

INTERNATIONAL COUNCIL
of OPHTHALMOLOGY

Updated 2017 ICO Guidelines for Diabetic Eye Care

ICO Guidelines for Diabetic Eye Care

The International Council of Ophthalmology (ICO) developed the *ICO Guidelines for Diabetic Eye Care* to serve a supportive and educational role for ophthalmologists and eye care providers worldwide. They are intended to improve the quality of eye care for patients around the world.

The *Guidelines* address the needs and requirements for the following levels of service:

- High Resource Settings: Advanced or state-of-the-art screening and management of DR based on current evidence, and clinical trials.
- Low-/Intermediate Resource Settings: Essential or core to mid-level service for screening and management of DR with consideration for availability and access to care in different settings.

The *Guidelines* are designed to inform ophthalmologists about the requirements for the screening and detection of diabetic retinopathy, and the appropriate assessment and management of patients with diabetic retinopathy. The *Guidelines* also demonstrate the need for ophthalmologists to work with primary care providers and appropriate specialists such as endocrinologists.

With diabetes and diabetic retinopathy a rapidly increasing problem worldwide, it is vital to ensure that ophthalmologists and eye care providers are adequately prepared.

The ICO believes an ethical approach is indispensable, as it is the first step toward quality clinical practices. Download the *ICO Code of Ethics* at: www.icoph.org/downloads/icoethicalcode.pdf (PDF – 198 KB).

The *Guidelines* are designed to be a working document and will be updated on an ongoing basis. They were first released in December 2013. This document was reviewed, revised, and updated in 2016.

The ICO hopes these *Guidelines* are easy to read, translate, and adapt for local use. The ICO welcomes any feedback, comments, or suggestions.

Please email us at: info@icoph.org.

2013 Task Force on Diabetic Eye Care

- Hugh Taylor, MD, AC, Chairman
- Susanne Binder, MD
- Taraprasad Das, MD, FRCS
- Michel Farah, MD
- Frederick Ferris, MD
- Pascale Massin, MD, PhD, MBA
- Wanjiku Mathenge, MD, PhD, MBChB

I. Introduction

Diabetes mellitus (DM) is a global epidemic with significant morbidity. Diabetic retinopathy (DR) is the specific microvascular complication of DM and affects 1 in 3 persons with DM. DR remains a leading cause of vision loss in working adult populations. Patients with severe levels of DR are reported to have poorer quality of life and reduced levels of physical, emotional, and social well-being, and they utilize more health care resources.

Epidemiological studies and clinical trials have shown that optimal control of blood glucose, blood pressure, and blood lipids can reduce the risk of developing retinopathy and slow its progression. Timely treatment with laser photocoagulation, and increasingly, the appropriate use of intraocular administration of vascular endothelial growth factor (VEGF) inhibitors can prevent visual loss in vision-threatening retinopathy, particularly diabetic macular edema (DME). Since visual loss may not be present in the earlier stages of retinopathy, regular screening of persons with diabetes is essential to enable early intervention.

1.1 Epidemiology of Diabetic Retinopathy

In many countries, DR is the most frequent cause of preventable blindness in working-aged adults. A Global meta-analysis study reported that 1 in 3 (34.6%) had any form of DR in the US, Australia, Europe and Asia. It is also noted that 1 in 10 (10.2%) had vision threatening DR (VTDR) i.e., PDR and/or DME. In the 2010 world diabetes population, more than 92 million adults had any form of DR, 17 million had PDR, 20 million had DME and 28 million had VTDR.

DR develops with time and is associated with poor control of blood sugar, blood pressure, and blood lipids. The longer someone has had DM, and the poorer their control, the higher their risk of developing DR. Good control reduces the annual incidence of developing DR and extends life by reducing risk of cardiovascular diseases. However, good control does not necessarily reduce the lifetime risk of developing DR, so everyone with DM is at risk.

The overall prevalence of DR in a community is also influenced by the number of people diagnosed with early DM:

- In high resource settings with good health care systems, more people with early DM will have been diagnosed through screening. The prevalence of DR in people with newly diagnosed DM will be low, resulting in a lower overall prevalence of DR.
- In low-/intermediate resource settings with less advanced health care systems, fewer people with early DM will have been diagnosed because early stage of DM is asymptomatic. People may be diagnosed with diabetes only when symptomatic or complications have occurred. Thus, the prevalence of DR in people with newly diagnosed DM will be high, resulting in a somewhat higher overall prevalence of DR.

1.2 Classification of Diabetic Retinopathy

The classic retinal lesions of DR include microaneurysms, hemorrhages, venous beading (venous caliber changes consisting of alternating areas of venous dilation and constriction), intraretinal microvascular abnormalities, hard exudates (lipid deposits), cotton-wool spots (ischemic retina leading to accumulations of axoplasmic debris within adjacent bundles of ganglion cell axons), and retinal neovascularization (**Annex Figures**). These findings can be utilized to classify eyes as having one of two phases of DR.

1.2.1 Nonproliferative Diabetic Retinopathy (NPDR)

Eyes with nonproliferative DR (NPDR) have not yet developed neovascularization, but may have any of the other classic DR lesions. Eyes progress from having no DR through a spectrum of DR severity that includes mild, moderate and severe NPDR. Correct identification of the DR severity level of an eye allows a prediction of risk of DR progression, visual loss, and determination of appropriate treatment recommendations including follow-up interval. **Annex Table 1** details the signs associated with DR.

1.2.2 Proliferative Diabetic Retinopathy (PDR)

Proliferative diabetic retinopathy (PDR) is the most advanced stage of DR and represents an angiogenic response of the retina to extensive ischemia from capillary closure. Retinal neovascularization is typically characterized as being new vessels on the disc (NVD) or new vessels elsewhere (NVE) along the vascular arcades. NVE often occur at the interface between perfused and nonperfused areas of retina. **Annex Table 2** includes the signs associated with PDR.

The stages of DR, from nonproliferative to proliferative DR, can be categorized using the simple International Classification of DR scale shown in **Table 1**.

1.2.3 Diabetic Macular Edema (DME)

Diabetic macular edema (DME) is an additional important complication that is assessed separately from the stages of retinopathy, as it can be found in eyes at any DR severity level and can run an independent course. Currently, diabetic eyes are generally classified as having no DME, noncentral-involved DME, or central-involved DME. The determination of DME severity based on these 3 categories will determine the need for treatment and follow-up recommendations.

The stages of DR can be classified using the International Classification of DR Scale shown in **Table 1**. Based on this Classification, referral decision can be used in high resource settings (**Table 2a**), and low-/intermediate settings (**Table 2b**). It is important to remember that advanced stages of DR and DME may be present even in patients who are not experiencing visual symptoms. An online self-directed course on the grading of diabetic retinopathy is available at: drgrading.iehu.unimelb.edu.au.

Table 1: International Classification of Diabetic Retinopathy and Diabetic Macular Edema

Diabetic Retinopathy	Findings Observable on Dilated Ophthalmoscopy
No apparent DR	No abnormalities
Mild nonproliferative DR	Microaneurysms only
Moderate nonproliferative DR	Microaneurysms and other signs (e.g., dot and blot hemorrhages, hard exudates, cotton wool spots), but less than severe nonproliferative DR
Severe nonproliferative DR	Moderate nonproliferative DR with any of the following: <ul style="list-style-type: none"> • Intraretinal hemorrhages (≥ 20 in each quadrant); • Definite venous beading (in 2 quadrants); • Intraretinal microvascular abnormalities (in 1 quadrant); • and no signs of proliferative retinopathy
Proliferative DR	Severe nonproliferative DR and 1 or more of the following: <ul style="list-style-type: none"> • Neovascularization • Vitreous/preretinal hemorrhage

Diabetic Macular Edema	Findings Observable on Dilated Ophthalmoscopy [#]
No DME	No retinal thickening or hard exudates in the macula
Noncentral-involved DME	Retinal thickening in the macula that does not involve the central subfield zone that is 1mm in diameter
Central-involved DME	Retinal thickening in the macula that does involve the central subfield zone that is 1mm in diameter

[#] Hard exudates are a sign of current or previous macular edema. DME is defined as retinal thickening, and this requires a three-dimensional assessment that is best performed by a dilated examination using slit-lamp biomicroscopy and/or stereo fundus photography.

Table 2a. Re-examination and Referral Recommendations Based on International Classification of Diabetic Retinopathy* and Diabetic Macular Edema for High Resource Settings.

Diabetic Retinopathy (DR)		
Classification	Re-examination Or next screening schedule	Referral to Ophthalmologist
No apparent DR, mild nonproliferative DR and no DME	Re-examination in 1-2 year	Referral not required
Mild nonproliferative DR	6-12 months	Referral not required
Moderate nonproliferative DR	3-6 months	Referral required
Severe nonproliferative DR	< 3-months	Referral required
PDR	< 1 month	Referral required
Diabetic Macular Edema (DME)		
Classification	Re-examination Or next screening schedule	Referral to Ophthalmologist
Noncentral-involved DME	3 months	Referral required
Central-involved DME	1 month	Referral required

* In cases where diabetes is controlled.

Table 2b. Re-examination and Referral Recommendations Based on Simplified Classification of Diabetic Retinopathy* and Diabetic Macular Edema for Low-/Intermediate Resource Settings.

Diabetic Retinopathy (DR)		
Classification	Re-examination Or next screening schedule	Referral to Ophthalmologist
No apparent DR, mild nonproliferative DR and no DME	Re-examination in 1-2 year	Referral not required
Mild nonproliferative DR	1-2 year	Referral not required
Moderate nonproliferative DR	6-12 months	Referral required
Severe nonproliferative DR	< 3 months	Referral required
PDR	< 1 month	Referral required
Diabetic Macular Edema (DME)		
Classification	Re-examination Or next screening schedule	Referral to Ophthalmologist
Noncentral-involved DME	3 months	Referral not required (referral recommended if laser resources available)
Central-involved DME	1 month	Referral required

* In cases where diabetes is controlled.

2. Screening Guidelines

2.1 Screening Guidelines

Screening for DR is an important aspect of DM management worldwide. Even if an adequate number of ophthalmologists are available, using ophthalmologists or retinal subspecialists to screen every person with DM is an inefficient use of resources.

A screening exam could include a complete ophthalmic examination with refracted visual acuity and state-of-the-art retinal imaging. However, in a low-/intermediate resource settings, the minimum examination components to assure appropriate referral should include a screening visual acuity exam and retinal examination adequate for DR classification. Vision should be tested prior to pupil dilation. **Annex Flowchart 1** shows an example of the screening process for DR.

The screening vision exam should be completed by trained personnel in any of the following ways, depending on resources:

- Refracted visual acuity examination using a 3- or 4-meter visual acuity lane and a high contrast visual acuity chart.
- Presenting visual acuity examination using a near or distance eye chart and a pin-hole option if visual acuity is reduced.
- Presenting visual acuity examination using a 6/12 (20/40) equivalent handheld chart consisting of at least 5 standard letters or symbols and a pin-hole option if visual acuity is reduced.

A retinal examination may be accomplished in the following ways:

- Direct or indirect ophthalmoscopy or slit-lamp biomicroscopic examination of the retina.
- Retinal (fundus) photography (including any of the following: widefield to 30°; mono- or stereo-; dilated or undilated). This could be done with or without accompanying optical coherence tomography (OCT) scanning. This could also include telemedicine approaches. (**Annex Table 3**)
- For the retinal examination, a medical degree may not be necessary, but the examiner must be well trained to perform ophthalmoscopy or retinal photography and be able to assess the severity of DR.

Using adequate information from the visual acuity and retinal examinations, one can decide on an appropriate management plan, as outlined in **Table 2a and Table 2b**. The plan may be modified based on individual patient requirements.

Patients with less than adequate retinal assessment should be referred to an ophthalmologist unless it is obvious that there is no DR, or at most, only mild nonproliferative DR (i.e., microaneurysms only). In addition, persons with unexplained visual-acuity loss should be referred.

As part of a screening exam, persons with diabetes should be asked about their diabetes control, including blood glucose, blood pressure, and serum lipids. In addition, women should be asked if they are or could be pregnant. Inadequate control and pregnancy may require further appropriate medical intervention.

2.2 Referral Guidelines

Minimum referral guidelines are as follows:

- i. Visual acuity below 6/12 (20/40) or symptomatic vision complaints
- ii. If DR can be classified according to the simplified International Classification of DR (**Table 1**), they should be referred accordingly (**Table 2a and Table 2b**).
- iii. If visual acuity or retinal examination cannot be obtained at the screening examination: refer to ophthalmologist.

3. Detailed Ophthalmic Assessment of Diabetic Retinopathy

3.1 Initial Patient Assessment

Detailed patient assessment should include a complete ophthalmic examination, including visual acuity and the identification and grading of severity of DR and presence of DME for each eye. The patient assessment should also include the taking of a patient history focused on diabetes and its modifiers.

3.1.1 Patient History (Key Elements)

- Duration of diabetes
- Past glycemic control (hemoglobin A1c)
- Medications (especially insulin oral hypoglycemics, antihypertensives, and lipid-lowering drugs)
- Systemic history (e.g., renal disease, systemic hypertension, serum lipid levels, pregnancy)
- Ocular history

3.1.2 Initial Physical Exam (Key Elements)

- Visual acuity
- Measurement of intraocular pressure (IOP)
- Gonioscopy when indicated (e.g., when neovascularization of the iris is seen or in eyes with increased IOP)
- Slit-lamp biomicroscopy
- Fundus examination

3.1.3 Fundus Examination Assessment Methods

Currently, the two most sensitive methods for detecting DR are retinal photography and slit-lamp biomicroscopy through dilated pupils. Both depend on interpretation by trained eye health professionals. Other methods are listed in **Annex Table 3**.

Fundus photography has the advantage of creating a permanent record, and for that reason, it is the preferred method for retinopathy assessment. However, well-trained observers can identify DR without photography and there are many situations in which that would be the examination of choice.

The use of all instruments requires training and competence but more skill is needed for indirect ophthalmoscopy and slit-lamp biomicroscopy than for fundus photography. Newer, semi-automatic nonmydriatic fundus cameras can be very easy to use. Media opacities will lead to image/view degradation and all photographs/images must be reviewed by trained personnel.

3.2. Follow-up Examination of Patients with Diabetic Retinopathy

In general, the follow-up history and examination should be similar to the initial examination. The assessment of visual symptoms, visual acuity, measurement of IOP, and fundus examination are essential.

3.2.1 Follow-up History

- Visual symptoms
- Glycemic status (hemoglobin A1c)
- Systemic status (e.g., pregnancy, blood pressure, serum lipid levels, renal status)

3.2.2 Follow-up Physical Exam

- Visual Acuity
- Measurement of IOP
- Gonioscopy when indicated
- Slit-lamp biomicroscopy
- Fundus examination

3.2.3 Ancillary Tests (High Resource Settings)

- OCT is the most sensitive method to identify DME. OCT can provide quantitative assessment of DME to determine the severity of DME. Retinal map scan is useful in locating the area with retinal thickening; single scan is useful in detailing the types of DME as diffuse, cystic changes, sub-retinal fluid/detachment, and vitreoretinal traction.
- Fundus photography is a useful way of recording the disease activity. It is useful in determining detailed severity of the disease.
- Fluorescein angiography is not required to diagnose DR, proliferative DR or DME, all of which are diagnosed by means of fundus examination.
- Fluorescein angiography can be used as a guide to evaluate retinal non-perfusion area, presence of retinal neovascularization, and microaneurysms or macular capillary non-perfusion in DME.

3.2.4 Patient Education

- Discuss results or exam and implications.
- Encourage patients with DM but without DR to have annual screening eye exams.
- Inform patients that effective treatment for DR depends on timely intervention, despite good vision and no ocular symptoms.
- Educate patients about the importance of maintaining near-normal glucose levels, near-normal blood pressure and to control serum lipid levels.
- Communicate with the general physician (e.g., family physician, internist, or endocrinologist) regarding eye findings.
- Provide patients whose conditions fail to respond to surgery and for whom treatment is unavailable with proper professional support (i.e., offer referrals for counseling, rehabilitative, or social services as appropriate).
- Refer patients with reduced visual function for vision rehabilitation and social services.
- Refer patients who have underwent treatment, including PRP and surgery, on timely follow-up.

Table 3a. Follow-up Schedule and Management based on Diabetic Retinopathy Severity for High Resource Settings.

Diabetic Retinopathy Severity	Follow-up Schedule for management by ophthalmologists
No apparent DR	Re-examination in 1-2 years; This may not require re-examination by an ophthalmologist
Mild nonproliferative DR	6-12 months; This may not require re-examination by an ophthalmologist
Moderate nonproliferative DR	3-6 month
Severe nonproliferative DR	<3 months; Consider early pan-retinal photocoagulation.
Proliferative DR	<1 month; Consider pan-retinal photocoagulation.
Stable (Treated) PDR	6-12 months
Diabetic Macular Edema severity	Follow-up Schedule for management by ophthalmologists
Noncentral-involved DME	3-6 month; Consider focal laser photocoagulation
Central-involved DME	1-3 month; Consider focal laser photocoagulation or anti- VEGF therapy
Stable DME	3-6 month

Table 3b. Follow-up Schedule and Management based on Diabetic Retinopathy Severity for Low-/Intermediate Resource Settings.

Diabetic Retinopathy Severity	Follow-up Schedule for management by ophthalmologists
No apparent DR	Re-examination in 1-2 years; This may not require re-examination by an ophthalmologist
Mild nonproliferative DR	1-2 years; This may not require re-examination by an ophthalmologist
Moderate nonproliferative DR	6-12 months
Severe nonproliferative DR	<3 month
Proliferative DR	<1 month; Consider pan-retinal photocoagulation.
Stable (Treated) PDR	6-12 month
Diabetic Macular Edema severity	Follow-up Schedule for management by ophthalmologists
Noncentral-involved DME	3-6 month
Central-involved DME	1-3 month; Consider focal laser photocoagulation or anti- VEGF therapy
Stable DME	3-6 month

4. Treatment of Diabetic Retinopathy

4.1 High Resource Settings

- i. **Optimize medical treatment:** Improve glycemic control if HbA1c > 58 mmol/mol (>7.5%) as well as associated systemic hypertension or dyslipidemia.
- ii. **No DR, Mild or Moderate NPDR:** Follow at recommended intervals with dilated eye examinations and retinal imaging as needed. Treat DME as needed (see below).
- iii. **Severe NPDR:** Follow closely for development of PDR. Consider early panretinal photocoagulation for patients at high risk of progression to PDR or poor compliance with follow-up. There are benefits of early panretinal photocoagulation at the severe NPDR stage for patients with type 2 diabetes. Other factors, such as poor compliance with follow-up, impending cataract extraction or pregnancy, and status of fellow eye will also help in determining the timing of the panretinal photocoagulation.
- iv. **PDR:** Treat with panretinal photocoagulation (PRP). There is increasing evidence from clinical trials demonstrating anti-VEGF injections (ranibizumab) as a safe and effective treatment of PDR through at least 2 years and that other intravitreal anti-VEGF agents (i.e. aflibercept and bevacizumab) are also highly effective against retinal neovascularization.

4.2 Low-Intermediate Resource Settings

- i. Generally similar to above. PRP is preferred for the treatment of severe NPDR and PDR.

4.3 Panretinal Photocoagulation (PRP)

4.3.1 Pre-treatment Discussion with Patients

- Patients usually need numerous follow-up visits and may require supplementary laser treatment.
- PRP reduces the risk of visual loss and blindness.
- Although laser treatment is effective, some patients may still develop vitreous hemorrhage. The hemorrhage is caused by the diabetes and not by the laser; it may mean the patient needs more laser treatment.
- Laser treatment often reduces peripheral and night vision; treatment may moderately reduce central vision.
- The conventional long pulse 100ms PRP treatments are associated with loss of vision. The recommended short pulse 20-30ms PRP treatments are less likely to cause this complication.

4.3.2 Lenses for PRP

- The three-mirror Goldmann contact lens has a central opening for treating the posterior pole, and side mirrors for treating the mid peripheral and peripheral retina. Disadvantages: small field of view, which requires continual manipulation of the lens to complete treatment. Spot size is set at 500µm.
- Newer wide-angle contact lenses are often used. Although the image is inverted, there is a large field of view allowing for many burns with the field while easily maintaining orientation to the disc and macula. The optics of these wide-angle lenses will affect the laser spot size on the retina (Table 4). Wide-angle indirect ophthalmoscopy lenses provide an inverted image, but show a large field of view and a magnification of the spot in the retina (Table 4). Scatter treatment can be applied to a large area of retina in a single image, and it is easy to visualize the disk and the macula.

Table 4: Laser Spot Size Adjustment Required for Different Lenses Contact

Lens	Field of Vision	Axial magnification	Spot magnification	Spot Size Setting for ~500 µm
Mainster Wide-Field	125°	0.46	1.50x	300µm
Volk TransEquator	120-125°	0.49	1.43x	300µm
Volk Quad/Aspheric	130-135°	0.27	1.92x	200 to 300µm
Mainster PRP 165	160°	0.27	1.96x	200 to 300 µm

4.3.3 Technique for PRP (refer to Annex A for more details)

- i. The pupil should be fully dilated and topical anesthesia is used. Retrobulbar or subtenons anesthesia to reduce pain and decrease eye motion can be employed as necessary.
- ii. Typical initial settings on the Argon laser would be 500 μm spot size, a 0.1 second exposure and 250-270 mw power. The power is gradually increased until a whitish reaction is obtained on the retina. The lesions are placed 1 burn width apart. (Table 5)
- iii. A total of 1600-3000 burns are placed in 1 or more sittings, carefully avoiding the macular area and any areas of tractional elevation of the retina. The burns are placed 2 to 3 disc diameters away from the center of the macula and 1 disc diameter away from the disc, usually outside the arcades and extended peripherally up to the equator and beyond.
- iv. Laser treatment should not be applied over major retinal veins, preretinal hemorrhages, darkly pigmented chorioretinal scars, or within 1 DD (200-300 μm) of center of macula, so as to avoid risk of hemorrhage or large scotomas.
- v. Other considerations:
 - Additional photocoagulation is needed if there is evidence of worsening of proliferative DR.
 - Add laser burns in between scars of initial treatment further peripherally and also at the posterior pole, sparing the area within 500-1500 μm from the center of the macula.
 - Favor quadrants with active new vessels or areas with intraretinal microvascular abnormalities where scars are more widely spaced and areas of severe ischemia not previously treated, such as the temporal part of the posterior pole.
 - There is increasing use of multi-spot laser machine.

Table 5. The burn characteristics for panretinal photocoagulation:

Size (on retina):	500 μm
Exposure	0.05 to 0.1 seconds recommended. 0.02 or 0.03 seconds can be considered for use in High Resource Settings (in certain laser machines, where applicable).
Intensity	mild white (i.e. 2+ to 3+ burns)
Distribution	Mild and moderate PDR: Edges 1 burn width apart Severe PDR: Edges 0.5 to 0.75 burn width apart
Number of sessions/sittings	1 to 3
Nasal proximity to disk	No closer than 500 μm
Temporal proximity to center	No closer than 3000 μm
Superior/inferior limit	No further posterior than 1 burn within the temporal arcades
Extent	Arcades (~3000 μm from the macular center) to at least the equator

5.3 Laser Technique for Diabetic Macular Edema

- i. Modified ETDRS guidelines recommends focal laser treatment of microaneurysms and grid treatment of areas of diffuse leakage and focal nonperfusion within 2DD of center of the macula. There is increasing evidence that laser for microaneurysms is not recommended and multiple re-treatments of microaneurysms can lead to heavy retinal laser burns and future laser scars and central scotomas. (Table 6)
- ii. Laser parameters used are 50-100 µm spot size, 120-150 mW energy and very light gray intensity of the burn. Care is taken to demarcate and avoid the foveal avascular zone.
- iii. If DME is associated with large areas of macular ischemia, only the areas of retinal thickening are treated.

Table 6. Modified-ETDRS and the Mild Macular Grid Laser Photocoagulation Techniques

Focal direct laser treatment	
Directly treat all leaking microaneurysms in areas of retinal thickening between 500 and 3000 µm from the center of the macula (but not within 500 µm of disc). Change in microaneurysms color with direct treatment is not required, but at least a mild gray-white burn should be evident beneath all microaneurysms.	
Burn size	50-100 µm
Burn duration	0.05 to 0.1 sec
Wavelength	Green to yellow wavelengths
Grid laser treatment	
Applied to all areas with diffuse leakage or non-perfusion area. Treat the area 500 to 3000 µm superiorly, nasally and inferiorly from the center of the macula, and 500 to 3500 µm temporally from macular center. No burns are placed within 500 µm of disc. Aim barely visible (light gray) laser burn and each burn should be at least two visible burn widths apart.	
Burn size	50-100 µm
Burn duration	0.05 to 0.1 sec
Wavelength	Green to yellow wavelengths

6 Indications for Vitrectomy

- i. Severe vitreous hemorrhage of 1–3 months duration or longer that does not clear spontaneously. Earlier intervention may be warranted in low-/intermediate resource settings as the underlying PDR disease may have been previously untreated and highly advanced. In these settings it may be reasonable to perform vitrectomy in eyes with vitreous hemorrhage of 4–6 weeks duration that has not cleared spontaneously.
- ii. Advanced active proliferative DR that persists despite extensive PRP. Surgery is reasonable in eyes with recurrent episodes of vitreous haemorrhage from PDR due to persistent vessels despite PRP or mechanical traction on NV.
- iii. Traction macular detachment of recent onset. Fovea-threatening or progressive macula-involving traction detachments benefit from surgical management.
- iv. Combined traction-rhegmatogenous retinal detachment.
- v. Tractional macular edema or epiretinal membrane involving the macula. This includes vitreomacular traction.

7 Management of Diabetic Retinopathy in Special Circumstances

7.1 Pregnancy

Progression of DR is a significant risk in pregnancy. The following are recommendations:

- i. Patients with pre-existing diabetes planning pregnancy should be informed on the need for assessment of DR before and during pregnancy. Pregnant women with pre-existing diabetes should be offered retinal assessment following their first antenatal clinic appointment and again at 28 weeks if the first assessment is normal. If any DR is present, additional retinal assessment should be performed at 16-20 weeks.
- ii. Diabetic retinopathy should not be considered a contraindication to rapid optimisation of glycaemic control in women who present with a high HbA1c in early pregnancy but retinal assessment is essential.
- iii. Diabetic retinopathy should not be considered a contraindication to vaginal birth.

7.2 Management of Cataract

DR progresses faster after cataract surgery, so principles of management are as follows:

- i. Mild cataract - carefully assess DR status. Patients without vision loss with clear fundus view may not require cataract surgery.
- ii. Moderate cataract - carefully assess DR status. Attempt to treat any severe NPDR with laser PRP, and/or DME with focal/grid laser or anti-VEGF therapy, before cataract surgery. Once DR/DME is stable, consider cataract surgery to improve vision.
- iii. Severe to advanced cataract with poor fundus view - if DR status cannot be adequately assessed, consider early cataract surgery followed by assessment and treatment as necessary. If DME is present, consider anti-VEGF before surgery, at the time of surgery, or after surgery if DME is discovered when the media is cleared.

8 List of Suggested Indicators for Evaluation of DR Programs

- i. Prevalence of diabetic retinopathy and DME related blindness and visual impairment*
- ii. Proportion of blindness and visual impairment due to DR*
- iii. Last eye examination for DR among known persons with diabetes (males/females)*
 - Never had eye examination for DR
 - 0–12 months ago
 - 13–24 months ago
 - >24 months ago
 - Could be simplified as: never/0-12 months ago/>12 months ago
- iv. Number of patients who were examined for DR during last year
- v. Number of patients who received laser and/or anti-VEGF treatment/surgery during last year
- vi. Number of patients that receive first PRP laser for screen positive/newly-diagnosed PDR
- vii. Tool for the Assessment of Diabetic Retinopathy and Diabetes Management Systems (WHO-TADDS)

This absolute number could be used to define ratios such as:

- viii. Number of patients who received laser and/or anti-VEGF treatments per million general population per year. [equivalent to Cataract Surgical Rate (CSR)]
- ix. Number of patients who received laser and/or anti-VEGF treatments per number of patients with diabetes in a given area (hospital catchment area, health district, region, country)
 - Numerator: number of laser and/or anti-VEGF treatments during the last year
 - Denominator: number of patients with diabetes (population x prevalence of DM; source: IDF Atlas)
- x. Number of patients who received laser and/or anti-VEGF treatments per number of persons with vision-threatening DR in a given area (hospital catchment area, health district, region, country)
 - Numerator: number of laser and/or anti-VEGF treatments during the last year
 - Denominator: number of patients with vision-threatening DR (population x prevalence of DM x 0.117; source: IDF Atlas)

* Data available from RAAB surveys

0.117: Estimated average prevalence of vision-threatening DR.

9 Equipment

Core/essential: for screening, initial assessment, and follow-up:

- Nonmydriatic retinal (fundus) camera (recommended for screening).
- Indirect ophthalmoscopy (optional for screening, panoramic view, low magnification). Pupils must be dilated.
- Noncontact biconvex indirect lenses used with the slit lamp (90 D for screening, 78 D for more magnification).
- Direct ophthalmoscopy (optional for screening). Pupils must be dilated.
- Three-mirror contact lens used with slit lamp for stereoscopic and high-resolution images of the macula (evaluation of macular edema). Pupils must be dilated.
- Slit-lamp biomicroscope.
- Laser equipment: Currently, the most used lasers are (1) The green laser 532 nm, frequency-doubled Nd:YAG or 514 nm argon laser. The 810 nm infrared laser, or diode laser – this causes deeper burns with a higher rate of patient discomfort, but tend to be cheaper, is effective, and requires less maintenance.

Recommended in tertiary/reference centers:

- OCT
- Fluorescein angiography
- Mydriatic retinal photography (large field conventional fundus camera)
- Green lasers are the most used, but the pattern-laser method, with a predetermined multispot treatment cascade and the 577 nm yellow laser can be used in selected cases

IAPB Standard List of Equipment

The online version of the International Agency for the Prevention of Blindness (IAPB) Standard List provides information for eye health providers on a carefully evaluated range of eye care technologies, supplies, and training resources suitable for use in settings with limited resources.

For more information and to get access, please register and log on at IAPB.standardlist.org.

Only registered users have access to the IAPB Standard List catalogue. Please be aware the registration process may take a few days for approvals to be granted.

Annex A. Technique for PRP

1. If there is a significant anxiety and pain with slit-lamp PRP, then patient can undergo indirect PRP in theatre using subtenon's block. The eye movements are restricted by retrobulbar/subtenons anesthesia. The peripheral retinal zones may not be visualized adequately and remain poorly treated by laser. This is often evident by the posterior pole "pepper-pot" configuration of PRP laser.
2. Indirect PRP with subtenons anesthesia enables indented scleral laser application to up to the posterior border of the ora serrata. In PDR, the mid-peripheral retina up to the ora serrata is the zone of highest retinal ischemia as confirmed with widefield Optos studies.

In the last 5 years, conventional long-pulse duration PRP treatment has changed. This is reflected in the new RCOphth Diabetic Retinopathy Guidelines 2012 published in the UK. The DRCRNet recommendations outlined in Table 5 are not routinely undertaken, as 1200-1600 burns delivered over 1-3 sittings is neither an efficient nor cost-effective treatment schedule for any resource-poor or resource-rich setting. In light of new short pulse settings, use of pattern scan laser, and new concepts on laser burn tissue interactions for PRP laser, laser practitioners globally are changing laser PRP treatment paradigms. There is a significant body of evidence to demonstrate that short pulse PRP laser treatment will produce less laser burn scarring, less damage to the visual field, and is less damaging to the retina than conventional long pulse 100ms PRP treatment. This is highlighted in the following section extracted from the UK RCOphth 2012 guidelines.

Section 9.2.7 Healing Responses (Diabetic Retinopathy Guidelines 2012)

The in vivo effects of 20ms burns have been demonstrated in animal studies. A potential explanation for laser burn healing responses is related to fluence, which is calculated as (power x time)/area. The fluence required to produce a threshold ETDRS type PRP burn on the retina is significantly lower for a pulse duration of 20ms compared with conventional 100ms pulse duration. A lower fluence laser dose results in fewer structural alterations in the outer retina. At shorter and longer pulse durations, the

RPE absorbs the laser light and is destroyed, and the adjacent RPE proliferates to fill the area destroyed. However, at shorter pulse duration, there is photoreceptor in-filling to sites of laser injury with healing responses produced over time. The MAPASS study showed that 20ms burns allow the tissues to undergo a healing response that may not occur after standard-duration (100-200ms) photocoagulation. This healing response is associated with a significant reduction in burn size across time for 20ms pulse duration, with no significant disruption to either the inner retina or the basal RPE. Higher-fluence 100ms burns developed larger defects due to thermal blooming and collateral damage, with no alteration in burn size across time or any healing laser-tissue interactions. Furthermore, at 6-months, the 20ms laser burns reduced in size without any overlapping laser scars, as the laser burns show healing responses over time. Hence, at different pulse durations, fluence should be titrated to achieve threshold burns in the outer retina, allowing for healing of laser burns and minimisation of photoreceptor injury.

The short pulse (10-30ms) laser burn healing responses have since been reproduced by a number of International groups in the USA and Europe. For visible end-point laser PRP, a 20ms exposure time is preferable for PRP. This pulse duration can be achieved with standard laser systems as well as with the pattern scan laser systems. Exposure time should be titrated for individual patient as well as depending on laser reaction observed at given laser power setting. Subthreshold PRP is not effective in treating PDR, and there is a risk of bleeding complications due to under-treatment with a subthreshold PRP regimen. Below are the recommendations from the UK RCOphth 2012 guidelines, with 20ms laser settings.

Laser PRP Settings

- 1) Pulse Duration and Spot Size
Use a 400µm retinal spot size. Smaller retinal spot size, e.g. 200µm and 300µm may lead to excessive higher fluence and risks of Bruch's rupture at 20ms exposure time. Furthermore, following laser burn healing, the final laser spot (burn) may be <100-150µm and patient will require more PRP treatment.
- 2) Laser burn spacing
Laser burns should be placed 1-burn widths apart for mild and moderate PDR. The space between the laser burns can be reduced for example, 0.5-burn widths apart for severe PDR, TRD and vitreous hemorrhage, with a higher density and number of laser spots.
- 3) Laser burn intensity
Laser surgeon should aim for a barely-visible, grey/white burn reaction on retina after laser application as the designated threshold. The laser surgeon should be aware that the laser burn intensity at 20ms will increase up to 1 minute after retinal application.
- 4) Retinal surface coverage
The PRP should be applied as far peripheral as possible using the laser contact lens, up to the ora serrata as the main areas of retinal ischemia in PDR exist in the far-peripheral retina while areas of ischemic penumbra is likely to be in pre-equatorial zones.

Laser Strategy for Primary PRP

- 1) Early PDR
Primary PRP should be completed by 2 weeks, fractionated if needed (1200- 1800 burns ETDRS strategy). If shorter duration of laser pulse (20ms) used, consider increasing number of laser burns appropriately. Based on laser burn ablation studies, approximately 2400-3500 burns using 20ms PRP are recommended for early PDR. Patient review: 4 months [in non-pregnant patient].
- 2) Moderate PDR/High-risk PDR
Primary PRP should be completed by 2 weeks, fractionated if needed (2000 -2500 burns ETDRS strategy). If shorter duration of laser pulse (20ms) used, consider increasing number of laser burns. Based on laser burn ablation studies, approximately 4000-5000 burns using 20ms PRP are recommended for early PDR. A complete PRP treatment should be completed over 4 weeks with aiming to deliver more laser spots in the initial sessions. (Level A)
Patient review: 3 months [in non-pregnant patient], however in poorly controlled diabetics, review interval should be shortened.
- 3) Severe PDR/High-risk PDR
These cases are high risk of continued traction and hemorrhagic complications following PRP. Laser surgeon should aim to deliver full PRP coverage of peripheral retina (3000 burns ETDRS) over 2-3 sessions in 3-4 weeks. If shorter duration of laser pulse (20ms) used, consider increasing number of laser burns appropriately. Based on laser burn ablation studies, approximately 5500-6000 burns using 20ms PRP are recommended for early PDR. The complete PRP treatment should be completed over 4 weeks with aiming to deliver more laser spots in initial sessions. (Level A)

Annex B. Recommended Practice for Intravitreal Injection

Intravitreal injections may be performed in an office setting, or an operating room.

Bilateral Injections

The injection for each eye should be considered to be a separate procedure and should be performed accordingly, using separate site preparation and individual syringes, needles, a different medication batch, etc.

Gloves

Sterile or nonsterile gloves may be used.

Talking and Use of Masks

Minimizing speaking and/or by the use of surgical masks during the injection preparation and procedure is recommended.

Application of Povidone–Iodine to the Ocular Surface and Eyelids

Povidone–iodine (5–10%) should be the last agent applied to the intended injection site before injection. Povidone–iodine may also be applied to the eyelid margins and eyelashes. After the final application of povidone–iodine, the eyelashes and lid margins should not be allowed to come into contact with the injection site until the injection has been completed.

Topical Anesthetics

Topical anesthetics should be applied to minimize patient discomfort.

Site of Injection

Intravitreal injections should be given between the horizontal and vertical rectus muscles at the pars plana, 3.5 to 4.0 mm posterior to the limbus. Quadrant selection should be dictated by both patient-specific considerations and injecting physician preference. A simple perpendicular injection approach is both convenient and preferred in most settings.

Needle Gauge and Length

A 30-gauge or smaller needle is generally preferred for anti-VEGF agents or nonviscous solutions. Larger bore needles can be considered for suspensions (e.g., steroids) and for solutions of higher viscosity. Needle length should be 5/8 inch (18 mm) or shorter but long enough to allow for complete penetration of the pars plana.

Protocol: Sequence of Events

1. Either surgical masks should be used or both the patient and providers should minimize speaking during the injection preparation and procedure;
2. Take a procedural time-out to verify patient, agent, and laterality;
3. Apply liquid anesthetic drops to the ocular surface;
4. Apply povidone–iodine to the eyelashes and lid margins (optional, most use 10%);
5. Retract the eyelids away from the intended injection site;
6. Apply povidone–iodine (most use 5%) to the conjunctival surface, including the intended injection site, at least 30 seconds before injection;
7. If additional anesthetic is applied, reapply povidone–iodine to the intended injection site immediately before injection (most use 5%);
8. Insert the needle perpendicular to the sclera, 3.5 to 4.0 mm posterior to the limbus between the vertical and horizontal rectus muscles.

Annex Table 1. Features of Diabetic Retinopathy (also see the photographs continued in the annex).

Feature	Description	Assessment Considerations
Microaneurysms	Isolated, spherical, red dots of varying size. They may reflect an abortive attempt to form a new vessel or may simply be a weakness of capillary vessel wall through loss of normal structural integrity.	They are easiest seen on fluorescein angiography
Dot hemorrhages	Dot hemorrhages cannot always be differentiated from microaneurysms as they are similar in appearance but with varying size.	The term dot hemorrhage/ microaneurysm (H/Ma) is often used.
Blot hemorrhages	Formed where clusters of capillaries occlude leading to formation of intraretinal blot hemorrhages.	The lesion can be seen to be in the outer plexiform layer on fluorescein angiography where it does not mask the overlying capillary bed unlike dot and flame hemorrhages, which lie more superficially in the retina.
Cotton wool spots	These represent the swollen ends of interrupted axons where build-up of axoplasmic flow occurs at the edge of the infarct.	These features are not exclusive to DR and do not in themselves appear to increase the risk of new vessel formation. For example, they may occur in hypertension HIV/ AIDS.
Intraretinal microvascular anomalies	These are dilated capillary remnants following extensive closure of capillary network between arteriole and venule. Associated features include: <ul style="list-style-type: none"> • Venous beading (foci of venous endothelial cell proliferation that have failed to develop into new vessels), • Venous reduplication (rare), • Venous loops (thought to develop due to small vessel occlusion and opening of alternative circulation) and • Retinal pallor and white vessels 	They are easiest seen on fluorescein angiography.
Macular changes in nonproliferative retinopathy – Macular edema – Macrovascular disease	Thickening of retina takes place due to accumulation of exudative fluid from damaged outer blood-retina barrier (extracellular edema) or as a result of hypoxia, leading to fluid accumulating within individual retinal cells (intracellular edema). It may be focal or diffuse. Flame hemorrhage and cotton wool spot formation. May occur due to arteriolar occlusion, without capillary occlusion, which frequently affects the horizontal nerve fiber layer of the retina.	The appearance of macular edema can be appreciated on stereoscopic examination or inferred by the presence of intraretinal exudate.
Optic disc changes	Occasionally swollen optic discs may be seen (diabetic papillopathy) in diabetic patients.	In diabetic papillopathy, vision is usually not significantly impaired.

Annex Table 2. Features of Proliferative Diabetic Retinopathy.

Feature	Description	Assessment Considerations
New vessels at the disc (NVD)	New vessels at the discs usually arise from the venous circulation on the disc or within 1 disc diameter of the disc NVD.	In order to differentiate NVD from fine normal small blood vessels note that the latter always taper to an end and do not loop back to the disc, while NVD always loop back, may form a chaotic net within the loop, and have the top of the loop of wider diameter than the base.
New vessels elsewhere (NVE)	New vessels, which usually occur along the border between healthy retina and areas of capillary occlusion.	Not to be confused with intraretinal microvascular abnormalities, which occur within areas of capillary occlusion.
Other sites of new vessels	New vessel formation on the iris (NVI) is uncommon but represents potentially more advanced ischemic changes. New vessel formation on the anterior hyaloid surface occurs rarely postvitrectomy if insufficient laser has been applied to the peripheral retina.	It is useful to perform gonioscopy in such cases to exclude new vessels in the anterior chamber angle (NVA), which can lead to neovascular glaucoma.
Fibrous proliferation	In proliferative retinopathy, new vessels grow on a platform of glial cells

OCT	<ul style="list-style-type: none"> • Optional for screening and management 	<p>Advantages</p> <ul style="list-style-type: none"> • One of the best ways to assess macular edema (retinal thickening and intraretinal edema) <p>Disadvantages</p> <ul style="list-style-type: none"> • Expensive • Dilatation needed • Cannot be used by non-medically trained staff

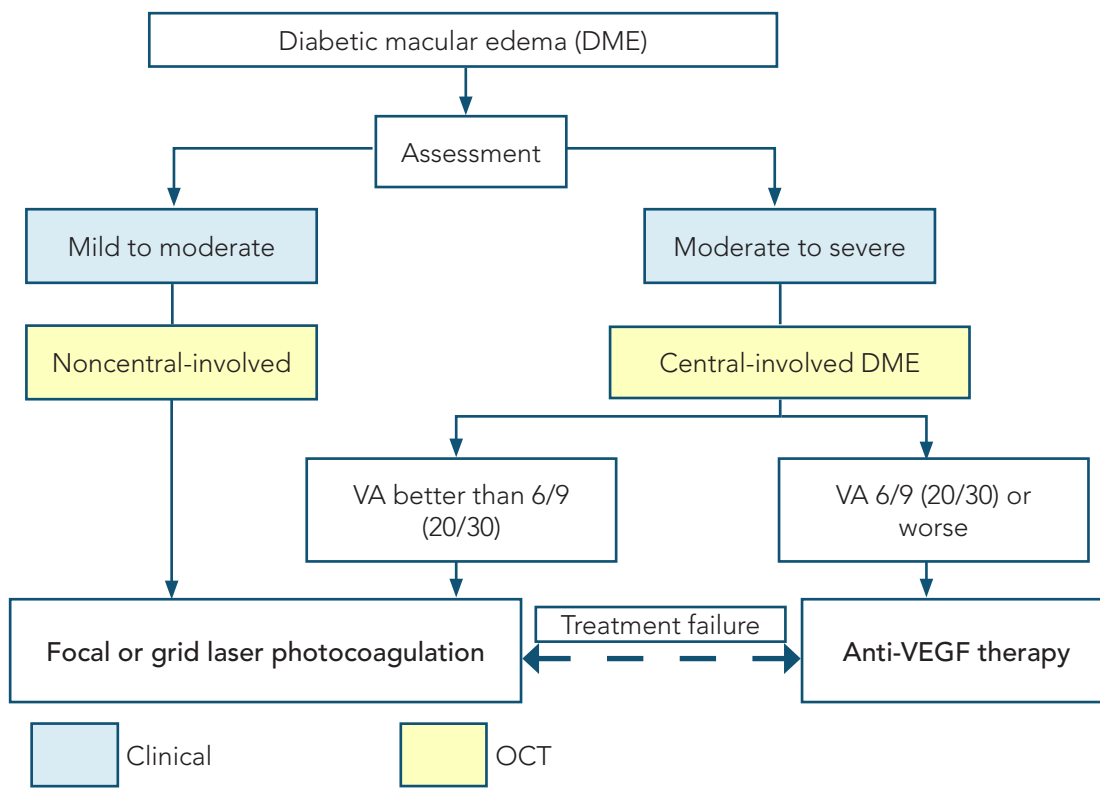

Annex Flowchart 1. Screening for Diabetic Retinopathy

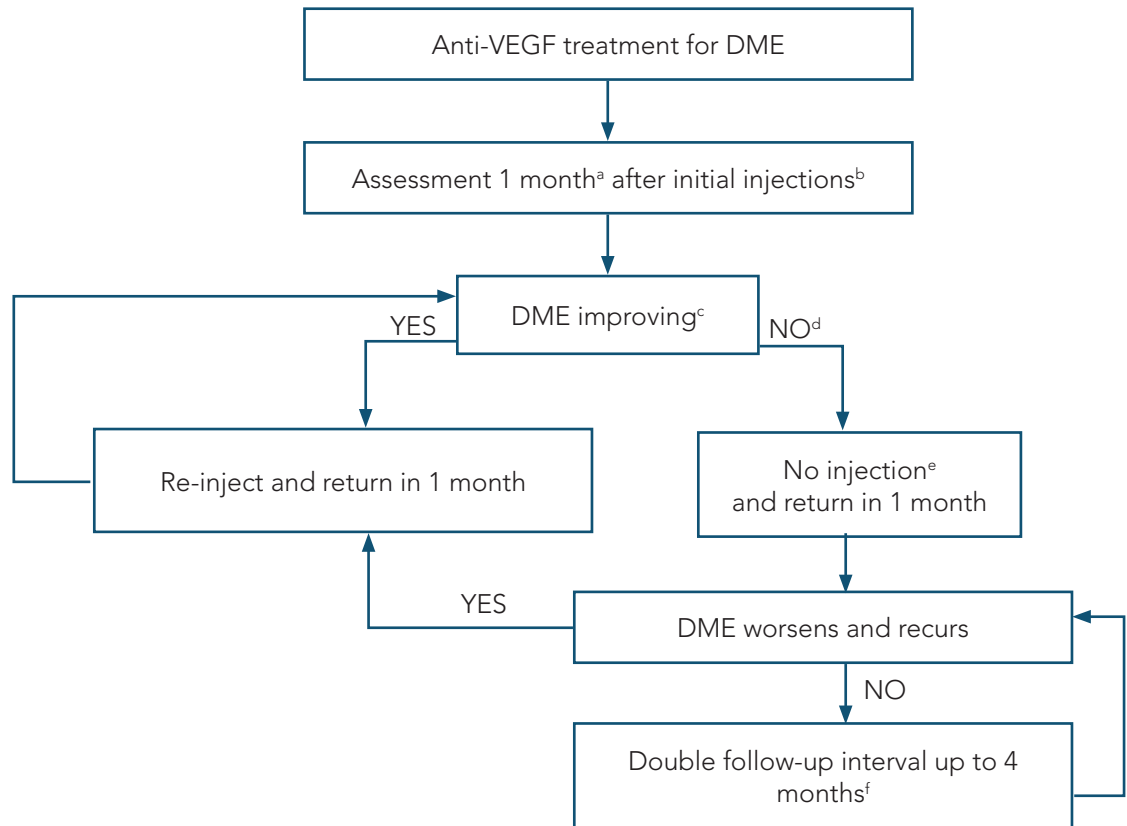

*Need to optimize medical treatment; glycemic control, hypertension and lipids.

NPDR = non-proliferative diabetic retinopathy
 PDR = proliferative diabetic retinopathy
 DME=diabetic macular edema
 VA=visual acuity

Annex Flowchart 2: Treatment decision tree of DME based on Central-Involvement and Vision.

Annex Flowchart 3: Anti-VEGF treatment decision tree based on the DRCR.net re-treatment and follow-up schedule

- a. In the DRCR.net study, 4-week, not 1-month, intervals were used.
- b. The DRCR.net study required 4 injections of intravitreal ranibizumab every 4 weeks initially; it is not known whether a different number of injections initially would have worked as well. DRCR.net also required 2 additional injections at months 5 and 6 if edema persisted and success had not been met, even in the absence of improvement.
- c. Relevant details from the DRCR.net study: 1) DRCR.net "improvement" on Zeiss Stratus OCT >10% decrease in central subfield thickness; 2) Even if no longer improving on OCT, injections continued if VA "improvement" (unless 6/6 or better); 3) VA improvement defined as 5 or more letter increase on Electronic ETDRS Visual Acuity Test.
- d. In the DRCR.net study, if focal/grid laser was deferred at baseline, it was added at or after 24 weeks if edema still present and OCT central subfield and vision no longer improving.
- e. In the DRCR.net study, all patients received at least 4 injections 4 weeks apart. The decision to re-inject was at investigator discretion, starting at 16 weeks for "success", defined as VA better than 6/6 or OCT central subfield <250µm. Starting at 24 weeks, re-injection was also at investigator discretion if no improvement in OCT central subfield or vision.
- f. The DRCR.net study continued to follow-up every 4 weeks through the 52-week visit and did not permit extension of follow-up until after the 52 week visit. If injection was withheld due to no improvement or success at 3 consecutive visits following the week 52 visit, follow-up interval was doubled to 8 weeks and then again to 16 weeks if still no change.

VEGF=vascular endothelial growth factor
 DME=diabetic macular edema
 VA=visual acuity

Guidelines for Screening, Assessing, and Treating Diabetic Eye Disease

To create the *International Council of Ophthalmology (ICO) Guidelines for Diabetic Eye Care*, the ICO collected guidelines from around the world for screening, assessing, and treating diabetic eye disease. This is part of an ICO initiative to reduce worldwide vision loss related to diabetes.

In addition to creating a consensus on technical guidelines, as encompassed in the *ICO Guidelines for Diabetic Eye Care*, these resources will also be used to focus on:

- Incorporating the critical competencies into ICO curricula and stimulating improved training and continuing professional development to meet public needs.
- Developing a framework for evaluation of public health approaches and stimulating development, strengthening, and monitoring of relevant health systems.

Please send questions, comments, or additional resources to: info@icoph.org.

**INTERNATIONAL
COUNCIL of
OPHTHALMOLOGY**

About the ICO

The ICO is composed of over 140 national and subspecialty Member societies from around the globe. ICO Member societies are part of an international ophthalmic community working together to preserve and restore vision. Learn more at: www.icoph.org.
