle

The distribution cycle begins when pharmaceuticals are dispatched by the manufacturer or supplier. It ends when medicine consumption information is reported back to the

Figure 22-2 The distribution cycle

procurement unit. Figure 22-1 illustrates a typical public-sector pharmaceutical distribution system and its interactions with the private sector.

The major activities of the distribution cycle are summarized in Figure 22-2. They include—

Pharmaceutical procurement (see Chapters 18–21): The distribution sequence intersects the procurement process at the point at which medicines and commodities are available for delivery to the health facilities.

Port clearing (see Chapter 24): Unless the medicines are acquired locally or the international supplier takes responsibility for port clearing, it is the purchaser's first step in making medicines available for distribution. Port clearing involves identifying shipments as soon as they arrive in port, processing all importation documents, completing any customs requirements, storing medicines properly until they leave the port, surveying the shipment for losses and signs of dam-

age, and collecting the medicines as soon as they have been cleared. Port clearing may be managed directly or through a separate contract with a port-clearing agent.

Receipt and inspection (see Chapter 44): Central stores staff must carry out a complete inspection of every shipment as soon as it is received from the port or local supplier. The shipment must be kept separate from other stock until this inspection has been completed. Inspectors should check for damaged and missing items and for compliance with the contract conditions concerning drug type, quantity, presentation, packaging, labeling, and any special requirements. Prompt and accurate inspection of all shipments is essential to ensure that suppliers fulfill their contracts. Insurance companies will demand an accurate record of any losses incurred before settling a claim.

Inventory control (see Chapters 23, 44, and 46): Establishing and maintaining effective inventory records and procedures are the basis for coordinating the flow of

pharmaceuticals through the distribution system and the primary protection against theft and corruption. The inventory control system is used for requisitioning and issuing medicines, for financial accounting, and for preparing the consumption and stock balance reports necessary for procurement. Record keeping must be sufficiently detailed to provide an “audit trail” that accurately traces the flow of medicines and funds through the system. This audit trail must be designed to satisfy the requirements of government auditors (and sometimes donor agencies) as well as program managers. An appropriate inventory management system should be adapted to suit the capacity and needs of personnel at all levels in the health program. Inventory records must be monitored regularly by supervisors to ensure accuracy and to avoid or detect losses. Careful inventory control is a key to providing a cost-effective and responsive distribution system.

Storage (see [Chapters 42, 44, and 46](#)): Storage facilities may range from large mechanized warehouses at the national level to small wooden boxes sitting in health centers or carried by community health workers. Proper location, construction, organization, and maintenance of storage facilities help maintain medication quality, minimize theft and loss through damage, and maintain regular supply to health facilities.

Requisition of supplies (see [Chapters 23, 44, and 46](#)): Pharmaceutical supply systems may operate under a push or a pull system (see Section 22.3). The forms and procedures for requisition are a key part of the inventory control system. They may vary from country to country and from one level to another within the same country. The requisition system may be manual or computerized or a combination of both, but it should always be designed to simplify distribution by facilitating inventory control, providing an audit trail for tracing the flow of medicines, assisting in financial accounting, and listing medicines issued.

Delivery (see [Chapter 25](#)): Medicines may be delivered by warehouse staff or collected by health facility staff. Transport may involve air, water, railway, or on- and off-road vehicles, porters, or a combination of means. Cost-effective choices between public- and private-sector carriers need to be made. Transport managers should select methods of transportation carefully and schedule deliveries realistically and systematically to provide punctual and economic service. Vehicle breakdowns; availability of fuel, lubricants, and spare parts; seasonal variations in access routes; safety along specific supply lines; the availability of private-sector services; and other local factors must all be considered in transport planning.

Dispensing to patients (see [Chapter 30](#)): The distribution process achieves its purpose when medicines reach hos-

pital wards, outpatient clinics, health centers, or community health workers and are appropriately prescribed and dispensed to patients.

Consumption reporting (see [Chapters 20 and 23](#)): The closing link in the distribution cycle is the flow of information on consumption (which takes into account actual demand—that is, what would have been consumed if not stocked out) and stock balances back through the distribution system, to the procurement office, for use in quantifying procurement needs. When adequate inventory and requisition records are kept, compiling consumption reports is straightforward.

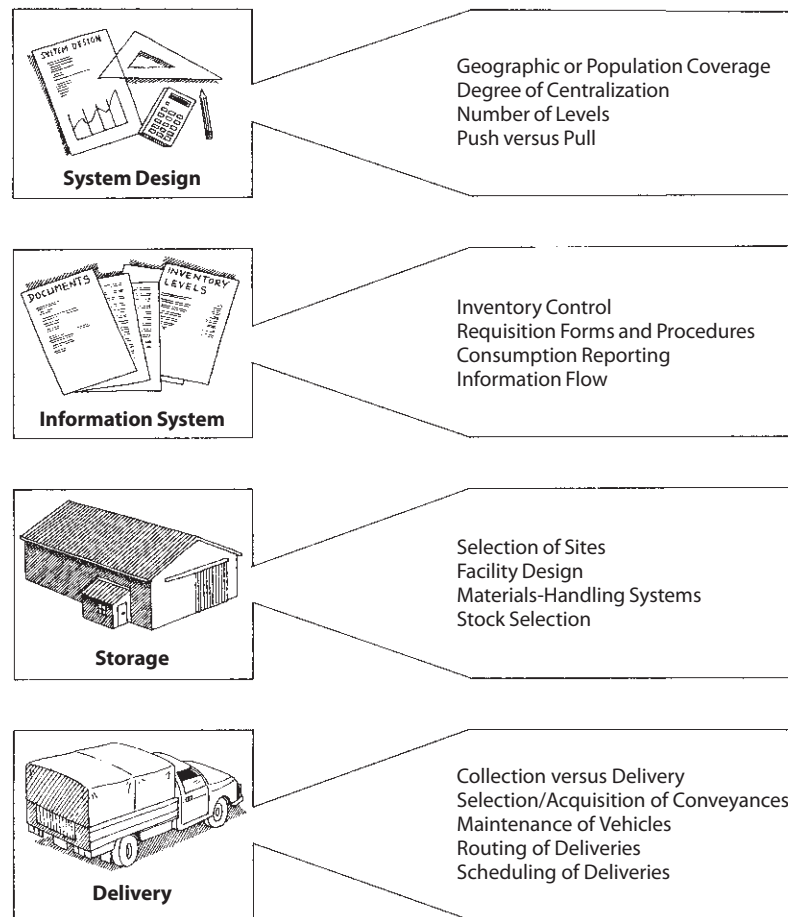

22.3 Distribution system design

Designing a new distribution system or, as is more likely in practice, evaluating and planning improvements to an existing system, requires systematic cost-effectiveness analysis and operational planning. Some guiding principles include—

- Managing and evaluating distribution and logistics as an integrated activity (for example, receipt, storage, distribution, and customer service operating together as a single system rather than as self-contained micro-systems unconnected to one another)
- Ensuring distribution system operations are linked to the overall objectives of the medical stores and the broader public health system
- Ensuring customer service needs are understood and accommodated
- Balancing the trade-offs between costs and service (for example, although every hospital might like to have a medical store on its premises, the increases in inventory-holding and operating costs are unlikely to make such an option cost-effective)
- Keeping stock moving
- Minimizing lead times, inventory, and costs
- Analyzing ways to improve effectiveness (for example, reduce number of warehouses, contract out transport, invest in new information systems) as well as efficiency (for example, ensure full transport loads, minimize inventory, mechanize materials handling, automate order processing)
- Minimizing the steps in storage and handling, which decreases the opportunity for damage and loss

When the system is in place, regular performance monitoring is needed to ensure that the system functions as intended. The major design characteristics for a distribution network (see [Figure 22-3](#)) are considered in detail in subsequent chapters and are mentioned only briefly here.

Figure 22-3 Design characteristics of distribution networks

Basic design features

The basic characteristics of a distribution system include its degree of centralization, the number of levels in the system, and the geographic or population coverage. [Country Study 22-1](#) highlights the challenges of supplying tuberculosis (TB) medicines in the sparsely populated, mountainous country of Nepal. Comparable problems are faced by small island states, such as those in the Pacific, and geographically large countries with small, partially nomadic populations, such as Mongolia.

In a typical central supply model, pharmaceutical procurement and distribution are coordinated at the national level. Medicines received at the central medical stores (CMS) are distributed to lower-level warehouses and onward to the health facilities. In a decentralized system, the districts or regions are responsible for receiving, storing, and distributing medicines according to their needs; in some cases, they may also be responsible for procurement. [Chapter 8](#) discusses various options for providing medicines to the public sector, some of which require in-house storage and some of

which eliminate part or all of public-sector supply system warehousing.

In designing a distribution system or redesigning an existing system, the following important steps have to be taken—

1. Determine the number of storage levels in the system
2. Determine the location of storage sites
3. Decide at which level of the supply system decisions will be made concerning orders
4. Fix resupply intervals or frequency of placing orders
5. Select a collection or delivery method for distributing medicines to user units
6. Select an appropriate mode of transport
7. Determine the amount of inventory to be held at each level in the system
8. Develop a set of feasible and economical delivery routes and work out a practical delivery schedule and appropriate modes of transport to service these routes; determine whether it is more efficient to keep and maintain vehicles or contract out the delivery service

Country Study 22-1 TB medicine distribution challenges in mountainous terrain

In the mountain kingdom of Nepal, the government is succeeding in treating TB and preventing thousands of deaths a year. Starting with four pilot projects in 1996, the DOTS program has been extended to reach all institutions (including primary health care centers, health posts, and 99 percent of sub-health posts), and treatment success rates more than doubled during the program expansion. But success has not been easy. Much of Nepal is remote mountainous and hilly terrain, and many areas are sparsely populated, making pharmaceutical distribution extremely difficult. Medicines are distributed from the central level to regional stores and then supplied to the district, usually by vehicle or plane. From there, the medicines have to be carried by bicycle or on foot to some remote treatment centers. In some areas, additional lower-level health posts are used to provide DOTS to maximize population coverage. Patients can be treated there and only have to go to a larger, more distant health center for occasional monitoring.

Sources: WHO n.d.; SEARO 2010.

9. Estimate the operating costs and assess the cost-effectiveness of contracting for storage and transport at one or more levels
10. Establish a warehouse management system based on a set of standard operating procedures

Distribution network

A public pharmaceutical distribution system may require several layers of stores, each with distinct functions.

In a typical three-level distribution system, purchases from a supplier are received by one or more *primary stores*, which generally serve a whole country or region and may or may not supply health facilities directly. The physical size of the primary stores is determined by national or regional demand for medicines and by the supply frequency. In some countries, this level has been eliminated, with direct delivery from suppliers to intermediate stores.

Medicines are distributed from the primary to the *intermediate stores*. Their size is determined by the demand of the area health facilities and the frequency of supply by the primary stores. Intermediate stores may be independent but are often on the site of a regional or district hospital. Intermediate stores distribute medicines to individual *health facility stores*. This would be a four-level system.

Sometimes two layers of intermediate stores are needed, with first-level intermediate stores supplying second-level intermediate stores. For example, a regional store might supply district stores. Determining the optimum number of levels should be done individually according to program needs and resource constraints, weighing benefits against cost considerations. Some countries eliminate both intermediate levels of store in favor of direct delivery to facilities from suppliers or a primary distributor (see [Chapter 8](#)). Having fewer warehouses can decrease the opportunity for losses, and enhances control. Additional factors to consider in determining the number of storage levels are—

- Geography
- Population
- Availability of storage space
- Staff
- Availability and cost of transport
- Political and other resource constraints

[Table 22-1](#) compares the three- and four-level systems in terms of management complexity, setup costs, operating costs, inventory costs, and applicability according to location and density of clinical facilities. Three-level systems are easier to manage and may be less expensive to set up and operate. However, when clinical facilities are widely dispersed and travel times are long, the four-level system may provide better service and may even prove less expensive to operate when all costs are considered.

[Figure 22-4](#) gives examples of four different distribution networks and shows how the quantity and, therefore, the value of stock held in the system tend to increase as more levels are added. Note that the relationships between costs and number of levels are not always as direct as shown in the figure; efficient inventory management in a CMS system might result in lower total inventory costs than would be found in a regional stores network with less efficient inventory management.

No foolproof method exists for establishing the optimal number of levels and facilities in the distribution system, but the following steps may provide a useful way of arriving at the best hierarchy for an individual country or program—

1. Diagram the existing distribution hierarchy (include all clinical and storage facilities and the supply lines connecting them).
2. Diagram three or four feasible alternative hierarchies (include patterns based on different linkages between existing facilities as well as patterns that require additional facilities).
3. For each of these alternatives, estimate as accurately as possible the values for the factors listed in [Table 22-1](#) (management complexity, setup costs, operating costs, inventory-holding costs, delivery times, and so forth).

Table 22-1 Comparison of three-level and four-level distribution hierarchies

Factors	Three-level	Four-level	Comments
Management complexity	Less complex	More complex	Four-level systems are more likely to have problems with transport, communications, and performance monitoring.
Setup costs <ul style="list-style-type: none"> • Buildings • Equipment • Vehicles 	Lower	Higher	In regions where clinical facilities are relatively numerous or widely dispersed, the costs of a four-level system may be justified.
Operating costs <ul style="list-style-type: none"> • Personnel • Utilities • Fuel • Expendable supplies 	Lower	Higher	The same observation as above.
Inventory-holding costs	Lower	Higher	If a four-level system results in more dependable delivery, lower safety stock is needed, and inventory-holding costs are not as high as expected.
Distribution of clinical facilities	Preferable with denser distribution	Often useful with sparser distribution	Distance can be measured in kilometers (miles), time, or transportation costs. Thus, an area that is small in square kilometers but is burdened with long travel times may benefit from a four-level system.
Quality of service <ul style="list-style-type: none"> • Number of stockouts • Ratio of interim and emergency to regular deliveries 	Variable, depending on the location of storage and clinical facilities and the reliability of transportation between facilities		Inventory control and delivery are harder to manage in extended systems, but with good management, such systems are more responsive to the needs of remote facilities.

Total cost analysis is a good way to model these costs (see [Chapter 40](#)).

4. Diagram the current and proposed information flows.
5. Select and implement the system that provides the best quality service with available funds.

This systematic approach may identify previously unrecognized possibilities for improving distribution. Furthermore, the information generated can be used to substantiate requests to senior officials or external aid sources for additional funds, to implement a more costly, but more effective, plan.

Push and pull systems

Distribution schemes can be defined by which levels of the system order medicines and which, if any, passively receive medicines distributed from higher levels. The two basic alternatives are—

1. *Pull system*: Each level of the system determines what types and quantities of medicines are needed and places orders with the supply source (which may be a warehouse in the system or a commercial supplier). This type of system is sometimes called an independent demand or a requisition system.
2. *Push system*: Supply sources at some level in the system determine what types and quantities of medicines will be delivered to lower levels. A delivery plan is made at

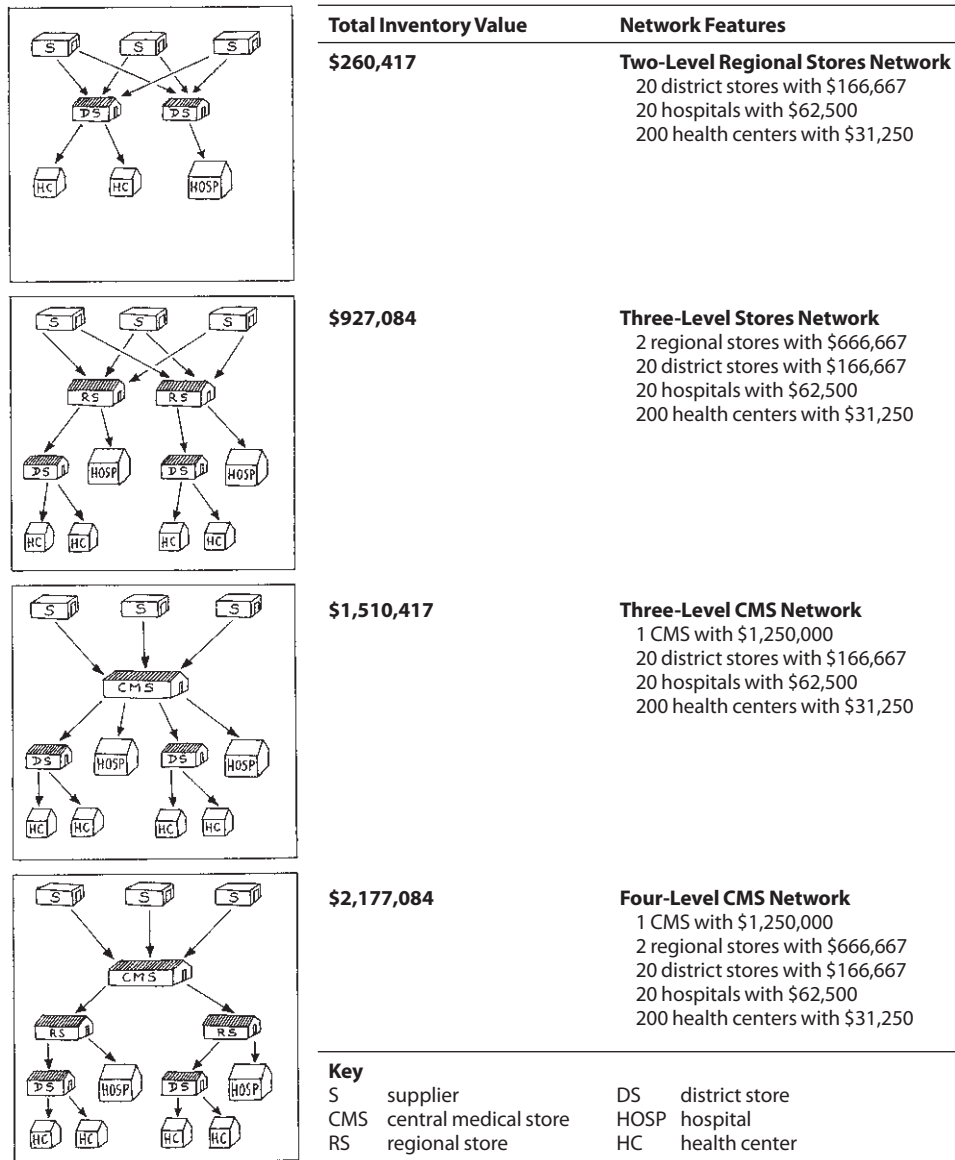

the beginning of a planning period, usually a year, and supplies are delivered according to the plan. This type of system is also known as an allocation or a ration system—the best-known example in pharmaceutical supply is the ration kit system (see [Chapter 26](#)).

When using a pull system, managers of operational units are expected to work out their own demand estimates and buffer stocks and submit requisitions to central stores indicating their requirements. In a push system, operational units are expected to supply certain stock and consumption information to the supply source so that issuing officers can plan allocations.

As discussed in [Chapter 26](#), pull systems are preferred whenever the capacity exists to manage them effectively. However, a push system can be useful in certain situations, such as for disaster relief and when the supply pipeline does not function at all levels of the system. Some countries use a mix of push and pull, with primary health medicines being supplied routinely in a kit, while district and regional hospitals determine their own needs. Making the transition from a push to a pull system may be the ideal, but it is not an easy undertaking and can involve complex and demanding changes in inventory management, warehouse operations, and distribution. [Country Study 22-2](#) shows the challenges Tanzania is facing as it moves from supplying essential medicines kits to a direct requisition system.

Conditions that tend to favor push and pull distribution systems are presented below.

Figure 22-4 Comparison of four distribution networks

Conditions favoring a pull system. Conditions favorable to a pull system of inventory management include—

- Lower-level staff members are competent in assessing needs and managing inventory.
- Sufficient supplies are available at supply sources to meet all program needs.
- A large range of products is being handled.
- Field staff members are regularly supervised, and performance is monitored.
- Good data are available to decision makers.

Conditions favoring a push system. Conditions favorable to a push system of inventory management include—

- Lower-level staff members are not competent in inventory control.
- Demand greatly exceeds supply, making rationing necessary.
- A limited number of products is being handled.
- Disaster relief is needed, or the situation calls for short-term supply through prepacked kits (see Chapter 26).

Resupply interval

The resupply interval determines whether deliveries are made to user units quarterly, monthly, weekly, or at any other time. If deliveries are made weekly, average stock levels will

Country Study 22-2

Transition from primary health kits to a direct requisition system in Tanzania

The Tanzanian Ministry of Health (MOH) is instituting a policy of replacing essential medicine kits with an indent (direct requisition) system in order to tailor medicine orders to fit the needs of each particular health facility and to reduce waste. The MOH introduced a pilot project in the Morogoro region in 1999, where health facilities placed their orders with the medical stores department (MSD) through the District Medical Officer. The pilot has since been rolled out to five of the country's twenty regions.

The scaling up of the indent system is placing MSD operations under some strain, contributing to a slower

rollout than planned. Inventory management, warehousing, and picking and packing operations all need to be re-engineered. The primary health care kits comprise four prepacked stock items that require only simple block stacking in the warehouse. Replacing the kits with the indent system means that instead of distributing more than 3,000 prepacked kits every month, MSD has to pick, pack, and deliver items according to customized orders, which is having a significant impact on the size and nature of MSD's inventory, storage, and distribution operations.

Source: SEAM 2003.

be low and the likelihood of stockouts will decrease, but transport costs will be very high. If deliveries are made only once a year, transport costs will be low, but the average stocks and storage costs will be high. See [Chapter 23](#) for discussion of the relationship between delivery frequency and stock levels (and associated costs). (See [Country Study 22-3](#) on how an imprest system of resupply is being used in Ghana.)

The optimum resupply interval should be worked out to suit individual program needs. Most public programs use intervals of one to three months. The following are helpful factors to consider before making a decision—

- Storage capacity at each level of the system
- Availability, order size, carrying capacity, and cost of transport
- Seasonal factors that influence transport reliability
- Staffing levels and competence of staff at each level of the system
- Other factors, such as expiration dates, security against pilferage, cash flow, and other locally relevant concerns

Storage

Geographic distribution of population and health facilities determines where medicines are needed. Storage planning starts with an analysis of existing and future supply requirements to establish the type and quantity of medicines required by each facility and the overall volume to be handled by the distribution system. Suitable locations and sizes for the central and intermediate stores can then be determined. Store locations should be chosen to make the most cost-effective use of existing public and private transport networks. [Chapter 42](#) covers planning for storage facilities in detail.

Buildings can be renovated, purchased, rented, or built. The design of large storage buildings should take into account the storage conditions required for different products and the need to move large volumes of material efficiently. Stores at health facilities may consist of a simple storeroom with shelving. However simple the store, storage facilities should always protect against theft and damage by water, pests, or fire.

Another type of facility that can play a role in the distribution system is the regional cross-docking center (or stockless distribution center). As can be inferred, the centers do not hold or manage stock. They can serve primarily as data warehouses to collect, assure the quality of, and report on inventory and order information. They also receive picked and packed orders for each health facility in the region from the central supply and deliver the orders within the prescribed time frame.

Well-sited stores are vital to the success of a distribution system. However, no such thing as a perfect site exists. Needs often conflict: a location may be close to a good road but too far from the health centers it must serve. It is the responsibility of the logistics team to balance these needs. The following steps will facilitate the decision-making process.

Map the demand for medicines. Map the geographical distribution of medicines demand. Where are the hospitals, clinics, and aid posts? Which ones serve the most people? Estimate the volume and weight of each facility's annual pharmaceutical requirements using morbidity data, medicine requisitions, and delivery records. Plan for expansion. Where are new or expanded health facilities likely to be located? Are new public health programs going to be scaled up? Are any recommended treatments changing? How will these changes affect the geographical relationship between existing facilities and storage sites?

Country Study 22-3**Improving pharmaceutical management using an imprest system in a clinic in Ghana**

The adoption of a top-up system of pharmaceutical supply has improved the pharmaceutical supply management at the Bank of Ghana Clinic, a parastatal outpatient health facility in Accra. A top-up system is a type of imprest system where running stock is replenished with quantities equal to those used. With the top-up system, the total responsibility for supply is given to the supplier, in this case, the clinic's pharmacy unit.

The maximum (imprest) level of stocks is agreed upon with the department in charge. The content of the list of stocks to be held is based on the regularly used medicines, and the final list is agreed on by the user and the pharmacy. The stock level of each medicine is based on the known average use of the medicine and the interval between stock replacements. In the Bank of Ghana Clinic, an initial survey determined the actual weekly consumption pattern of injectable medicines, with a 10 percent safety margin added. This information was the

basis of the maximum weekly stock levels (imprest levels). New supply forms were designed to provide data on quantity used, top-up quantity, and expiry dates. At the beginning of the week, the nursing staff fills in the current stock levels and sends the forms to the pharmacy, where the technician notes how much of each medicine is needed to make the stock up to the imprest level. The pharmacy staff then delivers the items to the department.

In this system, there is no need for the department staff to order; the stock is automatically renewed by the pharmacy. After the clinic instituted this new supply system, their trend toward overstocking was reversed, and there was a significant reduction in inventory value, and therefore, expenditure. The success of the clinic's initial trial with injectables was expanded to other medications and commodities. A successful system depends on good communication and trust between user and supplier.

Source: Marfo 1998.

Locate supply entry points. Most countries have a limited number of entry points capable of handling pharmaceutical imports. These include major seaports and international airports, railway terminals, and cross-border customs posts. The logistics team should decide which points are the most appropriately located and best equipped for handling pharmaceutical shipments. Some countries have several suitable entry points for medicines, and it may be efficient for pharmaceuticals to be delivered through more than one port to more than one primary store. Multiple primary storage points may be justified in large countries or where physical barriers exist, such as mountain ranges or wide rivers without bridges.

Another option to consider is a regional distribution center, which uses regional warehouses as a consolidation point to regulate the flow of pharmaceuticals into a country's central supply. Using a regional distribution center reduces the risk of holding large amounts of stock, such as expiry, damage, or theft (SCMS 2010).

Select primary storage points. Review the location of the existing primary stores and consider whether they are well placed for current and future needs. The most suitable location for a primary store depends on geographic, demographic, and communications factors. A good choice is a point on the national transport network centered in the region with the highest population density. Using this location will help reduce overall transport costs. It is not essential for the primary store to be located in or near a major city. A city location may be administratively convenient but logistically inefficient.

The location of in-country pharmaceutical manufacturers and suppliers may affect the location of stores. Medicines received from those sources are generally delivered directly to primary or intermediate stores, and the transport portion of the pharmaceutical prices can be reduced if stores are located near a large concentration of local suppliers.

Plan primary distribution routes and locate intermediate stores. Good transport routes between the primary and intermediate stores (including any second-level intermediate stores) are crucial. These routes handle the largest quantities of medicines and must be reliable. Intermediate stores should therefore be located on good, all-weather roads or close to railway stations or navigable waterways.

Depending on the volume of pharmaceuticals to be delivered, a supply route that serves two or more intermediate stores on a circuit is usually cheaper than a route that serves only one. However, lengthy primary delivery circuits should be avoided where roads are bad, where overnight security is a problem, or where quality of medicines may be at risk through long exposure to unacceptable temperatures (see [Chapter 25](#)).

Plan secondary distribution routes. Secondary distribution routes link intermediate stores to health facilities. The planning of these routes requires detailed knowledge of rural road conditions, travel times, and available transport. Local input is essential. Medicines can be delivered from the intermediate store, collected from the intermediate store, or collected from a convenient health facility on a delivery circuit. The most practical solution for each health facility will vary.

Figure 22-5 Stock volume in store design

Size the stores. The previous steps establish which of the existing primary and intermediate stores are suitably located (or cannot be relocated) and where new stores are required. The volume of medicines to be held in each store can be estimated as described in [Chapter 42](#). The maximum volume to be held depends on supply frequency: programs that receive single annual medicine deliveries require larger primary stores than those supplied more frequently. Estimates for maximum stock levels must also take into account the safety stock volume. However, deliveries do not always arrive exactly on time, and consumption is not entirely predictable (as shown in [Figure 22-5](#)). Available storage capacity should always be greater than the calculated maximum stock holding to allow for emergencies and for program expansion.

The capacity of each existing store should be assessed. If the existing storage capacity is insufficient, five possible solutions are available—

1. Reorganize the store by changing the shelving, changing the layout, or introducing pallet racking (see [Chapters 42 and 44](#)).
2. Build or rent additional warehouse space. This option involves capital costs for warehouse construction or recurrent costs for warehouse rental.
3. Increase the supply frequency to eliminate the need for additional storage space, probably at some increase in administrative costs. Suppliers may also charge extra for more frequent delivery. If the supply interval is already short, decreasing it may not be practical.
4. Upgrade one or more underused lower-level stores to higher-level status.
5. If insufficient space at the primary level is the problem,

consider holding larger stocks at the intermediate level, assuming the capacity exists. A system based on regular transfer of stock between stores at the same level should be avoided in most cases, because it is difficult to record such movements. However, some supply systems can manage redistribution, depending on the qualifications and motivation of the personnel involved.

Delivery systems versus collection systems

Basically, supplies are moved between the warehouse and the receiving facility in two ways: collection or delivery. In the case of a collection system, the receiving facility takes on the responsibility of collecting supplies from the warehouse. In a delivery system, the warehouse is responsible for delivering supplies by either in-house transport or a private-sector contract, or a combination of both. In planning a public health distribution system, considering all transport costs incurred in getting supplies to health facilities is important—not only the costs incurred by the medical store, but also those of each hospital and health facility that sends staff to collect supplies from a medical store depot or is responsible for distribution to lower levels. Although modifying medical stores' distribution systems might reduce costs, the financial impact on hospitals or local health authorities should also be considered before making final decisions.

Each method has advantages and disadvantages; the choice should be based on individual program needs and constraints. General advantages and disadvantages associated with collection and delivery are shown in [Table 22-2](#).

Transport

Transport is frequently the least reliable link in the distribution system and is often a source of great frustration. Transport planning requires the selection of appropriate means of transport and the procurement and maintenance of vehicles or other conveyances. Issues to be considered include—

- Using private-sector alternatives
- Evaluating fleet capacity
- Planning transport system improvements
- Acquiring and disposing of vehicles
- Managing vehicle use
- Maintaining vehicles
- Maintaining medicine quality during transport

Transport managers should make the best use of available transport through careful route planning and delivery scheduling, and should carefully consider private-sector alternatives; these issues are addressed in [Chapter 25](#).

Table 22-2 Comparison of delivery and collection systems

System	Advantages	Disadvantages
Delivery	<ul style="list-style-type: none"> • If proper delivery routes, order intervals, and delivery schedules are in place, the total cost of transport will be less. • Deliveries of supplies can be combined with other important scheduled and compulsory visits to the field. Also offers an opportunity to supervise fieldwork. • Medicine selection, assembly, and packing operations can be scheduled and accomplished efficiently. • Security and control can be enhanced by a well-managed, well-maintained transport fleet. 	<ul style="list-style-type: none"> • Needs reliable transport facilities. Outright purchase or leasing of vehicles gives rise to high capital and operating costs. • If the delivery route is long, there is the possibility of breakage and loss of quality. • Security lapses may occur because of a lack of a responsible officer accompanying goods in many instances. • Health facilities may be closed when the delivery truck arrives, or a responsible officer may not be on hand to receive supplies. • The delivery truck may be in a hurry to get to the next destination, making it difficult to check for short shipments, damage, and other problems before the truck departs. • Not always possible to make economic use of larger vehicles if delivering to individual hospitals and health facilities.
Collection	<ul style="list-style-type: none"> • Provides an opportunity for issuing personnel to meet people from the field and discuss common problems, and for field officers to meet and exchange ideas among themselves. • Frees central-level staff from providing transport facilities to the field. • Provides greater incentive to obtain supplies regularly, since the facility is responsible for collecting supplies. • Allows field personnel to attend to other business in town. • Offers the possibility of a greater choice of methods of transport. • Allows for better checking, handling, and security of goods received. 	<ul style="list-style-type: none"> • Takes up a lot of health facility staff time. • Time may be wasted waiting for assembly of supplies, or supplies might not be ready for collection on the first visit. • Total cost of transport may be high. • Health center personnel may tend to increase the frequency of visits for various reasons. • Health staff might become frustrated with the supply system if they find stockout situations at the end of a long trip to the sales depot.

Delivery schedules

Good planning is needed to ensure that each facility receives supplies regularly and on time. For example, an intermediate store may be responsible for forty clinical facilities with a delivery interval of one month. The total time required to supply all these facilities using available resources must not exceed one month. If analysis shows that a longer period is required to supply all facilities, then the delivery schedule must be changed or additional transport resources acquired. Figure 22-6 illustrates this concept.

When determining the appropriate delivery intervals for each store and health facility, consider the following factors.

Storage capacity of primary, intermediate, and health facility stores. Deliveries must never exceed the holding capacity of any store. This situation is more likely to occur with irregular or infrequent deliveries. Analysis of product throughput and delivery frequency can address this issue.

Increased transport costs per unit supplied for deliveries to small, remote facilities. An obvious solution is to supply these areas infrequently. The disadvantage is that this policy increases maximum stock levels at these facilities and

may also increase the risk of stockouts in places where environmental conditions make storage for extended periods difficult or expensive.

Efficient vehicle usage. If delivery intervals are too frequent, vehicles may travel half empty. If delivery intervals are long, large vehicles will be needed. Vehicles owned by the health service may stand idle for much of the time.

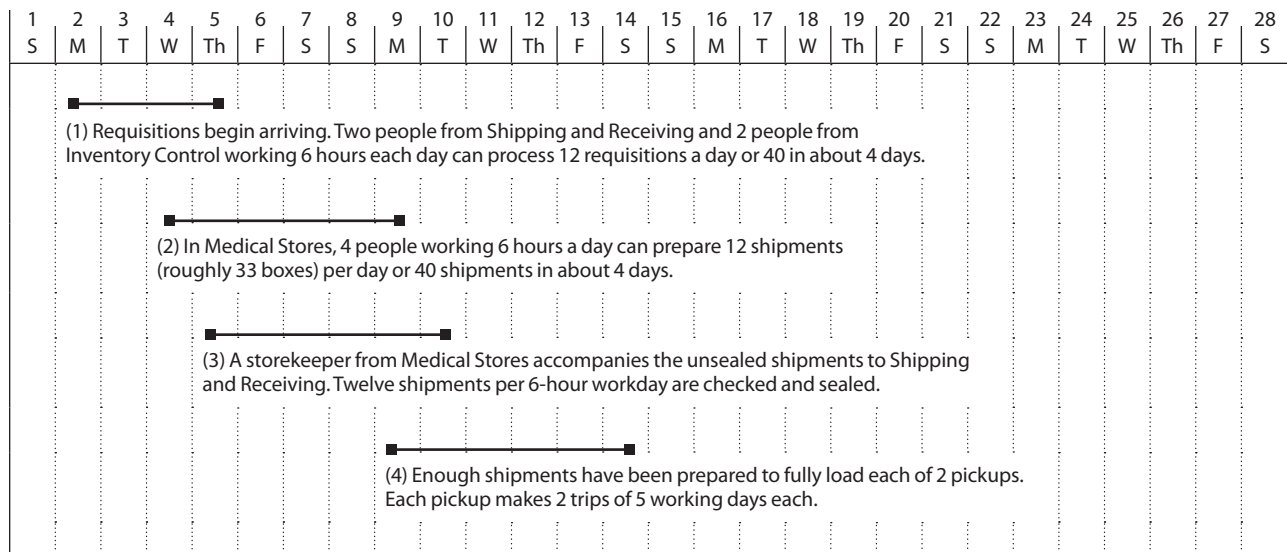

Climatic factors. Delivering to some facilities at certain times of the year may be impossible. Delivery frequency and volume must be scheduled to work around interruptions caused by rainy seasons or other recurring climatic constraints.

22.4 Resources for distribution management

Logistics managers

Under the traditional CMS supply paradigm, transport and warehouse managers and other officers with responsibility for logistics often had low professional status, and their skills and experience were frequently undervalued, if not

Figure 22-6 Planning for monthly requisitions and deliveries

ignored. However, as the importance of pharmaceutical supply management to health programs has become more apparent, many countries are undertaking serious reforms (for example, shifting toward more autonomous, commercially oriented systems) and are recognizing the need for experienced professionals. Therefore, logistics systems are now more often being run by well-trained, experienced professionals than previously.

Experienced professionals should be responsible for the operational planning, implementation, and monitoring of the tasks described in this chapter. In large countries, regional cadres may be more appropriate than a single group of national experts. Logistics managers must stress the importance of improving medicine availability and reducing distribution costs wherever possible. Major decision making may benefit from specialized providers of technical assistance.

To ensure efficient and effective management and planning, the logistics managers or planning team must be vested with sufficient status to resist political pressures; for example, to resist building a store in an area where one is not justified on operational grounds.

Staffing levels

The logistics managers must determine the staffing levels required to administer and operate the pharmaceutical distribution system effectively. Are sufficient staff members available? Are they appropriately trained? Are funds available to recruit and train additional personnel if necessary? The most well-designed distribution system will not work unless there are enough suitably qualified staff members to run it.

Information systems

Reliable management information is vital for coordinating the distribution network. Medicine consumption information flows up and down the network. The information system consists of forms and procedures to record inventory levels, cost and sale prices, and receipt and issue of medicines. The system may be manual, computerized, or both.

It is easy to visualize the one-way flow of medicines through the supply pipeline from CMS to regional or district stores and, finally, to hospitals, health centers, and community health workers. It is more difficult to understand and manage the complementary flow of forms and reports needed to coordinate pharmaceutical distribution.

Forms, records, and reports form the core of the supply information system. Forms are documents that move from one unit to another, carrying specific information about pharmaceutical needs, movements of medicines, and associated financial transactions. Copies of forms filed at various points in the distribution network comprise the audit trail to trace the flow of medicines and funds. Records may be maintained in computer databases, as card files, in ledgers, or in folders. Reports should be prepared regularly to summarize medicine consumption and expenditures. Individual health facilities report to district offices, which report to regional offices, which report to the central office. Such reports are used to project medicine needs, monitor trends in use, revise budgets, and assess medicine use.

The forms shown in [Chapters 44](#) and [46](#) can be adapted by any supply system to suit its requirements. Some forms may be usable as is, some forms may need modification, and additional forms may be required to suit special information needs.

When a new pharmaceutical supply program is initiated or an existing one is adapted, a complete information system should be established as part of the basic planning process (see [Chapter 49](#)). All necessary forms should be available, and all staff members should be trained in the use of these forms before pharmaceuticals start moving through the system. Without this type of preparation, the process of recording medicine consumption and forecasting medicine needs quickly breaks down.

Communications

Good communications are essential to a pharmaceutical distribution system. Where reliable telecommunications networks and postal services do not exist, especially in rural areas, staff often must travel long distances to deliver or collect reports and requisitions. These journeys should be combined with supervisory activities if possible.

Good telecommunications reduce the need for travel, save staff time, increase security, and reduce wear and tear on vehicles. Maximum use should be made of the telecommunications resources available, and appropriate investments in communications technology should be made. Providing a facility with a radio transmitter or a fax machine may help avoid unnecessary travel costs. Increasingly, the Internet may be used for electronic communications, saving resources and improving information delivery times. Other technologies include VSAT (very small aperture terminal) satellite systems and mobile phone technology, which provides a cost-effective communication mechanism, even in remote areas. Mobile phones are being used in many places to report inventory data from the field.

Products with a high market value are at greater risk from diversion and theft than those with a lower market value. Antiretroviral products and artemisinin-based combination therapies, for example, may be at heightened risk; therefore, distribution security will be of increased concern. To track vehicles, onboard computers in delivery vehicles can communicate with a central location (such as the CMS) via GPS, global system for mobile communications (GSM), and short message service (SMS) without any input from the driver. Other wireless communications options to communicate with drivers, such as high-frequency radio and cellular telephones, are becoming more commonly used as a means of managing distribution and protecting pharmaceutical supply systems. [Chapters 25](#) and [43](#), focusing on transport and security, respectively, cover these issues in more detail.

22.5 Cost analysis and performance monitoring

When designing or revising a distribution system, compiling and analyzing data on current operating costs are crucial,

especially for modeling the potential cost impact of various alternatives. Total cost analysis, described in [Chapter 40](#), is one method for analyzing costs and modeling alternatives in a supply system. This section gives an overview of the variable costs that apply to the distribution component of supply systems.

Cost analysis is not usually a continuous activity and should not be confused with performance monitoring (see [Chapter 48](#)), which should be carried out regularly using appropriate indicators to ensure that system performance is maintained.

Calculating costs

The first tasks in an evaluation of options are to calculate the *in-house costs* of the distribution system and then to estimate the costs of other alternatives for comparison. In-house costs include storage space, stores operation, equipment, staffing, holding and transport, administration and management, upgrading, and costs of contracting out (see [Chapter 41](#)).

Storage space includes the annual cost of rent paid to private warehouse owners and the annual amortized cost of warehouses owned by the health care service.

Operation costs include local building taxes and utility costs (electricity, gas, water, and insurance).

Equipment costs are annual amortized costs for equipment such as forklifts, for security equipment such as fire alarms and fire extinguishers, for specialized equipment such as cold rooms, for computer equipment used in stock control, and for other similar items. Costs should be amortized for items that are expected to have a useful life of more than one year.

Distribution staff costs include overhead and wages paid to storekeepers, drivers, mechanics, and laborers.

Holding stock (carrying cost) is the real cost associated with maintaining stock in inventory, as discussed in [Chapter 23](#). Sufficient inventory must be kept to protect against stock-outs and to take full advantage of bulk purchasing agreements. Holding too much stock increases storage costs and locks up funds; a good distribution system balances these two factors.

Transport includes all distribution charges not covered by the supplier's contract, which may end at the factory gate, at the dockside, or at the client's own warehouse (see [Chapter 25](#)). Transport costs may include—

- Air freight or shipping
- Insurance
- Demurrage
- Port clearing
- Transferring goods between forms of transport
- Distributing pharmaceuticals within the country
- Packing and unpacking

If government vehicles are used for medicines distribution, the costs include fuel, vehicle repair and maintenance, salaries and daily expenses for drivers, and vehicle amortization. Where financial management and accounting systems are not strong or are integrated into the general ministry of health accounting system, estimating the costs related to the in-house service may be difficult. When parastatal or private haulers are used, fixed and variable transport costs are more transparent.

In most cases, some costs (such as insurance and port-clearing fees) are outside the control of the pharmaceutical program. However, freight charges depend on the volume, value, and/or weight of the supplies ordered, as well as the fees charged by the shipping agent. Shipping costs are important considerations when evaluating pharmaceutical tenders. It is easiest to compare costs from competing suppliers when prices are CIF (cost, insurance, and freight) or CIP (carriage and insurance paid) (see [Chapter 39](#)).

Administrative overhead comprises all administrative costs incurred by, or allocated to, the distribution system.

Losses caused by poor management include the following direct costs—

- Damage from incorrect storage or transport conditions
- Theft of stock
- Misdirection of stock
- Unnecessary supplies in stock
- Supplies that expire before they can be used

Costs are also attributable to stock shortages. Extra costs are usually incurred when emergency purchases are made. When medicines are not available, it may be necessary to keep patients in the hospital for a longer period, thereby increasing nursing costs and making beds unavailable for other patients. When patients cannot be treated properly, they may infect others. These indirect losses are difficult to calculate, but they may be estimated using techniques of cost-effectiveness analysis (see [Chapter 10](#)).

Upgrading may require additional expenditures to bring an in-house distribution system to an acceptable level of efficiency. These costs must be compiled and included with other in-house costs for comparison with alternatives.

Contracting out incurs costs for private storage and distribution that should be estimated so that a comparison can be made with existing expenditures. These costs can be estimated by assessing private-sector capacity (see [Chapter 36](#)) and conducting a nonbinding tender to determine the costs of private-sector services (see [Chapter 39](#)).

Collecting and analyzing cost and performance data

In order to calculate costs accurately, collecting data from in-house accounting and reporting systems and from other

sources is necessary. Data should be collected from natural cost centers; for example, if the system is organized on a regional basis, analysis of the costs by region will indicate how each region is performing.

Skilled staff or consultants are needed to design and carry out cost surveys, analyze data from survey questionnaires, and make useful inferences from imperfect data sets. The most informative survey collects field-based information from stock and vehicle maintenance records and from discussions with local staff. [Chapter 36](#) discusses the management of an ad hoc assessment. [Chapter 40](#) discusses data collection for total cost analysis. [Chapter 48](#) addresses general principles of monitoring and evaluation, both valuable considerations when designing and implementing performance monitoring of the distribution system. In monitoring schemes, the same data should be collected from more than one source so that results can be cross-checked to assess the accuracy of existing record-keeping and reporting procedures.

22.6 The private-sector option

Pharmaceutical shortages are a common feature of government health services in many countries, even where such supplies are available through the formal and informal private sector. This situation is especially prevalent in major towns and cities. This private availability in the midst of public shortage suggests that, in these countries, the private sector is able to distribute pharmaceuticals more effectively than the public sector.

As discussed in [Chapter 8](#), alternatives exist in many countries to a government-run storage and distribution system. With a well-developed private sector, contracting out both storage and distribution to a private company may be possible and appropriate. The first step should always be to identify local private-sector capacity. Determining the appropriate combination of private and public systems is then possible. A health service can contract all distribution services to the private sector, or may find that some combination of private and public systems is the most appropriate.

In many countries, the private sector can offer a comprehensive and effective distribution service only to the regional or district level. In small or low-income countries, very few private-sector distribution companies may be available, and when competition is limited, a contracted service may not be cheaper or better than the public sector (Bennett 1992).

Many formerly socialist economies have parastatal pharmaceutical distribution companies. Under the pressures of structural adjustment, these organizations are now forced to operate in the market economy. Parastatals can be well placed to provide distribution and transport services where a clear contractual (quasi-private sector) relationship

between the parties incorporates performance targets and penalties for noncompliance.

The decision to use contracted services must be carefully considered because properly managing a contractor's work requires considerable staff time and expertise. To decide whether private provision of distribution systems is truly cheaper, the cost of the existing transport and distribution system must be assessed. Comprehensive tender documents must be prepared, specifying contractual and performance requirements precisely and unambiguously. It is then necessary to assess the capabilities and financial stability of the tender participants. After the contract is signed, the performance of the contractor must be carefully monitored. Contracting is discussed in [Chapter 39](#).

22.7 Considering improvement and replacement

Most health services already have a pharmaceutical distribution network, but needs and systems evolve. For instance, a program might begin by using medicine kits and then wish to move to a requisition-based system, which is more complex and usually increases the number of individual items handled (see [Chapter 26](#)).

A distribution system may be outdated; storage points chosen long ago may not suit the present situation, or record keeping may be inadequate. Data may be inaccurate, out-of-date, or not available in a clear, user-friendly form.

If the distribution system does not meet current needs, changes are necessary. The problems might be solved by improving the present system, but sometimes a complete and radical change is the best solution, although it may be difficult to carry out. Even a good system requires frequent minor adjustments to respond to changing needs.

The four examples that follow illustrate typical distribution problems and the types of action that may be appropriate to solve them.

Example 1. Poor administration

Problems in this system include failure to comply with standard operating procedures, inadequate reporting of shortages by peripheral health facilities, and excessive losses due to theft.

Action: Review and strengthen supervision, administrative procedures, and reporting standards. It may be necessary to change personnel, to provide incentives to improve performance, or both.

Example 2. Seasonal variations

Medicine shortages occur because roads are closed during periods of heavy rain or snow.

Action: Review delivery intervals and delivery quantities to take account of predictable weather hazards. Deliver more supplies when the weather is good. Check storage capacity.

Example 3. Major transport problems

Major transport problems, such as lack of fuel or lack of vehicles in working order, arise.

Action: Are the causes of these transport problems local or general? Local problems may be solved by providing more spare parts or installing a fuel depot. General, widespread problems may be a sign of structural weakness, necessitating more radical solutions. Contracts with private-sector or parastatal organizations may be a more cost-effective way to manage all or part of the transport system.

Example 4. Increased volume

New or expanding health programs may result in greatly increased distribution volumes.

Action: Evaluate existing storage and transport capacity and performance and determine how easy it would be to expand the existing in-house system. Existing systems may already be working close to capacity, and expansion might be constrained by limited human resources and management systems. Evaluate the capacity and interest of the private sector to provide a cost-effective service. Determine the optimum mix of public- and private-sector services. Contract accordingly.

Successfully implementing new distribution systems or modifying existing ones depends on many factors. Some of the most important factors include—

- Active commitment of management and staff
- Human resource readiness—having prepared staff members in all departments and at all levels
- Management's full understanding of its own organization
- Willingness at all levels to change and adapt—learn new skills, do new jobs, accept new responsibilities
- Openness to new ideas and creativity
- Continuous, institutionalized effort to improve ■

Glossary

Bin card: Card that records receipts, issues, and balances held in the stores. The bin card is kept in the warehouse with the physical stock.

Card file: A stock record based on the use of cards stored in a file box or a plastic, visible-edge record tray (Kardex).

Cold chain: A system of freezers, refrigerators, cold boxes, and other devices needed to maintain the proper temperature for vaccines (and other perishable supplies) from the point of manufacture to the point of administration.

Collection system: Pharmaceutical distribution system in which the health facilities are responsible for providing transport of supplies from the warehouse to the health facility. Compare *delivery system*.

Delivery system: Pharmaceutical distribution system in which the warehouse is responsible for providing transport of supplies from the warehouse to the health facilities. Compare *collection system*.

Demurrage: A charge assessed by shippers to purchasers that fail to unload and return containers. It can also apply when carriers are unable to off-load shipments because of delay through the fault of the purchaser.

Distribution system: A system of administrative procedures, transport facilities, storage facilities, and user facilities through which supplies move from a central point to the user facilities.

Double-shelf system: A system for stock control in which the stock of each item is physically separated onto two shelves. When the stock on one shelf is expended, the stock from the other shelf is used, and an order for replacement stock is placed.

First-expiry/first-out procedure (FEFO): A method of inventory management in which products with the earliest expiry date are the first products issued, regardless of the order in which they are received. This method is more demanding than *FIFO* but should be used for short-dated products such as vaccines.

First-in/first-out procedure (FIFO): A method of inventory management in which the first products received are the first products issued. This method generally minimizes the chance of drug expiration.

Holding costs: The costs of carrying inventory, usually expressed as a percentage of the average inventory. These costs include both the capital costs and the storage costs.

Imprest system: A form of periodic inventory control in which stocks are replenished up to a pre-established level. No running stock records are kept. The only stock control document is a pre-printed sheet showing each item, its description, the unit of issue, and the imprest level. Generally used only at small facilities.

Indent system: A type of pull distribution system where facilities make direct requisitions for stock rather than receive pre-allotted quantities from a central facility.

Inventory: The total stock kept on hand at any storage point to protect against uncertainty, permit bulk purchasing, minimize waiting time, increase transportation efficiency, and buffer against seasonal fluctuations.

Inventory control: The function of supply management that aims to provide sufficient stocks of medicines at the lowest costs possible.

Inventory models: Systems of inventory control that determine how much stock is bought and how often it is bought. See [Chapter 23](#) for a discussion.

Inventory taking: A periodic activity in which a physical count is made of the stock and compared with inventory control records. Also known as *physical stock count*.

Issue: To distribute a specific amount of an item to an intermediary stocking facility or a health facility.

Lead time: The time between the initiation of a purchase order and receipt at the warehouse from the supplier.

Lead-time demand: The number of units demanded and issued during the lead time.

Order picking: The systematic extraction of items from warehouse shelving to fill a client's order. Staff work from a picking list that defines the quantity and location of each item required.

Pallet: A transportable flat storage base, with or without sides, designed to hold goods and to permit handling by mechanical aids such as pallet trucks and forklifts.

Pipeline: The total storage capacity that must be filled in a pharmaceutical supply system, including the central medical stores, regional warehouses, district warehouses, and all regional facilities.

Pipeline analysis: The systematic diagramming of the supply system and calculation of the amount of stock held at each point in the system. The analysis determines the amount of stock actually needed and the amount of stock to be held at each storage point.

Prepacked kits: Also known as *ration kits* or *set packs*. An assortment of medicines and medical supplies to cover a set number of patient attendances, which are distributed unopened to health facilities.

Preventive maintenance: A series of maintenance and service activities performed regularly by a technician or operator and designed to prevent the breakdown of vehicles and other equipment. This form of maintenance is the least expensive.

Pull system: Pharmaceutical distribution system in which each peripheral facility determines the medicine quantities to be requisitioned from the procurement unit or warehouse. Compare *push system*.

Push system: Pharmaceutical distribution system in which the procurement unit or warehouse determines what medicine quantities are to be issued to the peripheral facilities. Compare *pull system*.

Receiving report: A document indicating when items were received, from whom, the total quantity in the shipment, the invoice price, and the amount of damaged or lost stock.

Routing: Determining the order in which facilities will receive their deliveries, based on the geographic location of facilities and an attempt to minimize delivery costs.

Safety stock: The buffer, cushion, or reserve stock kept on hand to protect against stockouts caused by delayed deliveries or markedly increased demand.

Service level: Most commonly defined as the percentage of items requested that are supplied, in the quantity requested, by a supplier or warehouse in one delivery. This term is sometimes used to describe the percentage of demand that is met from stock on hand.

Stock: Goods and materials stored for future use.

Stock count/physical inventory: The process of inventory taking, in which a physical count is made of all items in inventory and compared with the written record.

Stock numbers: Sequential numbers designating each item in inventory.

Stock position: All stock now available and soon to be available, including stock on hand and outstanding orders. This is sometimes called the *total inventory*.

Stock records: A generic term that applies to bin cards, Kardex records, stock ledgers, and computer files. These provide basic information for inventory management by recording all transactions for an item, including receipts, issues, orders placed, orders received, and stock losses.

ASSESSMENT GUIDE

Pharmaceutical distribution system

- Which levels of the supply system order pharmaceuticals from suppliers?
- Is distribution through a push or a pull system?
- Does the system include semi-autonomous vertical distribution components, such as EPI?
- How many levels are there in the distribution hierarchy? How many stores, clinical facilities, or pharmacies are at each level? How many levels of warehouses are needed (for example, central, provincial, district)?
- What are the catchment populations of warehouses, stores, clinical facilities, or pharmacies? Map the geographical distribution of each.
- Is the current distribution system based on collection or delivery?
- How many warehouses are needed? Where should they be? What geographic areas should they serve? What products should they store?
- What volume of medicines is distributed to each warehouse, store, clinical facility, and pharmacy per year? How often is each supplied? What is the physical capacity of each store? Is physical capacity ever exceeded? Map the current demand distribution.
- What criteria are used to calculate the resupply quantities at each level in the system?
- What changes in demand distribution are anticipated in the future?
- What mode of transport is used for each link in the distribution chain? What alternatives are available? What are the travel times for each link?

Supply sources

- What percentages in terms of bulk, value, and number of items do overseas and in-country suppliers contribute annually?
- Which ports of entry are used by each of the overseas suppliers? Which ports clear imports most efficiently and with the least loss?
- Where are the in-country pharmaceutical supply sources located?

Communications

- What methods of communication are available and actually used between each node in the distribution system (telephone, fax, radio link, physical visit)?

Performance indicators

- Cost of stock held as a percentage of stock turnover
- Percentage of health facilities submitting requisitions on time

- Frequency of delivery
- Number of emergency deliveries
- Number of items supplied out of total requested by clients (service level)
- Average stock position in months (quantity on hand and on order, divided by average monthly consumption)
- Stockout frequency for indicator medicines
- Percentage availability of indicator medicines at each level
- Quantity and value of expired items in stock
- Losses caused by damage and theft
- Distribution costs per ton per kilometer
- Vehicle availability and frequency of breakdowns
- Vehicle fuel availability in different parts of the country (a good indicator of the transport system's ability to make deliveries)
- Mechanical breakdown frequency for vital temperature control equipment such as cold rooms and air-conditioners
- Staff attendance rate and sick time used
- Variation between actual and recorded inventory level
- Currency of record maintenance
- Supplier and warehouse lead time

Monitoring and evaluation

- Are there effective systems for monitoring and evaluating distribution system costs and performance? If not, which elements are missing?
- How much can demand forecasts change without affecting the distribution system? For example, what would be the effect of a 50 percent increase in demand?
- What is the annual operating cost of the distribution system as a percentage of pharmaceuticals distributed? Are there significant regional variations?
- What are the costs of private-sector alternatives to in-house services?

Private-sector alternatives

- What private-sector pharmaceutical distribution systems exist? Identify the location of private-sector pharmacies within catchment areas of clinical facilities or pharmacies.
- Who are the private-sector storage and transport providers? Assess whether they are capable of handling medicines and delivering services to areas where they are needed.
- How would contracting out any services to the private sector affect customer service or costs?

Stocking cost: The cost of maintaining stock, including the capital and storage costs.

Stockout: Complete absence of an item that is normally expected to be on hand. In many cases, this indicator can be misleading, because a warehouse may always reserve a small stock—the warehouse is not literally out of stock, but a functional stockout exists because the warehouse will not issue the reserved stock.

Tachograph: A device that records comprehensive details of every journey and can provide a check on the accuracy of a driver's log.

Trans-shipment: Shipment of supplies to an intermediate location, from which they are forwarded by another means of transport to a facility.

Two-bin inventory control: Same as *double-shelf system*, except that two physically separate bins rather than shelves are used.

Unique identifiers: Techniques by which medicines can be identified as originating within the government supply system. Unique identifiers include labels with a program logo, reserved batch numbers, and imprinting of tablets and capsules.

Visual inventory system: A no-paper inventory control method in which the need to order is determined simply by looking at the inventory on the shelf. This system usually provides acceptable performance only in small facilities with a limited number of items in stock.

Working stock: That part of the inventory that is expected to be issued or consumed. It fluctuates between zero and the order quantity. The other component of inventory is the safety stock.

SUMMARY

This chapter discusses inventory management—the management of the routine ordering process. Seven basic issues must be considered for effective, efficient inventory management—

- The supply system's purpose and the type of distribution system
- The records and reports that will provide the foundation for inventory management
- The selection of items to be stocked
- The balance between service levels, including stock-out costs, ordering costs, and stock-holding costs
- The policy on when to order
- The policy on how much to order and methods for determining reorder quantities or reorder intervals
- The control of costs associated with inventory management (ordering, stockout, and stock holding)

The type of inventory management system needed depends first on the context—different systems are used for dependent demand systems (manufacturing) and independent demand systems (distribution of finished goods). Similarly, a different system may be needed in a push system as opposed to a pull system (see [Chapter 22](#)), although ordering has to be done in both push and pull systems. Clearly, most inventory management for pharmaceutical supply concerns the distribution of finished goods.

Accurate and current stock records are essential to good inventory management. They are the source of information used to calculate needs, and inaccurate records produce inaccurate needs estimations (and problems with stockouts and expiry). Each inventory system should monitor performance with indicators and produce regular reports on inventory and order status, operating costs, and consumption patterns.
